#### Abstract

An Abstract of the Dissertation of Jason Trevor Gatlin for the degree of Doctor of Philosophy in the Department of Chemistry to be taken December 2007 Title: SYNTHESIS AND CHARACTERIZATION OF NOVEL GROUP 13 TRIDECAMERIC INORGANIC NANOCLUSTERS.

Approved:

## Prof. Dr. Darren W. Johnson

Tridecameric inorganic hydroxo/aquo nanoclusters comprise a very small fraction of compounds under the large and varied umbrella of inorganic clusters. The AndersonEvans cluster is a subset of these larger polymetallic tridecameric clusters. A novel synthesis of $\mathrm{M}_{13}$ nanoclusters containing the Anderson-Evans cluster as cores has been discovered. This synthesis proceeds with the aid of a key organic reagent, which reacts with the nitrate counter anions of the starting material removing them from the solution. This forces the formation of a higher nuclearity species. Research continues to focus on the generality of the reaction as it applies to both inorganic and organic synthesis, as well as on extensive characterization of the novel clusters by a variety of analytical methods. These nanoclusters have proven to be useful as single-source precursors for the preparation of thin film oxides due to their high purity and crystallinity.

Chapter $I$ is a literature review of Anderson-Evans clusters in the context of how they comprise the core substructure in the reported tridecameric nanoclusters. Attention is also given to the numerous clusters or complexes that are absent from this series. Chapter II chronicles the discovery and synthesis of $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2-}\right.\right.$ $\left.\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$, a nanocluster previously thought to be unstable. Chapter III describes the modification of the reaction to prepare other tridecameric inorganic nanoclusters with increases in yield and purity. Chapter IV reports the isolation of a series of new heterometallic tridecameric nanoclusters and a potential predictive strategy for tuning the metal ratios in the crystalline products. Chapter IV also highlights the application of the nanoclusters as precursors to thin film oxides. Initial characterization of tridecameric inorganic nanoclusters using powder and single crystal XRD, NMR, ToFSIMS, EPMA and SEM instrumentation is explained in Chapter V. Finally, Chapter VI is a summary and a report of the current standing of a different project aimed at developing a template-assisted self-assembly of organic nanocages using two different ligand classes that were explored.

This dissertation includes previously published and co-authored material.

## CURRICULUM VITAE

NAME OF AUTHOR: Jason Trevor Gatlin
PLACE OF BIRTH: Lexington, KY
DATE OF BIRTH: December $21^{\text {st }}, 1976$

## GRADUATE AND UNDERGRADUATE SCHOOLS ATTENDED:

University of Oregon, Eugene OR Colby College, Waterville ME

## DEGREES AWARDED:

Doctor of Philosophy, 2007, University of Oregon
Master of Science, 2003, University of Oregon
Bachelor of Arts, 2000 Chemisty-Biochemisty, Colby College

## AREAS OF SPECIAL INTEREST:

Supramolecular Chemistry
Single Crystal XRD
Organic synthesis

## PROFESSIONAL EXPERIENCE:

Ph.D. Summer Intern, Invitrogen. June 2007 - September 2007
Graduate Research Assistant, University of Oregon, July 2002 - December 2007
Research Assistant - Encoding Specialist, Harvard Institute of Chemistry and Cell Biology, June 2000 - June 2002

Research Assistant - Summer Intern, Harvard Institute of Chemistry and Cell Biology, May 1999 - August 1999

Undergraduate Research Assistant, Colby College, February 1999 - May 2000
Research Intern, Biogen Inc., January 1999

## PUBLICATIONS:

Rather, E.; Gatlin, J. T.; Nixon, P. G.; Tsukamoto, T.; Kravtsov, V.; Johnson, D. W. "A Simple Organic Reaction Mediates the Crystallization of the Inorganic Nanocluster $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$." J. Am. Chem. Soc. 2005, 127, 3242.

## ACKNOWLEDGMENTS

Support from the ARL-ONAMI Nanoarchitectures for Enhanced Performance Center and the University of Oregon is gratefully acknowledged. The purchase of the Xray diffractometer was made possible by a grant from the National Science Foundation (CHE-0234965). I am grateful to my committee for their continued support and helpful discussions. I am grateful to my advisor - Prof. Dr. Darren W. Johnson - for his support and the freedom to explore new chemistry. I am grateful to my reviews: Julie Larios, Melanie A. Pitt, and Dr. Nathan Lien. I am grateful to my lab mates for their help throught this research. I am very grateful to my parents, Larry and Carol Gatlin, for this support and belief. Most of all I am extremely grateful for all the support and patience from my wife Mary C. Gatlin.

To Mary C. Gatlin and Jackson T. Gatlin

## CHAPTER I

## ANDERSON AND ANDERSON-CORED TRIDECAMERIC INORGANIC NANOCLUSTERS

## Section 1 Background

Polyoxometalate, hydroxyl/aqua bridged clusters and their variations have been known for quite some time. ${ }^{1,2}$ There are a wide range of reported polyoxometalate clusters as well as many reviews covering them. ${ }^{3-16}$ The spectrum of clusters ranges from the Anderson-Evans cluster, which consists of small repeating units of the brucite lattice, to much larger $100+$ metal discrete clusters. ${ }^{17-22}$ This review will focus on the small metal clusters that are based upon the Anderson-Evans, Wells-Dawson, Keggin and tridecameric clusters. Background on Wells-Dawson clusters, Keggin clusters and their dimers will be presented. A focus on Anderson-Evans clusters will follow. Emphasis will be placed on how each of these clusters relates to the tridecameric cluster, with special attention given to the Anderson-Evans core. The polyhedron cartoons of these clusters are shown (Figure 1.01), where the vertices are bridging atoms and the metal center is in the middle of the each solid polyhedron.

Figure 1.01. Survey of Inorganic Clusters. A. Wells-Dawson ( $\mathrm{M}_{18} \mathrm{M}^{\prime}{ }_{2}$ ), B. AndersonEvans $\left(\mathrm{M}_{7}\right)$, C. Keggin ( $\left.\mathrm{M}_{13}{ }^{ }\right)$, and D. Flat $\mathrm{M}_{13}{ }^{\circ}$.

The Wells-Dawson cluster (Figure 1.01A) is an $\mathrm{M}_{18}$ cluster that consists of eighteen octahedral metals encapsulating two tetrahedral atoms, that may not always be transition metals. Twelve metal centers form a "belt" made up of two rings of six that stack over each other to form a mirror plane along the equator of the molecule with an empty central space much like the ring of six from Anderson-Evans cluster (Figure 1.01B). Half of the belt is made up of a $\mathrm{M}_{6}\left(\mu_{2}-\mathrm{O}\right)_{6}$ ring that is isostructural to the first ring of the Anderson-Evans structure (Figure 1.01B). In addition, the cluster contains three metal centers at each end that comprise a trimeric cap. This trimer is very similar to one of the faces of a Keggin cluster.

Anderson-Evans clusters contain an inorganic $\mathrm{M}_{7}$ core that has a hexagonal close packing arrangement. The core position can be substituted with a variety of transition metals or non-transition metals such as the main group, alkaline earth, lanthanide or actinide metals. ${ }^{5}$ Both the first reported Anderson cluster as a $\mathrm{Mo}_{7} \mathrm{O}_{24}$ cluster, with its most-studied derivative bearing central iodine substitution $\left(\mathrm{IMo}_{6} \mathrm{O}_{24}\right)$, have been studied extensively. ${ }^{2,23}$ Anderson-Evans clusters make up a large percentage of known inorganic
clusters while the tridecameric congers are rare in relation and can be considered as a subset of the Anderson-Evans cluster family.

Figure 1.02. Ball and stick and polyhedron view of Brucite lattice of the same array. ${ }^{24}$
The brucite lattice could be described as a series of hexagonal close packed metal clusters that form a planar lattice of edge-sharing octahedra with the six perpheral metal centers of the cluster. That is, it is a series of interlocking Anderson core clusters that are offset when a peripheral metal center becomes the central metal of an adjacent cluster of seven metal ions. $\mathrm{A} \mathrm{Mn}_{19}$ cluster reported by Pohl et al. contains a similar connectivity (Figure 1.09D) compared to a $\mathrm{Fe}_{19}$ cluster reported by Heath and coworkers which is more "layered" (Figure 1.09C). ${ }^{25,26}$ Counter-anions act as bridges between the planes of the brucite lattice. ${ }^{27,28}$

Keggin clusters contain four trimers of octahedral metal centers arranged around a central tetrahedral metal center core. ${ }^{1,29}$ The tetrahedral metal center of the Keggin clusters can be a variety of metals as well. ${ }^{3,4,30}$ There are five different isomers of the Keggin cluster, $\alpha$ through $\varepsilon$ (Figure 1.03). The difference between the Keggin isomers is
in their successive rotations, $60^{\circ}$ for each trimer surrounding the central metal $\left(\alpha^{31}, \beta^{32}\right.$, $\left.\gamma^{33}, \delta^{34}, \varepsilon^{35}\right) .^{3,36}$ The rotations changes the orientation of the timers from vertex-sharing to edge-sharing octahedra. There are different notations for different tridecameric clusters to differentiate the central metal coordination. The notation for a Keggin cluster is $\mathrm{M}_{13}{ }^{\mathrm{t}}$, while Anderson-Evans-like expanded tridecameric flat clusters are denoted $\mathrm{M}_{13}{ }^{\circ}$, where $o$ and $t$ refer to the coordination geometry of the central metal, octahedral or tetrahedral. Keggin clusters are also seen as units of larger clusters (Figure 1.04). ${ }^{3}$ Two $M_{13}{ }^{t}$ Keggin clusters appear to dimerize with an $M_{4}$ bridge of octahedral metals between the two units to yield a $\mathrm{M}_{30}$ cluster. ${ }^{3}$ Similar "trimers" are also formed where the clusters share a face of three octahedral metals. ${ }^{36,37}$

Figure 1.04 Keggin $\mathrm{M}_{30}$ and other "aggregates",3,36
There is also a class of clusters that falls between the Keggin and Anderson-Evans type clusters, the $\mathrm{M}_{13}{ }^{\circ}$ clusters. Anderson-Evans structures are only a two-dimensional array of metal sheets that are bridged in the same manner as the small repeating unit of the brucite lattice. This larger class shares the same core of seven octahedral metal centers arranged in a hexagonal close packed array. The $\mathrm{M}_{13}{ }^{\circ}$ cluster contains an Anderson-Evans-type planar $\mathrm{M}_{1}\left(\mu_{3}-\mathrm{OH}\right)_{6} \mathrm{M}_{6}\left(\mu_{2}-\mathrm{OH}\right)_{6}$ core fragment that forms a central plane. ${ }^{38}$ Six $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ groups are connected to this core via two alkoxo ( $\mu_{2}-\mathrm{OH}$ ) bridges; the groups alternate above and below the central plane. ${ }^{39-41}$ The Anderson-type core of the flat $\mathrm{M}_{13}{ }^{\circ}$ clusters contains octahedral metals arranged in planar sheets, similar to the arrangement of seven concentric metal centers in a brucite lattice.

Figure 1.05. Hexagonal close packed metal centers of a brucite lattice
These new types of clusters have been called "flat" - $\mathrm{M}_{13}$, clusters, to distinguish them from the more spherical $\mathrm{M}_{13}{ }^{\mathrm{t}}$ Keggin clusters. The term "flat" is somewhat misleading, because these clusters are not flat like the Anderson-Evans core and brucite lattices; instead, they have outer metal centers that lie above and below the central planar core of seven metals. However, these flat clusters are not Keggin or "Keggin-like", as they lack a central tetrahedral metal ion. Furthermore, Keggin clusters are more spherical than planar, with a diameter of $5.5 \AA$. The flat $\mathrm{M}_{13}{ }^{\circ}$ clusters themselves are more disc-like with a diameter of $12 \AA$ and a cylindrical height of about $8 \AA$. As the Anderson-Evans cluster continues to grow*, new metal centers are not added in the plane, producing more concentric rings or growing in the $a$ or $b$ directions. ${ }^{43}$ While the $\mathrm{M}_{13}{ }^{\circ}$ cluster has more metals that are not in the same plane as the core, they grow off in the $c$ direction. A hexagonal close packed array is seen from above as just an Anderson-Evans cluster (Figure 1.05A). When more metals are added in the plane to expand into a brucite

[^0]lattice, an original metal is now the center of the new adjacent unit (Figure 1.05B).
Instead if the three new metals are added above the plane of the original seven, they can either be packed tightly in the center or offset to the outside. The same cluster is shown from both the top and the side to show stacking (Figure 1.05C \& E).

Figure 1.06. Interconversion of Keggin clusters to yield Wells-Dawson and Anderson clsters.

When the Anderson-Evans core begins to grow ${ }^{*}$ in the $c$ direction, the clusters stop at 13,15 or 19 metal centers. Smaller all-octahedral metal clusters that look like the Anderson core precursor have been synthesized. ${ }^{44}$ The vast majority of these clusters
contain Group 13 metals. The Anderson core that is contained in the $\mathrm{M}_{13}{ }^{\circ}, \mathrm{M}_{15}{ }^{\circ}$ and $\mathrm{M}_{19}{ }^{\circ}$ clusters are homometallic while the Anderson-Evans cluster often contains substitutions at the central metal. There have been several reported single substitutions of the central position. ${ }^{5,24}$ New additions to the variation of the central metal and an improved synthesis of these cores (personal communication) have recently been discovered. Metals of smaller radii are seen quite often in these hexagonal close packed arrays using oxo bridges while larger radii metals are almost exclusively seen in a bridging fashion between complexes where they are not as sterically confined. ${ }^{27,45,46}$ The larger radii metals are also seen using acetate bridges. The difference in ionic radii may play an important factor in cluster stability, which depends on both the charge of the metal and the high/ low spin of electron configuration. ${ }^{47,48}$ It must be noted that data from the ionic radii on group 13 metals and their bond distances in metal clusters is missing in the Orpen paper. ${ }^{47}$

Figure 1.07. Anderson Core as a critical substructure for $\mathrm{M}_{13}$ clusters.
The Lorenzo-Luis review of Anderson-Evans clusters is slightly dated and needs some updating. It does not mention larger inorganic clusters, while Casey's review describes briefly the flat $\mathrm{M}_{13}{ }^{\circ}$ cluster. ${ }^{3,5}$ These reviews do not describe how some clusters are fragments of larger clusters; for example, the Anderson-Evans cluster is a fragment of the "flat" $\mathrm{M}_{13}{ }^{\circ}$ cluster. The following sections describe how the AndersonEvans cluster is a component of the larger $\mathrm{M}_{13}{ }^{\circ}$ metal clusters and show relevant structural data.

## Section 2 Searches and Criteria

There are two main databases to search for inorganic compounds, the Cambridge Structure Database (CSD) and the Inorganic Chemical Database (ICD). ${ }^{49}$ The structures found in the ICD are purely inorganic, while entries into the CSD database must have at
least one carbon atom per unit cell. Therefore, it is ironic that something as small as a disordered methanol in an inorganic cluster would allow for submission into the organic CSD.

The CSD allows for the drawing of desired components and substructures, while the ICD is text driven with a choice of elements, but not their arrangement in space nor connectivity to each other. The results from the two databases are not easily compared because the search criteria are so different. Hits from data are not always accurate for searches being conducted. However, there is a way to combine multiple searches using Boolean operators to allow for better searching of the ICD.

Searches were done with the CSD using stick compounds where " 4 M " represents any metal and $O$ is any oxygen-containing bridging group (Figure 1.08). This ambiguity of the oxygen allows for the bridging ligand to be oxide, hydroxide or an oxo from an alkoxy group ( O can be $\mathrm{OH}, \mathrm{OH}_{2}$, or OR ). The same goes for the acetate bridge where it can be any R group from formic acid on up. The search does not state that the bridging motifs are not connected to each other; this allows for multidentate ligands to be included in the results. The search can also be restricted to transition metals. The 4 M was purposely used in order to allow for the greatest potential of metal variety, including the alkali earth metals. Some clusters require organic stabilizing ligands as an external shell. Some are inorganic clusters, which only need organic additives to from (in some cases) in the solid state. The CSD searches yield only limited connectivity allowing for large variation in the types of structures found. The inclusion of OR and RCOO in the search
criteria yielded too many results, therefore constraints were added for geometry and rigidity of larger polymetallic clusters.

Figure 1.08. Search criteria for various metal-oxo bindings from the CSD.
Multiple searches were performed with the CSD that had varying degrees of rigidity. Each search contained a fragment of the tridecameric cluster; each successive search increased the rigidity. The first was the $\mathrm{M}_{6}$ fragment, while subsequent searches were contained as subsets of previous searches. It was extremely difficult to perform the same search in the ICD. Specific elements and their stoichiometry could be chosen but no connectivity or structural data could be selected. When searching for any metal, the number of metals in a cluster could not be chosen. The ICD proved to be useful only if the exact composition or unit cell parameters are known. Specific clusters could be found, but a general search for a topology was difficult. The user interface is more text driven in nature than GUI as in the CSD. Screening hits was also more difficult because the data was tabular; to visualize the structure, a second program had to be launched for
each view. Previous queries made in the ICD could not be modified for future searches by utilizing the back function. A new query needed to be built each time, which increases the possibility of user input error from search to search. What took thirteen searches with the ICD could be done in one search with the CSD, where $M=M o, N i$, $\mathrm{Mn}, \mathrm{Ga}, \mathrm{Al}, \mathrm{In}, \mathrm{Fe}, \mathrm{W}, \mathrm{Te}, \mathrm{Cu}, \mathrm{Co}, \mathrm{Cr}$, which would allow it to fall under the CSD designation 4M. The ICD does allow for metal counts to be include but only with individual metals not with a wild card for all metals, therefore mixed metal clusters were not found. There were far too many hits with the first three searches, but with increased structural rigidity the specificity improved (Figure 1.09). Major omissions in the data were possible when looking for specific compositions.

Figure 1.09. Substructures searched on the CSD.
For this review a ligand is bound to at least one metal of the cluster while an additive is co-crystallized out with the metallic cluster. The ligands found in the CSD search are shown in Figure 1.10. A summary of the hits from search 3 that are not in Search 5 of the $\mathrm{M}_{13}$ clusters are shown in Table 1.1.

The CSD data set was current as of November 2006, and validity of the data can only be confirmed through that edition. Additional data has been provided via personal communication and research done by the author and co-workers that is included in this dissertation. A question remains as to how useful the CSD and ICD can be due to the number of false positives and false negatives found, since the data found is only accurate to the parameters entered but not always accurate for what is actually needed. Each structure that is out put from the search as a hit should be evaluated carefully to confirm its accuracy to the criteria.

## Section 3 Ligands and Stability

The searches outlined in section 2 yield a large variety of clusters which contain organic supporting ligands or that co-crystallize with organic additives. Smaller monodentate ligands like pyridine seem only form monometal complexes. The $\mathrm{Ga}_{13}{ }^{\mathbf{}}$
cluster had previously been synthesized using stabilizing aminocarboxlate ligands, such as HEIDI. ${ }^{42}$ The only example of an unstabilized $\mathrm{Al}_{13}{ }^{\circ}$ cluster was produced in low yields requiring both caustic conditions and long reaction times. ${ }^{40}$ A very similar $\mathrm{M}_{15}$ cluster was synthesized using HDTP as s stabilizing ligand. ${ }^{98}$ There were also a variety of multidentate ligands like HEIDI and HDTP used to stabilize metal cluster. ${ }^{25,39,42,50,98,}$
${ }^{110}$ This led the way for researchers to explore even larger ligands like EDTA or DTPA.

Figure 1.10. Organic binding ligands commonly found in inorganic cluster crystal structures.

The coordination chemistry of gallium is of interest because of its similar ionic radii to iron. ${ }^{48}$ Gallium also poses an interesting target because of its use in PET scanning. ${ }^{116,117}$ The majority of the ligands for Ga are catechol ${ }^{118-120}$ or aminocarboxolate derivatives. ${ }^{39}$ Recently, an unstabilized $\mathrm{Ga}_{13}$ cluster was synthesized. ${ }^{41}$ Since then, a faster and cleaner synthesis of both the $\mathrm{Ga}_{13}$ cluster and other $\mathrm{M}_{13}$ clusters has been reported in Chapters II-V. ${ }^{121}$

Figure 1.11. Ball and stick representations of common clusters A. HEIDI bridged $\mathrm{M}_{13}{ }^{\circ}$, B. unbridged $\mathrm{M}_{13}{ }^{\circ}$, C. HEIDI-bridged $\mathrm{M}_{19}$, D. unbridged $\mathrm{M}_{19}$

The actual number of discrete tridecameric clusters is much smaller than the twenty hits from the CSD. In fact, there are only about eight that count as containing the $\mathrm{M}_{13}{ }^{\circ}$ core, a few are $\mathrm{M}_{15}$ or $\mathrm{M}_{19}$ clusters. ${ }^{25,98}$ These are distinct from the Pohl $\mathrm{M}_{19}$ cluster (Figure 1.11D), which is more Anderson-Evans like because of the pattern of growth from the central core. ${ }^{26}$ The Pohl M19 cluster is filling in between the existing outer shell metals with more centers to make a continuous array of planar metals. ${ }^{42}$

We have synthesized a series of heterometallic $\mathrm{M}_{13}{ }^{\circ}$ clusters. We now have the complete set of $\mathrm{Ga}_{13-\mathrm{x}} \mathrm{In}_{\mathrm{x}}$, where $0 \geq \mathrm{x} \geq 6$. Two of the corresponding aluminum and indium series have been synthesized, $\mathrm{Al}_{13}$ and $\mathrm{Al}_{8} \mathrm{In}_{5}$. Analogous heterometallic clusters
were not observed in the results from either the CSD or the ICD. Despite the lack of substitution in the central ring, the second ring substitutions may help determine cluster growth and stability of precursor fragments in how the clusters form. ${ }^{42}$ Elemental analysis will only tell the relative abundance of metals present. A problem with x-ray structural analysis of heterometallic clusters is their high symmetry $\left(\mathrm{D}_{3 \mathrm{~d}}\right)$, which often leads to disorder within the heterometallic cluster. However, the ratio of metals can be determined based on occupancy factors by counting the electrons of the metals in the symmetrically equivalent positions (Figure 1.12).

## Section 4 Results of Cluster Synthesis

Anderson-Evans clusters are quite stable, which is why the original $\mathrm{Mo}_{7}$ Anderson cluster can easily be used as a starting material for substitution at the central position; many examples are known in which the core metal has been exchanged. ${ }^{5}$ This review is quite old though, and there are more examples that have been discovered since its publication, in fact more than 70 new Anderson-Evans and cored clusters have been synthesized (Table 1.1 \& 1.2). The $\mathrm{Mo}_{7}$ cluster now seems quite easy to alter. The stability of the Anderson-Evans cluster, as well as larger structures built off of it, may offer some insight into how these clusters form. ${ }^{42}$

New work has augmented the field of inorganic nanoclusters by the use of organic reagents and additives to form nanoclusters. The use of organic reagents, such as nitrosobenzene, can allow the synthesis of multiple metal (Chapter II). ${ }^{41}$ The same clusters and new analogs have been synthesized by using DBNA, however the organic by-product has not been isolated. ${ }^{121}$ Other additives have also been used to induce crystallization and/or to help to nucleate the cluster. Fedin's work with Cucurbit[6]uril (CB[6]) is an excellent example of organic additives serving as nucleation sites (Figure 1.13). ${ }^{122,123}$ The same additive has not always yielded the analogous cluster with different metals. Fedin used $\mathrm{CB}[6]$ in an attempt to make the flat $\mathrm{Al}_{13}{ }^{\circ}$ cluster ${ }^{3}$ but instead obtained the $\mathrm{Al}_{13}{ }^{\mathrm{t}}$ Keggin cluster. ${ }^{123}$ It is surprising that there are no reports using the analogous additives $\mathrm{CB}[7]$ or $\mathrm{CB}[8]$ to co-crystallize similar clusters. The use of bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) as an additive has also been in the crystallization of these clusters (IBAXUF ${ }^{69}$, INIMOH $^{70}$, NOCLAS $^{82}$, NOCLEW $^{82}$,,

RASMEE ${ }^{93}$, RASMII $^{93}$, RASMOO $^{93}$, WADKOC ${ }^{100}$, XUYRAK $^{106}$ ). ${ }^{106}$ However, some additives may not be entirely innocuous, in that they in fact modulate the electronics of the inorganic cluster. ${ }^{124-126}$

Figure 1.13. Additives that co-crystalize with metal clusters
Metals of different oxidation states can be contained in the same cluster. This is quite common for manganese. ${ }^{80,81,87,112,127}$ These clusters have a potential use as single molecule magnets. ${ }^{18,26,51,62,108,115,128-135}$ For these mixed oxidation state clusters it appears that the oxidation state of one of the reagents changes throughout the reaction from starting material to crystal. Hydroxyl oxygens are the most common heteroatoms used as bridges. The only heterometallic clusters observed in the literature of AndersonEvans cord clusters are the Anderson-Evans clusters themselves. ${ }^{5}$ The very large clusters seem to have different metals involved in different roles as bridges between smaller subunits.

## Section 5 - Results, Series that are present or Missing

The data obtained from the CSD is significant, but there were many other structures of interest that were found that were not found in the CSD search. A search of the ICD found the original $\mathrm{Al}_{7}$ Anderson-Evans cluster; however the analogous $\mathrm{Ga}_{7}$ and $\mathrm{In}_{7}$ clusters are not present in the database. We expected to see the $\mathrm{Ga}_{7}$ cluster, as that
fragment was observed in our heterometallic series. The large ionic radius of indium explains why we did not see the $\mathrm{In}_{7}$ Anderson-Evans cluster. ${ }^{48}$ A very interesting structure that appears in the $\mathrm{M}_{6}$ core but not in the $\mathrm{M}_{7}$ Anderson-Evans or $\mathrm{M}_{7}$ AndersonEvans fragment searches is an $\mathrm{In}_{6}$ ring that is the same as the core of the tridecameric clusters, Figure 1.14C, $\left(\mathrm{BEQRAR}^{136}\right)$. Additionally, there is the same ring but with manganese or iron inserted into the central position (OCEZUS, OCIBAE, OCIBEI ${ }^{83}$ ). This is also true of both the Anderson core and the Anderson fragment search. From the $\mathrm{M}_{7}$ Anderson-Evans core CSD search we do find a $\mathrm{M}_{15}$ isomer that is not included in the tridecameric search (UDAZUU ${ }^{98}$ ).

Other clusters of interest were found which contain thirteen or more metals that have the same binding as the $\mathrm{M}_{13}{ }^{\circ}$ cluster, but the three metals that are above and below the $\mathrm{M}_{7}$ core are now offset from the outer rim but instead are packed directly above the core. There are a few examples of cluster that are still $\mathrm{M}_{13}{ }^{\circ}$ but spherical (Figure 1.14A), in this case the metals added are in the voids above the plane between the central and two adjacent ring metals (Figure 1.05D \& F). The Anderson-Evans core forms an equator; this plane contains the most metals per plane, additional parallel to the core. There can be three additional metals added to the top and bottom of the ring to make a sphere $\left(\right.$ CUDGEN $^{57}$, DAQNUE $^{61}$, DAWBAE $^{62}$, DAWBOS $^{62}$, JIDNIT $^{109}$, MEXZOX $^{111}$, PADPOA ${ }^{85}$, TUNYIK ${ }^{95}$ ). The second layer above the equatorial plane does not need to continue in the hexagonal close packed array. Similar to the $\mathrm{M}_{13}{ }^{\circ}$ clusters where additional metals are added outside the Anderson-Evans core the addition metals can be added in a column above the first ring only offset by $30^{\circ}$. Typically, this layer contains
six co-planar metals (KUPDII, ${ }^{76}$ ), though sometimes only four metals are present in the second layer with vacancies at $180^{\circ}\left(\right.$ POZRAX $^{108}$, YEBLIB $\left.^{137}\right)$. Three more metals can be added to the second layer in distal positions with the third layer offset on top for a $\mathrm{M}_{25}$ cluster, which stacks in layers of $3,6,7,6$ and 3 metal centers, Figure 1.14B. $\left(\right.$ BETCOT $^{108}$ ) There is one example where the growth is not symmetric: additional layers are only on top of the Anderson-Evans core (Figure 1.14B) (UKUMIW ${ }^{115}$ ).

Figure 1.14. Interesting clusters discovered in the search. A. $\mathrm{M}_{13}{ }^{\circ}$ Sphericical 3,6,3 metals, B. 3,6,7,6 and 3 array of Mn centers, C. $\mathrm{In}_{6}$ ring.

Two $\mathrm{M}_{8}$ clusters were discovered through other searches of the literature. The clusters $\mathrm{Al}_{8}{ }^{44}$ and $\mathrm{Ga}_{8}\left(\right.$ PAFJUC ${ }^{42}$ ), though not Anderson-Evans or $\mathrm{M}_{13}$ clusters, have portions that are structurally similar in about half of the complex. The $\mathrm{M}_{8}$ cluster has six metals that closely resemble the $\mathrm{M}_{7}$ core of the indium Anderson-Evans cluster. If one of the six metals from the first ring of the core is removed, the two adjacent metals will twist out of the plane to relieve the torsional strain imposed by the planarity of the seven metals. These clusters may help to explain the stability of other clusters like the $\mathrm{M}_{13}$ as
well as fragments that are observed from ToF-SIMS experiments to be discussed later (Chapter V).

Figure 1.15. Ball and stick representations of $A . \mathrm{M}_{8}$, B. $\mathrm{M}_{15}$ and $\mathrm{C} . \mathrm{M}_{32}$ Clusters
The original search for tridecameric and Anderson-Evans clusters and component fragments only looked for a ring of six metals. The CSD does not allow definition of cyclic or repeating units. Follow-up searches copied the $\mathrm{M}_{6}\left(\mu_{2}-\mathrm{O}\right)_{12}$ fragment for the larger $\mathrm{Mn}\left(\mu_{2}-\mathrm{O}\right)_{2 \mathrm{n}}$ rule. The same $2 \mathrm{~N}+2$ rule for organic degrees of unsaturation applies to inorganic rings as well. A ring has one degree of unsaturation, which subtracts two bridges from the corresponding chain. These other ring structures may be of interest to help explain the stability of the clusters. There are clusters containing up to twelve metals, which would begin to resemble the second metal shell in a brucite lattice. These larger ring systems have a cavity size the same as the smaller Anderson-Evans clusters and could be used as templates or nucleation sites for the formation of these smaller clusters.

The identical search was performed for $n=7,8,9,10,11$ and 12 . The search in the CSD that yielded hits was the $n=8$ ring. ${ }^{138,139}$ A structure was found that has a single oxo bridge between ring one and ring two, opening up a position on each metal of
ring one and therefore changing the bonding geometry between the Anderson core and the second ring of metals. ${ }^{71}$ There might need to be an additional review of metallic ring structures that are not solid in the middle such as those given in (Figure 1.16A). ${ }^{131,140,141}$

$\mathrm{M}_{13}\left(\mu_{3}-\mathrm{O}\right)_{6}\left(\mu_{2}-\mathrm{O}\right)_{12}$ tridecatmeric search

Figure 1.16. Secondary CSD searches criteria
The modified $\mathrm{M}_{13}$ structure should yield structures that fall between the previous searches of the Anderson-Evans cluster and the rigid tridecameric cluster. It also presents the possibility of other heteroatoms acting as bridging or coordinating ligands. The single bridged $\mathrm{M}_{13}$ cluster yielded thirty nine hits. The previous tridecameric search hits are included in this data set. Some new observations include the incorporation of larger metal ions in the other ring, as well as much larger ligands that contain functionalized pyridine rings. There are fifteen analogous $\mathrm{M}_{8}$ ring clusters found in searching the CSD, Figure 1.17A. Eleven of them did not require a larger ligand to force the formation of the larger ring, however most encapsulate an ion such as oxolate (AWEWEE ${ }^{142}$, AXEPAU $^{143}$, DAWYAB $^{144}$, EDUNOG $^{145}$, FAFQOT01 $^{146}$, PAQFAO $^{147}$, SAKPID $^{148}$,

SWJYOV \& SEJYUB ${ }^{149}$, TASMIK $^{150}$, XOVPED ${ }^{151}$ ). The remaining four used the functionalized $p$-tert-butylsulfonylcalix[4]arene and large diameter lanthanides to form the cluster, Figure 1.17B and C. ${ }^{152}$

Figure $1.17 \mathrm{~A} \mathrm{M}_{8}$ ring with a disordered oxolate cation, and calix[4]arene ligand supported clusters

## SUMMARY

Recent searches of the CSD and ICD show there are numerous clusters that contain the Anderson cluster as a fragment in their full structure. Despite the wide variety of metal substitution seen at the central metal substitution of the Anderson-Evans and Keggin clusters, there are few other heterometallic structures found. Database updates are far behind the research, and the interfaces are not always friendly. It is crucial that databases provide an option to combine a completely inorganic search with a full CSD search. Prior to this, the $\mathrm{M}_{13}{ }^{\circ}$ clusters have typically been called tridecameric clusters, though an extensive review by Casey distinguishes them from a classical Keggin cluster by calling them "flat- $\mathrm{M}_{13}$ " clusters. We have contributed to this field with new substitution at the core position and with our expansion of the $\mathrm{M}_{13}{ }^{\circ}$ chemistry as well. ${ }^{41}$,
${ }^{121}$ The dilemma presented by this research is in the naming of the flat tridecameric clusters because of their different expansion on the Anderson-Evans core. These cluster are already showing their potential use as synthons. These clusters will need their own name and naming scheme as more of these clusters are synthesized and used.

## CHAPTER II

## A SIMPLE ORGANIC REACTION MEDIATES THE CRYSTALLIZATION OF THE INORGANIC NANOCLUSTER $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$

I initially identified the novel cluster and performed the collection of the Single Crystal XRD data. I was the primary contributor to the optimization of the synthetic conditions including the determination of the active functional group and developed the purification procedure. Dr. Elisabeth Rather was helpful in solving the crystal structure. Dr. Victor Kravtsov was helpful in verifying the charge state of the cluster. Dr. Paul G. Nixon and Dr. Takuji Tsukamoto contributed to this publication by providing the original organic reagents. This work was published in Volume 125 of the Journal of the American Chemical Society in February of 2005. Dr. Prof. Darren W. Johnson was the principle investigator for this work.

A series of NMR titration experiments were run to determine the binding of $\mathrm{Ga}(\mathrm{III})$ with proprietary organic ligands developed by Chemica Technologies, Inc. The NMR reaction was allowed to evaporate and yielded large crystals (Figure 2.1). Evaporation of the solvent from the experiment solutions yielded crystallographic grade single crystals of the $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ nanocluster (Figure 2.2A). However, the crystal structure does not contain the organic ligand from the titration. The isostuctural unstabilized $\left[\mathrm{Al}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ nanocluster has been previously reported (Figure 2B), ${ }^{1}$ and Goodwin et al. had theorized that the $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ was unstable. ${ }^{2}$ The $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\right.\right.$ $\left.\mathrm{OH})_{12}(\mathrm{HEIDI})_{6}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{NO}_{3}\right)_{15}$ and $\left[\mathrm{Al}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{12}(\mathrm{HEIDI})_{6}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{NO}_{3}\right)_{15}$ organic ligand-stabilized clusters have also been isolated (Figure 2.2C and D). ${ }^{2,3}$

Figure 2.1.Screen capture of microscope image of the $\mathrm{Ga}_{13}$ crystals

Figure 2.2. A. Crystal structure of $\mathrm{Ga}_{13} ; \mathrm{B}$ Crystal structure of the pervious $\mathrm{Al}_{13} ; \mathrm{C}$. HEIDI ligand; D. Crystal structure of HEIDI Stabilized $\mathrm{Ga}_{13}$.

Since there were no organic binding ligands in the structures, and $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ recyrstallized on its own will not form $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ clusters like this, the organic additives must have had some effect. Follow-up experiments to determine the active functionality of the proprietary ligand yielded the discovery that the nitroso functionality is necessary for the formation of the Ga nanocluster.

Nitrosobenzene acts as an organic reductant by reducing the nitrate counter ions; this forces the formation of the multiple metal $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ inorganic nanocluster. The other functionalities from the proprietary ligand yielded ligand substituted products or starting materials. A functional group testing approach was taken to determine the active functional group. Each functionality of the ligand was tried individually. Multiple combinations of functional groups were tested also for reactivity.

Nitrosobenzene

Nitrobenzene

Scheme 2.1.Organic reductants or ligands used to determine the functional group responsible for the formation of the $\mathrm{Ga}_{13}$ cluster.

After the publication of our method utilizing the nitroso functionality as an organic reductant, another group published research yielding the same $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\right.\right.$ $\left.\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ inorganic nanocluster. However, their cluster co-crystallized with cucurbit[6]uril (CB[6]) and an oxo bridged $\mathrm{Ga}_{32}$ species. ${ }^{4}$ The Fedin group was not sure how their additive aided in the formation of the flat $\mathrm{Ga}_{13}$ clusters. Their group continues to use $\mathrm{CB}[6]$ as an organic additive to make other clusters in the same manner, allowing our two routes to diverge. ${ }^{5,6}$ They were able to visually sort their crystals based on their physical morphology from just $\mathrm{CB}[6]$ and the $\mathrm{Ga}_{32}$ cluster .

Scheme 2.2. Synthesis of $\mathrm{Ga}_{13}$ using $\mathrm{CB}[6]$ as an organic additive. ${ }^{4}$
The following pages summarize our initial publication of the synthesis, isolation and characterization of the flat $\mathrm{Ga}_{13}$ nanocluster. Other work on these types of clusters is in the chapters which follow. Included is an in-depth characterization chapter and a discussion of future works.

Developing predictive design strategies to prepare inorganic cluster compounds has attracted much research interest, due in part to the potential applications of these novel materials. ${ }^{2,7-11}$ We present a potentially new synthetic strategy for preparing discrete inorganic clusters, and we use this strategy to prepare the first crystalline example of an inorganic tridecameric Ga cluster. By using $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$ as a nitrate source for the conversion of nitrosobenzene to nitrobenzene - which is known to proceed using nitric acid - robust crystals of the nitrate-deficient gallium cluster $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$ form. To the best of our knowledge, this is the first synergistic use of a simple organic reaction to mediate the formation of a polynuclear inorganic cluster compound.

Studies on polycationic metal oxo- and hydroxo- aggregates of gallium and aluminum have centered around understanding their environmental impact (e.g. soil
science, water treatment), ${ }^{10,12-14}$ determining their biological relevance (e.g. toxicity and transport of metallic species), ${ }^{14,15}$ and preparing new materials (e.g. catalysis, magnetism, porous solids). ${ }^{16-18}$ In this context, aqueous complexes of gallium(III) have received less attention than their aluminum counterparts, largely due to difficulties in preparing stable single crystal forms of these clusters. ${ }^{13}$ Solid state and solution investigations on the formation of inorganic gallium clusters reveal that the majority of the compounds are polyoxycations based upon the modified-Keggin structure, which possesses octahedral peripheral gallium cations bridged to a central tetrahedral $\mathrm{Ga}(\mathrm{III}) .{ }^{17,18}$ While the presence of chelating organic ligands stabilizes a range of polynuclear clusters and allows for their crystallization, ${ }^{2,3,7,19}$ the structural characterization of purely inorganic Ga (III) clusters analogous to the $\mathrm{Al}_{13}$ clusters is lacking. ${ }^{1,13}$ We report the single crystal structure of an inorganic $\mathrm{Ga}_{13}$ cluster $\mathbf{1}^{1}$ prepared using a simple organic reaction to drive the formation of the crystalline inorganic cluster.

Robust crystals up to $15 \mathrm{~mm}^{3}$ in volume of $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\right.$ $\left.\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, 1, (Figure 1) were obtained from slow evaporation at room temperature of a methanolic solution of hydrated $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ in the presence of nitrosobenzene. In this process the nitrosobenzene acts as a scavenger of nitrate ions and facilitates the nucleation of $\mathrm{Ga}_{13}$ clusters via a redo process in which the nitrosobenzene is oxidized into nitrobenzene with concomitant reduction of some of the nitrate counter ions. High-Pressure Liquid Chromatography-Mass Spectrometry (HPLC-MS) and ${ }^{1} \mathrm{H}$ NMR spectroscopic data prove that nitrobenzene is indeed formed in the crystallization

[^1]process. ${ }^{\dagger}$ Furthermore, it is known that nitric acid can oxidize nitroso derivatives into the corresponding nitro compounds; this procedure simply represents a milder form of this reaction, in which nitrate oxidizes nitrosobenzene at a slightly acidic $\mathrm{pH}^{20-22}$ In effect, as a result of consumption of some of the nitrate counter ions of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$, the remaining gallium-containing species must form a higher nuclearity cluster where the ratio of nitrate to gallium(III) is less than 3:1. In this case, the stoichiometry descends to 15:13. In this redox process one $\mathrm{Ga}_{13}$ cluster must be produced per 24 nitrosobenzene oxidized.

[^2]

Figure 2.3 Polyhedral (a) and ball and stick (b) representations of the crystal structure of the polycationic $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]^{15+}$.

The crystal structure of the mixed hydroxo/aquo cluster 1 reveals the compound does not crystallize as the modified Keggin structure seen in the related $\mathrm{Al}_{13}$ or $\mathrm{MAl}_{12}$ clusters, ${ }^{23,24}$ but rather is similar to $\mathrm{Ga}_{13}$ clusters stabilized by supporting ligands, where the central gallium is octahedral, not tetrahedral. ${ }^{\ddagger}$ Each tridecamer consists of a central $\mathrm{Ga}(\mathrm{III})$ bridged via hydroxyl groups to six surrounding gallium cations forming an inner core of seven edge-shared $\mathrm{Ga}(\mathrm{O})_{6}$ polyhedra. The six inner polyhedra are further vertexshared to six peripheral tetrahydrated $\mathrm{Ga}(\mathrm{III})$ ions generating a disk-like compound with an effective diameter of $c a .1 .81 \mathrm{~nm}$ and a thickness of $c a .1 .03 \mathrm{~nm}$. The central, inner

[^3]$\mathrm{Ga}($ III ) lies at a special position on the $\overline{3}$ axis of the unit cell and is coplanar with respect to the six surrounding edge-shared $\mathrm{Ga}(\mathrm{O})_{6}$ polyhedra (mean plane deviation of 0.06 to $0.07 \AA$ ). The distances between edge-shared gallium cations and the corresponding oxygen atoms $\mathrm{d}\left(\mathrm{Ga}-\mu_{3}-\mathrm{OH}\right)$ are in a range of 1.96 to $2.15 \AA$. The six external $\mathrm{Ga}(\mathrm{O})_{6}$ polyhedra are bonded to the inner core of seven Ga (III) each via two vertices with corresponding distances $\mathrm{d}\left(\mathrm{Ga}-\mu_{2}-\mathrm{OH}\right)$ of 1.91 to $1.92 \AA$. The peripheral $\mathrm{Ga}(\mathrm{III})$ are each coordinated to four water ligands with distances $\mathrm{d}\left(\mathrm{Ga}-\mathrm{OH}_{2}\right)$ in a range of 1.98 to $2.01 \AA$.

Figure 2.4 Crystal packing of the polycations $\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]^{15+}$ in 1 representing the stacking of sheets in an ABCABC mode orthogonal to the $z$-axis (a) and orthogonal to the $y$-axis (b), hydrogen atoms, counter-anions $\mathrm{NO}_{3}{ }^{-}$and water molecules have been omitted for clarity.

The peripheral tetrahydrated gallium centers deviate from the mean plane of the inner core formed by the seven edge-sharing cations by $c a .30^{\circ}$ and they are positioned alternatively above and below the plane of the $\mathrm{Ga}_{7}$ core. The main difference with respect to the structure of $\left[\mathrm{Al}_{13}(\mathrm{OH})_{24}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right] \mathrm{Cl}_{15} \cdot 13 \mathrm{H}_{2} \mathrm{O}$ lies in the crystal packing adopted by
$\mathbf{1}$ (Figure 2.1.2): the $\mathrm{Ga}_{13}$ clusters crystallize in a hexagonal array. The polycationic units arrange in layers parallel to [001] and repeat in an ABCABC mode along the $z$-axis with an interlayer separation of $6.12 \AA$. Cluster $\mathbf{1}$ is a highly hydrophilic compound with a surface rising with hydrogen bond donors and acceptors. These particles are completely surrounded by counteranions forming shells around the polycations through an intricate hydrogen bonding network in which interstitial $\mathrm{NO}_{3}{ }^{-}$and uncoordinated guest water molecules interact with coordinated water and hydroxide ligands with distances $\mathrm{d}(\mathrm{O} \cdots \mathrm{O})$ in a range of 2.57 to $3.00 \AA$.

In summary, a straightforward method to generate mixed aquo/hydroxo gallium clusters in the form of large robust single crystals has been presented and provides an alternative to the hydrolysis of the cations in the presence of base, which usually results in the formation of poor quality crystals. Further work is currently underway to investigate the properties in solution of the $\mathrm{Ga}_{13}$ clusters. These purely inorganic aggregates might be relevant as starting materials for the generation of a wider range of particles via exchange of the water ligands with appropriate organic species. We are exploring the generality of our synthetic route to see if treatment of other metal nitrate salts with nitrosobenzene provides higher nuclearity metal clusters as well.

Supporting Information Available: Crystallographic data for $\mathbf{1}$ in .CIF format is available as CSD 414322. These data can be obtained from the Fachinformationzentrum (FIZ) Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany) www.fizinformationsdienste.de. This material, details of the synthetic procedure and x-ray
powder diffraction patterns are also available free of charge via the Internet at http://pubs.acs.org.

## CHAPTER III

## NOVEL SYNTHESIS OF ALUMINUM 13 INORGANIC NANOCLUSTERS

The synthetic procedure in this chapter was developed by a number of lab members including Jason T. Gatlin and Zachary L. Mensinger. Zachary L. Mensinger contributed substantially to this chapter by participating in the development of a standard synthetic procedure. I was the primary contributor to the optimization of the synthetic conditions and developed the purification procedure. Dr. Lev N. Zakharov was helpful in solving the crystal structure. Dr. David MacInnes was helpful in reviewing and editing the manuscript. This work has not yet been published but will be submitted in the summer of 2007 to the journal Inorganic Chemistry. Zachary L. Mensinger initially identified the alternate nitroso reductant for cluster synthesis, which yields the identical cluster to the Nitrosobenzene synthesis. Dr. Prof. Darren W. Johnson was the principle investigator for this work.

Since the synthesis of our first "flat"-Ga ${ }_{13}{ }^{\circ}$ cluster", we sought to explore the generality of the reaction. There were two different directions of experiments to explore; the organic side and the inorganic side. The first was to determine if the identical unstabilized $\mathbf{G a}_{13}{ }^{\circ}$ cluster can be made with other reductants and determine the importance of the nitroso functionality. The second was to determine if other similar clusters could be synthesized via the same reaction conditions. Chapter 2 will discuss the results of the organic experiments, and Chapter 3 will address the synthesis of other $\mathrm{M}_{13}{ }^{\circ}$ nanoclusters via the same reaction.

We began changing the conditions of the crystallization in hopes of increasing the isolated yield of the nanocluster. We were hoping to see what drove the crystallization of the nanocluster and to determine if it was the observed oxidation of nitrosobenzene and, therefore removal of the nitrate counter ions or if it was the evaporation of the solvent. Crystallizations set up in the refrigerator or freezer yielded large, stable, colorless crystals very quickly. However the only crystalline product isolated was the dimer of nitrosobenzene which can be isolated by lowering the temperature or by chromatography of the reaction mixture before completion. This structure was already know and was present in the CSD (reference code: CAZBZO10 and JTG46.) ${ }^{2,3}$

Figure 3.1. Known crystal structure the nitrosobenzene dimer. (Orthorhombic $\mathrm{P}, \mathrm{Pbcn}, a$ $=10.292(1) \AA, b=13.796(1) A, c=15.005(1) A, \alpha=\beta=\gamma=90^{\circ} \mathrm{V}=2137.8 A^{3}, Z=8$ )

Since determining that the nitroso functionality was the active functional group, commercial suppliers were searched for other nitroso-containing organic compounds as well as potential reductants with similar electrochemical potentials Figure 3.2. Typically, it is difficult to determine reduction potentials for organic compounds and only a few have been determined (Scheme 3.1). ${ }^{4}$

Figure 3.2.Some of the commercially available nitroso group containing compounds

Scheme 3.1. Reduction potentials of three nitroso containing organic compounds versus a SCE. ${ }^{4}$

All the reactions were set up following the same procedure as the synthesis with nitrosobenzene, except for the exchange of organic reductants in the same stoichiometry. Scheme 3.2 shows the crystalline products isolated from the reactions of the alternate reductants with $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$. Cuperferron has been known to bind copper and iron in a similar manner, hence the name, as well as aluminum. ${ }^{5}$ The nitroso functionality of the guanidine and the diazald are not stable: both compounds denitrosolate under reaction conditions, with or without metal being present. From the series of organic compounds in Figure 3.2, only one, N,N-Dibutyl-N-nitrosoamine (DBNA), yielded the same flat $\mathrm{Ga}_{13}{ }^{\circ}$ nanocluster. Figure 3.3 shows a side-by-side comparison of the two reactions with the different nitroso compounds: nitrosobenzene (on the left) and DBNA (on the right), both of which yield the nanocluster in respectable yields.

Scheme 3.2. Nitroso compounds that show activity and the isolated crystalline products yielded.

The difference in the two reactions is very clear. The yields are higher in the DBNA reaction, most likely because of the great ease in which we can isolate crystals by just decanting the oil byproduct. The new organic additive DBNA can also be recycled and reused for further reactions making this synthesis greener than using the nitrosobenzene. This suggests that the organic byproduct of the cluster synthesis with DBNA is not as stable as the nitrobenzene product of the nitrosobenzene reductant. Current works to track down the oxidized product of the DBNA reductant have not been successful. We hope to determine if the reaction can be used in the future as gentle organic oxidant.

Figure 3.3. The decomposition of the organic reductants post oxidation. Nitrosobenzene product and DBNA product (left to right)

Tweaking the conditions for $\mathrm{Ga}_{13}{ }^{\circ}$ cluster formation allowed us to synthesize the analogous $\mathrm{Al}_{13}{ }^{\circ}$ cluster. This new organic reductant allows for the formation of our previous $\mathrm{Ga}_{13}{ }^{\circ}$ cluster in a higher yield and allowed for the isolation of the previously known $\mathrm{Al}_{13}{ }^{\circ}$ nanocluster as well with the same reaction conditions. The Fedin group also tried to use their $\mathrm{CB}[6]$ strategy to synthesize the flat $\mathrm{Al}_{13}{ }^{\circ}$ nanocluster, which they reported to Casey ${ }^{6}$ as a personal communication, but their later published results indicate that they in fact synthesized the Keggin $\mathrm{Al}_{13}{ }^{\text {}}$ cluster not the "flat"- $\mathrm{Al}_{13}{ }^{\circ}$ cluster. ${ }^{7}$ Due to the other stability issues the use of nitrosobenzene will be discontinued in favor of DBNA.

We tested a variety of other organic compounds that we believed were easily oxidized and that do not contain the nitroso functionality as possible reductants for the formation of the flat $\mathbf{G a}_{13}{ }^{\circ}$ nanocluster Figure 3.4. As of yet none of them have yielded a metal cluster.

Triphenyl Phosphine

Figure 3.4. Other potential organic reductants screened
One conversion of interest with low oxidation potential is the oxidation of a phosphine or an arsine to its oxide. ${ }^{4}$ The ease of oxidation of the pnictogens follows the established trend ( $\mathrm{P}>\mathrm{Sb}>\mathrm{As}$ ), with P the easiest to oxidize. It is clear that phosphines are easily oxidized to phosphine oxides while arsines are more stable to oxidation. Triphenyl
phosphine, triphenyl arsine and their oxides are used extensively for initiating polymerization reactions and as ligands in transition metal complexes and catalysis. ${ }^{8}$ The thermodynamically stable pentavalent oxides are generally made from phosphines and arsines either with strong oxidants or activating with a transition metal, followed by oxidization by a less powerful reagent. ${ }^{9.14}$ Some preliminary results have been achieved with the use of triphenyl pnictogens as reductants.

$$
\mathrm{Y}=\mathrm{P}, \mathrm{As}, \mathrm{Bi}, \text { and } \mathrm{Sb}
$$

Scheme 3.3. The oxidation with formation of pnictogen oxides for the reactions.
The use of gallium nitrate was explored in oxidizing both triphenyl phosphine and arsine while concomitantly producing a $\mathbf{G a}_{13}{ }^{\circ}$ nanocluster. Allowing a solution of gallium nitrate and triphenyl phosphine to incubate at room temperature for 5 days resulted in isolation of only the starting materials. Only after heating for one to two hours at $69^{\circ} \mathrm{C}$ did a reaction occur, giving the known $\left[\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3} \mathrm{As}=\mathrm{O}-\mathrm{H}-\mathrm{O}=\mathrm{As}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right]$ complex which contains a hydrogen bond between two triphenyl arsenic oxides entities. This complex contains a $\left[\mathrm{NO}_{3}\right]$ counter ion, as oppossed compared to other previously formed clusters. ${ }^{15-18} \mathrm{~A} \mathrm{Ph}_{4} \mathrm{P}^{+} \mathrm{NO}_{3}{ }^{-}$species was also crystallized. Triphenyl phosphine can also be oxidized by $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ but it appears that the analogous $\mathrm{Fe}_{13}$ cluster is not formed; instead, a $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{Ph}_{3} \mathrm{PO}\right)_{3}$ salt is formed. A control reaction run without metal salts showed no oxidization of the pnictogens.

Figure 3.5. The isolated products from the pnictogen oxidation.
Although the preliminary results for non-nitroso reductants are encouraging, it is problematic that the $\mathrm{Ga}_{13}{ }^{\circ}$ cluster was not isolated in addition to the organic reagent nor was any other multiple metal complex, Figure 3.5. A balanced equation cannot be written; therefore, this reaction is not useful to the project until a new inorganic product can be isolated. There is a solved crystal structure of the triphenyl arsenic oxide dimer and the tetraphenyl phosphine cation, but only IR confirmation of the triphenyl phosphine oxide. This set of experiments needs to be repeated because a metal product could not be isolated, not even as the starting salt, which is important to demonstrate the generality of the reaction for forming $\mathrm{M}_{13}{ }^{\circ}$ clusters.

A functional group of great interest was oximes because they tautomerize to nitroso functionality, but the tautomerization equilibrium lies heavily to the oxime isomer, Scheme 3.4. This tautomerization is not possible for nitrosobenzene because the $\alpha$ carbon is tied up in the aromatic ring and fully substituted. Unfortunately, the oxime reactions only yielded the recrystallization of the starting materials, with no nanocluster formation.

oxime
Nitroso
Scheme 3.4. Oxime-Nitroso tautomerization
We preformed a series of experiments of the group 13 metals ( $\mathrm{Al}, \mathrm{Ga}$ and In ) with DBNA at different pH 's by adding KOH or $\mathrm{HNO}_{3}$. Not surprisingly the yields of cluster were lower with decreased pH by addition of $\mathrm{HNO}_{3}$ addition because we were driving the reaction the wrong way with addition of the nitrate anion. The yield of the reaction did not improve when the acid was changed to HCl . Only the addition of base had a positive outcome for the aluminum; the isolation of the flat $\mathbf{A l}_{13}{ }^{\circ}$ cluster. We have not yet been able to isolate the isostructural flat $\mathrm{In}_{13}{ }^{\circ}$ from any of these reactions. The large ionic radius of indium might prevent the formation of the cubic closed packed array of the Anderson core. In the following chapter I describe the current syntheses of the flat $\mathbf{A l}_{13}{ }^{\mathbf{o}}$ cluster using different bases.

Treatment of aluminum nitrate with an organic nitroso-containing compound yields the "flat", tridecameric nanocluster, $\mathrm{Al}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}\left(\mathbf{A l}_{13}{ }^{\mathbf{0}}\right)$ in good yields on a preparative scale under ambient conditions. Synthetic procedures yielding two different single crystal forms of the $\mathbf{A l}_{13}{ }^{\mathbf{0}}$ cation with two varying counterion compositions are described.

Aluminum is the third most abundant element and the most abundant metal in the earth's crust, found in many minerals and ores. Aluminum complexes are widespread in our environment, occurring in natural waters and clays usually as hydrated salts or clusters containing multiple aluminum ions held together through various bridging
groups. ${ }^{6,7,19-26}$ Despite the widespread prevalence of natural aqueous aluminum oligomers, relatively few have been synthesized on preparative scale and analyzed by single crystal X-ray diffraction. ${ }^{6}$ Furthermore, existing syntheses of many of these inorganic aqueous clusters suffer from long reaction times and/or poor yields (in cases where yields have been reported), hampering efforts to study the applications and bulk properties of these materials. ${ }^{6,23-27}$ Herein we report facile syntheses that yield bulkscale single crystals of inorganic $\mathrm{Al}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}{ }^{15+}$ clusters with various counter-anions (Scheme 3.5).

Oligomeric aluminum clusters are found in two general structure types: 1) structures similar to the $\varepsilon$-Keggin tridecameric clusters composed of a central tetrahedral metal ion surrounded by edge-shared octahedral $\mathrm{AlO}_{6}$ units; $;^{21,28-30}$ and 2) clusters comprised entirely of octahedrally coordinated Al cations (such as "flat"-Al $\mathbf{1 3}_{13}{ }^{\mathbf{0}}$, Figure 3.6). Only a few reports of the latter class of clusters exist. ${ }^{6,23-27}$ We report the synthesis of the purely inorganic salt $\mathrm{Al}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}\left(\mathrm{Al}_{13}{ }^{\mathbf{0}}\right)$, a member of the latter class. The synthesis of purely inorganic aluminum salts has been reported as difficult and often elusive: ${ }^{6}$ the synthesis reported herein proceeds in reasonable isolated yields under ambient conditions and in preparative scales in a manner similar to the route we reported recently for the $\mathbf{G a}_{13}{ }^{\circ}$ congener.

Scheme 3.5 Synthesis of "flat" $\mathbf{A l}_{13}{ }^{0}$ nanocluster using the organic reductants nitrosobenzene (A) or $N$-nitroso-di-n-butylamine (B). The average Al-( $\mu_{3}-\mathrm{O}$ ), Al- $\left(\mu_{2}-\mathrm{O}\right)$ and $\mathrm{Al}-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distances $(\AA)$ are $1.879(7), 1.850(9), 1.917(15)$ and $1.877(6), 1.848(5)$, 1.92(2), respectively, in $\mathbf{1}$ and $\mathbf{2}$. Base $=\mathrm{KOH}, \mathrm{NH}_{4} \mathrm{OH}$, or $\mathrm{Al}(\mathrm{OH})_{3}$ (Note: in the case of $\mathrm{Al}(\mathrm{OH})_{3}$, the use of 1.3 eq of base necessitates only an additional 11.7 eq of $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$.)

[^4]Two recent syntheses of the "flat" $\mathbf{G a}_{13}{ }^{\mathbf{0}}$ Keggin-like structure $\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\right.$ $\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}$ were independently reported using gallium nitrate and an organic additive such as nitrosobenzene ${ }^{1}$ or cucurbit[6]uril (CB[6]). ${ }^{31}$ A related $\mathbf{A l}_{13}{ }^{\circ}$ core structure has been reported previously: both a structure supported by exogenous aminocarboxylate ligands and the inorganic chloride salt are known. ${ }^{25,26}$ However, the synthesis of the chloride salt suffers from a four and a half month preparation and only data on a single crystal were reported. Therefore, we sought to apply our synthetic strategy using nitroso organic compounds to prepare the analogous $\mathbf{A l}_{13}{ }^{0}$ structures.

We have previously shown the simple conversion of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ into the flat- $\mathrm{Ga}_{13}{ }^{0}$ nanocluster proceeds in the presence of nitrosobenzene. In this reaction, nitrosobenzene is believed to act as a scavenger for the nitrate counter-ions, in effect forcing the $\mathrm{Ga}^{3+}$ cations to form a higher nuclearity species. The stoichiometry for the process involves reaction of 13 eq $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ with 24 eq of nitrosobenzene to prepare one eq of $\mathrm{Ga}_{13}{ }^{\mathbf{o}}$ in gram quantities and up to $65 \%$ yield. ${ }^{1}$ Modification of this method to form the related tridecameric aluminum cluster involves a key modification (Scheme 3.4): The reaction to form $\mathbf{A l}_{13}{ }^{\mathbf{}}$ requires the addition of 1.3 eq of base, presumably a result of the increased pKa of hydrated aluminum complexes over gallium. ${ }^{32+}$ Single crystals of $\mathbf{A l}_{13}{ }^{\circ}$ were isolated in un-optimized yields of up to $47 \%$ in under two weeks from a methanolic

[^5]solution of aluminum(III) nitrate nonahydrate, KOH and nitrosobenzene. A similar procedure using N -di- $n$-butylnitrosamine also affords $\mathbf{A l}_{13}{ }^{\mathbf{o}}$ in reasonable yields ( $15-60 \%$, depending on the base), and provides for a far easier workup, as crystals are isolated from the remaining liquid nitrosoamine rather than the tarry sludge left over from the nitrosobenzene procedure. We have also found that this nitrosoamine provides higher yields of the related $\mathbf{G a}_{13}{ }^{\mathbf{0}}$ complex as well as a series of related mixed-metal clusters, all of which can be isolated in gram quantities. ${ }^{33}$

A drawback to the use of KOH as the base in this procedure is isolation of pure $\mathbf{A l}_{13}{ }^{\mathbf{}}$ from the powdery $\mathrm{KNO}_{3}$ that presumably forms in the reaction as well. To avoid this time-consuming workup, we have successfully employed $\mathrm{Al}(\mathrm{OH})_{3}, \mathrm{NH}_{4} \mathrm{OH}$, and $\mathrm{NBu}_{4} \mathrm{OH}$ as alternate bases; all the salts that form as byproducts are soluble in the final oily mixture from which the $\mathbf{A l}_{13}{ }^{\circ}$ crystals are collected (Route B, Scheme 3.5).

The single crystal X-ray structure of the "flat"- $\mathbf{A l}_{13}{ }^{\mathbf{0}}$ cluster reveals a planar centrosymmetrical Anderson-type ${ }^{34,35} \mathrm{Al}\left(\mu_{3}-\mathrm{OH}\right)_{6} \mathrm{Al}_{6}\left(\mu_{2}-\mathrm{OH}\right)_{6}$ core fragment surrounded by six aluminum ions. ${ }^{\ddagger}$ The outer six aluminum cations alternate above and

[^6]below the planar core defined by the central 7 metal ions, and they are coordinated by four terminal aquo ligands. Two $\mu_{3}$-bridging hydroxide ligands connect each of these $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ fragments to each other and to the central core. ${ }^{1,19,25,26}$ Two different single crystal forms were obtained from the syntheses; however, the cluster cations are nearly identical (see bond lengths in Scheme 3.4 and Supporting Information). Synthetic routes $\mathbf{A}$ and $\mathbf{B}$ (base $=\mathrm{KOH}$ or $\left.\mathrm{Al}(\mathrm{OH})_{3}\right)$ both provide structure $\mathbf{1}\left(\mathbf{A l}_{13} \cdot 9\left(\mathrm{H}_{2} \mathrm{O}\right)\right.$ ), whereas route $\mathbf{B}$ (base $\left.=\mathrm{NH}_{4} \mathrm{OH}\right)$ provides structure $2\left(\mathbf{A l}_{13} \cdot\left(\mathrm{NO}_{3}\right)\left(\mathrm{NH}_{4}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{10}\right)$, which has an extra nitrate and ammonium counter-ion.

The $\mathbf{A l}_{13}{ }^{\mathbf{}}$ polycations determined in this work have a similar structure to the $\mathbf{G a} \mathbf{1 3}^{\mathbf{0}}$ cluster cation in which all the metal centers are octahedral (Figure 1A). ${ }^{1,31}$ In the crystal structures, both the $\mathbf{A l}_{13}{ }^{\circ}$ clusters are centrosymmetric in contrast to the $\overline{3}$ crystallographic symmetry of the $\mathrm{Ga}_{13}$ cluster cation, although the idealized symmetry of the $\mathbf{A l}_{13}{ }^{\mathbf{o}}$ clusters cations is close to $\overline{3}$. In $\mathbf{1}$ the $\mathbf{A l}_{13}{ }^{\circ}$ clusters are surrounded by $\mathrm{NO}_{3}{ }^{-}$ anions and solvent water molecules forming $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds. In the case of the crystals grown from the reaction using $\mathrm{NH}_{4} \mathrm{OH}$ as base, one molecule of $\mathrm{NH}_{4}{ }^{+}$also cocrystallizes, necessitating the presence of an extra $\mathrm{NO}_{3}{ }^{-}$counter-ion (16 total) for charge balance. The hydrogen atoms of both the coordinating water molecules and those of the bridging $\mu$-OH ligands are involved in numerous intermolecular H -bonds. Similar hydrogen bonding is observed between clusters in $\mathbf{G a}_{13}{ }^{\mathbf{0}}$ as well.

Figure 3.6 A) Polyhedral representation of "flat" $\mathrm{M}_{13}$ Keggin-like nanoclusters; B) Polyhedral representation of $\varepsilon$-Keggin $\mathrm{M}_{13}{ }^{t}$ structure-type comprising 12 octahedral metal centers (blue) that share vertices with a central tetrahedral (purple) metal center.

Our method has allowed for the facile synthesis of $\mathbf{A l}_{13}{ }^{\circ}$ clusters showing the generality of our strategy for preparing inorganic nanoclusters. A procedure for synthesizing preparative amounts of clusters of this type may have utility to researchers in the field trying to use these clusters as discrete molecular mimics of minerals or as single source precursors for thin film oxide materials. ${ }^{6,21}$

Supporting Information Available. X-ray data and details of X-ray diffraction studies in CIF format, powder XRD and TGA data on $\mathbf{A l}_{13}$. This material is available free of charge via the Internet at http://pubs.acs.org.

## CHAPTER IV

## NOVEL HETEROMETALLIC TRIDECAMERIC INORGANIC NANOCLUSTER

The synthetic procedure in this chapter was developed by a number of lab members including Jason T. Gatlin and Zachary L. Mensinger. Zachary L. Mensinger contributed substantially to this chapter by participating in the development of a standard synthetic procedure. I was the primary contributor to the optimization of the synthetic conditions and developed the purification procedure. Dr. Lev N. Zakharov was helpful in solving the crystal structures. Stephen T. Meyers and Dr. Prof. Douglas A. Keszler were helpful in the VT PXRD characterization of the clusters. Stephen T. Meyers and Dr. Prof. Douglas A. Keszler also used the tridecameric clusters as synthons for the synthesis of the think film oxides. This work has not yet been published but will be submitted to the journal Angewandte Chemie International Edition. Zachary L. Mensinger initially identified the alternate nitroso reductant for cluster synthesis, which yields the identical cluster to the Nitrosobenzene synthesis. Dr. Prof. Darren W. Johnson was the principle investigator for this work.

The following chapter discusses the inorganic side of the tridecameric cluster formation. This bridge and the following chapter detail new research into heterometallic tridecameric nanoclusters. Modifications of the $\mathbf{G a}_{13}{ }^{\mathbf{}}$ synthesis via a slight change in the reaction pH allowed for the synthesis of the previously known analogous flat $\mathbf{A l}_{13}{ }^{\circ}$ inorganic nanocluster. An alternate reductant was discovered that delivers both the $\mathbf{G a}_{13}{ }^{\mathbf{}}$ and the $\mathbf{A l}_{13}{ }^{\circ}$ clusters in higher yields; this is presumably because of the ease of isolation.

There are numerous examples of mixed metal Keggin clusters of the ratio $\mathrm{MO}_{4}\left(\mathrm{M}^{\prime} \mathrm{O}_{6}\right)_{12}$, where M is the central tetrahedral metal and all the peripheral metal centers are octahedral. The previously know flat $\mathrm{M}_{13}{ }^{\circ}$ clusters, $\mathbf{A l}_{13}{ }^{\circ}$ and $\mathbf{G a}_{13}{ }^{\circ}$, have all been homometallic and the question raised is whether other flat $\mathrm{M}_{13}$, both homo- and heterometallic clusters besides the previously known $\mathbf{A l}_{13}{ }^{01,2}$ and $\mathbf{G a}_{13}{ }^{03,4}$ clusters be synthesized in the same manner. Searches of the literature have yielded no reported synthesis of heterometallic flat $\mathrm{M}_{13}{ }^{0}$ clusters.

Scheme 4.1. Mixed group binary Metal combinations.
Multiple combinations and ratios of metals were used in an attempt to synthesize new heterometallic $\mathrm{M}_{13}{ }^{\circ}$ clusters. In an attempt to determine the generality of this new
found reaction, over one hundred binary combinations of commercially available metal nitrate salts were combined with stoichiometric amounts of the original reductant nitrosobenzene in methanol and allowed to evaporate in the same manner as the original cluster formation. A major problem with the reaction set is that the organic additive of nitrosobenzene yields a very viscus dark oil. When these experiments were run, the new alternate reductant of DBNA had not yet been discovered. The vast majority of crystals screened using nitrosobenzene yielded only starting materials. In addition to mixing metals from groups a series of experiments was to set up that only contained group 13 metals with a 1:12 ratio of metal salts (Table 3.2.1), in the hope that the substitution would occur only at the central location.

Table 4.1. Ratios of the mixed group 13 cluster synthesis

| Al | Ga | In |
| :--- | :--- | :--- |
| 1 | 1 |  |
| 1 |  | 1 |
|  | 1 | 1 |
| 1 | 12 |  |
| 12 | 1 |  |
|  | 12 | 1 |
|  | 1 | 12 |
| 1 |  | 12 |
| 12 |  | 1 |

A series of new tridecameric heterometallic $\mathrm{Ga} / \mathrm{In}$ clusters were synthesized by varying the starting ratio of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ and $\mathrm{In}\left(\mathrm{NO}_{3}\right)_{3}$ salts (Scheme 4.1). An n:m ratio of $1: 12, \mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}: \operatorname{In}\left(\mathrm{NO}_{3}\right)_{3}$ resulted in a $\mathbf{G a}_{7} \mathbf{I} \mathbf{n}_{6}{ }^{\mathbf{0}}$ nanocluster. $\mathrm{A} \mathbf{G a} \mathbf{a}_{8} \mathbf{I n}_{5}{ }^{\mathbf{0}}$ cluster is obtained when the $\mathrm{n}: \mathrm{m}$ ratio was $1: 6$, and a n:m ratio of 7:6 afforded $\mathrm{Ga}_{10} \mathbf{I} \mathbf{I n}_{3}{ }^{0}$. Symmetry of the $\mathbf{G a}_{7} \mathbf{I n}_{6}{ }^{\mathbf{0}}$ cluster cation is $\overline{3}$ which is analogous flat $\mathbf{G a}_{\mathbf{1 3}}{ }^{\mathbf{0}}$ and flat $\mathbf{A l}_{13}{ }^{\mathbf{0}}$ nanoclusters. ${ }^{4,5}$ All of the heterometallic clusters are isostructural with $\mathbf{G a}_{13}{ }^{\mathbf{0}}$. They
posess the same $\mathrm{Ga}_{1}\left(\mu_{3}-\mathrm{OH}\right)_{6} \mathrm{Ga}_{6}\left(\mu_{2}-\mathrm{OH}\right)_{6}$ core, but vary in the gallium or indium atoms forming the third M-shell of the cluster (Figure 4.1). Unfortunately, there is no quick way to screen the crystal composition aside from collecting full XRD data sets. Bond distances and electron count allow for identification of the clusters (all clusters are similar, but possess different disorder in $\mathrm{Ga} / \mathrm{In}-$ See Supplemental). This could be used as a predictive strategy for the formation of other heterometallic clusters.

Table 4.2. Starting material ratios compared to XRD and EPMA data of crystals.

|  | Starting Material |  | Characterization |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | XRD |  | EA |  | EPMA |  |
|  | Gallium | Indium | Gallium | Indium | Gallium | Indium | Gallium | Indium |
| $\mathbf{G a}_{13}$ | 13 | 0 | 13 | 0 | 13 | 0 | - | - |
| Ga $\mathbf{1 2}^{12} \mathbf{n}$ | 5 | 1 | 12 | 1 | 12 | 1 | 12 | 1 |
| $\mathrm{Ga}_{11} \mathbf{I n}_{2}$ | 2 | 1 | 11 | 2 | 11 | 2 | 11 | 2 |
| $\mathrm{Ga}_{10} \mathrm{In}_{3}$ | 7 | 6 | 10 | 3 | 9 | 4 | 10 | 3 |
| $\mathrm{Ga}_{9} \mathrm{In}_{4}$ | 1 | 2 | 9 | 4 | - | - | - | - |
| $\mathbf{G a}_{8} \mathrm{In}_{5}$ | 2 | 11 | 8 | 5 | - | - | - | - |
| $\mathbf{G a}_{7} \mathbf{I n} \mathbf{6}$ | 1 | 12 | 7 | 6 | 6 | 7 | 6 | 7 |

The addition of acid did not yield new clusters, as the $\mathrm{NO}_{3}{ }^{-}$anion was used up and the starting metal salts were able to recrystalize back. The crystal structures and starting material ratios were successfully used to form a predictive method for future heterometallic clusters.

Number of Galliums in Starting Material versus Crystal

Graph 4.1. Plot of gallium numbers in crystal product versus starting material

Unfortunately, heterometallic and homometallic clusters of metals other than those from group 13 have not been obtained. Currently success with these experiments has centered on heterometallic group 13 metals of just $\mathrm{Al}, \mathrm{Ga}$ and In metal centers. A few data points have been successful in predictively making all seven in the series from $\mathbf{G a}_{13}{ }^{\mathbf{o}}$ to $\mathbf{G a}_{7} \mathbf{I} \mathbf{n}_{6}{ }^{\mathbf{0}}$, Figure 4.2. However there has been no observable indium substitution in the inner core. We theorize that it is related to the large ionic radius of the indium cation. Future work will need to explore the potential to incorporate other metals from other groups into the nanoclusters, as well as finishing out the mixed metal Group 13 series in both the gallium:indium and the aluminum:indium series. In addition to the mixed gallium and indium clusters, an analogous $\mathbf{A l}_{8} \mathbf{I n}_{5}{ }^{\circ}$ tridecameric nanocluster was also successfully synthesized.

Figure 4.1. Gallium and Indium Heterometallic nanocluster series, with distribution.
After isolation of $\mathbf{G a}_{13}{ }^{\mathbf{0}}$ and $\mathbf{A l}_{13}{ }^{\mathbf{0}}$ using DBNA, further experiments were carried out using the alternative reductant. This made screening for new crystals much easier, since the presence of crystals could easily be seen without magnification. Since decanting the oil formed as a byproduct made isolating the remaining crystalline product easy. There was less hunting in the organic residue for crystals.

Figure 4.2. The heterometallic $\mathrm{Al}_{8} \mathrm{In}_{5}{ }^{\circ}$ cluster, synthesized by Z.L.M.
Surface chemistry of our nanoclusters by SEM and EPMA is being explored and will be discussed in Chapter V. In the following chapter the first synthesis of the heterometallic $\mathrm{Ga}_{7} \mathbf{I n}_{6}{ }^{0}$ nanocluster is discussed. A potential use for these clusters is in
thin film oxides. This will be explored as part of a collaboration with the Keszler group at Oregon State University.

Our research has focused on inorganic metal-hydroxo nanoclusters of group 13 metals, such as our recently reported $\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}\left(\right.$ flat- $\left.-\mathrm{Ga}_{13}{ }^{\circ}\right)$ cluster (this structure was independently isolated and reported by Fedin, et al.). ${ }^{6}$ The $\mathrm{M}\left(\mu_{3}-\mathrm{OH}\right)_{6} \mathrm{M}_{6}\left(\mu_{2}-\mathrm{OH}\right)_{6}$ central fragment of this cluster forms a planar core with six additional $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ groups bound to the core via two $\mu_{2}-\mathrm{OH}$ bridges each. The outer metal ions occupy alternate positions above and below the plane formed by the central seven metal ions. Metal complexes of this class are fairly rare, and typically consist of aluminum ${ }^{1,7,8}$, though several gallium complexes have recently been reported as well (ours, Fedin, Heath). Inorganic-only and ligand-supported clusters have been synthesized, with the latter generally being more common. One aspect that has been notably absent so far in this class is mixing of metal compositions within the same molecule, as well as clusters containing indium. Mixed-metal clusters are well known for other metal-oxo-hydroxo and metal-oxo clusters, such as Keggin- $\mathrm{Al}_{13}{ }^{\text {t }}$ and Anderson-type clusters, two classes of molecules that are related to our flat- $\mathrm{M}_{13}{ }^{\circ}$. In the case of Keggin tridecamers, the central tetrahedral metal can be substituted, forming compositions of $\mathrm{M}_{1} \mathrm{Al}_{12}(\mathrm{M}=\mathrm{Al}, \mathrm{Ga}$, or Ge have been conclusively demonstrated, with others suggested).
${ }^{9-19}$ Extensive reports exist for substitution of the central metal in B-type Anderson clusters as well, affording clusters of general formula $\mathrm{M}(\mathrm{OH})_{6} \mathrm{Mo}_{6} \mathrm{O}_{18}{ }^{\mathrm{n}}$, $\left(\mathrm{M}=\mathrm{Mn}^{2+}, \mathrm{Fe}^{2+}\right.$, $\mathrm{Fe}^{3+}, \mathrm{Co}^{2+}, \mathrm{Co}^{3+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Al}^{3+}, \mathrm{Ga}^{3+}, \mathrm{Cr}^{3+}, \mathrm{Rh}^{2+}$, and $\mathrm{Pt}^{2+}$ and $\mathrm{n}=2$ or 3 ) in addition to various tungstates. To the best of our knowledge however, no such larger
nuclearity mixed-metal metal-hydroxo clusters consisting of aluminum or gallium have been reported.

Figure 4.3. 1 is $\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}$ and $2 \mathrm{Ga}_{7} \mathrm{In}_{6}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\right.$ $\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}$

Prior synthetic preparation of this class of compounds has at times also proven quite difficult. Their synthesis often requires caustic or acidic conditions and high temperatures. Crystallization periods of months or even years are not uncommon. ${ }^{1,7,20}$ Due to these difficulties, relatively few metal-hydroxo clusters of aluminum and other group 13 metals have been synthesized, fewer still inorganic only clusters. An additional synthetic method for clusters of this class would be welcomed by researchers in the fields of environmental and geochemistry. Herein we report a previously unknown structure, $\mathrm{Ga}_{7} \mathrm{In}_{6}\left(\mu_{3}-\mathrm{OH}\right)_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}\left(\right.$ flat- $\left.\mathrm{Ga}_{7} \mathrm{In}_{6}\right)$, consisting of a mixed-metal gallium-indium structure. This cluster can be synthesized reliably in moderate yields utilizing our previously reported synthetic method, and in excellent yields with the use of a different nitroso compound, presented herein.

As an example, we have already begun exploring one application for theses clusters, driven by a rising interest in printed macroelectronics and the high carrier mobilities recently reported in disordered Group-13 and other p-block oxides. ${ }^{21-23}$ Most solution precursors for printed oxide films involve controlled hydrolysis of metal-organic compounds and the condensation of metal-hydoxo "sols" which are then pyrolyzed to form the oxide. Such films are beset by a variety of density, defect, and segregation issues relating to the inhomogeneous nature of the sol and retention of significant organic components. From this perspective, soluble all-inorganic, heterometallic hydroxoclusters provide model oxide precursors driven by similar hydrolysis and condensation principles, but lacking detrimental organic moieties.

In this contribution we report a previously unknown structure, $\mathrm{Ga}_{7} \operatorname{In}_{6}\left(\mu_{3}-\right.$ $\mathrm{OH})_{6}\left(\mu_{2}-\mathrm{OH}\right)_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\left(\mathrm{NO}_{3}\right)_{15}\left(\right.$ flat- $\left.\mathrm{Ga}_{7} \mathrm{In}_{6}\right)$, consisting of a mixed-metal gallium-indium structure. This cluster can be synthesized reliably in moderate yields utilizing previously reported synthetic methods, and in excellent yields with the use of a different nitroso compound, presented herein. Finally, we describe the adaptation of these structures as precursor solutions for oxide semiconductor thin-films by fabricating high-performance thin-film transistors (TFTs) with spin-coated $\mathrm{In}_{0.92} \mathrm{Ga}_{1.08} \mathrm{O}_{3}$ channel layers.

Our previous report describes the mild preparation of the inorganic flat- $\mathbf{G a}_{13}{ }^{0}$ compound, prepared by dissolving $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ and nitrosobenzene in MeOH followed by slow evaporation. Crystals are then manually separated from the resultant black tar-like product mixture. Using this method, yields up to $65 \%$ of flat- $\mathbf{G a}_{13}{ }^{\circ}$ could be obtained in small scale. This same procedure was applied to a mixture of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$ and $\mathrm{In}\left(\mathrm{NO}_{3}\right)_{3}$ in a

1:12 ratio, which afforded a mixed-metal, flat- $\mathbf{G a}_{7} \mathbf{I n}_{6}{ }^{\circ}$ cluster in $25 \%$ yield. Again, crystals were manually separated from the black product mixture. The prospect of mixed-metal clusters of this class has not been addressed to our knowledge.

Scheme 4.2. Redox reaction forming $\mathbf{G a}_{13}{ }^{\mathbf{}}$ and heterometallic clusters.
Scheme 4.2 depicts the synthetic route to structures $\mathbf{1}$ and $\mathbf{2}$ using two different nitroso compounds. Symmetry of the flat- $\mathbf{G a}_{7} \mathbf{I n}_{6}{ }^{\circ}$ cluster cation is $\overline{3}$ as with the analogous flat- $\mathbf{G a}_{13}{ }^{0}$ cluster. ${ }^{4}$ Compound $\mathbf{2}$ is isostructural with $\mathbf{1}$, possessing the same $\mathrm{Ga}\left(\mu_{3}-\mathrm{OH}\right)_{6} \mathrm{Ga}_{6}\left(\mu_{2}-\mathrm{OH}\right)_{6}$ core, but varies with indium atoms forming the third M -shell in the cluster connected via $\mu_{2}$-OH bridges (Figure 4.2). We have also conducted experiments aimed at controlling the ratio of Ga:In present in these mixed-metal clusters, and these results will be presented in a future publication. Unfortunately, there is currently no quick way to screen the crystal composition aside from collecting full XRD data sets, where bond distances and electron count allow for identification of the clusters. Surface chemistry by SEM and EPMA are being explored.

To address the problems of difficult isolation and limited reaction scale, we sought alternative nitroso compounds to nitrosobenzene. The most successful so far has been $N$-nitroso-di- $n$-butylamine. This compound is a slightly yellow viscous liquid with low vapor pressure. Use of this alternative nitroso compound affords clusters $\mathbf{1}$ and $\mathbf{2}$ in
superior yields, $85 \%$ and $95 \%$ respectively. The yields are likely increased in part because the reaction with $N$-nitroso-di- $n$-butylamine produces a mixture that is a transparent oil instead of the viscous black tar found in the reaction with nitrosobenzene. The solid crystalline product is thus easier to isolate from the reaction with $N$-nitroso-di-$n$-butylamine. $N$-nitroso-di- $n$-butylamine is removed via syringe, and the remaining crystals are washed with cold EtOAc (three times) and dried. $N$-nitroso-di- $n$-butylamine allows preparation of compounds $\mathbf{1}$ and $\mathbf{2}$ in gram scale quantities.

All-inorganic hydroxocation condensation routes to dense, high-quality oxide dielectric films have been lately demonstrated ${ }^{24,25}$ Based on these results, the discrete hydroxo clusters $\mathbf{1}$ and $\mathbf{2}$ were immediately recognized as potential oxide precursors operating on similar principles. Cluster $\mathbf{2}$ is of particular interest due to the large indium fraction and the excellent performance of $\mathrm{In}_{2} \mathrm{O}_{3}$-based semiconductors.

Thin Film Transistors with amorphous $\mathrm{In}_{0.92} \mathrm{Ga}_{1.08} \mathrm{O}_{3}(\mathrm{IGO})$ channels derived from spin-coated aqueous solutions of $\mathbf{2}$ will be described more fully in a forthcoming publication, though preliminary device characteristics are presented in Figure 4.4. Von for the device shown is, -6 V while on-to off current ratios are $>10^{6}$ on thermally grown $\mathrm{SiO}_{2}$ dielectrics. Field-effect mobilities for these bottom-gate devices are $\sim 9 \mathrm{~cm}^{2} \mathrm{~V}^{-1} \mathrm{~s}^{-1}$ after annealing to $600^{\circ} \mathrm{C}$. The direct deposition of such high-performance semiconductors from aqueous solutions is unprecedented, and an important step towards printed macroelectronics.

Figure 4.4. Preliminary TFT Characterisitic trace. Representative transfer and (inset) output characteristics for a bottom-gate IGO-channel TFT with a thermally grown $\mathrm{SiO}_{2}$ dielectric. $\mathrm{V}_{\text {GS }}$ in the output curve is stepped from $0-40 \mathrm{~V}$ in 10 V steps

We have been able to devise a new green synthetic strategy for making clusters of gallium, which proceeds faster using fewer caustic chemicals and milder temperatures. We have expanded this strategy and shown general utility by synthesizing new heterometallic clusters of aluminum, gallium, and indium, doing so in a controlled fashion. The synthesis utilizes the organic oxidation of the easily oxidized compounds nitrosobenzene and $N$-nitroso-di- $n$-butylamine, coupled with the crystallization of a gallium cluster from solution. ${ }^{4}$ Insofar as these molecules might hold promise as single source precursors for novel materials (e.g., thin films), developing a green synthetic method is highly relevant. We have also helped shed light on the mechanism of cluster growth. Previous work suggests that a $\mathrm{M}_{2}$ fragment forms initially. We have yet to see any structure with different composition of the first seven metal atoms, suggesting the $M_{7}$
core might be particularly stable. The mixed-metal nature of this structure may also provide insight into the nature of mineral formation, as many minerals contain multiple metal ions.

## CHAPTER V

## ToF-SIMS CHARACTERIZATION OF $\mathrm{M}_{13}$ INORGANIC NANOCLUSTERS

I was the primary contributor to the optimization of the synthetic conditions in this study and developed the purification and sample preparation procedure. Dr. Stephen L. Golledge was very helpful in the operation of the ToF-SIMS instrumentation, and in training and aiding me on data analysis. I was the primary contributor to the assignment and determination of peaks. This work has not yet been published but will be submitted to either Surface and Interface Analysis or the Journal of the American Chemical Society. Dr. Prof. Darren W. Johnson was the principal investigator for this work.

Characterization of the flat $\mathrm{M}_{13}$ nanoclusters has proven to be very difficult, especially in solution. The hydroxo protons of the nanocluster provide very little in the way of a spectroscopic handle in proton nuclear magnetic resonance ( $\left.{ }^{1} \mathrm{H}-\mathrm{NMR}\right)$ due to their rapid exchange in aqueous solution. No signal was seen for either ${ }^{69} \mathrm{Ga}$ or ${ }^{71} \mathrm{Ga}$ in solution NMR. This could be because of a low functional concentration for the instrument or it could be due to the difficultly in tuning a to new nucleus, although acquisition of aqueous $\mathrm{Ga}-\mathrm{NMR}$ spectra has been reported in the literature. Solution high performance liquid chromatography-mass spectrometry (HPLC-MS) has aided in the isolation of the nitrobenzene product from the oxidation of nitrosobenzene (Chapter II). However, the HPLC-MS did not yield definitive results for the methanol dissolved tridecameric clusters. Current conditions tested for the cluster and other for organic byproducts from the reaction have not yet yielded results. The stability of the intact cluster in aqueous solvents is not known, but it can be recrystalized after dissolving in MeOH .

As a result we have moved toward characterizing the crystalline products as solids. Solid state Ga-NMR has not yet been attempted but will most likely suffer from the same tuning problems as the solution studies; however, concentration should not be a factor here. All the tridecameric nanocluster products have been characterized by single crystal X-ray diffraction (SXRD) and then by thermogravometric analysis (TGA) of the crystals to determine the products. This information is very useful but only tells starting and ending points. In addition, the data collection process takes over half a day.

Elemental analysis has been attempted via normal induced coupled plasma (ICP) and with ionization from scanning electron microscopy (SEM) and electron probe micro analysis (EPMA) instruments. For EA, SEM and EPMA data collection itself is very fast, but there is much more time devoted to sample preparation. Characterization of the tridecameric nanoclusters or the organic product by various mass spectroscopic techniques has been attempted in the solid state on single crystals by Time of Flight Secondary Ionization Mass Spectrometry (ToF-SIMS). The following work describes in detail the solid-state characterization we have completed with SEM, EPMA and ToFSIMS. This is a summary explaining characterization of current clusters; data analysis continues on previously collected samples.

The research strategy for producing tridecameric clusters yielded all seven variations of the outer ring substitution in the heterometallic $\mathrm{M}_{13}$ cluster, as detailed in chapters II and IV (Figure 5.01). The same samples were used for EA, SXRD, SEM, EPMA and ToF-SIMS. Not all instruments were used to collect data on all samples. ToF-SIMS instrumentation data were collected on samples 1-5 and 7. Due to difficulty in data analysis, ToF-SIMS results from sample 1 are presented here with explanations of relevant future data analysis on the other collected data.

Figure 5.01. Samples collected and analyzed by various solid state techniques

All samples were first screened by single crystal XRD, and an electron count was performed in order to determine the occupancy of indium atoms in the outer ring. The same samples were then prepared for other analytical methods. All samples were used as solid single crystals. SEM samples were prepared with single crystals that were glued onto wafers of polished silica. SEM spectra of compounds $\mathbf{1}$ and $\mathbf{7}$ are shown in Figure 5.02 and Figure 5.03, respectively. For sample 7 the areas under the gallium and indium peaks are integrated and yield a 7.5 to 5.5 ratio of gallium to indium. EPMA required the samples to be very flat; single crystals were embedded in resin, polished on an oillubricated grinder, then tested. The EPMA data did not agree with the data collected by other methods because of a poor instrument calibration. The results from SXRD, EA and EPMA data are shown in Table 5.3. The results are in reasonable agreement with the elemental analysis that was sent out for collection by ICP.

Surface chemistry from crystal ionization to catalyst screening has used ToFSIMS for the characterization of metal complexes. ${ }^{1}$ ToF-SIMS has proven to be useful in the quantitative analysis of surface complexes and depth profiling of thin films. ${ }^{2 \cdot 4}$ The literature thus far has focused on the first row transition metals. ${ }^{5}$ The high resolution of the ToF-SIMS will aid in peak identification, although cluster fragmentation and isotope distributions will present challenges in data analysis. ${ }^{5,6}$

For compounds containing an element with an isotope distribution, MS can be both difficult because of the complex data generated and helpful in providing isotope
patterns. For the mixed metal clusters 2-7 the isotope distribution problem is compounded due to the addition of a second metal species with its own isotopic distribution. The distribution of multiple metals would be even more complicated. For that reason cluster $\mathbf{1}$ was analyzed first, to work out the issues in data analysis on a simpler compound.

$$
\begin{aligned}
& \text { A }
\end{aligned}
$$

B
Figure 5.04. A.Standard Pascal's triangle distribution of a $1: 1$ isotope pattern of metals,
B. Statistical distribution of isotopes of gallium species. The triangles show the relative
abundance of isotope peaks for mulliple metal species of a simple 1:1 ratio and then the
more complicated 1.5:1 gallium ratio.

A 1:1 ratio of isotopes would follow the standard Pascal Triangle, Figure 5.04A.
The distribution pattern gets much more difficult when the isotopes are not in a $1: 1$ ratio. ${ }^{7}$
The gallium isotope ratio is $60: 40$ of the ${ }^{69} \mathrm{Ga}$ and ${ }^{71} \mathrm{Ga}$ isotopes, which yields the distribution seen in Figure 5.04B. There is an " $\mathrm{N}+1$ rule" for the dual isotopes of gallium. The analysis of that data is made more complex by the introduction of indium with ${ }^{113} \mathrm{In}$ and ${ }^{115} \mathrm{In}$ in a ratio of 4:96.

When two elements each with its own isotopes are present, the distribution patterns become much more complex. Figure 5.05 shows a $\mathrm{Ga}_{4}$ isotope pattern, an $\mathrm{In}_{4}$ pattern, and a $\mathrm{Ga}_{2} \mathrm{In}_{2}$ pattern. Spectra $\mathrm{C} \& \mathrm{E}$ had to be enlarged in order to see all the peaks. The $\mathrm{N}+1$ rule still applies for the number of metals present.

Figure 5.05. Isotope distributions of $\mathrm{Ga} a_{4}, \mathrm{In}_{4}$, and $\mathrm{Ga}_{2} \mathrm{In}_{2}$.

The isotope distribution of the metals which originally concerned us actually proved to be quite useful, as the isotope patterns greatly aided in the determination of the number of metal centers that are in isolated clusters. They are much more complex with different isotopes. This has helped in the analysis of different spectra.

Different ionization energies in ToF-SIMS should allow for observation of different fragments, much as changing the cone voltage does on LC-MS. The AndersonEvans cluster is held together with six $\left(\mu_{3}-\mathrm{OH}\right)$ bonds aided with six $\left(\mu_{2}-\mathrm{OH}\right)$ bonds, while the peripheral six metals in the tridecameric cluster are only held to the core by two ( $\mu_{2}-\mathrm{OH}$ ) bonds each. The central core of seven metals of the tridecameric cluster should be a stable fragment, because it is the Anderson-Evans cluster, Figure 1.01. Thus, stable fragments should be ejected, although in these high-energy experiments small fragments could recombine into a larger stable clusters. A milder technique or other complementary analytical methods like MALDI or LC-MS would augment collected data and provide useful data.

In data analysis there are potentially two types of errors in the difference between actual fragments and the calculated components. Absolute error is the difference between the two, measured in $\mathrm{m} / \mathrm{z}$ values Daltons/charge, while relative error is that difference divided by the target fragment then multiplied by one million, in units of ppm. As with NMR, the relative ppm error allows the signals to be related. Relative error shows the error progression along the spectra, which demonstrates how the error decreases as new points are added to the calibration curve, making each subsequent prediction more accurate.

There are very common fragments seen for metal oxo species depending on the oxidation state of the metals. ${ }^{8,9}$ There are also fewer options at such a low mass and almost no multiple metal species. All this allows for the entering of element counts into a spreadsheet to act as a mass calculator. This proved to be very useful, providing the beginning of the calibration curve for a more accurate peak fragment analysis and identification. The beginning of the calibration table is shown in Table 5.2. Patterns have already started to emerge of adding protons and isotope mixtures with multi metal clusters.

Figure 5.06. Low Mass range peak assignments..

When the mass and element are entered, a mass spectrum fragment calculator finds potential fragments that fit that stoichiometry. This calculator as well as most simple general chemistry calculators (that is, not part of a MS instrumentation package) do not take into account the isotopes of elements as seen, Figure 5.06. They only use the average mass, which means that no single peak can be entered in for its isotope clustering; only the middle or most intense peak is the target. This is where the real data is much more complicated than the simulated data without isotopes included. However, the same iMass program is able to show isotope distribution for a given molecular formula, Figure 5.08b. There appears to be a long range "AB; pattern, which could correlate to GaO and $\mathrm{GaO}_{2}$ additions to the previous cluster. Figure 5.07 shows a section of the ToF-SIMS spectra of compound $\mathbf{1}$ with an enlargement of the peaks clustered around 495 Daltons. This shows the interdigitated patterns as well as other small peaks that may be multiply-charged species.

Figure 5.07. Mass spectrum of 1 from 550 to 1000 Daltons

With the aid of computer programs, data analysis has become much easier. There are programs used for protein characterization that use the spacing between the peaks to determine the charge of the fragments and, therefore, the mass of the parent ion. There are two ways of manually analyzing the data, either the plug and chug method of entering the mass and finding corresponding compounds via the commercially available mass spec fragment calculator, or plugging in chemically reasonable formulae and determining their mass. Both of these involve trial and error, but they do provide a good starting point. Alternately, the isotope distribution can be used to help determine a starting point with the ratios of the peaks revealing the number of gallium centers contained in each fragment. The difference is building up from the bottom or taking a top-down approach to peak assignment. The expanded section of Figure 5.07B is shown again in Figure
5.08A and the two interdigitated patterns that are offset by a single proton are colorcoded. The red spectrum in A is very similar to the predicted pattern seen in B.

Figure 5.08. Expansion of Spectra 1 at 495 Daltons corresponding to a $\mathrm{Ga}_{5} \mathrm{O}_{7}(\mathrm{OH})_{2}$ fragment

A series of stable fragments were expected to be present, one of which was the Anderson-Evans core of $\mathrm{M}_{7}$. The Anderson-Evans fragment was not observed. However, it was observed that there are other existing multiple metal clusters that could be potential fragments of a tridecameric cluster. There are two known $\mathrm{M}_{8}$ clusters that are similar to the core of the $\mathrm{M}_{13}$ cluster. ${ }^{10,11}$ The physical difference between the two clusters involves the removal of one of the inner ring metal centers. This allows the two adjacent metals to bend out of the plane, relieving torsional strain. The remaining four metals are still planar as seen in Figure 5.09. If one outer metal is removed, and the structure is minimized and compared to the corresponding formula for the AndersonEvans $\mathrm{M}_{7}$ cluster, there is a large difference in minimized energies, with approximately $30 \mathrm{kcal} / \mathrm{mol}$ stabilizing energy for the Anderson-Evans cluster as determined by CAChe using the MM3 force field. ${ }^{12}$

Figure 5.09. Stable $\mathrm{M}_{7}$ POM fragments
Data that appears to be missing from the table is actually the result of peaks that are too small to resolve out the noise. This is where the isotope pattern has now provided diminishing returns, and where the smaller cluster that is made up exclusively of the lower isotope is very difficult to identify. ToF-SIMS is a highly energetic environment where electrons are easily transferred to the matrix and other fragments during flight, where actual fragments may not match expected ones. ${ }^{13-19}$ Based on this data we can start to assign structures to the peaks that we see. Figure $\mathbf{5 . 1 0}$ represents what we believe the fragments to be. This data assignment will help identify more peaks in the set and should be applicable to the heterometallic clusters 2-7.

## Conclusions

We have shown that TOF-SIMS has the potential to be used for the characterization of polyoxometalates. While still not a fully developed method, it does show an increased potential for this technique in other characterizations of materials, and in some peak isolation and identification that can be adapted to other species. The first step is to try to apply these results to compound 7, which has a complete substitution of the outer ring. This data shows that there are stable fragments in the gas phase.

Previously this has been a concern. This new data could open the door for the use of
these clusters as synthons in a CVD or PVD method of film preparation, not just in the SILAR method that has been utilized thus far. ${ }^{20,21}$

## Future Works

Work continues on the calibration curve for additional peak assignments. The lessons learned here should next be applied to the compound 7. In the future we should also screen the analogous $\mathrm{Al}_{13}$ cluster using TOF-SIMS. The aluminum data will be useful for two reasons: the analogous cluster should yield very similar if not the same fragments, and the lack of isotopes should simplify the spectra with fewer peaks, helping improve the signal to noise ratio of the data. The slightly smaller ionic radii of aluminum may make the cluster more stable. Core fragments that are identified and predicted for the Ga samples should be able to be seen in heterometallic clusters. Organic ligands such as HEIDI may allow for large fragments to be seen because of stability imparted to the cluster by the ligand.

Working up the existing data with other programs would help with pattern identification. ${ }^{22}$ Recent observations should allow for fragment predictions to be applied to some of the heterometallic clusters starting with 7. The same clusters can be continued to be screened using other MS instruments, MALDI would be a prime starting point.

A parallel study should be to screen the ToF-SIMS of the known $\mathrm{Ga}_{8}$ and $\mathrm{Al}_{8}$ clusters, in order to test if they are indeed viable fragments of the Anderson-Evans core. Tof-SIMS has the potential to be used as much more than just an elemental analysis technique. The different heterometallic clusters in the series could help provide very useful data on the labiality of different metal bonds in analogous clusters under similar
conditions. Once we have finished with the gallium indium series we could use it as a base for the aluminum and indium series.

## BRIDGE

The first five chapters of this thesis focused on inorganic oxo clusters. They include a small review, the synthesis, experiments, uses and characterization of tridecameric nanoclusters. Throughout these experiments there were numerous leads were not explored due to time constraints. The following chapter turns to a summary of the organic templated nanocages project that I researched for the first year and a half in Dr. Johnson's laboratory. I conducted the research on templated nanocages with assistance from three undergraduate (Michael N. Gonsalves, Pratistha Ranjitkar and Jean-Michel Moreau) and two rotation students (Eric L. Spitler and Charles A. Johnson, Jr.). Dr. Prof. Darren W. Johnson was the principle investigator for this work.

## CHAPTER VI SUMMARY OF INORGANIC TEMPLATED NANOCAGES

The goal of my original graduate research project was to create a rigid bisbidentate organic ligand that would bridge multiple metal centers allowing for the creation of an enclosed cavity. Two different classes of rigid bis-bidentate ligands were explored: first the pyridine-imine binding motif based on a known self-assembled tetrahedron synthesized by $\mathrm{Yan}^{1}$; and second, a pyridine-pyrazole binding motif based on other self-assembled clusters by Ward. ${ }^{2-5}$ A third binding motif based on the work of Saalfrank ${ }^{6.9}$ was suggested and outlined but not yet tried. All of these ligands are modifications of previous ligands, with distal functionality built in to allow for the covalent coupling of the ligands into one nanocage templated by the four non-co-planar metals.

Scheme 6.1. The general scheme to use an $\mathrm{M}_{4} \mathrm{~L}_{6}$ capsule as a template to form an organic nanocage, L'.

The general $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron template strategy is depicted above (Scheme 6.1). Six equivalents of an appropriately designed ligand (blue lines) are combined with four equivalents of metal (red spheres) to self-assemble a $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron (metal-ligand
nanocage template) related to the $\mathrm{Zn}_{4} \mathrm{~L}_{6}{ }^{8+}$ from the literature precedent. The next step is. a covalent capture by a cap (green) that binds all six ligands together to yield the $\mathrm{M}_{4} \mathrm{~L}$, complex. The final step of demetallation yields the organic nanocage, L'. This complex has a volume that is defined by its covalently linked shell.

The known appropriate crystal structures were imported into CAChe ${ }^{10}$ with geometries locked. Then to the distal ends of the ligands carboxylic acids were added as handles for condensation with a three-fold symmetric compound. The overall structures were then minimized with a MM3 force field. In each case the propyl spacer of tris-(3aminopropyl)amine (TRPN) provided a better fit than the ethyl spacer of the tris-(2aminoethyl)amine (TREN).

## Pyridine-Imine Type Ligands

The carboxylic acid derivative of the desired ligand was synthesized. The Yan procedure for crystallization of the tetrahedron was followed for the two different esterprotected ligands (ethyl and benzyl) as well as the deprotected carboxylic acid. Synthesis of the ester-protected ligands was carried out despite some serious solubility issues regarding the benzyl ester once it was condensed with benzidine. The condensation product of the terphenyl spacer of the 4.4 "-terphenyl-diamine suffered from extremely poor solubility in various organic solvents. The deprotection of those ligands proved to be very difficult. The same condensation conditions did not work for other esters and spacer combinations, Scheme 6.2. In addition, there was a remarkable difference in the reactivity of the two different ester-protecting groups.

A second plan of attack was to try a capping-first strategy where the three-fold symmetric cap was first coupled to the 2 -acyl-pyridine, then the pyridine was condensed to the rigid backbone spacer to form the imine. A series of two-fold symmetric backbones was explored, Scheme 6.3. This strategy allowed for the insertion of different rigid backbone scaffolds in a modular synthesis, Figure 6.1. Benzidine was the only diamine that was condensed with the acyl nicotinate and was still soluble for use as a ligand. The octofluoro version of benzidine did not condense with the 2 -acyl pyridine. The $p$-terphenyl diamine did condense but was so insoluble that characterization of the deprotected product was almost impossible. Because of these difficulties, these two rigid spacers were not used, and work continued with the benzidine spacer.

Scheme 6.2. Deprotection of benzyl ester ligand and metal-ligand self-assembly.
The benefit of a modular route allows for the order of reaction to be rearragned while reaching the same target. The capping-first strategy uses the same starting materials and even the same first reaction. But the deprotection happens second, as opposed to the condensation with the di-amine, in order to set up for the covalent capping. The 2-acylnicotinic acid as either the carboxylic acid or the activated ester could be coupled to the three-fold symmetric cap to yield the vertex 11. The product was formed in very low over-all yields. An alternate scheme (Scheme 6.3) was not completed which had the potential for an even lower yield where the low yielding acylation reaction would need to be run on the three pyridines, yielding the same multiple
products. The acylation reactions of the nicotinic esters proceed in low yield; the redeeming quality is the low cost of the reagents and the easy reaction conditions. If the same acylation were tried on $\mathbf{1 2}$, there would be a large mixture of products, and the increased bulk of the whole cap might help with the yield of the reaction, by favoring more acylation on the para position, making the difference between the two routes negligible.

Scheme 6.3. The capping first strategy.

Use of other rigid spacers would allow for variations in the size of the cavity. Altering the symmetry of the scaffold would allow for different types of tetrahedra. The only tests so far have been on the first three linear para-substituted diamines that should have yielded the $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron. Using a three-fold symmetric backbone should yield a $\mathrm{M}_{4} \mathrm{~L}_{4}$ tetrahedron, where the ligands are the faces of the tetrahedron instead of the edges. Changing the backbone phenyl spacers to acetylene spacers will change the edge length as well as the electronics of the system and the cavity size of the final product.

Figure 6.1. Rigid amine functional spacers, both two-fold and three-fold symmetric.

Before this project continues, Yan's ligand synthesis and tetrahedron assembly should be repeated. This will ensure that they can be synthesized in the lab. There are questions and issues about the self-assembly of the ligands into a discrete species. After those conditions have been successfully worked out, they can be applied to the tetrahedron self-assembly with any of the ligands available. Follow-up work needs to be done on a clean and reliable deprotection scheme for the ester-protected ligands. Then self-assembly attempts on the free carboxylic acid can be explored. Synthesizing the activated esters may make them too reactive under self-assembly conditions.

## Pyridine-Pyrazole Type Ligands

An idea similar to the Yan synthesis is to prepare a known core ligand that selfassembles as a tetrahedron with distal functionality. The benefit of this scheme is that it allows for the use of the same nicotinic esters, $\mathbf{2 a} / \mathbf{b}$ from the previous schemes, as the starting material for the same acylation, and the $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron has literature precedent. ${ }^{4,11,12}$

Scheme 6.4. The Ward based Pyridine-Pyrazole ligand self assembled and space filling surface with a $\mathrm{BF}_{4}{ }^{-}$counter ion encapsulated.

The conditions for the acylation reaction have already been worked out as a synthetic step for the pyridine-imine analog. In the pyridine-pyrazole ligand synthesis the second step was the condensation of the 2-acyl pyridine with DMF-DMA to make a vinylic amide. This step led to the unexpected product $\mathbf{1 5 g}$ (methyl ester, not the desired benzyl) so continuing the synthesis proved to be problematic.

Scheme 6.5. Modification of Ward Pyridine-Pyrazole ligand synthesis with distal functionality.

The deprotection of the methyl ester ligand is a future goal. In the original work by Ward there is no distal functionality, just the vinylagous amide that can react with the hydrazine. In this case, the methyl ester reacted with hydrazine to yield no isolable product. The plan was to couple a dibromo compound to the pyrazole to form the bisbidentate ligand. Ward synthesized and published this binding motif with several different spacers. Each spacer would allow access to different cluster types, including some three-fold symmetric spacers as well as others with alternate built-in functionality, Figure 6.1. Using a backbone spacer based on 2,6-lutidine would allow for the nitrogen in the ring to face into the cavity, changing the cavity properties by point the pyridine nitrogen into the cavity. A spacer built off of an $\alpha, \alpha$-dibromo- $o$-xylene with functionality on the 4 and 5 positions would have the opposite effect: to place some functionality facing the outside of the cluster.

Figure 6.2. Crystal of Ligand $\mathbf{1 5 g}$ post deprotection

The same reactivity and side product issues have arisen with the pyridinepyrazole class of ligands as well. Because of this, Ward's ligand synthesis and tetrahedron self-assembly should be repeated in order to prove that the same products can be isolated and that the cage self-assembles. The major difference now is the new distal reactive functionality: the ester is not stable under the conditions of the DMA-DMF reation. The distal functionality should not interfere with the self-assembly of the ligands because according to modeling prformed on the target ligands .

The order of the reactions appears to be problematic, since the benzyl ester is too reactive as a protecting group for the acid. The same rearrangement of reaction sequence for this ligand should be explored, where the ligand is covalently capped before forming the pyrazole via the hydrazine closure reaction to form the pyrazole. Once there, many options for spacers are commercially available, and others with additional functionality are easily accessible., ${ }^{4} 13$

J. Chem Soc. Dalton, 2000, 845
Aust. J Chem. 2003, 56, 665

Figure 6.3. Dibromo spacers for coupling with Pyridine-Pyrazole
The reaction sequence with the pyridine-pyrazole based ligands needs to be changed, and proof-of-concept work needs to be done to prove that known ligands selfassemble in this laboratory. The functional group incompatibilities for the DMF-DMA reaction with the ester group will be difficult to over come. Once this is accomplished, the question of how to solve the reactivity issues can be addressed.

## Diketone Type Ligands

Another type of ligand class that can be explored are the diketones. This class of ligands has been synthesized by the Saalfrank group. ${ }^{14,15}$ These ligands chelate to metals through two ketone oxygens, Figure 6.4A. Two binding units can be coupled together to yield a two-fold symmetric ligand, Figure 6.4B. The level of difficulty for differentiation of the two ends of the binding motif will depend on the synthetic scheme chosen. Designing a scheme that allows for the orthogonal synthesis of both the bind motif and a distal capping functionality will be difficult. If a linear method is chosen, where the core spacer is added first, then the active distal functionality can easily be added for the three-fold linked covalent capture into the complete inorganic nanocage.

A

B

Figure 6.4. Saalfrank based ligands and diketo binding motif.

Spacers from the previous ligand classes could still be used with different reactions to yield complexes of similar size. This would allow a synthesis of the corresponding two-fold and three-fold ligands, varying only in the binding motifs, for the corresponding $\mathrm{M}_{4} \mathrm{~L}_{6}$ and $\mathrm{M}_{4} \mathrm{~L}_{4}$ type of templated nanocages. This modular synthesis allows for the same variation in electronics and functionality, as well as for the use for different ligand spacers.

The specific metals used for the self-assembly could be changed for other metals that bind more specifically, because they are there for the templating of the organic ligands. A bigger problem than the metal for all the self-assemblies might prove to be the counter-ions. A weakly coordinated counter ion is preferred in order to avoid competition with the ligand. A self-assembly with metal triflate or toslyate salts should be tried, to promote dissociation.

## Mixed Atom Binding Sites

Currently all the ligands outlined here involve the same coordination atoms. There is also a variation on these that could be explored. The Yan-based pyridine-imine ligand motif uses two nitrogen atoms. The Ward-based pyridine-pyrazoles also uses two nitrogen atoms. While the Saalfrank type diketos still use lone pairs obtained from two oxygen atoms. Mixed ligand types could be added involving one nitrogen atom and one
oxygen atom. The ligands that currently contain oxygen could be substituted with sulfur, in order to change the HSAB properties of the ligands. This could allow for selectivity and tuning of the ligands for different metals.

## APPENDIX B

## SUPPLEMENTAL INFORMATION FOR $\mathrm{Ga}_{13}$ SYNTHESIS

## Supporting Information

## Experimental Section

1 forms via slow evaporation of a 5 mL methanolic solution of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$
$(0.182 \mathrm{~g}, 0.500 \mathrm{mmol})$ in the presence of nitrosobenzene $(0.0535 \mathrm{~g}, 0.500 \mathrm{mmol})$, yield of $0.905 \mathrm{~g}(0.326 \mathrm{mmol}, 65 \%)$ was obtained. Crystals of 1 were shown to be representative of the bulk by comparison of the X-ray powder pattern collected on a fresh sample with the corresponding pattern calculated from the crystal structure (Figures S1 and $S 2$ ). The initial light blue solution turns pale yellow after 1 day indicating the oxidation of nitrosobenzene to nitrobenzene. The pH of a solution of $\mathbf{1}$ dissolved in water $(1.6 \mathrm{mM})$ was measured as 2.28 . Dissolution of $\mathrm{Ga}_{13}$ cluster, $\mathbf{1}$, in water followed by recrystallization via evaporation resulted in the sole formation of $\mathbf{1}$ as determined by single crystal unit cell determination and X-ray powder diffraction. In a preliminary effort to determine the effect of nitrozobenzene on the formation of 1 , the same reaction was conducted in presence of water, pyridine, 2,6-lutidine and nitrobenzene. These attempts were unsuccessful to generate 1 and resulted in the recrystallization of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}$
or in the formation of $\mathrm{GaL}_{2}\left(\mathrm{NO}_{3}\right)_{3}$ (where $\mathrm{L}=2,6$-lutidine). As an interesting caveat, crystals of the title compound were originally prepared by slow evaporation of a methanolic $\left(-\mathrm{d}_{4}\right)$ solution of a confidential proprietary compound in the presence of an excess of gallium nitrate hydrate. This proprietary compound contained a nitroso functional group, and the crystallization of $\mathbf{1}$ has since been successfully repeated using only nitrosobenzene to mediate the crystallization.

Figure B1. X-ray powder diffraction pattern of a fresh sample of 1.

Figure B2. X-ray powder diffraction pattern calculated from the single crystal structure of 1 .

Figure B3. LC-MS trace of oily residue

Figure B4. TGA of tridecameric inorganic nanocluster.

## JTG6 XRD Data

The crystal was grown by evaporation from MeOH at $22^{\circ} \mathrm{C}$ over 1 week. The crystal was mounted on a quartz fiber with paratone oil. Data in the frames corresponding to an arbitrary hemisphere of data ( $\omega$ scans, 10 sec frames) were intergrated using SAINT. ${ }^{1}$ Data were corrected for Lorentz and polarization effects. The data were further analyzed using XPREP. ${ }^{2}$ An empirical absorption correction based on the measurement of redundant and equivalent reflections and an ellipsoidal model for the
absorption surface were applied using SADABS. ${ }^{3}$ The structure solution and refinement were performed using SHELXTL (refined on F2). ${ }^{2}$ All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined on all appropriate atoms. Special positions for the nitros.

Crystal size $0.45 \times 0.25 \times 0.15 \mathrm{~mm} ; \mathrm{T}=21^{\circ} \mathrm{C}$; Rhombohedral, $\mathrm{R}-3$ (\#148), $\mathrm{a}=$ 20.214 (3) $\AA, \mathrm{b}=20.214$ (3) $\AA, \mathrm{c}=18.353$ (4) $\AA, \alpha=90^{\circ}, \beta=90^{\circ}, \gamma=120^{\circ} ; \mathrm{V}=6494.7$ (19) $\AA^{3}, \mathrm{Z}=3, \mu=4.128 \mathrm{~mm}^{-1}, \mathrm{~F}(000)=4116 \rho_{\text {calcd }}=2.127 \mathrm{~g} \mathrm{~mL}^{-1}, 2 \Theta_{\max }=52.8^{\circ}$. Of the 12652 reflections that were collected, 2832 were unique ( $\operatorname{Rint}=0.0318$ ); equivalent reflections were merged. Empirical absorption correction: $\operatorname{Tmax}=0.999, \operatorname{Tmin}=0.660$. Final R1 $=0.0404$ for 2832 data for $\mathrm{I}>2 \sigma(\mathrm{I})(189$ Parameters, 6 restraints); for all 2832 data, $w \mathrm{R} 2=0.1120, \mathrm{GOF}=1.153$.

Symmetry codes:
(i) $2-y, 1+x-y, z$;
(ii) $2-\mathrm{x}, 2-\mathrm{y},-\mathrm{z}$;
(iii) $y, 1-x+y,-z$;
(iv) $1-x+y, 2-x, z$;
(v) $1+x-y, x,-z$.

We are exploring the generality of the nitroso oxidation reaction to see if other inorganic nanoclusters can be synthesized via the same method and if there are other possible oganic reductants that can be used to make the same type of clusters. Follow up work on making new clusters, trying other reductants and checking their functional group tolerance.

After publication in the Journal of the American Chemical Society our results were highlighted in the March $4^{\text {th }}$ issue of Science as an Editor's choice.

## virology

Doubly Active Protease
Evasion of hast immune responses is a common defensive strategy used by viruses and is clearly illustrated by the ability of hepatitis C virus (HCV) to cause chronic liver infection. HCV achieves evasion, in part, through expression of the NS3/4A protease, which interrupts the induction of u/b interferon (IFN) gene expression by interferon regulatory factor 3 (iff3).

Two studies identify the targets of NS3/4A, and both pathways are shown to be pivotal in IRF 3 induction. Ul etal. abserved that the Toll-lke receptor 3 (TLR3) adapter protein TRIF was cleaved by N53/4A in an in vitro assay system. This was sufficient to prevent the induction of IFN- P by an activating ligand of TLR3. Furthermore, compromising TLR3 signaling was found to be sufficient to permit the cellular replication of HCV RNA. Foy et al. determined that the retinoic acid-

Inducible gena 1 (bIG-1] signaling pathway was disupted by NSJ/4A, again leading to loss of IRFS induction of IFN- 1 . The development of $\mathrm{NS} 3 / 4 \mathrm{~A}$ inhibitors may help gulde improved therapeutic intervention in HCV infection. - S.] 5

In eukaryotic cells, the enzymatic activites of RNA polymerases 1 , II, and III produce ribosomal RNA (rANA), messenger RNA and transfer RNA (and 55 rRNA), respec-

Centromeres (green) and 5 S rRNA genes (red) in wild-type (upper) and rpdz (lewer) plants.
tively. Howevar, the genome sequence of Arabidopsis thatiana revealed that another RNA polymerase $m$ ight exist, and Onodera et al. provide evidence for a functional RNA polymerase IV (Pol IM). Mutant plants lacking MPD1 and RPD2, genes ancoding the two largest subunits of the putative Pol V , ware still viable, but higher order heterochromatin assembly into centromeres was disrupted. Generally, an increase in cytosine methylation favors the formation of concensed heterochromatin, in rpdz plants, cytosine methylation of the pericentromeric $5 S$ riNA gene clusters was low, and these clusters did not cycle from a decondensed transcriptionally active state into inactive heterochromatin. Because small Interfering RNAs (sikNAs) complementary to 55 rINA genes ware also reduced, the authors suggest that Pol PV affects amplification of silRNAs that direct DNA methylation fof their corresponding genes) and hence
promote the organization of condensed nuclear chromocenters. - LDC

## CHEMISTRY

Fast and Accurate
Methods for detecting explosives in a range of settings. such as airports, should be highly sensitive, highly specific, and applicable to nonvolatile and thermally unstable substances. Furthermore, they should be fast and not require much sample preparation. Current methods do not measure up; they involve manual sample transfer and are not ideal for detecting, nonvolatile or thermally unstable substances.
Takats et al. show that the recently developed desorption electrospray lonization
(DESI) method meats these requirements. An electrospray is directed onto a surface bearing the analyte, and the resuiting secondary lons are collected and analyzed by mass spectrometry Subnanogram amounts of several explosives, including TNT, can be detected on a variety of surfaces such as paper, skin. and metal. Analysis takes jus: a few seconds, and no sample preparation is required. - JFU

| Absorption coefficient | $0.311 \mathrm{~mm}^{-1}$ |
| F(000) | 1170 |
| Crystal size | $0.31 \times 0.18 \times 0.09 \mathrm{~mm}^{3}$ |
| Theta range for data collection | 1.58 to $28.29^{\circ}$. |
| Index ranges | $-15<=\mathrm{h}<=16,-17<=\mathrm{k}<=16,-17<=1<=17$ |
| Reflections collected | 22455 |
| Independent reflections | $9682[\mathrm{R}(\mathrm{int})=0.0203]$ |
| Completeness to theta $=28.29 \infty$ | 91.8\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 1.000 and 0.570 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |
| Data / restraints / parameters | 9682/26/542 |
| Goodness-of-fit on $\mathrm{F}^{2}$ | 1.069 |
| Final R indices [ $\mathrm{I}>2$ sigma( I ] $]$ | $\mathrm{R} 1=0.0479, \mathrm{wR} 2=0.1264$ |
| R indices (all data) | $\mathrm{R} 1=0.0571, \mathrm{wR} 2=0.1322$ |
| Largest diff. peak and hole | 0.862 and -0.434 e. $\sim^{-3}$ |

Table C.13. Bond lengths $[\AA]$ and angles $\left[{ }^{\circ}\right]$ for jtg27.

Figure C. 04 Crystal structure of JTG81.

Table C.15. Crystal data and structure refinement for JTG81.

| Identification code | jtg81 |
| :---: | :---: |
| Empirical formula | H96 Al13 N17 O106 |
| Formula weight | 2381.68 |
| Temperature | 173(2) K |
| Wavelength | 0.71073 Å |
| Crystal system | Triclinic |
| Space group | P-1 |
| Unit cell dimensions | $a=12.623(3) \AA \quad a=74.877(4)^{\circ}$. |
|  | $b=13.251(3) \AA \quad b=72.419(4)^{\circ}$. |
|  | $\mathrm{c}=13.597(3) \AA \quad \mathrm{g}=86.790(4)^{\circ}$. |
| Volume | 2092.4(8) $\AA^{3}$ |
| Z | 1 |
| Density (calculated) | $1.890 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $0.326 \mathrm{~mm}^{-1}$ |
| F(000) | 1232 |
| Crystal size | $0.08 \times 0.08 \times 0.05 \mathrm{~mm}^{3}$ |
| Theta range for data collection | 1.59 to $25.00^{\circ}$. |
| Index ranges | $-14<=\mathrm{h}<=15,-15<=\mathrm{k}<=15,-16<=1<=16$ |
| Reflections collected | 15065 |
| Independent reflections | $7308[\mathrm{R}(\mathrm{int})=0.0700]$ |
| Completeness to theta $=25.00^{\circ}$ | 99.1\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.9839 and 0.9744 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |
| Data / restraints / parameters | 7308 / / / 617 |
| Goodness-of-fit on $\mathrm{F}^{2}$ | 1.051 |
| Final R indices [ $1>2 \operatorname{sigma}(\mathrm{I})$ ] | $\mathrm{R} 1=0.0836, \mathrm{wR} 2=0.1961$ |
| R indices (all data) | $\mathrm{R} 1=0.1399$, wR2 $=0.2315$ |
| Largest diff. peak and hole | 0.811 and -0.588 e. $\AA^{-3}$ |

Table C.16. Atomic coordinates ( $\times 10^{4}$ ) and equivalent isotropic displacement parameters ( $\AA^{2} \times 10^{3}$ ) for JTG81. U(eq) is defined as one third of the trace of the orthogonalized $U^{i j}$ tensor.

## APPENDIX D

## SUPPLEMENTAL INFORMATION FOR HETEROMETALLIC NANOCLUSTERS

Other heterometallic clusters

Figure D.01. Ball and stick representation of crystal structures.
EXPERIMETNAL
$\left[\mathrm{Al}_{7} \mathrm{Al}_{1} \mathrm{In}_{5}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}\left(\mathbf{A l}_{8} \mathbf{I n}_{5}\right)$
N-nitroso-di-n-butylamine ( $0.64 \mathrm{~g}, 4.02 \mathrm{mmol}, 24 \mathrm{eq}$.) is added to a solution of aluminum(III) nitrate ( $0.25 \mathrm{~g}, 1.2 \mathrm{mmol}, 7 \mathrm{eq}$.$) and indium(III) nitrate ( 0.30 \mathrm{~g}, 1.01$ mmol, 6 eq.) in 5 mL of $0.26 \mathrm{M} \mathrm{NaOH} / \mathrm{MeOH}$. The mixture is allowed to evaporate over 2-5 days at which point crystals begin to form in the same manner as before. This method
affords the $\mathrm{Al}_{8} \mathrm{In}_{5}$ cluster in $10 \%$ yield with respect to aluminum.
$\left[\mathrm{Ga}_{7} \mathrm{Ga}_{3} \mathrm{In}_{3}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}\left(\mathbf{G a}_{10} \mathbf{I n}_{3}\right)$
Gallium (III) nitrate ( $0.5 \mathrm{~g}, 1.95 \mathrm{mmol}, 7$ equivalent) and indium (III) nitrate ( 0.5 g , $1.66 \mathrm{mmol}, 6$ equivalents) are dissolved in 5 mL of methanol and nitrosobenzene $(0.7 \mathrm{~g}$, $6.53 \mathrm{mmol}, 24$ equivalents) is dissolved in 2 mL of methanol, the solutions are mixed together. The mixture is allowed to slowly evaporate at room temperature over 4-8 days, yielding large single crystals in $35 \%$ yield with respect to gallium nitrate.

Alternative reductant. N -nitroso-di- $n$-butylamine ( $1.06 \mathrm{~g}, 6.69 \mathrm{mmol}, 24 \mathrm{eq}$.) is added to $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}(0.5 \mathrm{~g}, 1.95 \mathrm{mmol}, 7 \mathrm{eq}$.$) and \operatorname{In}\left(\mathrm{NO}_{3}\right)_{3}(0.5 \mathrm{~g}, 1.66 \mathrm{mmol}, 6$ eq. $)$ in methanol, as a homogenous solution. The mixture is allowed to evaporate over 2-5 days at which point crystals begin to form in the same manner as before. This alternative method produces the same $\mathrm{Ga}_{7} \mathrm{In}_{6}$ cluster in $47 \%$ yield with respect to gallium. More crystals can be isolated by ppt from the oil with EtOAc, this power can be re-crystallized from MeOH to yield an additional $35-40 \%$ of crystals over the evaporation. These crystals are crystallographically identical to the original batch. The total over all crystal yield is $85-90 \%$ in respect to Gallium.

The refinement of the crystal structure of $\mathbf{G a}_{10} \mathbf{I n}_{\mathbf{3}}$ without symmetry restrictions on occupation factors for the Ga and In atoms shows that the refined occupation factors of the $\mathrm{Ga}(1)$ and $\mathrm{Ga}(2)$ atoms are very close to those based on the crystal symmetry. The occupation factor of the In atom is less than the needed occupation factor of 1.0 based on symmetry. Refinement of the structure with the Ga and $\operatorname{In}$ atoms sharing the same $\operatorname{In}(1)$ position shows that the ratio of the occupation factors of Ga and In in this position is 1:1,
i.e. the investigated compound is $\left[\mathrm{Ga}_{7} \mathrm{Ga}_{3} \mathrm{In}_{3}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}$. The average $\operatorname{In}(\mathrm{Ga})-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distance in $\mathbf{G a}_{10} \mathbf{I n}_{\mathbf{3}}, 2.073(6) \mathrm{A}$, is between the average $\mathrm{Ga}-$ $\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ and $\mathrm{In}-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distances in $\mathrm{Ga}_{13}$ and $\left[\mathrm{Ga}_{7} \mathrm{In}_{6}\right.$ clusters, $1.997(16)$ and 2.162(4) $\AA$, respectively.

Crystal data for $\boldsymbol{G a}_{7} \boldsymbol{I n}_{6}$ (Dave4): $\mathrm{C}_{6} \mathrm{H}_{96} \mathrm{Ga}_{7} \mathrm{In}_{6} \mathrm{~N}_{15} \mathrm{O}_{99}, \mathrm{Mr}=3139.94$. Colorless block, $0.15 \times 0.15 \times 0.07 \mathrm{~mm}$, rhombohedral, space group $R \overline{3}$ (no. 148), $a=20.694(2), b=20.694(2)$, $c=18.266(4) \AA, V=6774(2) \AA^{3}, \mathrm{Z}=3, \quad \rho_{\text {calcd }}=2.309 \mathrm{~g}^{\mathrm{g} \cdot \mathrm{cm}^{-3}}, \mu=3.703 \mathrm{~mm}^{-1}, \mathrm{~F}(000)=4620$, $2 \theta_{\max }=56.50^{\circ}, 16202$ reflections collected, 3588 unique $\left[R_{\text {int }}=0.0203\right], R$ indeces $[1>2 \sigma(I)]: R 1=0.0211, w R 2=0.0582, \mathrm{GOF}=1.035$.

Crystal data for 3a(jtg63): $\mathrm{C}_{6} \mathrm{H}_{96} \mathrm{Ga}_{9.1} \mathrm{In}_{3.9} \mathrm{~N}_{15} \mathrm{O}_{99}, \mathrm{Mr}=3045.23$ Colorless block, $0.20 \times 0.20 \times 0.10 \mathrm{~mm}$, rhombohedral, space group $R \overline{3}$ (no. 148), $a=20.4329$ (10), $b=20.4329(10), c=18.4080(18) \AA, V=6655.8(8) \AA^{3}, Z=3, \quad \rho_{\text {calcd }}=2.279 \mathrm{~g} \cdot \mathrm{~cm}^{-3}, \mu=3.86$ $\mathrm{mm}^{-1}, \mathrm{~F}(000)=4507,2 \theta_{\max }=56.50^{\circ}, 14035$ reflections collected, 3500 unique $\left[R_{\text {int }}=0.0176\right], R$ indeces $[I>2 \sigma(I)]: R 1=0.0237, w R 2=0.0698, \mathrm{GOF}=1.034$.

Crystal data for $\mathbf{G a}_{10} \mathrm{In}_{\mathbf{3}}$ (jtg65): $\mathrm{C}_{6} \mathrm{H}_{96} \mathrm{Ga}_{10.3} \mathrm{In}_{2.7} \mathrm{~N}_{15} \mathrm{O}_{99}, \mathrm{Mr}=2991.11$. Crystal data for $\mathrm{Ga}_{12} \mathbf{I n}_{1}(\mathrm{jtg} 66)$ : $\mathrm{C}_{6} \mathrm{H}_{96} \mathrm{Ga}_{11.9} \mathrm{In}_{1.1} \mathrm{~N}_{15} \mathrm{O}_{99}, \mathrm{Mr}=2918.95$. Colorless block, $0.10 \times 0.10 \times 0.05 \mathrm{~mm}$, rhombohedral, space group $R \overline{3}$ (no. 148), $a=20.1387(14)$, $b=20.1387(14), c=18.490(3) \AA, V=6494.3(11)(2) \AA^{3}, Z=3, \quad \rho_{\text {calcd }}=2.239 \mathrm{~g} \cdot \mathrm{~cm}^{-3}, \mu=4.08$
$\mathrm{mm}^{-1}, \mathrm{~F}(000)=4355,2 \theta_{\max }=56.48^{\circ}, 13623$ reflections collected, 3412 unique $\left[R_{\text {int }}=0.0317\right], R$ indeces $[1>2 \sigma(I)]: R 1=0.0328, w R 2=0.0886, \mathrm{GOF}=1.055$.

Crystal data for $\mathbf{A l}_{8} \mathrm{In}_{5}$ (dwjr21): $\mathrm{C}_{6} \mathrm{H}_{96} \mathrm{Al}_{7,7} \mathrm{In}_{5.3} \mathrm{~N}_{15} \mathrm{O}_{99}, \mathrm{Mr}=2779.27$. Colorless block, $0.18 \times 0.14 \times 0.08 \mathrm{~mm}$, rhombohedral, space group $R \overline{3}$ (no. 148), $a=20.4094(13$ ), $b=20.4094(13), c=18.500(2) \AA, V=6673.8(10) \AA^{3}, Z=3, \quad \rho_{\text {calcd }}=2.075 \mathrm{~g} \cdot \mathrm{~cm}^{-3}, \mu=1.58$ $\mathrm{mm}^{-1}, \mathrm{~F}(000)=4166,2 \theta_{\max }=56.50^{\circ}, 15029$ reflections collected, 3481 unique $\left[R_{\text {int }}=0.0247\right], R$ indeces $[I>2 \sigma(I)]: R 1=0.0359, w R 2=0.0960, \mathrm{GOF}=1.134$.

X-ray diffraction experiments were carried out on a Bruker Smart Apex diffractometer at $153 \mathrm{~K}\left(\mathbf{G a}_{7} \mathbf{I n}_{\mathbf{6}}\right)$ and $173 \mathrm{~K}\left(\mathbf{G} \mathbf{a}_{9} \mathbf{I n}_{4}, \mathbf{G a}_{10} \mathbf{I n}_{\mathbf{3}}, \mathbf{G a}_{\mathbf{1 2}} \mathbf{I n}_{\mathbf{1}}, \mathbf{A l} \mathbf{I n}_{\mathbf{8}} \mathbf{I n}_{5}\right)$ using MoK $\alpha$ radiation $(\lambda=0.71070 \AA$ ). Absorption corrections were applied by SADABS $\left(T_{\min } / T_{\text {max }}=0.762\left(\mathbf{G a}_{7} \mathbf{I n}_{6}\right), 0.709\left(\mathbf{G a}_{9} \mathbf{I n}_{\mathbf{4}}\right), 0.769\left(\mathbf{G a}_{10} \mathbf{I n}_{\mathbf{3}}\right), 0.743\left(\mathbf{G a}_{\mathbf{1 2}} \mathbf{I} \mathbf{n}_{1}\right)\right.$ and 0.825
$\left(\mathbf{A l}_{8} \mathbf{I n}_{5}\right)$ ). Crystals of $\mathbf{G a}_{7} \mathbf{I n}_{6}, \mathbf{G a}_{9} \mathbf{I n}_{4}, \mathbf{G a}_{10} \mathbf{I n}_{3}, \mathbf{G a}_{12} \mathbf{I n}_{1}$ and $\mathbf{A l}_{8} \mathbf{I n}_{5}$ are hexagonal and have the same space group $R \overline{3}$ (no. 148). In all structures the $\mathrm{M}_{13}$ cations are on a $\overline{3}$ axes. Two $\mathrm{NO}_{3}$ anions (in general positions) provide twelve $\mathrm{NO}_{3}$ anions per the $\mathrm{M}_{13}$ cation. Three other $\mathrm{NO}_{3}$ anions and solvent methanol molecules (in general positions as well) are highly disordered and randomly fill six other possible positions around the $\mathrm{M}_{13}$ cation. In all structures highly disordered $\mathrm{NO}_{3}$ anions and solvent methanol molecules were treated by SQUEEZE. Corrections of the X-ray data by SQUEEZE (638 ( $\mathbf{G a}_{7} \mathbf{I n}_{6}$ ), $642\left(\mathbf{G a}_{9} \mathbf{I n}_{4}\right), 596\left(\mathbf{G a}_{10} \mathbf{I} \mathbf{n}_{3}\right), 620\left(\mathbf{G a}_{12} \mathbf{I n}_{1}\right)$ and $637\left(\mathbf{A l}_{\mathbf{8}} \mathbf{I n}_{5}\right)$ electron/cell) are close to the required value of 603 electron/cell for $9 \mathrm{NO}_{3}$ anions and 18 methanol molecules in the full unit cell. All non-H atoms were refined with anisotropic thermal parameters. H atoms in $\mathbf{G a} \mathbf{a}_{7} \mathbf{I} \mathbf{n}_{6}$ were found on the difference F-map and refined with isotropic thermal
parameters. In other structures H atoms have not been taken into consideration.
Refinements of the crystal structures of $\mathbf{G a}_{7} \mathbf{I} \mathbf{n}_{6}$ without symmetry restrictions on occupation factors for the Ga and In atoms show that the refined occupation factors of the $\mathrm{Ga}(1)$ and $\mathrm{Ga}(2)$ atoms are very close to those based on the crystal symmetry. The found
 close each other and the similar distances found in the $\mathrm{Ga}_{13}$ cation. It indicates that in all these structures the central $\mathrm{M}_{7}$ part of the $\mathrm{M}_{13}$ cations are formed by the Ga atoms only. The same situation was found for the structure of $\mathbf{A l}_{\mathbf{8}} \mathbf{I n}_{5}$ where the central $\mathrm{Al}_{7}$ core of the $\mathrm{M}_{13}$ cations are formed by the Al atoms only. In contrast refinement of occupation factors for the In atom in " $\mathrm{Ga}(3)$-position" show that only in structure of $\mathbf{G a} \mathbf{7 n}_{\mathbf{6}}$ occupation factor for the In atom is close to required value of 1.0. In all other structure occupation factors for the In atoms in this position are less than the needed occupation factor of 1.0 based on symmetry. The final refinement of the structures of $\mathbf{G a} 9 \mathbf{I n}_{4}, \mathbf{G a}_{10} \mathbf{I n}_{\mathbf{3}}$, $\mathbf{G a}_{12} \mathrm{In}_{1}$ and $\mathbf{6}$ were done for a model with the Ga and In atoms sharing the same " $\mathrm{Ga}(3)$ position" position. It was found that based on single crystal X-ray diffraction data the ratios $\mathrm{Ga} / \mathrm{In}$ in the investigated compounds are $\mathrm{Ga}_{7} \mathrm{In}_{6}\left(\mathbf{G a}_{7} \mathbf{I n}_{6}\right), \mathrm{Ga}_{9.1} \mathrm{In}_{3.9}\left(\mathbf{G a}_{9} \mathbf{I n}_{4}\right)$, $\operatorname{Ga}_{10.3} \mathrm{In}_{2.7}\left(\mathbf{G a}_{10} \mathbf{I n}_{\mathbf{3}}\right), \mathrm{Ga}_{11.9} \mathbf{I n}_{1.1}\left(\mathbf{G a}_{\mathbf{1 2}} \mathbf{I} \mathbf{n}_{1}\right)$ and $\mathrm{Al}_{7.7} \mathbf{I n}_{5.3}\left(\mathbf{A l}_{\mathbf{8}} \mathbf{I n}_{\mathbf{5}}\right)$. The found ratio are close to those found for these compounds by other methods (Table *). The values of the $\mathrm{Ga}(\mathrm{In})-\mathrm{O}(\mathrm{H})$ and $\mathrm{Ga}(\mathrm{In})-\mathrm{OH}_{2}$ distances found in these compounds are also indicate that in all compounds the Ga atoms in the " $\mathrm{Ga}(3)$-position" positions only are replaced by the In atoms. The average $\mathrm{In}-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distance in $\mathbf{G a}_{7} \mathbf{I n}_{6}, 2.162(4) \AA$, is close to the distances found before in complexes with the $\mathrm{Bi}-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ bond, for example 2.156 and $1.158 \AA$ in
catena-[( $\mu 2$-Oxalato- $\left.\mathrm{O}, \mathrm{O}^{\prime}, \mathrm{O}^{\prime}, \mathrm{O}^{\prime \prime \prime}\right)$-bis ( $\left(\mu 2-\mathrm{O}^{\prime}, \mathrm{O}^{\prime \prime}, \mathrm{O}^{\prime \prime \prime}\right)$-tetraaqua-diindium dihydrato $]^{1}$. Decreasing the $\operatorname{In}$ ratio in the row $\operatorname{Ga}_{7} \mathrm{In}_{6}\left(\mathbf{G a}_{7} \mathbf{I n}_{6}\right), \mathrm{Ga}_{9.1} \mathrm{In}_{3.9}\left(\mathbf{G a}_{9} \mathbf{I n}_{4}\right), \mathrm{Ga}_{10.3} \mathrm{In}_{2.7}$ $\left(\mathbf{G a}_{\mathbf{1 0}} \mathbf{I n _ { 3 }}\right), \mathrm{Ga}_{11.9} \mathbf{I n}_{1.1}\left(\mathbf{G a}_{\mathbf{1 2}} \mathbf{I} \mathbf{n}_{\mathbf{1}}\right), G a 13$ is followed by decreasing the average $\operatorname{In}(\mathrm{Ga})$ $\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distances in this row: $2.162(4) \AA\left(\mathbf{G a}_{7} \mathbf{I n}_{6}\right), 2.105(6) \AA\left(\mathbf{G a} 9 \mathbf{I n}_{4}\right), 2.074(7) \AA$ $\left(\mathbf{G a}_{10} \mathbf{I} \mathbf{I n}_{\mathbf{3}}\right), 2.033(6) \AA\left(\mathbf{G a}_{12} \mathbf{I} \mathbf{I n}_{1}\right)$ and $2.00(2) \AA$ (the $\mathrm{Ga}_{13}$ cation). The average $\mathrm{In}(\mathrm{Al})-$ $\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distance in $\mathbf{A l}_{8} \mathbf{I n}_{5}\left(\mathrm{Al}_{7.7} \mathrm{In}_{5.3}\right)$ is $2.156(7) \AA$.

The $\mathrm{Al}_{13}{ }^{\circ}$ cluster cation has the similar structure as the $\mathrm{Ga}_{13}{ }^{\circ}$ cluster cation where all the metal centers are octahedrally coordinated (Figure 1). The $\mathrm{M}_{1}\left(\mu_{3}-\mathrm{OH}\right)_{6} \mathrm{M}_{6}\left(\mu_{2}-\right.$ $\mathrm{OH})_{6}$ core fragment $(\mathrm{M}=\mathrm{Ga}, \mathrm{Al})$ forms a central core and six $\mathrm{M}_{1}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ groups $\left(\mathrm{M}_{1}=\mathrm{In}\right.$, $\mathrm{Ga}, \mathrm{Al})$ are connected to this core via two alkoxo $\left(\mu_{2}-\mathrm{OH}\right)$ bridges each group alternating above and below the plane and forming the third M -shell in the cluster cation. In all these structures the $\mathrm{Al}_{13}$ cluster cations have $\overline{3}$ symmetry as for the $\mathrm{Ga}_{13}$ cluster cation.

In the all crystal structures the $\mathrm{M}_{13}$ clusters are surrounded by $\mathrm{NO}_{3}$ anions and solvent water or methanol molecules forming $\mathrm{O}-\mathrm{H}^{\cdots} \mathrm{O}$ hydrogen bonds. Both H atoms of water molecules coordinated to the $\mathrm{M}(\mathrm{Al}, \mathrm{Ga}, \mathrm{In})$ atoms and the H atoms at the bridging $\mu$-O atoms are involved in such H -bonds.

#8 -y+2/3,x-y+1/3,z+1/3 #9 -x+y+1/3,-x+2/3,z-1/3
```

## Supplimental information for Heterometallic paper

## Experimental Section

All chemicals were used as received: metal salts from Strem, N-nitroso-di-nbutylamine from TCI, and nitrosobenzene from Aldrich. IR spectra were taken using a Nicolet Magna 550 spectrometer and UV-visible spectra were measured on a Hewlett Packard 8453 spectrometer. TGA was performed on a Thermal Analysis 2950.

$$
\left[\mathrm{Ga}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}(\mathbf{1})
$$

Synthesized as previously described. ${ }^{2}$
Alternative organic additive. N -nitroso-di- $n$-butylamine $(1.15 \mathrm{~g}, 7.26 \mathrm{mmol}, 24$ equivalents.) is added to gallium(III) nitrate ( $1.0 \mathrm{~g}, 3.91 \mathrm{mmol}, 13$ equivalents) in 10 mL of methanol, as a homogeneous solution. The mixture was evaporated over 5 days at which point the methanol and nitrosoamine are no longer miscible and crystals begin to form on the sides and bottom of reaction vessel. After 4 more days the methanol completely evaporates giving a single liquid layer. The remaining oil is decanted and single crystals of $\mathbf{1}$ are washed with cold ethyl acetate (3x) and dried under air. This alternative method produces the identical $\mathrm{Ga}_{13}$ cluster in $85 \%$ yield with respect to gallium. The yield can be increased to nearly quantitative by precipitation of poorer quality crystals from the residual oil with cold ethyl acetate and re-crystallizing from methanol.

$$
\left[\mathrm{Ga}_{7} \mathrm{In}_{6}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}(2)
$$

Gallium(III) nitrate ( $1.73 \mathrm{mg}, 0.006 \mathrm{mmol}, 1$ equivalent) and indium(III) nitrate ( 24.7 $\mathrm{mg}, 0.082 \mathrm{mmol}, 12$ equivalents) are dissolved in 5 mL of methanol. Nitrosobenzene
( $17.6 \mathrm{mg}, 0.165 \mathrm{mmol}, 24$ equivalents) was dissolved in 2 mL of methanol, and the solutions were mixed together. The mixture was evaporated at room temperature over 1012 days, yielding large single crystals of 2 in $25 \%$ yield with respect to indium nitrate. Alternate method. N -nitroso-di- $n$-butylamine ( $0.93 \mathrm{~g}, 5.9 \mathrm{mmol} 24 \mathrm{eq}$.) was added to a solution of $\mathrm{Ga}\left(\mathrm{NO}_{3}\right)_{3}(0.068 \mathrm{~g}, 0.267 \mathrm{mmol}, 1 \mathrm{eq}$.$) and \mathrm{In}\left(\mathrm{NO}_{3}\right)_{3}(0.872 \mathrm{~g}, 2.97 \mathrm{mmol}, 12$ eq.) in methanol, and formed a homogenous solution. The mixture was evaporated at room temperature over 10-12 days, affording $\mathbf{2}$ in $94 \%$ yield.

Crystal data for 2 (Dave4): $\mathrm{C}_{6} \mathrm{H}_{96} \mathrm{Ga}_{7} \mathrm{In}_{6} \mathrm{~N}_{15} \mathrm{O}_{99}, \mathrm{Mr}=3139.94$. Colorless block, $0.15 \times 0.15 \times 0.07 \mathrm{~mm}$, rhombohedral, space group $R^{\prime} 3$ (no. 148), $a=20.694$ (2), $b=20.694(2), c=18.266(4) \AA, V=6774(2) \AA^{3}, \mathrm{Z}=3, \quad \mathrm{r}_{\text {calcd }}=2.309 \mathrm{gXcm}^{-3}, \mathrm{~m}=3.703 \mathrm{~mm}^{-1}$, $\mathrm{F}(000)=4620,2 \theta_{\max }=56.50^{\circ}, 16202$ reflections collected, 3588 unique $\left[R_{\mathrm{int}}=0.0203\right], R$ indeces $[I>2 \sigma(I)]: R 1=0.0211, w R 2=0.0582, \mathrm{GOF}=1.035$.

X-ray diffraction experiments were carried out on a Bruker Smart Apex diffractometer at 153 K (2) using MoKa radiation ( $\mathrm{l}=0.71070 \AA$ ). Absorption corrections were applied by SADABS $\left(\mathrm{T}_{\min } / \mathrm{T}_{\max }=0.570(1)\right.$ and $0.762(2)$. Crystal of 2 , is hexagonal and have the same space group $R `$ (no. 148). In all structures the $\mathrm{M}_{13}$ cations are on a`3 axes. Two $\mathrm{NO}_{3}$ anions (in general positions) provide twelve $\mathrm{NO}_{3}$ anions per the $\mathrm{M}_{13}$ cation. Three other $\mathrm{NO}_{3}$ anions and solvent molecules (methanol in 2) are highly disordered and randomly fill six other possible positions around the $\mathrm{M}_{13}$ cation. In the crystal structure of $\mathbf{1}$ a disorder of $\mathrm{NO}_{3}$ anions and solvent water molecules are more complex. In all structures highly disordered $\mathrm{NO}_{3}$ anions and solvent methanol molecules
were treated by SQUEEZE. ${ }^{3}$ Corrections of the X-ray data by SQUEEZE are 353 and 638 electron/cell, respectively for $\mathbf{1}$ and $\mathbf{2}$; to the required values are 349 electron/cell for 9 $\mathrm{NO}_{3}$ anions and 7 water molecules in $\mathbf{1}$ and 603 electron/cell for $9 \mathrm{NO}_{3}$ anions and 18 methanol molecules in 2. All non-H atoms were refined with anisotropic thermal parameters except the atoms of the disordered $\mathrm{NO}_{3}$ anion. In all structures H atoms were found on the difference F-map and refined with isotropic thermal parameters except those in disordered water molecules, which were not taken into consideration.

Refinements of the crystal structures of $\mathbf{2}$ without symmetry restrictions on occupation factors for the Ga and In atoms show that the refined occupation factors of the $\mathrm{Ga}(1)$ and $\mathrm{Ga}(2)$ atoms are very close to those based on the crystal symmetry. The found $\mathrm{Ga}(1)-\mathrm{O}$ and $\mathrm{Ga}(2)-\mathrm{O}$ distances in structure 2 is similar distances found in the Ga 13 cation [*]. It indicates that in all these structures the central $\mathrm{M}_{7}$ part of the $\mathrm{M}_{13}$ cations are formed by the Ga atoms only. In contrast refinement of occupation factors for the In atom in " $\mathrm{Ga}(3)$-position" show that only in structure of 2 occupation factor for the In atom is close to required value of 1.0. In all other structure occupation factors for the In atoms in this position are less than the needed occupation factor of 1.0 based on symmetry. The values of the $\mathrm{Ga}(\mathrm{In})-\mathrm{O}(\mathrm{H})$ and $\mathrm{Ga}(\mathrm{In})-\mathrm{OH}_{2}$ distances found in these compounds are also indicate that in all compounds the Ga atoms in the " $\mathrm{Ga}(3)$-position" positions only are replaced by the In atoms. In the all crystal structures the $\mathrm{M}_{13}$ clusters are surrounded by $\mathrm{NO}_{3}$ anions and solvent water or methanol molecules forming $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds Both $H$ atoms of water molecules coordinated to the $M(G a, I n)$ atoms and the H atoms at the bridging $\mathrm{m}-\mathrm{O}$ atoms are involved in such H -bonds. The average
$\operatorname{In}(\mathrm{Ga})-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ distance in $\mathrm{Ga}_{13}$ and $\left[\mathrm{Ga}_{7} \mathrm{In}_{6}\right.$ clusters, $1.997(16)$ and 2.162(4) $\AA$, respectively. These distances are close to the distances found before in complexes with the $\mathrm{Bi}-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right)$ bond, for example 2.156 and $1.158 \AA$ in catena-[ $(\mu 2$-Oxalato$\left.\mathrm{O}, \mathrm{O}^{\prime}, \mathrm{O}^{\prime}, \mathrm{O}^{\prime \prime \prime}\right)$-bis $\left(\mu 2-\mathrm{O}^{\prime}, \mathrm{O}^{\prime \prime}, \mathrm{O}^{\prime \prime \prime}\right)$-tetraaqua-diindium dihydrato]. ${ }^{1}$

# APPENDIX G <br> <br> TEMPLATED ORGANIC NANOCAGES 

 <br> <br> TEMPLATED ORGANIC NANOCAGES}

#### Abstract

Synthetic schemes and characterization of new bis-bidentate Schiff base ligands for making of three dimensional nanoscale organic cages. The organic nanocages will be achieved by a templated approach to the formation of covalently capped $M_{4} L_{6}$ tetrahedron. These tetrahedron are beginning characterization and will later be internally and/or externally functionalized for application.

## Introduction

Supramolecular chemistry governs many process vital to life from DNA replication to inter cellular communication. ${ }^{1,2}$ It is not surprising that nature used the principles of supramolecular chemistry in forming the blueprint of life itself - DNA. A double stranded DNA helix is held together by hydrogen bonding between the strands allowing it to be unwound and copied during replication without breakage. A single strand of DNA is a template for its complementary strand resulting in spontaneous selfassembly. ${ }^{2,3}$

Figure G. 1 DNA, Crown ether, general cartoon figures on the reaction of a template. ${ }^{1,4}$

Single metal ions can be used as a template for the synthesis of corands, cryptands or catenanes. ${ }^{1}$ Single metals can also be used as templates, similar to DNA, in which they act as a guide to bring two different compounds together, allowing the organic pieces to react to form cryptands or catenanes. ${ }^{5-7}$

Another useful strategy in organic synthesis is the use of multiple metal centers as template to form large macrocyclces. In this case, the metal ions exist in a plane ${ }^{8-12}$ however a variety of supramolecular compounds (e.g. tetrahedron or octahedron) possess multiple metal ions lying in three dimensions in order to enclose a volume. ${ }^{13-15}$ These metal centers are not part of a template scheme; they represent core components of the supramolecular assembly. Without the metals these complexes would simply fall apart. It is surprising then that no one has tried to use multiple metals (in three dimensions) as a template, trapping the complex and removing the metal to provide a classical organic cage compound. ${ }^{16,17}$

The proposed research will utilize metal centers as templates for the supramolecular self-assembly of nanoscale organic cages. Multiple metals can obviously be used to make larger or more complex structures than a single metal template would provide. ${ }^{18}$ The key difference in the strategy outlined below versus previous strategies is
that four metals centers are in a non-planar arrangement. This will lead to a three dimensional complex, with additional functionality to allow for covalent capture. Careful ligand design coupled with selection of appropriate metals will force the ligand to bridge multiple metals forming the three dimensional complexes to be used as templates
(Schemes G. 1 and G.2). ${ }^{5,19-25}$

Scheme G.1. Yan's self-assembled tetrahedron with perchlorate counter ion with $\mathrm{Zn}^{2+}$ vertices ${ }^{19}$. Literature precedent with crystals structure of metal-ligand nanocage synthesis \& Crystal structure of Yan's tetrahedron with an encapsulated perchlorate anion.

Our preliminary work is based on a related tetrahedron synthesized by Yan and co-workers. ${ }^{19}$ The Yan complex is not templated, they have no way of removing the metal without destroying the complex, but it does self-assemble. The fundamental change from the Yan group to this project is to add functionality to the distal ends of the ligand, allowing for the covalent capping to occur (Scheme G.2).

The general $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron template strategy is depicted below (Scheme G.2). Six equivalents of an appropriately designed ligand (blue lines) are combined with four equivalents of metal (red spheres) to self-assemble a $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron (metal-ligand
nanocage template) related to the $\mathrm{Zn}_{4} \mathrm{~L}_{6}{ }^{8+}$ from Scheme G.1. The next step is covalent capture by a cap (green) that binds all six ligands together to yield the $M_{4} L$ ' complex. The final step of demetallation yields the organic nanocage, $\mathrm{L}^{\prime}$. This complex has a volume that is defined by its covalently linked shell, which we hope to exploit for guesthost and metal binding studies.

$\underset{\sim}{\text { functionalize }}$
applications

Scheme G.2. The general scheme to use an $\mathrm{M}_{4} \mathrm{~L}_{6}$ capsule as a template to form an organic nanocage, L'

There are numerous possibilities for the uses of the organic nanocages once they are made. Once the organic nanocage is created, it is pre-organized to be a specific chelator for metals. This is both its strength and weakness. This attribute will make it difficult to remove the template metal from the cage, because as the organic nanocage is a wrap-around-ligand, it will have stronger binding. ${ }^{1,26-29}$ The cages can be modified on the interior or the exterior for a variety of applications after demetallation, such as sensing, extracting or catalysis. ${ }^{30}$

## Results

The proposed synthetic route of $\mathbf{5 d}$ (Scheme G.3) is a modification with increased yields. ${ }^{31}$ The products are then coordinated with $\mathrm{Zn}^{2+}$ followed by capping and
demetallation to yield the desired L' organic nanocage is shown below (Scheme G.4). Functionalization at the five position on the pyridine ring, from the Yan tetrahedron will allow for a capping amide reaction to covalently bind adjacent ligands together. After the covalent capture of the template the nanocage can be demetallated.

Scheme G.3. Synthetic scheme to make the L' nanocages. ${ }^{19,31}$

Scheme G.4. Self-assembly of ligands $\mathbf{5}$ or $\mathbf{6}$ to form the template organic nanocage $\mathbf{7}$ and 8.

The starting pyridine ring for this synthesis can be substituted with either a carboxylic acid or an ester (ethyl or benzyl) in the 3 position. These different groups affect the yields of the first step. The rigid diamine spacer has also been varied, using benzidine, 3 (4-4'-diaminobiphenyl) and $\mathbf{4}$ (4-4"-diaminoterphenyl) modification of the ligand at the distal end and the 3 position of the pyridine ring (Scheme G.3). Figure G. 2 shows the models of complexes that we wish to make as the carboxylic acid, the capped ester and the dovetailed organic nanocage. Computer modeling shows that the ester is far enough away from the Schiff base binding motif not to interfere in the complexation with the metal (Figure G.2A). ${ }^{32}$ Figure G.2B addresses the sterics of the cap and Figure
G.2C is the goal of phase one: the demetallated organic nanocage.

Figure G.2. Computer model with MM3 of target $\mathrm{M}_{4} \mathrm{~L}_{6}$ tetrahedron, capped $\mathrm{M}_{4} \mathrm{~L}$ ' and then de-metallated L' complexes. ${ }^{32}$

## Ligand Synthesis

The target ligands of $\mathbf{5 d}$ and $\mathbf{6 d}$, substituted with activated ester groups, pose a better likelihood of yielding the tetrahedron template. This would avoid having to remove all 12 ester groups on complex $\mathbf{7 a , b}$ and $\mathbf{8 a , b}$ simultaneously and provides tetrahedron complex 7 d ready to be capped with the amine without changing a functional group.

The first target ligand, 5a, has an ethyl protected carboxylic acid at its distal ends. The first step of the synthesis (Scheme G.3) proceeds with an acceptable yield of 11 to $23 \% .^{31}$ The acylation reaction works on a variety of ester R groups ( $\mathrm{R}=\mathrm{OH}$, OEt or $\mathrm{OBn})$. The different R groups affect the yield and solubility of the ligands after the condensation reaction to yield ligands $\mathbf{5 a}, \mathbf{5 b}, \mathbf{6 a}$ and $\mathbf{6 b}$. Although TLC of the acylation reaction shows that only one species is isolated from column chromatography, NMR reveals 6:1 ratio of compounds 2a and 11, respectively is obtained (Figure G.3A).

Overall crude yields can be increased by shortening the reaction time to limit the
formation of side product 11. Repeated attempts to separate the desired product from the side product gave the same result so the mixture was carried onto the following step, condensation with 3.

Figure G.3. Acylation side products 11a \& 12a from the formation of ketone 2a.

The condensation reaction of 2a with $\mathbf{3}$ (Scheme G.5) is done in absolute ethanol by adding two equivalents of ketone, 2a, to one equivalent of benzidine, $\mathbf{3}$, at reflux with catalytic acetic acid for four hours to provide $\mathbf{5 a}$ in $\mathbf{8 6 \%}$ yield. Ligand 5a precipitates out of the reaction mixture, helping with yield and purification. Washing with cold methanol removes unreacted starting materials. Analytically pure ketone, 2a, is not needed for the condensation reaction because the disubsituted ketone (11a) can easily be removed after the condensation reaction to yield pure $\mathbf{5 a}$ (Figure G.3A and C) by precipitation.

Many different reaction conditions have been tried to optimize the yield of $\mathbf{4 a}$ (see experimental). ${ }^{33,34}$ Increasing the ratio of ketone to benzidine to five to one should drive the reaction to completion in benzidine and thus make the column chromatographic separation easier ( $\mathbf{3}$ and $\mathbf{5 a}$ have very similar $\mathrm{R}_{\mathrm{f}}$ values). Unreacted 2a can then be recovered and reused. Current yields in absolute ethanol with the acetic acid catalyst are
in excess of $85 \%$ analytically pure ligand $\mathbf{5 a}$. Single crystal x-ray structure confirms the structure of 5a as the free base ligand (Figure G.4).

Figure G.4. Ortep of $\mathbf{5 a}$ single crystal structure, and packing pictures.

Benzidine, 3, and 4-4"-terphenyldiamine, 4, both crystallize with the rings completely planar; this is not the lowest energy confirmation that we would expect, but it does allow for greater edge to face interaction between adjacent molecules in the cell. The angle of the plane of one biphenyl to the adjacent is about $70^{\circ} .{ }^{35}$ The biphenyl portion of 5a crystallizes in a planar fashion as well, but it places the adjacent ligands in a complete $90^{\circ}$ edge to face arrangement. This increases the strength of the edge to face interactions and it stacks the pyridine rings face to face with an offset angle. This packing in the solid state may help to explain the unusual behavior of $\mathbf{5 a}$ in DMSO solution. (Figure G.5)

Ligand $\mathbf{5 a}$ has an expected spectrum in $\mathrm{CDCl}_{3}$, but when dissolved in DMSO it behaves quite differently (Figure G.5), suggesting it forms a not-well-understood,
concentration-dependent oligomer in DMSO. This issue is not only concentration dependent, but also solvent dependent.

Figure G.5. ${ }^{1} \mathrm{H}$ NMR spectra of ligand 5a in DMSO at various concentrations, showing the concentration dependent behavior. At 1/16 concentration mostly monomer appears to be present.

The same batch of pure ligand is sequentially dissolved in one solvent, analyzed, dried down and resuspended in a different NMR solvent. The ligand, in going from chloroform to DMSO, shows first the simple then the complex spectra, then back to a clean spectrum, again in chloroform (Figure G.6).

Figure G. $6{ }^{1} \mathrm{H}$ NMR of ligand 5a showing the solvent and concentration effects are reversible.

Concurrently ligand $\mathbf{6} \mathbf{b}$ was synthesized by the same procedure. ${ }^{36}$ Ligand $\mathbf{6 b}$ has very poor solubility in all solvents. The same route from intermediate ketones $\mathbf{2 a}$ and $\mathbf{2 b}$ also synthesized the two crossover ligands $\mathbf{5 b}$ and $\mathbf{6 a}$. All four ligands are concurrently being carried on for self-assembly and de-protection reactions.

## Deprotection

Two different routes for deprotection have been explored. The first route was to deprotect ketone $\mathbf{2 b}$ with potassium carbonate into the carboxylic acid $\mathbf{2 c}$ then activate with 2-mercaptothiazoline to yield the activate ester 2d for capping and condensation
reactions. ${ }^{37}$ This same route is being explored to convert ligands 5d and 6a into 5d and 6d. The second route under investigation involves heating of 5 a in $\mathrm{DMSO} /$ water solution at $95^{\circ} \mathrm{C}$ with potassium hydroxide. By NMR spectroscopy both reactions appear to have removed the ethyl groups, although the ligand has not yet been purified.

## Self-assembly of Ligands

Because of the unusual behavior of $\mathbf{5 a}$ in DMSO, metallation and further studies will be attempted in DMF. Ligand 5a has been heated with two-thirds equivalents of $\mathrm{Zn}\left(\mathrm{BF}_{4}\right)_{2}$ or $\mathrm{Zn}(\mathrm{OTf})_{2}$ to yield a new compound that is currently being characterized in d7-DMF. By ${ }^{1} \mathrm{H}$ NMR spectroscopy there are new peaks that do not correspond to any of the starting materials. It seems that both the tetrafluoroborate and the triflate counter ions yield similar results, although it appears to take longer for the reaction to occur with the triflate salt. ${ }^{38,39}$

Figure G.7. Time points of $\mathbf{5 a}$ in DMF with 2/3rds equivalents of $\mathrm{Zn}\left(\mathrm{BF}_{4}\right)_{2}$.

A different ${ }^{1} \mathrm{H}$ NMR spectrum can be obtained on multi milligram scale by running the reaction in a Schlenk tube. A pasty solid is obtained by heating 2 equivalents of ligand $\mathbf{5 a}$ with 1 equivalent of $\mathrm{Zn}\left(\mathrm{BF}_{4}\right)_{2}$ in DMF at $60^{\circ} \mathrm{C}$ for 16 hours, reducing the volume, and precipitating with ethyl acetate. Unreacted ligand was extracted by washing with ethyl acetate. The paste was dried in vacuo. Other metallation reactions with ligand 5a and other metals are currently being tried.

Figure G.8. Time points of $\mathbf{5 a}$ in DMF with 2/3rds equivalents of $\mathrm{Zn}(\mathrm{OTf})_{2}$.

Metallation reactions are being tried with the other isolated and characterized ligands ( $\mathbf{5 b}, \mathbf{6 a}$ and $\mathbf{6 b}$ ). Metallation will also be attempted on deprotected acid ligands ( $\mathbf{5 c}$ and $\mathbf{6 c}$ ) as well as the target thiazoline activated esters ( $\mathbf{5 d}$ and $\mathbf{6 d}$ when they are prepared). Ligands $\mathbf{6 a}$ and $\mathbf{6 b}$ exhibit very poor solubility. Heating and cooling to room temperature causes the ligand crash out very quickly. The addition of $\mathrm{Zn}\left(\mathrm{BF}_{4}\right)_{2}$ to the solution helps keep the ligands in solution. Many other attempts at crystalization and characterization of the complex are in progress.

## Concurrent Work on Alternate schemes

## Activated Esters

Anticipating that the capping of the templated cage will be very difficult in high yields; possible solutions to this problem are to increase the yield or to change the order of the reactions to do the more difficult reaction earlier. The first method we are trying is to activate the ester to facilitate the formation of 12 amide bonds simultaneously. The main goal is to get to ligand $\mathbf{5 d}$ or $\mathbf{6 d}$ from Scheme 3. This is a modification of the project as it was unfolding

Scheme G. 5 projected route to get to intermediate eight and nine, as alternative to scheme 3

The modified Scheme G. $\mathbf{5}$ to get to ligand $\mathbf{5 d}$ by an alternate route proved to be just as difficult. The thiazoline-activated ester is characteristically yellow because of the conjugation of the atoms. The activated thiazoline ester works so well that the diamine
that is the backbone for the condensation instead makes an amide bond. ${ }^{37}$ This characteristic color disappears during the condensation reaction attempts as the diamine reacts with the thiazoline to form an amide. This has proved that the condensation needs to be done before the activation or the capping needs to be done before the condensation.

## Capping First

The second possibility to solve the capping problem is to cap the ligands before they are fully assembled. This alternate scheme will run the same reactions but in a different order. The burgundy line is the spacer, the benzidine (3) or the 4,4 "diaminotertphenyl (4) that is used in the condensation with the ketone to make the Schiff base. An orange-burgundy-orange line is the same as a blue line from Scheme 3. The orange end is the ketone for the condensation. The R group could be ethyl ester, benzyl ester, acid or the activated thiazoline esters, but here instead the ketone is capped to yield a new intermediate. This new intermediate will undergo self-assembly (using the metals) and condensation (with the diamine core) at the same time. By CAChe modeling, a $\mathrm{L}_{3}$ helicate should be able to form without metal, but because of ligand design the $\mathrm{M}_{2} \mathrm{~L}_{3}$ complex should not be stable.

Scheme G. 6 Alternate scheme for the capping of the ligands before self-assembly

A major concern about condensing the backbone and self-assembling the complex at the same time is that the new intermediate (13) would be a good metal chelator, because it would have the ability to wrap around the metal, much like EDTA. ${ }^{40,41}$ But CAChe modeling suggests that the Zn center would be strained. Starting with benzyl nicotinate, $\mathbf{1 b}$, and acylation to $\mathbf{2 b}$ affords a higher yield than using nicotinic acid, $\mathbf{1 c}$, or ethyl nicotinate, 1a. Then ketone $\mathbf{2 b}$ is modified into ketone $\mathbf{2 d}$; as seen before, $\mathbf{2 d}$ cannot be condensed with $\mathbf{3}$ or $\mathbf{4}$ to yield ligand $\mathbf{5 d}$ or $\mathbf{6 d}$ respectively. Therefore $\mathbf{2 d}$ will be reacted with TRPN, 9 , to yield the capped ketone. This new intermediate will be condensed with a diamine ( $\mathbf{3}$ or $\mathbf{4}$ ) either in the presence or absence of $\mathrm{Zn}^{2+}$, which should afford the capped metal templated organic nanocage (14) or the non-metal helicate (15).

Scheme G. 7 acylation, activation, capping condensation coupled with SA.

## Future Work

Currently we stand two steps from the completion of the first main goal the templated organic nanocage. Those two steps are the capping and then demetallation of the cage. The first objective is to complete the ligand synthesis route and the characterization of the intermediates. Ligands $\mathbf{5 a}$ and $\mathbf{5} \mathbf{b}$ need to be converted into the acid of $\mathbf{5 c}$, which then must be fully characterized. The same functional group interconversion needs to be finished on the larger ligand 6 . Both ligands $5 c$ and $\mathbf{6 c}$ will be metallated and the resulting complexes will be characterized. Then free ligands $\mathbf{5 c}$ and $\mathbf{6 c}$ will be activated into ligands $\mathbf{5 d}$ and $\mathbf{6 d}$, which will also be metallated.

Each of the ligands ( $\mathbf{a}, \mathbf{b}, \mathbf{c}$ or $\mathbf{d}$ ) should self-assemble into the supramolecular complex. The biggest problem will be the formation of all 12 amide bonds to yield 7 or $\mathbf{8}$ from Scheme G.4. The current progress is showing that we may need to use activated esters to prepare for capping (ligands $\mathbf{5 d}$ and $\mathbf{6 d}$ ). The complexes made with $R$ functional groups $\mathbf{a}, \mathbf{b}$ or $\mathbf{c}$ will still need to be capped after assembly.

The final step to yield the organic nanocage is the demetallation of the capped template. The basic plan is to make the metal less stable in the cage and then extract it. Possible demetallation solutions are to reduce the Schiff base to the amine then remove the metal with EDTA ${ }^{7,42,43}$ or couple a chromatographic separation ${ }^{44}$ for the easy release of the metal by precipitation of an insoluble metal salt.

We will continue working with the existing ligand $\mathbf{5 a} \mathbf{a} \mathbf{b}$ and $\mathbf{6 a , b}$ to assemble cages and characterize them. One plan is to use these ligands with other metals centers. Other metals have different coordination geometries. We could exploit this in an attempt to make coordination polymers. ${ }^{45-47}$ If coordination polymers are made then they could still be covalently capped and demetallated. They would be very interesting and possibly very useful structures for metal remediation or possibly drug delivery. ${ }^{48}$ If coordination polymers are not made, instead a discreet species like a square or a grid can be made. ${ }^{49,50}$

The self-assembly was not accurate because of the DMSO concentration effects (Figure 5). There are a series of experiments to try in DMF, since it appears to allow for the formation of a new discreet species. We will try the same self-assembly reactions with adamantane present, looking for the encapsulation of it as guest during complex formation. Ward noticed that an anionic guest helps with self-assembly their complexes [ref]; we will work more on the self-assembly of tetrahedron $5 \mathbf{5}$ using $\mathrm{Zn}(\mathrm{OTf})_{2}$ as the metal source, but determine if the addition of $\mathrm{KBF}_{4}$ as a possible guest will accelerate the formation of the complex. The larger cages (8) made from the longer ligand 6, will need a larger anionic guest like $\mathrm{IO}_{4}^{-}, \mathrm{MnO}_{4}^{-}$or $\mathrm{ReO}_{4}^{-}$. We will try to self-assemble ligand and
complex in one step, using a one-pot synthesis of $\mathbf{2 b}$ or $\mathbf{2 d}$, with $\mathbf{3}$ and $\mathrm{Zn}\left(\mathrm{BF}_{4}\right)_{2}$ in DMF, or chloroform to see if complex 7b or 7d will form. ${ }^{51,52}$

## New Ligands

A major branch point is to synthesize different ligands. We plan to build off this existing strategy by using new diamine spacers. ${ }^{47,53}$ Increased size and bulk as well as added flexibility should allow for the synthesis of $\mathrm{M}_{2} \mathrm{~L}_{3}$ helicates. ${ }^{54-58}$ New topologies can also be explored by changing to three- or four-fold symmetric linkers. The new spacers would allow for the formation of $M_{4} L_{4}$ cube complexes. ${ }^{59,60}$

Another aspect of the project would be to work on a new design of ligands that still have a similar binding motif of the Schiff base but are assembled differently and with higher yields. Using a bipyridyl functionality for the binding motif would require alternate functionality on the ends to allow for a linker to make a bis ligand and the covalent cap at the other end. ${ }^{10,61}$ Another prime alternative is to use a pyrazolylpyridine binding motif as the bidentate ligand. ${ }^{18,62}$ The pyrazolylpyridine rings would be able to be differentially functionalized. Using a catechol adjacent Schiff base would create a new binding motif for the metal. ${ }^{15}$ This new binding group could be coupled with any of the current or future diamine cores. These new ligands would be able to achieve different complexes and should also be able to make the coordination polymers. ${ }^{63}$

This project has many directions that it can go. The existing ligand strategy will yield multiple organic nanocages soon. These cages can then be tested for guest-host chemistry and functionalized for testing with external applications.

## Experimental

General Experimental. All NMR spectra were taken on a 300 MHz or a 500 MHz Varian INOVA Spectrometer instrument in $\mathrm{CDCl}_{3}$, unless otherwise noted. All reactions were performed under an inert $\mathrm{N}_{2}$ atmosphere. Compounds were purchased from a commercial supplier and used without further purification unless otherwise noted. ESIMS was performed on an Agilent 1100 LC-ESIMS by means of direct injection, using THF as the mobile phase. Desert Analytic of Tucson, AZ performed elemental analysis. Single crystal X-ray data were collected using a Bruker SMART APEX diffractometer equipped with a CCD area detector using $\mathrm{Mo}-\mathrm{K}_{\alpha}(\lambda=0.71073 \AA)$ radiation.

6-Acetyl-ethyl nicotinic (2a Scheme 3) A chilled solution of $\mathrm{H}_{2} \mathrm{SO}_{4}(5.2 \mathrm{~mL}, 92 \mathrm{mmol}$ ), ethyl nicotinate $\mathbf{1 a}(4.6 \mathrm{~mL}, 33 \mathrm{mmol})$ and acetaldehyde $(5.5 \mathrm{~mL}, 96 \mathrm{mmol}$, added via a pre-chilled syringe) in water ( 15 mL ) was prepared. A suspension of iron sulfate (26.9 $\mathrm{gm}, 97 \mathrm{mmol}$ ) in water ( 65 mL ) was added drop wise by one syringe while t-butyl peroxide ( $9.8 \mathrm{~mL}, 67 \mathrm{mmol}, 70 \%$ solution in water) was added by a second syringe. Both reagents were added dropwise over three minutes. The reaction was stirred for a total of 15 minutes from the beginning of addition until the removal of the ice bath.

The reaction was extracted twice with chloroform ( $2 \times 20 \mathrm{~mL}$ ). The organic layers were combined and washed once with brine ( $1 \times 20 \mathrm{~mL}$ ), then dried over $\mathrm{MgSO}_{4}$, filtered and reduced by rotary evaporation. Crude yield a mixture of 1a, 2a, 12a and 11a was 3.29 gm , ca. $51.6 \%$. The product was purified by column chromatography (silica
gel, 9:1 hexanes: ethyl acetate). The desired product, 2a, is the first to elute. The other products can be isolated by this method as well. Final yield of $\mathbf{2 a}$ was $0.300 \mathrm{gm}, 9 \%$ of crude. ${ }^{1} \mathrm{H}$ NMR $\delta=9.26(\mathrm{~s}, 1 \mathrm{H}), 8.41(\mathrm{dd}, \mathrm{J}=8.1,2.7 \mathrm{~Hz}, 1 \mathrm{H}), 8.09(\mathrm{dd}, \mathrm{J}=8.1,0.6 \mathrm{~Hz}$, $1 \mathrm{H}), 4.44(\mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, 2 \mathrm{H}), 2.75(\mathrm{~s}, 3 \mathrm{H}), 1.43(\mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, 3 \mathrm{H})$

Undesired products
$1 \mathbf{1 a}^{1} \mathrm{H}$ NMR $\delta=9.22(\mathrm{~s}, 1 \mathrm{H}), 8.76(\mathrm{dd}, \mathrm{J}=4.5,1.8 \mathrm{~Hz}, 1 \mathrm{H}), 8.27(\mathrm{~d}$ of $\mathrm{t}, \mathrm{J}=6.0,1.8 \mathrm{~Hz}$, 1H), $7.38(\mathrm{dd}, \mathrm{J}=7.8,2.7 \mathrm{~Hz}, 1 \mathrm{H}), 4.42(\mathrm{q}, \mathrm{J}=7.2 \mathrm{~Hz}, 2 \mathrm{H}), 1.30(\mathrm{t}, \mathrm{J}=7.2 \mathrm{~Hz}, 3 \mathrm{H})$
$11 \mathrm{a}{ }^{1} \mathrm{H}$ NMR $\delta=9.19(\mathrm{~s}, 1 \mathrm{H}), 8.22(\mathrm{~d}, \mathrm{~J}=4.8 \mathrm{~Hz}, 1 \mathrm{H}), 7.20\left(\mathrm{~d},{ }^{4} \mathrm{~J}=0.6 \mathrm{~Hz}, 1 \mathrm{H}\right), 4.41$ $(\mathrm{q}, \mathrm{J}=7.2 \mathrm{~Hz}, 2 \mathrm{H}), 2.55(\mathrm{~s}, 3 \mathrm{H}), 1.38(\mathrm{t}, \mathrm{J}=7.2 \mathrm{~Hz}, 3 \mathrm{H})$

12a ${ }^{1} \mathrm{H}$ NMR $\delta=9.16(\mathrm{~s}, 1 \mathrm{H}), 7.95(\mathrm{~s}, 1 \mathrm{H}), 4.42(\mathrm{q}, \mathrm{J}=6.9 \mathrm{~Hz}, 2 \mathrm{H}), 2.75(\mathrm{~s}, 3 \mathrm{H}), 2.58$ $(\mathrm{s}, 3 \mathrm{H}), 1.40(\mathrm{t}, \mathrm{J}=6.9 \mathrm{~Hz}, 3 \mathrm{H})$

6-Acetyl-benzyl nicotinate. (2b Scheme G.3) A chilled solution of $\mathrm{H}_{2} \mathrm{SO}_{4}(3.4 \mathrm{~mL}, 58$ $\mathrm{mmol})$, benzyl nicotinate, $\mathbf{1 b},(5.0 \mathrm{gm}, 23 \mathrm{mmol})$ and acetaldehyde $(3.3 \mathrm{~mL}, 58 . \mathrm{mmol}$, added via a pre-chilled syringe) in water ( 10 mL ) was prepared. A suspension of iron sulfate ( $16 \mathrm{gm}, 58 \mathrm{mmol}$ ) in water ( 20 mL ) was added dropwise by one syringe while tbutyl peroxide ( $8.0 \mathrm{~mL}, 58 \mathrm{mmol}, 70 \%$ solution in water) was added by a second syringe. Both reagents were added dropwise over three minutes. The reaction was stirred for a total of 10 minutes from the beginning of addition until the removal of the ice bath.

The reaction was extracted ten times with chloroform ( $10 \times 10 \mathrm{~mL}$ ). The organic layers were combined and washed once with brine ( $1 \times 20 \mathrm{~mL}$ ), then dried over $\mathrm{MgSO}_{4}$, filtered and reduced by rotary evaporation. The product was purified by column chromatography (silica gel, $9: 1$ hexanes: ethyl acetate). The desired product, $\mathbf{2 b}$, is the first to elute. The other products can be isolated by this method as well. Final yield of $\mathbf{2 b}$ was $1.27 \mathrm{gm}, 21.3 \%$ yield overall. ${ }^{1} \mathrm{H}$ NMR $\delta=9.26(\mathrm{~s}, 1 \mathrm{H}), 8.41(\mathrm{dd}, \mathrm{J}=8.1,2.7 \mathrm{~Hz}$, $1 \mathrm{H}), 8.09(\mathrm{dd}, \mathrm{J}=8.1,0.6 \mathrm{~Hz}, 1 \mathrm{H}), 7.41(\mathrm{~m}, 5 \mathrm{H}), 5.42(\mathrm{~s}, 2 \mathrm{H}), 2.75(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta$ $=164.9,156.0,151.2,150.5,138.2,124.2,121.3,62.1,26.2,14.5$.

## 6-Acetyl-nicotinic Acid, (2c Scheme G.3) (synthesized by CAJ)

To a solution of $\mathbf{2 b},(0.5 \mathrm{gm}, 1.9 \mathrm{mmol})$ in 3:1 THF/water two equivalents of KOH was added. The reaction was stirred for three hours without heat. The THF was removed by rotary evaporation and the water was washed with methylene chloride ( $3 \times 10 \mathrm{~mL}$ ). The organic layers were combined and dried by rotary evaporation to yield un-reacted starting material, 2b. The aqueous layer was acidified with HCl (2 equivalents) to yield a
precipitate, which was filtered and washed with water, yielding $0.18 \mathrm{gm}(47 \%)$ of $\mathbf{2 c}$ when dried. ${ }^{1} \mathrm{H}$ NMR $\delta=8.67(\mathrm{~s}, 1 \mathrm{H}), 8.04(\mathrm{dd}, \mathrm{J}=8.1,1 \mathrm{H}), 7.73(\mathrm{dd}, \mathrm{J}=8.1,1 \mathrm{H}), 4.67$ (s, 4H), 2.45 ( $\mathrm{s}, 3 \mathrm{H}$ )

## 6-Acetyl-nicotinic Acid Thiazoline Ester, (2d Scheme G.3) (synthesized by CAJ)

To a solution of $\mathbf{2 c}(0.180 \mathrm{gm}, 1.08 \mathrm{mmol})$ in 5 mL methylene chloride and 5 mL tetrahydrofuran, one equivalent of 2-mercaptothizaoline ( $0.119 \mathrm{gm}, 1 \mathrm{mmol}$ ) one equivalent of DCC (dicyclohexylcarboimide) ( $0.206 \mathrm{gm}, 1 \mathrm{mmol}$ ) and one-twentieth equivalent of DMAP (4-(dimethylamino)-pyridine) ( $0.0061 \mathrm{gm}, 0.05 \mathrm{mmol}$ ) was added. The reaction was stirred at room temperature under nitrogen for 5 hours, at which point the solution was a deep yellow color. A white precipitate formed and the reaction was filtered to remove the DCU (dicyclohexylcarbourea). The crude product was purified by column chromatograph ( $2: 1$ hexanes: ethyl acetate), yield 0.040 gm of yellow solid (thick oil) $\mathbf{2 d}(15 \%) .{ }^{1} \mathrm{H}$ NMR $\delta=8.85(\mathrm{~s}, 1 \mathrm{H}), 8.03(\mathrm{~s}, 2 \mathrm{H}), 8.09(\mathrm{dd}, \mathrm{J}=8.1,0.6 \mathrm{~Hz}, 1 \mathrm{H}), 4.60$ $(\mathrm{t}, \mathrm{J}=6.9 \mathrm{~Hz}, 2 \mathrm{H}), 3.52(\mathrm{t}, \mathrm{J}=6.9 \mathrm{~Hz}, 2 \mathrm{H}), 2.72(\mathrm{~s}, 3 \mathrm{H})$

Schiff Base Ligand. (5a Scheme G.3) Table 2 entries A-G. To a solution of ketone, 2a, $(0.26 \mathrm{gm}, 1.3 \mathrm{mmol})$ in 4 mL of methanol 0.49 equivalents of benzidine $\mathbf{3}(0.124 \mathrm{gm}$, 0.67 mmol ) was added. The reaction was stirred at reflux for four hours. The reaction was then reduced by rotary evaporation and re-suspended in a minimal amount of 9:1 $\mathrm{CHCl}_{3}: \mathrm{MeOH}$ solution. Hexanes were then carefully layered on top and crystals formed overnight. The liquid layer was filtered off and the remaining crystals were the desired product 5a. Yield $0.075 \mathrm{gm}, 0.14 \mathrm{mmol}, 20 \%$.

Schiff Base Ligand. (5a Scheme G.3) Table 2 entries H-L. To a solution of ketone, 2a, $(0.203 \mathrm{gm}, 1.05 \mathrm{mmol})$ in 4 mL of solvent 0.2 equivalents of benzidine $3(0.038 \mathrm{gm}, 0.2$ mmol) was added. To the reaction a catalytic amount of acid was added ( 5 drops of concentrate acid, notes column). The reaction was stirred at reflux for four hours. Within 30 minutes the transparent solution had become opaque with a precipitate. After four hours the reaction was removed from the heat and allowed to cool to room temperature. The reaction was filtered and washed with methanol; the solid was the desired product. Yield $0.095 \mathrm{gm}, 0.17 \mathrm{mmol}, 85 \%$.
$3{ }^{1} \mathrm{H}$ NMR $\delta=7.34(\mathrm{~d}, \mathrm{~J}=8.7 \mathrm{~Hz}, 4 \mathrm{H}), 6.73(\mathrm{~d}, \mathrm{~J}=8.1 \mathrm{~Hz}, 4 \mathrm{H}), 3.65(\mathrm{~s}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta$
$=145.3,127.5,115.7$.
$5 \mathbf{a}^{1} \mathrm{H}$ NMR $\delta=9.26(\mathrm{~s}, 2 \mathrm{H}), 8.36(\mathrm{~s}, 4 \mathrm{H}), 7.64(\mathrm{~d}, \mathrm{~J}=8.1 \mathrm{~Hz}, 4 \mathrm{H}), 6.94(\mathrm{~d}, \mathrm{~J}=8.4 \mathrm{~Hz}$, $4 \mathrm{H}), 4.44(\mathrm{q}, \mathrm{J}=7.1 \mathrm{~Hz}, 4 \mathrm{H}), 2.43(\mathrm{~s}, 6 \mathrm{H}), 1.43(\mathrm{t}, \mathrm{J}=7.1 \mathrm{~Hz}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta=166.78$, $165.05,159.62,150.05,149.80,137.18,136.31,127.25,126.76,120.85,119.73,61.47$, $16.52,14.20$, there are fewer than predicted ${ }^{13} \mathrm{C}$ resonances. Based on the purity of 5 a according to ${ }^{1} \mathrm{H}$ spectra, it is assumed that several ${ }^{13} \mathrm{C}$ resonances have coincidentally identical shifts ; ESI-MS m/z: $\mathrm{MH}^{+}$(calc. 535.23 , obs. $535.3,100 \%$ ), $\mathrm{MNa}^{+}($calc. 557.22 , obs. $557.225 \%$ ).

The crystal was mounted on a quartz fiber with paratone oil. Data in the frames corresponding to an arbitrary hemisphere of data ( $\omega$ scans, 10 sec frames) were
intergrated using SAINT ${ }^{64}$ [SAINT, SAX Area Detector Intergration Program, Bruker AXS, Inc., Madison, 1995] Data were corrected for Lorentz and polarization effects. The data were further analyzed using XPREP ${ }^{65}$ [G. M. Sheldrick, SHELXTL, Bruker AXS, Inc., WI, USA, 1997]. An empirical absorption correction based on the measurement of redundant and equivalent reflections and an ellipsoidal model for the absorption surface were applied using SADABS. ${ }^{66}$ The structure solution and refinement were performed using SHELXTL (refined on F2). ${ }^{67}$ All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined on all appropriate atoms.

Crystal size $0.49 \times 0.33 \times 0.002 \mathrm{~mm} ; \mathrm{T}=-120^{\circ} \mathrm{C}$; monoclinic, $\mathrm{P} 2_{1} / \mathrm{c}(\# 14), \mathrm{a}=$ 27.95 (1) $\AA, b=6.230$ (2) $\AA, c=7.747$ (3) $\AA, \beta=93.870(6)^{\circ}, ; V=1346.0(8) \AA^{3}, Z=2$, $\mu=.088 \mathrm{~mm}^{-1}, \mathrm{~F}(000)=564 \rho_{\text {calcd }}=1.319 \mathrm{~g} \mathrm{~mL}^{-1}, 2 \Theta_{\max }=52.272^{\circ}$, . Of the 5980 reflections, which were collected, 1909 were unique $($ Rint $=0.0319)$; equivalent reflections were merged. Empirical absorption correction: $\mathrm{Tmax}=0.999, \mathrm{Tmin}=0.660$. Final R1 $=0.0468$ for 1466 data for $\mathrm{I}>2 \sigma(\mathrm{I})(241$ Parameters, 0 restraints); for all 1906 data, $w \mathrm{R} 2=0.122, \mathrm{GOF}=1.059$.

Table G. 2 - Condensation results for Ligand 5a

Schiff Base Ligand Benzyl ester benzidine core (5b Scheme G.5) To a solution of ketone, $\mathbf{2 b},(0.200 \mathrm{gm}, 0.783 \mathrm{mmol})$ in 4 mL of Ethanol 0.2 equivalents of benzidine 3 ( $0.029 \mathrm{gm}, 0.157 \mathrm{mmol}$ ) was added. To the reaction a catalytic amount of acetic acid ( 5 drops) was added. The reaction was allowed to stir at reflux for four hours. Within 30 minutes the transparent solution had become opaque with precipitate. After four hours the reaction was removed from the heat and cooled to room temperature. The reaction was filtered and washed with methanol, the solid was the desired product. Yield 0.054 $\mathrm{gm}, 0.082 \mathrm{mmol}, 52 \%$.

5b ${ }^{1} \mathrm{H}$ NMR $\delta=9.26(\mathrm{~s}, 2 \mathrm{H}), 8.36(\mathrm{~s}, 2 \mathrm{H}), 8.02(\mathrm{~s}, 2 \mathrm{H}), 7.75(\mathrm{~d}, \mathrm{~J}=8.4 \mathrm{~Hz}, 2 \mathrm{H}), 7.5(\mathrm{~m}$, $5 \mathrm{H}), 6.94(\mathrm{~d}, \mathrm{~J}=8.4 \mathrm{~Hz}, 4 \mathrm{H}), 5.44(\mathrm{~s}, 4 \mathrm{H}), 2.43(\mathrm{~s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta=166.82,165.0$, $159.85,149.95,149.83,137.35,136.41,135.46,128.66,128.26,127.32,120.96,119.77$, 115.39, 67.14, 16.53; ESI-MS m/z: $\mathrm{MH}^{+}$(calc. 659.27 , obs. Inconclusive)

Schiff Base Ligand. (5c Scheme G.3) To a solution of ligand 5a (0.100 gm, 0.187 mmol ) in 4 mL of DMSO , 10 equivalents of 1 M KOH ( 2 mL of sol.) was added. The reaction was heated for 16 hours at $95^{\circ} \mathrm{C}$, then reduced by rotary evaporation and the product was precipitated with acetone. The reaction was centrifuged and the supernate
was decanted and dried down by rotary evaporation. The dried solution was resuspended in minimal 1:1 DMSO:water then precipitated with acetone again. The pellets were combined and washed with excess acetone and then dried. Yield $0.01 \mathrm{gm}, 0.01 \mathrm{mmol}, 10$ $\%$.

Schiff Base Ligand Ethyl ester terphenyl core (6a Scheme G.3) To a solution of ketone $\mathbf{2 a}(0.25 \mathrm{gm}, 1.2 \mathrm{mmol})$ in 4 mL of ethanol, 0.2 equivalents of $4-4$ "terphenyldiamine $4(0.127 \mathrm{gm}, 0.689 \mathrm{mmol})$ was added. To the reaction a catalytic amount of acetic acid ( 5 drops) was added. The reaction was stirred at reflux for four hours. Within 30 minutes the transparent solution had become opaque with precipitate. After four hours the reaction was removed from the heat and cooled to room temperature as product precipitated. The reaction was filtered and washed with methanol, then dried, and the solid was the desired product. Yield $0.170 \mathrm{gm}, 0.278 \mathrm{mmol}, 40 \% .{ }^{1} \mathrm{H}$ NMR $\delta=$ $9.23(\mathrm{~s}, 2 \mathrm{H}), 8.34(\mathrm{~s}, 4 \mathrm{H}), 7.68(\mathrm{~s}, 4 \mathrm{H}), 7.65(\mathrm{~d}, \mathrm{~J}=7.2 \mathrm{~Hz}, 4 \mathrm{H}), 6.91(\mathrm{~d}, \mathrm{~J}=7.2 \mathrm{~Hz}, 4 \mathrm{H})$, $4.41(\mathrm{q}, \mathrm{J}=7.1 \mathrm{~Hz}, 4 \mathrm{H}), 2.41(\mathrm{~s}, 6 \mathrm{H}), 1.40(\mathrm{t}, \mathrm{J}=7.1 \mathrm{~Hz}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta=166.78$, $165.05,159.62,150.05,149.80,137.18,136.31,127.25,126.76,120.85,119.73,61.47$, $16.52,14.20$ there are fewer than predicted ${ }^{13} \mathrm{C}$ resonances. Based on the purity of 5 a according to ${ }^{1} \mathrm{H}$ spectra, it is assumed that several ${ }^{13} \mathrm{C}$ resonances have coincidentally identical shifts; ESI-MS m/z: $\mathrm{MH}^{+}$(calc. 611.27 , obs. $611.2,15 \%$ ).
$4^{1} \mathrm{H}$ NMR $\delta=7.34(\mathrm{~d}, \mathrm{~J}=8.7 \mathrm{~Hz}, 4 \mathrm{H}), 6.73(\mathrm{~d}, \mathrm{~J}=8.1 \mathrm{~Hz}, 4 \mathrm{H}), 3.65(\mathrm{~s}, 2 \mathrm{H})$

Schiff Base Ligand Benzyl terphenyl core (6b Scheme G.3) To a solution of ketone 2b ( $0.376 \mathrm{gm}, 1.47 \mathrm{mmol}$ ) in 4 mL of solvent 0.2 equivalents of 4-4"terphenyldiamine 4 $(0.084 \mathrm{gm}, 0.323 \mathrm{mmol})$ was added. To the reaction a catalytic amount of formic acid (5 drops) was added. The reaction was allowed to stir at reflux for four hours. Within 30 minutes the transparent solution had become opaque with precipitate. After four hours the reaction was removed from the heat and allowed to cool to room temperature. The reaction was filtered and washed with methanol and hexanes through a plug of silica gel. Yield $0.15 \mathrm{gm}, 63 \% .{ }^{1} \mathrm{H}$ NMR $\delta=9.26(\mathrm{~s}, 2 \mathrm{H}), 8.36(\mathrm{~s}, 4 \mathrm{H}), 7.70(\mathrm{~s}, 4 \mathrm{H}), 7.67(\mathrm{~d}, \mathrm{~J}=$ $8.1 \mathrm{~Hz}, 4 \mathrm{H}), 6.93(\mathrm{~d}, \mathrm{~J}=8.4 \mathrm{~Hz}, 4 \mathrm{H}), 4.44(\mathrm{q}, \mathrm{J}=7.1 \mathrm{~Hz}, 4 \mathrm{H}), 2.43(\mathrm{~s}, 6 \mathrm{H}), 1.43(\mathrm{t}, \mathrm{J}=$ $7.1 \mathrm{~Hz}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta=166.78,165.05,159.62,150.05149 .80,138.2$ 137.18, 136.31, $127.6,127.25,126.76,120.85,119.73,61.47,16.52,14.20$, there are fewer than predicted ${ }^{13} \mathrm{C}$ resonances. Based on the purity of 5 a according to ${ }^{1} \mathrm{H}$ spectra, it is assumed that several ${ }^{13} \mathrm{C}$ resonances have coincidentally identical shifts; ESI-MS m/z: $\mathrm{MH}_{2}{ }^{2+}$ (calc. 368.15 , obs. $368.2,100 \%$ ), $\mathrm{MH}^{+}($calc. 735.3 , obs. $735.410 \%)$.

Schiff Base Ligand. ( $\mathbf{6 c}$ Scheme G.3) To a solution of ligand, $\mathbf{6 b},(0.6 \mathrm{gm}, 2 \mathrm{mmol})$ in 3:1 THF/water two equivalents of KOH was added. The reaction was stirred for five hours without heat. The THF was removed by rotary evaporation and the water was washed ( $3 \times 10 \mathrm{~mL}$ ) with DCM. Organic layers combined and dried down to yield unreacted starting material, 6b. The aqueous layer was acidified with HCl (2 equivalents) to yield a precipitate, the solid was filtered and washed with water, yielding 0.141 gm ( $23.5 \%$ ) of $\mathbf{6 c}$ when dried. Carried on to 6 d without characterization.

Schiff Base Ligand. ( $\mathbf{6 d}$ Scheme G.3) To a solution of ligand, $\mathbf{6 c}(0.180 \mathrm{gm}, 1.08 \mathrm{mmol}$ ) in 5 mL DCM and 5 mL THF, one equivalent of 2-mercaptothiazoline ( $0.119 \mathrm{gm}, 1.08$ $\mathrm{mmol})$ one equivalent of $\mathrm{EDCI}(0.192 \mathrm{gm}, 1 \mathrm{mmol})$ and one twentieth equivalent of DMAP ( $6.2 \mathrm{gm}, 0.05 \mathrm{mmol}$ ) was added. The reaction was stirred at room temperature under nitrogen for 5 hours, at which point the solution was a deep yellow color. A white precipitate formed, the reaction was filtered to remove the EDUI. The crude product was purified by column chromatograph (2:1 hexanes: Ethyl acetate). Yields 0.05 gm of yellow solid (thick oil) 6d (28\%). Characterization is currently being done.

[^0]:    * The term "grow" may be a misnomer as it implies that there is a known mechanism for cluster formation, a discrete growth pattern. The term is only used here to describe the addition of new metal centers to an existing cluster or stable fragments. There have been a few predictions on how clusters grow.42. Goodwin, J. C.; Teat, S. J.; Heath, S. L., How do clusters grow? The Synthesis and Structure of Polynuclear Hydroxide Gallium(III) Clusters. Angew. Chem. Int. Ed. 2004, 43, 4037-4041. Work is continuing to determine stable fragments under mass spectrometry conditions in order to extrapolate back to nucleation sites, (Chapter V).

[^1]:    *Crystal data for 1: Trigonal, $R-3, a=20.214(3), c=18.353(4) A$, volume $=6494.7(19) \AA^{3}, Z=3, D_{\mathrm{c}}=2.127 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=4.128 \mathrm{~mm}^{-1}, F(000)=$ 4116, $2 \theta_{\text {max }}=52.80^{\circ}(-24=h=25,-25=k=25,-22=l=22$ ). Final residuals (for 228 parameters) were $R 1=0.0310$ for 2500 reflections with $I>2 \sigma(I)$, and $R 1=0.0349, w R 2=0.0988, G 00 F=1.035$ for all 2831 data. Residual electron density was 0.949 and $0.567 \mathrm{e} . \AA^{-3}$.

[^2]:    ${ }^{\dagger}{ }^{1} \mathrm{H}$ NMR and LC-MS spectra of the mother liquor remaining after crystallization of 1 showed peaks characteristics of both nitrosobenzene and nitrobenzene.

[^3]:    ${ }^{\ddagger}$ In the structure of the related aluminium tridecamer reported by Seichter et al.,1. Seichter, W.; Mogel, H.-J.; Brand, P.; Salah, D., Crystal Structure and Formation of the Aluminum Hydroxide Cloride $\left[\mathrm{Al}_{13}(\mathrm{OH})_{24}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right] \mathrm{Cl}_{15} \cdot 13 \mathrm{H}_{2} \mathrm{O}$. Eur. J. Inorg. Chem. 1998, 795-797. not all hydrogen atoms positions could be determined. Therefore, charge balance considerations based on the number of chloride counterions were used to determine the number of hydroxo versus aqua ligands, and it was assumed that only the hydroxo ligands were counterions were used to determine the number of hydroxo versus aqua ligands, and it was assumed that only the hydroxo ligands were
    bridging. The structure of 1 , in which all hydrogens atoms from the coordinated $\mathrm{O}-\mathrm{H}$ groups were located in the Fourier difference map, corroborates this.

[^4]:    ${ }^{-}$Synthesis of $\left[\mathrm{Al}_{13}\left(\mu_{3}-\mathrm{OH}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathrm{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}(\mathbf{1}$, route B). Aluminum nitrate nonahydrate ( $0.25 \mathrm{~g}, 0.667 \mathrm{mmol}, 13 \mathrm{eq}$ ) was dissolved in 2.5 mL of MeOH and N -nitroso-di- $n$-butylamine ( $0.34 \mathrm{~g}, 2.17 \mathrm{mmol}, 42 \mathrm{eq}$ ) was added via a syringe. 2.5 mL of a 0.18 M KOH solution in MeOH was then added to make a 0.09 M solution. This solution was thoroughly mixed and left

[^5]:    uncapped in a scintillation vial to evaporate over the course of $6-10$ days. The remaining $N$-nitroso-di- $n$-butylamine was then removed via a syringe and the solution was washed with EtOAc ( $3 \times 4 \mathrm{~mL}$ ), yielding a mixture of $\mathrm{KNO}_{3}$ powder and single crystals of $\mathrm{Al}_{13}{ }^{\text {. }}$. Crystals of $\mathbf{1}$ form in $60 \%$ yield with respect to aluminum nitrate. Alternate bases also effect the same transformation: $\mathrm{NH}_{4} \mathrm{OH}\left(0.1 \mathrm{eq}\right.$ per eq of $\left.\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}\right)$ provides a slightly different crystal form of the cluster (2) in $15 \%$ yield; while $1.3 \mathrm{eq} \mathrm{Al}(\mathrm{OH})_{3}$ combined with 11.7 eq of $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$ provide $\mathrm{Al}_{13}$ in $15 \%$ yield.
    ${ }^{\dagger}$ Synthesis of $\left[\mathrm{Al}_{13}\left(\mu_{3}-\mathbf{O H}\right)_{6}(\mu-\mathrm{OH})_{18}\left(\mathbf{H}_{2} \mathrm{O}\right)_{24}\right]\left(\mathrm{NO}_{3}\right)_{15}(\mathbf{1}$, route A$)$. Methanolic solutions of aluminum nitrate nonahydrate $(0.50 \mathrm{~g}$, $1.33 \mathrm{mmol}, 13 \mathrm{eq}$ in 5 mL MeOH ) and nitrosobenzene $(0.303 \mathrm{~g}, 2.82 \mathrm{mmol}, 24 \mathrm{eq}$ in 5 mL MeOH$)$ were mixed together and 1.3 eq KOH was added. The mixture evaporated slowly at room temperature over 4-8 days in a scintillation vial covered with tissue paper, yielding a dark thick oil embedded with large single crystals of 1 , which were isolated in $47 \%$ yield (with respect to aluminum nitrate).

[^6]:    ${ }^{\ddagger}$ xray X-ray diffraction experiments were carried out on a Bruker Smart Apex diffractometer at 153 K (1) and 173 K (2) K using MoKa radiation ( $1=0.71070 \AA$ ). Absorption corrections were applied by SADABS. The structures were solved by direct methods, completed by subsequent difference Fourier syntheses, and refined by full matrix least squares procedures on $\mathrm{F}^{2}$. Highly disordered $\mathrm{NO}_{3}$ anions and solvent water molecules in the crystal structure of 1 were treated by SQUEEZE. ${ }^{36}$. Correction of the X-ray data by SQUEEZE is 353 electron/cell; the calculated value for these nine $\mathrm{NO}_{3}$ anions and seven water molecules in 1 is 349 electron/cell. All non-hydrogen atoms were refined with anisotropic thermal parameters. H atoms in 1 were found on the difference F-map and refined with isotropic thermal parameters. Some of the H atoms in the coordinated water molecules in 1 are disordered over three positions due to their involvement in three different H -bonds, and they were refined with occupation factor $\mu=0.66 . \mathrm{H}$ atoms in 2 were not found and have not been taken into consideration. There is also a partial occupancy $\mathrm{NH}_{4}{ }^{+}$cation in 2 on a special position ( $\mu=0.5$ ). All calculations were performed by the Bruker SHELXTL package.

    Crystal data for 1: $\mathrm{H}_{90} \mathrm{Al}_{13} \mathrm{~N}_{15} \mathrm{O}_{102}, \mathrm{M}_{\mathrm{r}}=2283.61$, colorless block, $0.31 \times 0.18 \times 0.09 \mathrm{~mm}$, Triclinic, space group P-1 (no.2), $a=$ $12.8256(8), b=13.1667(8), c=13.4201(8) \AA, \alpha=77.6010(10), \beta=74.0590(10), \gamma=87.6480(10)^{\circ}, \mathrm{V}=2127.9(2) \quad \AA^{3}, Z=1$,
     indices $[\mathrm{I}>2 \sigma(\mathrm{I})]: \mathrm{R} 1=0.0479, \mathrm{wR} 2=0.1267, \mathrm{GOF}=1.069$.

    Crystal data for 2: $\mathrm{H}_{96} \mathrm{Al}_{13} \mathrm{~N}_{17} \mathrm{O}_{106}, \mathrm{M}_{1}=2381.68$, colorless block, $0.08 \times 0.08 \times 0.05 \mathrm{~mm}$, Triclinic, space group $P-1$ (no.2), $a=$ $12.623(3), b=13.251(3), c=13.597(3) \AA, \alpha=74.877(4), \beta=72.419(4), \gamma=86.790(4)^{\circ}, \mathrm{V}=2092.4(2) \AA^{3}, Z=1, \mathrm{r}_{\text {calcd }}=1.890$ $\mathrm{g} / \mathrm{cm}^{-3}, \mu=0.326 \mathrm{~mm}^{-1}, \mathrm{~F}(000)=1232,2 \theta_{\max }=50.0^{\circ}, 15065$ reflections collected, 7308 unique $\left[\mathrm{R}_{\mathrm{int}}=0.0700\right], \mathrm{R}$ indices $[\mathrm{I}>2 \sigma(\mathrm{I})]: \mathrm{R} 1=0.0836, \mathrm{wR} 2=0.1961, \mathrm{GOF}=1.051$.
