ABSTRACT

This Final Environmental Impact Statement (FEIS) describes the seven alternatives for the Land and Resource Management Plan for the Willamette National Forest. The total area of the Willamette National Forest is 1,675,408 acres.

This FEIS has been prepared following public review periods for the Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan, during which 177,701 comments were received and considered. The seven alternatives of the FEIS acknowledge the substantive public and other agency comments received. Each alternative responds differently to identified major issues and concerns. The alternatives are: (NC) Continuation of management under the 1977 Land and Timber Management Plan; (A) continuation of management under the 1977 Plan modified to meet Management Requirements (National Forest Management Act of 1976); (D) an emphasis on nonmarket resource values, particularly wildlife habitat, with a moderate emphasis on commodity production; (J) a moderate emphasis on nonmarket resource values with an emphasis to maintain commodity production near historic levels; (K) a high emphasis on commodity production with a low emphasis on most nonmarket resource values (high emphasis on developed recreation); (L) a high emphasis on nonmarket resource values reflected by preservation of many areas in a natural condition and a low emphasis on commodity production; (W) a moderate emphasis on both nonmarket resource values and commodity production, with a slightly greater emphasis on nonmarket values such as water quality, diversity of plant and animal species and old growth. Alternative W is the Forest Service Preferred Alternative.

SUMMARY

INTRODUCTION

The Final Environmental Impact Statement (FEIS) defines and analyzes alternative strategies for management of the Willamette National Forest, one of which has been selected and developed into the accompanying Final Land and Resource Management Plan (Forest Plan).

This is a general summary of the information and analysis contained in the FEIS. It emphasizes the issues and concerns raised by the public and local, state, and Federal agencies regarding the management of the Forest. It briefly describes the purpose and need for the FEIS, the major issues, the seven alternatives, and the environmental consequences of implementation of each of the alternatives. Detailed information and analysis of each of these topics is in the FEIS and its appendices. A thorough reading of the complete FEIS will aid in understanding the Proposed Action which forms the basis for the Final Forest Plan.

This FEIS presents in detail seven different alternatives for managing the lands and resources of the Forest. These alternatives explore varieties of ways of responding to issues identified during the planning process. Each alternative represents a unique combination of land allocations, management prescriptions, activity scheduling, and results in different mixes of goods and services, land uses, and environmental effects.

Federal planning regulations require an analytical process which includes an evaluation of various minimum and maximum resource and economic production levels. In addition, a wide range and relatively even distribution of alternatives must be developed to respond to issues and to reflect national goals such as the Resources Planning Act (RPA) program.

In some alternatives the Forest would be managed to emphasize the production of commodities with a market price. Other alternatives would emphasize resources that do not have a market price, such as dispersed recreation, wildlife, and scenery. One alternative, the No Change Alternative, reflects current management direction projected into the future. Another alternative, the No Action Alternative, reflects current management direction projected into the future including NFMA requirements. Two alternatives were developed in response to requests from public interest groups. One alternative was developed in response to public comments on the DEIS.

The basis for developing alternatives is outlined in the implementing regulations of the National Environmental Policy Act (NEPA) and the National Forest Management Act (NFMA).

AFFECTED ENVIRONMENT

The Willamette National Forest is an administrative unit of the Pacific Northwest Region of the Forest Service, U.S. Department of Agriculture, and is located within the Second, Fourth, and Fifth United States Congressional Districts. It lies primarily in Lane, Linn, and Marion Counties, but also extends south into Douglas County, east into Jefferson County, and north into Clackamas County. The Forest

headquarters is the Supervisor's Office located in Eugene, Oregon. There are seven Ranger Districts, with offices in Oakridge, Westfir, Lowell, Blue River, McKenzie Bridge, Sweet Home, and Detroit (Figure S-1), Vicinity Map).

The Forest stretches for 110 miles along the western slopes of Oregon's Cascade Mountains. The western edge of the Forest borders the Willamette Valley from east of Salem to the Calapooya Mountains northeast of Roseburg. The crest of the Cascade Range defines the eastern boundary of the Forest.

There are over 1.7 million acres within the Forest boundary--1,675,408 acres of National Forest land and 123,330 acres of land in private ownership or managed by other public agencies. Over 380,000 acres of land within the Forest have been designated by Congress as Wilderness.

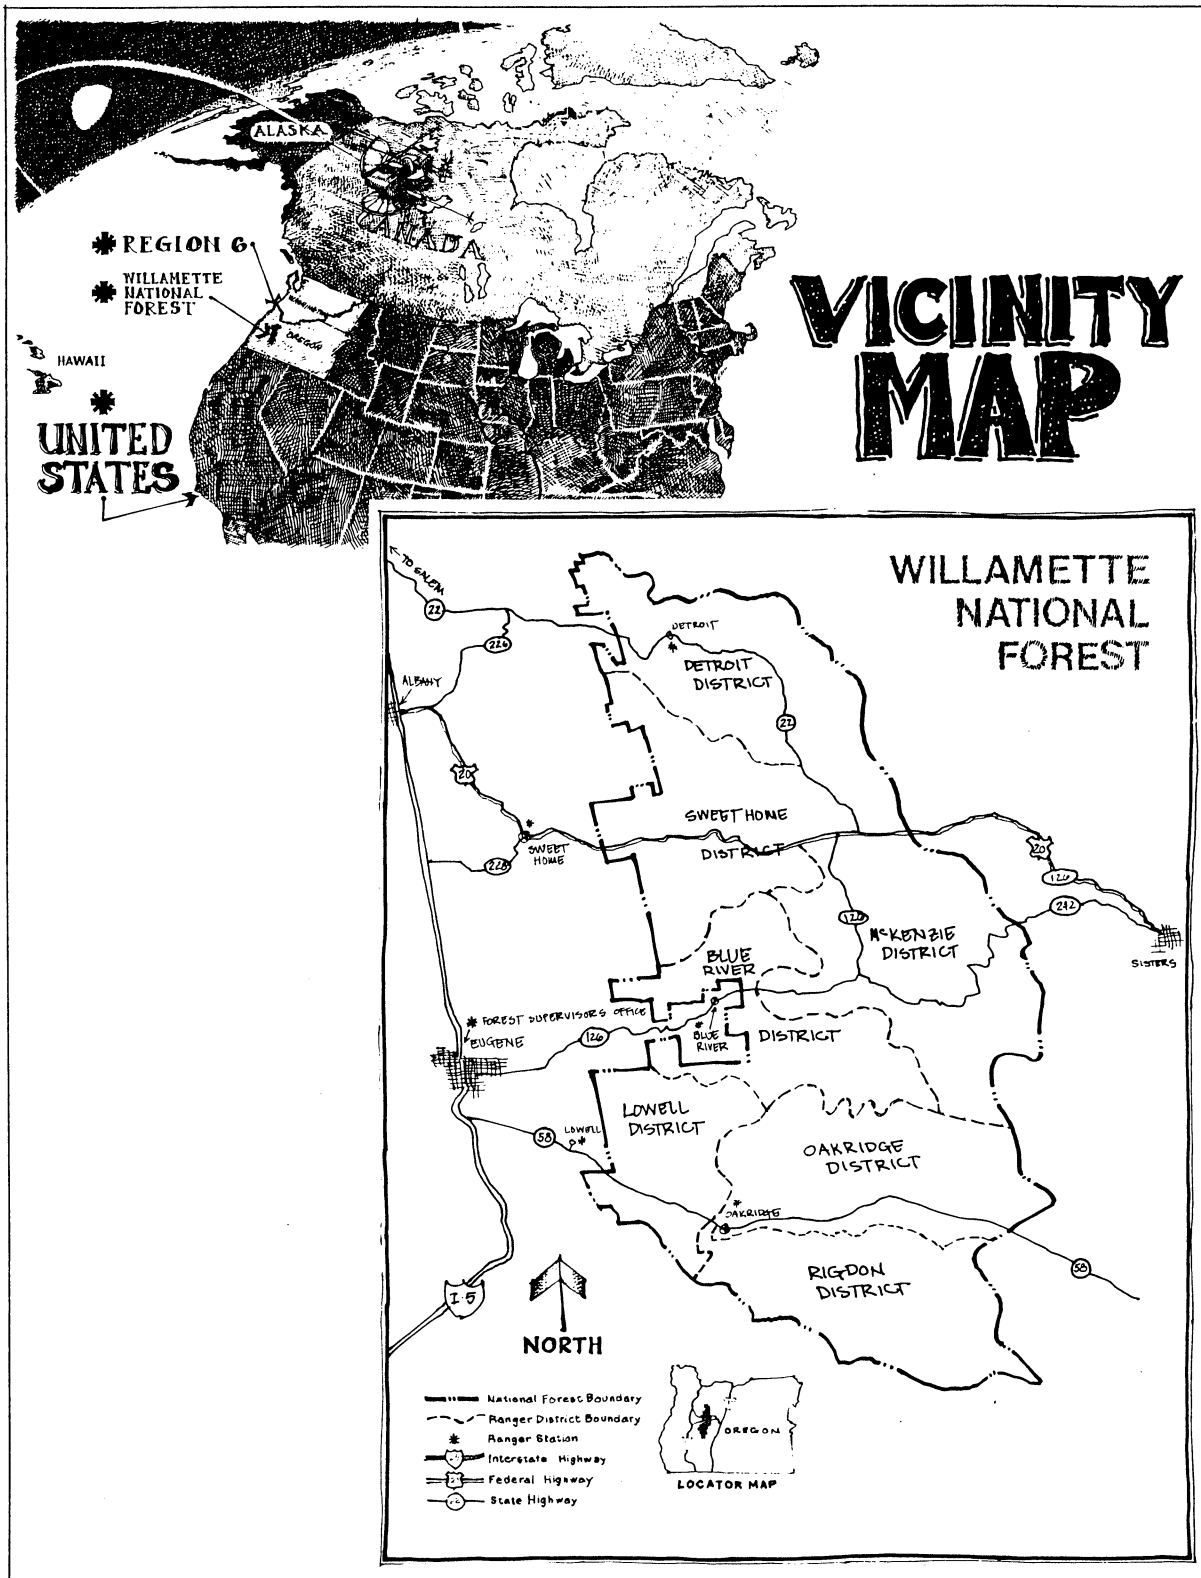
The physical and social environments that comprise the Forest are determined by a number of distinctive components: geology, climate, soil, water, air, vegetation, fire, fish and wildlife, insects and disease, cultural resources, recreation opportunities and areas, scenery, wild and scenic rivers, wilderness, roadless areas, special interest areas, range, roaded areas, facilities, timber, minerals and energy, and the social and economic environment.

Knowledge of the characteristics of the Forest provides an understanding of the land's capabilities and limitations for sustaining various resources and for predicting subsequent effects of management activities.

Physical Environment

The Oregon Cascade Range of the Forest is divided into two major geologic provinces: the Western Cascades Province and the High Cascades Province. These provinces are influenced by the Pacific Maritime climate which is typified by wet, cool winters and mild warm summers. Composition and origin of Forest soils, along with climate and geology, are fundamental components of the environment. Generally, Forest soils are volcanic in origin and composed of basalts, andesites, and intrusions of various kinds. Water, another fundamental component, draining from Forest lands is generally of high quality and provides for municipal and domestic uses, fish hatcheries, electricity, recreation, fish and wildlife habitat, and supports the vegetative environment.

There are a number of plant communities on the Forest including coniferous forests primarily of Douglas fir, grand fir, western hemlock, and Pacific silver fir; meadows; and subalpine and alpine parklands and wetlands. Fire regimes have played a key role in the development of these plant communities through time. Factors such as fire frequency, duration, intensity, and size all have had a bearing on Forest ecosystems. Fish and wildlife are abundant on the Forest and adapted to a variety of habitats. Of the 30 species of fish on the Forest, most are native to the natural streams and lakes of the western slope of the Cascades. The diversity of habitats supports over 260 wildlife species including 170 avian breeding species, 64 mammalian species, and 30 amphibian and retilian species.



Environments retained in a natural or wild state are represented by wilderness lands and some Forest rivers. There are eight designated Wildernesses on the Forest along with several river segments that are characterized by outstandingly remarkable values and remain free-flowing.

Social Environment

The Forest offers a diversity of social settings as well as natural environments. In addition, within the Forest boundaries is evidence of past and current human use. Human use of lands and resources in

and around the Forest extends over approximately 8000 years. More recent populations utilize Forest lands in ways distinct from the prehistoric populations. Today, Forest users can choose from a wide spectrum of recreation opportunities ranging from primitive to roaded modified settings to developed ski areas or visit and enjoy special interest areas, old-growth groves, and National natural landmarks.

Many local communities rely on the employment and income generated from the use of Forest resources. A measure of stability is derived from a continuous supply of timber being available for harvest from the Forest even though supply is not the only determinant of stable markets. Income and employment are also derived from people traveling through communities on their way to Forest lands for recreation. An awareness of tourism's importance as a source of future economic and social activity for communities in and adjacent to the Willamette Valley is growing.

PURPOSE AND NEED

National Forest System Land and Resource Management Planning is a process for developing, adopting, and revising land and resource management plans for the National Forest System as required by the Forest and Rangeland Renewable Resources Planning Act of 1974 and as amended by the National Forest Management Act (NFMA) of 1976. The resulting Land and Resource Management Plans (Forest Plans) provide for multiple use and sustained yield of goods and services from the National Forest System in a way that maximizes long-term net public benefits while responding effectively to public issues in an environmentally sound manner. The National Forest System Land and Resource Management Planning process is described in Title 36, Part 219 of the Code of Federal Regulations.

This Final Environmental Impact Statement (FEIS) document discloses the analysis and the significant environmental effects of seven alternatives including a proposed action, for the future management of land and resources of the Forest. The purpose of the FEIS is to provide decisionmakers with an environmental disclosure sufficiently detailed to aid in the selection of a Forest Plan which delineates new management direction for the Forest. Equally important, its purpose is to make information available to the public and to encourage public participation regarding implementation and refinement of that direction.

The Preferred Alternative is the "proposed action" (40 CFR 1502.14) for this FEIS and is the basis for the "Willamette National Forest Land and Resource Management Plan" document (Forest Plan). The alternatives presented in this FEIS contain management direction for the next 10 to 15 years. The Forest Service is required to revise the plan within 15 years of its adoption; revision may establish different long-term goals with different projected effects and outputs. The Plan may also be revised or amended, if needed, prior to the scheduled revision date.

The preparation of an Environmental Impact Statement is required because the Forest Plan is a major Federal action which may have a significant effect on the quality of the human environment. Its development follows the direction of the National Environmental Policy Act of 1969 (NEPA) and the Council on Environmental Quality NEPA Regulations (40 CFR 1500-1508). For purposes of disclosure under NEPA, the FEIS and the accompanying Forest Plan are treated as combined documents.

PUBLIC ISSUES

By the time of publication of the DEIS, modifications were made to the 1981 list of primary issues resulting in a revised list that included dispersed recreation; developed recreation; wilderness; cultural resources; livestock grazing; logging residue; air quality; minerals; energy; individual well-being; local economies; economic efficiency;old-growth; roadless lands; scenic quality; timber supply; water quality and quantity; wildlife, fish and plant habitat. These modifications were made to reflect refinements in public opinion during that interval and to reduce complexity within the planning documents. In some cases, interrelated issues were grouped together. Other topics, such as old-growth and roadless lands, had vastly increased in public interest.

While all of the issues were considered during development of the DEIS alternatives, the degree of response to the major ones was of greatest importance in selecting the Preferred Alternative for the Draft Forest Plan. Issues were considered of major importance if they were the subject of continually recurring correspondence, individual visits, or meetings involving other public agencies, organized groups and industry, or the public at large. These issues were also often discussed in media reports. The major issues that provided the focus for the DEIS were Dispersed Recreation; Old Growth; Roadless Lands; Scenic Quality; Timber Supply; Water; and Wildlife, Fish, and Plant Habitat.

The following is a brief discussion of the seven major issues which were the subject of special focus in the DEIS. These issues with some refinements remain the major issues considered in the FEIS and Final Forest Plan.

Dispersed Recreation

Demand for recreation opportunities on the Forest remains high. People are interested in maintaining a wide variety of options for recreation activities. The subject of roaded and unroaded dispersed recreation opportunities carry the greatest potential to vary among Alternatives. There is concern about how the management decisions made in the Forest Plan will increase or decrease these opportunities.

There is continuing, although somewhat less intense, interest in managing for developed recreation, as well. Developed sites are tracked through the process; but they are not treated as a major issues, because there is less land involved and less intensity of public interest. Decisions made regarding developed recreation have a low significance in affecting the overall management of other Forest resources.

Old Growth

In the early stages of development of this Forest Plan, the management of old-growth stands was considered part of the timber production and fish and wildlife habitat issues. By the publication of the DEIS, however, increasing public attention had warranted treating it as a separate category despite its particularly strong interrelationships with other issues.

Part of the public sees a need to preserve old growth for its benefits to plant and wildlife habitat diversity, soil and water productivity, and its recreational and aesthetic values. Another segment of the public recommends utilizing old growth for its high value timber products, at the same time converting the old growth stands to more vigorously growing second growth stands to support future timber production needs.

Roadless Lands

Although the Oregon Wilderness Act of 1984 resolved part of the issue concerning Wilderness, interest in some of the Forest's roadless lands has remained high. "Wilderness" as an issue was rated highly important by the 1981 respondents. In 1983 a reinventory of the roadless lands on the Forest included extensive public involvement, including a 1200-piece mailing and a series of public meetings. The 1984 Act increased the amount of designated Wilderness on the Forest to about 25% of the total land base.

The nature of the roadless lands issue revolves around using these lands for timber production; or deferring harvest to preserve old growth trees, provide habitat diversity, provide dispersed recreation opportunities, and protect aesthetic values. A no-harvest allocation assigned to unroaded areas would also maintain options for future designation as Wilderness. Some people feel that the marketable resources in these areas should be developed; some feel that they should remain undeveloped. Still others feel that some lands currently in a developed condition should be returned to an undeveloped condition, particularly if the lands are adjacent to designated Wilderness.

Scenic Quality

The visual quality of the Forest landscape is of concern to adjacent landowners, travelers, and Forest visitors. Many people prefer not to see evidence of timber harvesting from major highways and popular

recreation areas such as trails, campgrounds, and scenic overlooks. Other people, who tend to favor utilization of Forest resources, feel that most visual effects of resource management activities are temporary, so that Visual Quality Objectives should play a reduced role in planning such activities.

Timber Supply (Current and Future Timber Production)

The Forest annually provides the largest amount of timber production in the National Forest System. The amount of timber produced on the Forest therefore assumes some level of national as well as local importance. In addition, since the wood products industry is one of the three major components of the economy of the State of Oregon, concern has also been high for several years about the level of contribution the Forest's timber resource makes to the overall timber supply within the State, as well. In the 1981 survey current and future timber production received the highest weighted importance. Interest has remained high since then.

Some people feel that the allowable harvest is too high, resulting in unacceptable adverse effects to other resource values. Others believe that the level of harvest should be maintained or increased to provide the raw material to help satisfy demand for wood products and to provide a stabilizing force on the economies of local communities which may be highly dependent upon the various wood products industries.

Additional components of the timber supply issue include: logging residues and firewood, harvest schedules and methods, use of herbicides and fertilizer, reforestation, species mix, and access.

Water Quality and Quantity

Water quality received the second highest rating for issue importance in the 1981 issue development survey. The natural level of water quality on the Forest is generally quite high. Consequently, unlike many of the other issues addressed by the Forest Plan, the concern centers more on minimizing degradation than taking specific actions to enhance the resource over natural levels. Accordingly, much of the treatment given this issue can be found in the Standards and Guidelines and Monitoring sections of the documents.

Water quantity was of less concern than quality. Adequate and consistent water supply for streamflow for fish habitat and domestic uses was of greatest concern.

Wildlife, Fish, and Plant Habitat

The broad issue of habitat represents a complex of concerns about the living components of the Forest. Central to the issue are matters of species survival and maintaining ecological diversity.

Concerns range from continuation of game species for hunting and fishing to preservation of reptiles and insects to threatened, endangered, and sensitive plant species. Differences of opinion arise about the extent and nature of land allocations and mitigation requirements associated with various individual, commercial, and management activities which are needed to assure adequate support for the viability and distribution of the various native species.

Issue Refinement Between the DEIS and the FEIS

The key issues did not change between the DEIS and the FEIS, but some refinements in focus occurred, most notably to five of the key issues. Responsiveness to these refinements ultimately led to analysis of three new alternatives in the FEIS.

Dispersed Recreation

A segment of the McKenzie River and the North Fork of the Middle Fork of the Willamette River received Wild and Scenic River designation by Congress in 1988. Congress also required that Blue River and the South Fork of the McKenzie River be studied for their suitability for Wild and Scenic River status. The State of Oregon added two additional rivers to its State Scenic Waterways inventory. Interest in studying additional rivers and their segments for similar designations has intensified.

Special designations of these types affect management practices on the rivers and surrounding lands. Timber harvest, road building, and recreation site development may be constrained or eliminated for some distance from the rivers themselves. Retaining the special values of study rivers pending suitability determination similarly affects the nature and extent of new management activities in those areas until suitability is resolved.

Old Growth

The intensification of public interest surrounding old growth has involved a number of key issues: old growth as forest structure; old growth as a reservoir of timber supply; old growth as an ecosystem providing a unique habitat in support of other plant and animal species.

One of the more perplexing aspects to addressing old growth concerns was the apparent lack of unanimity of definition. Definitions have been proposed by various groups, including USFS - Region 6 (Regional Guide), the Pacific Northwest Range and Experiment Station (PNW 447), the Wilderness Society, and the Society of American Foresters. Data is analyzed and displayed in the FEIS using the USFS Region 6 definition.

Increased attention has focused on the silvicultural values of old growth structure, including its capability to retain and enhance soil and water productivity. This attention has not limited its scope to preservation of existing stands. Indeed, interest in old growth structure has been instrumental in the development of changing philosophies of site utilization and stand regeneration techniques, known as "New Forestry" and "New Perspectives in Forestry."

Differences in public and professional opinion exist about the extent to which increased preservation of old growth and "New Perspectives" forestry should occur; the specific nature of indicated practices; the best locations in which to undertake the practices; and the attendant risks involved, such as susceptibility to fire and disease.

Timber Supply

The timber supply issue intensified to near-crisis proportions during the period between the DEIS and the FEIS. Although the values of harvested timber on the Forest reached all-time highs, the volume sold for eventual harvest dramatically decreased by fiscal year 1989. Much of the reduction in sold volume was in response to court injunctions associated with spotted owl habitat litigation. The current and intermediate term availability of timber from all sources within the State of Oregon achieved

high levels of public concern. Central to this concern was the contribution made by the Federal sector, particularly in the form of old growth timber.

Ultimately, Congress balanced the habitat needs of the spotted owl with the Federal supply needs of old growth dependent mills by passing the Northwest Timber Compromise as Section 318 of the Fiscal Year 1990 Appropriations Act. This legislation was acknowledged not to represent a permanent solution, however. Consequently, the public issues remain for evaluation under the planning process.

In addition, many public comments alerted the Forest to improvements which could be made to the technical analysis of timber availability.

Water Quality and Quantity

Public comments during the response period after publication of the DEIS sent a strong message that many of the alternatives in the DEIS, including the preferred alternative, proposed unacceptable levels of watershed degradation. This did not so much represent a refinement of public concern as it represented a reaffirmation of the intensity with which the concern was held and the need for the Forest to address the issue with greater sensitivity.

Wildlife, Fish, and Plant Habitat

During the interval between the DEIS and FEIS, concerns surrounding plant and animal diversity and habitat preservation intensified. These concerns spanned a wide variety of species, habitats, and management practices. The most notable representatives of these concerns were spotted owl habitat, old growth as a reservoir of a unique and valuable ecosystem, and riparian areas as critical ecosystems.

These issues were central to examining notions such as habitat connectivity and preserving options. In many cases, however, decisions to provide or enhance such connectivity or to preserve options produce reductions in timber supply or suggest relatively more costly harvest techniques.

DEVELOPMENT OF ALTERNATIVES

The following section describes how resource issues were identified and developed into a range of alternative land allocations and management direction responsive to the National Forest Management Act, National Environmental Protection Act, and the public.

Information on the amount and location of resources has been compiled through inventories of timber conditions, recreation use, wildlife populations, soil and water resources, and roads. These inventories were combined in the Geographical Mapping System (GMS) for use in the development and analysis of alternatives. This information was collected on a common map base, with different map layers developed for the various resources and inventory components. This data base was updated between the DEIS and FEIS to reflect changes in land suitability, timber harvest and growth, and a revision of the spotted owl, pileated woodpecker, and pine marten habitat networks.

The alternative formulation process began in November 1984 with a review of Forest issues, concerns, opportunities and resource inventories; resource production capabilities identified in the analysis of the management situation; and applicable planning direction. Based on a review of these items resource management options were developed for nine resource areas: Recreation; Fish and Wildlife; Timber; Range; Soil, Water, and Air; Minerals and Energy; Lands; Facilities; and Protection. Each option was comprised of management direction statements for the important factors for that resource. The resource management options were designed to incorporate issues, reflect a particular level of management emphasis, and serve as a potential building block for Forest management alternatives.

The draft resource management options were reviewed by the public during 1985, with the knowledge that these options would be used as building blocks for alternatives. Public response was evaluated and the resource options were modified to reflect public comments. The resulting options were utilized in the development of preliminary alternatives.

A review of the options for the nine resource areas indicated that some resources relate primarily to the allocation of land and scheduling of timber harvests for achievement of their objectives (Timber, Recreation, and Fish and Wildlife), while other resources are primarily dependent on program budget and/or administrative action (Facilities).

From the combinations of resource option descriptions nine preliminary alternative descriptions were written and rough estimates of some outputs were made. Two preliminary alternatives were dropped due to significant overlap and duplication. Subsequently, seven alternatives were examined as to how well they resolved Forest issues.

Two alternatives required by NFMA regulations, No Action and one demonstrating ability to meet the goals of the Resource Planning Act (RPA), were added to the list for consideration at this time. Two additional variations on preliminary alternatives were developed which allowed for departure from long-term sustained yield. Due to significant overlap and duplication, three preliminary alternatives were dropped leaving eight alternatives in the DEIS. In June of 1987 a ninth alternative was included in the array of alternatives in response to decisions made regarding an appeal brought by the Northwest Forest Resources Council. In the DEIS, the ninth alternative is referred to as the "No Change" (NC) alternative and is based on the potential yield of the Forest's 1977 Timber Management Plan.

During the review period for the DEIS, many comments were received indicating how well the public felt the key issues were addressed by the alternatives. A large number of the commentors expressed the opinion that not all reasonable and viable means of addressing the issues were considered (or at

least considered in sufficient detail) in the DEIS. With public comments for direction, the Forest IDT and management team revisited the alternative formulation process used in the development of the DEIS. The resource options, the management prescriptions and the acre allocations were reviewed and revised. The result of the revisions were three additional alternatives in the FEIS that were not considered in the DEIS.

CHANGES BETWEEN THE DRAFT ENVIRONMENTAL IMPACT STATEMENT AND THE FINAL ENVIRONMENTAL IMPACT STATEMENT.

The DEIS and Proposed Forest Plan documents were available for public review from January to May 1988. The public review process and comments received during this period are described in the FEIS Chapter I, Appendix A, and Appendix I. After the public comment period had closed and the comments had been reviewed, the Forest interdisciplinary team (IDT) explored ways to respond to public concerns.

Many of the comments suggested that:

- Alternatives be modified;
- Alternatives be developed or evaluated that were not given adequate consideration in the DEIS;
- Analyses presented in the DEIS be supplemented, modified, or improved;
- Factual corrections be made in information or data used in the analyses.

After reviewing these comments, the IDT and Forest management team agreed on changes that should be made in the FEIS. In some cases, the changes involved analysis methods and data common to all of the alternatives. Other changes involved considering alternatives not analyzed in the DEIS while dropping others that had been analyzed. The new alternatives were developed based on public response to specific issues and the proposed resolution of these issues displayed in the DEIS. The new alternatives propose different land allocations, management prescriptions, and standards and guidelines from the set of alternatives analyzed in the DEIS as means of resolving those issues.

The IDT updated or reanalyzed all of the alternatives considered in the FEIS. As a result, a new Preferred Alternative was identified: Alternative W. The Forest Plan was revised to reflect the proposed changes between Alternative J, the Preferred Alternative in the DEIS, and Alternative W. The Plan and the FEIS were submitted to the Regional Forester for review.

Following is a summary of revisions made between the DEIS and FEIS to respond to concerns raised during the public comment period.

- Alternatives B and J-Departure were dropped from the set of alternatives considered in detail. Both proposed a timber sale schedule that departed from long-term sustained yield capacity. Public responses were largely indifferent to the departure alternatives as a means of addressing the timber supply issue. Concerns were raised, however, about the environmental effects associated with the departure alternatives. Environmental effects of the departure alternatives were generally the most adverse of the range of alternatives considered in the DEIS (see Chapter IV, DEIS).

- Alternatives C and I were also dropped as alternatives considered in detail in the FEIS. While there was a moderate amount of favorable public comments on both of these alternatives, other alternatives were proposed and considered in the FEIS that address similar goals and objectives.

- Alternative K was added in response to public comments. Many individuals, as well as timber industry organizations, expressed a desire for an alternative that would maintain the timber harvest near the level in the current plan (1977). Although similar to Alternative I in the DEIS in some respects, differences in specific resource goals and objectives led to developing Alternative K. The Willamette Forestry Council (WFC) played a major role in advising on the development of Alternative K.

- Alternative L was also added in response to public comments that noncommodity uses of the Forest were not adequately represented in the alternatives in the DEIS. Many people were concerned that an alternative proposed by the Oregon Natural Resources Council (ONRC) for the DEIS was not fully analyzed. Alternative L was developed with suggestions from ONRC and affiliated groups.

- Alternative W (Preferred Alternative) was added to the set of alternatives largely in response to comments on Alternative J, the PA in the DEIS. Although the initial thought was to modify Alterative J in response to the criticism, it became apparent that the significance of the changes in specific resource practices as well as overall goals and objectives were as great as the differences between some of the alternatives considered in the DEIS. A new alternative was developed to help clarify the differences.

ALTERNATIVES, INCLUDING THE PROPOSED ACTION

Seven alternatives are considered in detail in the FEIS: Alternatives NC, A, D, J, L, K, and W. These offer differing approaches as to how land and resources of the Forest could be managed. Each contain a set of land allocations, management practices, and activity shedules which, when implemented, would result in a unique combination of resource outputs and environmental consequences. Together, they present a broad range of possible management alternatives.

ALTERNATIVE NC (No Change)

The No Change (NC) Alternative represents implementation of the Forest's existing Land Management and Timber Management Plan to achieve timber production at potential yield levels.

The No Change Alternative has been developed in response to decisions made regarding Appeal Number 1588, brought by the Northwest Forest Resources Council on May 19, 1986. The appeal centered on a decision by Regional Forester James F. Torrence to "require inclusion of Minimum Management Requirements (MMRs) in the No Action Alternative for each Forest Plan." The substance of the appeal was that a "true No Action Alternative representing current management plans" was not included in the DEIS and is not included in the FEIS. In response to this, a No Change Alternative has been developed to represent the existing timber management plan, and consequently does not comply with all provisions of the National Forest Management Act (NFMA) and regulations promulgated by the Secretary of Agriculture to implement NFMA.

ALTERNATIVE K

Alternative K represents a low emphasis on nonmarket values and a high emphasis on commodity production. The management philosophy of this alternative is one which emphasizes a public understanding of the practices which are undertaken to maximize production of market goods from the forest, under multiple-use principles. The focus is to maintain high levels of timber harvest by making most of the Forest's tentatively suited land available for timber production. The objective is to maintain a timber supply level equal to the historical levels. This Alternative was formulated with input from the Willamette Forestry Council (WFC).

Roadless areas not designated as Wilderness in the 1984 Oregon Wilderness Act would be managed for a variety of multiple use values including timber, except for Bull of the Woods Roadless Area. The visual quality objective would be to allow all types of management activities to be seen in all areas, but the activities would not dominate the views.

Developed recreation would be emphasized with all existing and inventoried potential developed recreation sites being managed and protected. The Forest transportation system would increase, making larger areas accessible for motorized recreation.

An objective would be to maintain water quality by insuring strict adherence to operational Best Management Practices.

ALTERNATIVE A (No Action)

Alternative A represents implementation of the Forest's existing land allocations with the addition of management requirements for wildlife habitat and riparian areas, and updates on inventories of land suitability and timber yield tables. This alternative emphasizes a high level of timber production and a low emphasis on roadless recreation and other non-commodity forest uses.

ALTERNATIVE J

Alternative J represents a moderate emphasis on nonmarket resources and on commodity production. The focus is to balance the need for timber supply at near historical levels while maintaining several important roadless areas, important old-growth areas, and scenic values in a way that provides some degree of issue resolution for each. This was the Preferred Alternative of the DEIS.

ALTERNATIVE D

Alternative D represents a high emphasis on non-market resources with a moderate emphasis on commodity production.

Habitat for management indicator species pileated woodpecker, martens, and spotted owls would exceed levels required for Management Levels. Many areas would be managed for high quality big game habitat, and many unique special wildlife habitat areas would be recognized.

Dispersed Recreation would be emphasized by maintaining several roadless areas in their current condition. The scenic quality from many major highways would remain natural.

Riparian areas would be managed to provide input of near-natural levels of large woody material for fish habitat maintenance and improvement.

ALTERNATIVE L

Alternative L places a high emphasis on nonmarket values, and low emhasis on timber commodity values by preserving areas currently not highly impacted by past management activities in their natural condition and by proposing other areas for natural recovery from the effects of past management. This alternative was formulated with input from the Oregon Natural Resources Council (ONRC).

High levels and quality of recreation opportunities and experiences would be provided. Scenery would be enhanced by managing all areas according to Visual Quality Objectives and by rehabilitating unacceptable modifications.

The full inventory of roadless areas would be maintained in an undeveloped condition with an emphasis on semi-primitive nonmotorized activities. Opportunities for high quality wilderness experiences would be increased by proposing additional areas for Wilderness study and for Wilderness designation.

The quantity, quality, and diversity of plant and animal communities would be maintained at high levels. All management requirements for pileated woodpeckers, martens, and spotted owls would be exceeded and habitat would be provided for the full inventory of verified Spotted Owl pairs. All areas of diverse habitats, geologically significant areas, and "millenium" old-growth groves would be managed

to protect and enhance desirable attributes. Old-growth characteristics would be retained in all managed stands.

Riparian areas would be managed to maintain and enhance riparian dependent species and connective corridors across the landscape.

ALTERNATIVE W (Preferred Alternative)

This alternative is designed to provide a healthy, diverse, and productive ecosystem that would ensure the capability of the Forest to produce a continuous flow of a variety of goods and services to the public over the long-term. Alternative W was formulated to respond to public comments to the DEIS.

The ability to provide a dependable supply of timber to the market would continue. This alternative recognizes the importance of maintaining old-growth characteristics in some managed stands. Where timber production is either reduced below biological potential or removed from scheduled timber production to recognize other resource goals and benefits, this alternative would emphasize the use of these areas to support complementary resource goals such as wildlife, dispersed recreation, watershed protection, biological diversity and ecological studies.

Additional recreation opportunities would include expanding activities compatible with areas withdrawn from timber harvesting as well as providing opportunities such as low elevation hiking trails within areas intensively managed for timber production.

A special emphasis of this alternative would be to recognize the role of river corridors and streamside zones on the Forest as critical components in the ecosystem. Management activities in these areas would focus on maintaining and enhancing the long term productivity, first, for those uses dependent on rivers and streams and secondly, for other resources. Timber scheduling would be responsive to the cumulative effects of watershed conditions.

Table S-1. Resource Outputs, Effects, Activities, and Costs

Output/Effects	Unit	Decade	Alternatives

Footnotes for Table II-21.

[1] NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the DEIS describes these differences.

[2] Approximately 7% of these acres would be shelterwood harvests

[3] TSI includes release from competing vegetation, precommercial thinning, and fertilization.

[4] Includes net green volume plus salvage, cull, unregulated, and miscellaneous convertible products. The average annual amount of timber sold 1977-1986 was 784 MMBF, and the amount harvested was 607 MMBF.

[5] Includes only live, sound wood.

[6] Historically the firewood supply has come from a portion of the cull material, and is included in the Timber Sale Program Quantity above.

[7] Old growth based on the Pacific Northwest Regional Guide definition.

[8] Includes both existing and potential habitat areas.

[9] Areas include contributing habitat from SOHAs and/or pileated woodpecker habitat.

[10] Population Trend Index; Population trend values by decade are compared to a current level of 1.00.

[11] Recreation visitor day use for the No Change Alternative was developed from previous inventories and yield tables and does not incorporate the latest methods of calculating RVD outputs.

[12] RVD outputs for the No Change Alternative are available for total dispersed use.

MRVDs = Thousands of Recreation Visitor Days
PAOT = Persons at One Time
M Acres = Thousand Acres
MWFUDs = Thousand of Wildlife and Fish User Days
M Smolt = Thousand Smolt (Young Anadromous Fish)
PTI = Population Trend Index%/bio-pot = Percent of Bio-potential
AUMs = Animal Unit Months
MMBF = Million Board Feet
MMCF = Million Cubic Feet
M Ac-Ft = Thousand Acre-Feet
Cu. Yds/Yr = Cubic Yards per Year
Additional information about these terms is included in the Glossary

MANAGEMENT AREAS

Management areas are portions of the Forest to which a specific set of management practices are applied and for which standards and guidelines have been developed. Although a specific use or resource may be featured or emphasized in each description, other uses and resources are provided for in the standards and guidelines established for each management area. The alternative maps in the accompanying map packet display the actual management area allocations for each alternative. The management area allocations associated with each alternative are shown in Table S-2.

Table S-2. Management Area Acreage of Alternatives

	Alternatives

[1] Wilderness Resource Spectrum management is not applicable to the No change Alternative.

[2] All alternatives include 1,207 acres of Wild and Scenic River designation (wild classification) in the Waldo Wilderness. These acres are included in Management Area 1.

[3] Includes Existing nest area habitat only.

[4] Acres of network sites that overlap with other no harvest management areas are not included in MA9a, 9b, 9c acres. Refer to Figure II-4 FEIS for total habitat acres by alternative.

[5] Riparian acres which are not included in other management areas with no programmed harvest are allocated to MA15. Harvest rates in these Riparian Management Acres differ between alternatives, as described in Chapter II, Riparian. Riparian acres in NC are distributed throughout other management areas.

[6] Alternative L recommends designation of 169,360 acres of roadless area as Wilderness or wilderness study areas.

MAJOR TRADE-OFFS AND ECONOMIC COMPARISONS AMONG ALTERNATIVES

One of the primary reasons for developing alternatives is to provide varities of responses to the issues and concerns affecting the Forest and the public. Each alternative represents a unique approach to issue resolution. While all alternatives address the entire range of issues and concerns, none can successfully resolve all of them concurrently. This is because the issues and concerns reflect the full range of desires for, use of, and outputs from a limited land and resource base. Some of these outputs and uses are competitive or mutually exclusive, thus, creating the need for a variety of issue resolution packages or alternatives. The following is a brief and general description of the issue and concern resolution by alternative.

Old Growth

There are currently 594,800 acres which meet the Region Six definition of old growth. The amount of old growth maintained after 5 decades of harvest ranges from 44% in the NC Alternative to 88% in Alternative L. After 5 decades:

NC - Maintains 44%
K - 51%
A - 57%
J - 57%
W - 61%
D - 62%
L - 88%

Dispersed Recreation

The percentage of the Forest's inventoried potential semiprimitive motor and nonmotorized recreation opportunities provided ranges from 33% to 71%.

NC - Maintains 33%
K - 21%
A - 32%
J - 39%
W - 39%
D - 71%
L - 66%

Roadless Lands

Inventoried lands to be maintained in an undeveloped condition range from 26% to 85%.

NC - Maintains 26%
K - 15%
A - 35%
J - 46%
W - 53%
D - 80%
L - 85%

Scenic Quality

The expected future condition of the Forest's 10 major viewsheds varies according to alternative.

NC - One viewshed remains in a natural appearing condition.
K - None of the viewsheds will be maintained in a natural or slightly altered condition.
A - One viewshed will remain in a natural appearing condition.
J - One viewshed will remain in a natural appearing condition.
W - One viewshed will remain in a natural appearing condition.
D - Six of the viewsheds will remain in a natural appewaring condition.
L - Seven viewsheds will remain in a natural appearing condition.

Allowable Sale Quantity

The amount of timber estimated to be sold annually (in million board feet) ranges from 150 MMBF to 810 MMBF. The acres suitable for timber management range from 553,000 to 1,064,000.

NC - This alternative represents the potential yield of the current timber management plan : ASQ 810 MMBF; landbase 1,064,600 acres.
K - ASQ 650 MMBF; landbase 932,800 acres.
A - ASQ 608 MMBF; landbase 874,300 acres.
J - ASQ 530 MMBF; landbase 853,400 acres.
W - ASQ 491 MMBF; landbase 774,600 acres.
D - ASQ 476 MMBF; landbase 719,400 acres.
L - ASQ 150 MMBF; landbase 553,100 acres.

Water Quality

The risk to water quality and stream conditions varies according to alternative.

NC - Approximately 50% of the Forest land is at High Risk of adverse effects to water quality and stream conditions.
K - Approximately 29% high risk; 27% moderate risk; 44% low risk.
A - Approximately 28% high risk; 25% moderate risk; 47% low risk.
J - Approximately 18% high risk; 17% moderate risk; 65% low risk.
W - All of the Forest is at low risk.
D - Approximately 12% high risk; 10% moderate risk; 78% low risk.
L - All of the Forest is at low risk.

Wildlife and Plant Habitat

Capability of habitats to sustain wildlife populations or effects from management activities varies according to alternative. Distribution of snags and protection of Threatened and Endangered species also varies.

NC - Elk and deer habitat capability declines rapidly; mature and old-growth habitat is maintained in Wilderness; sensitive plant habitat impacted; potential loss of snag dependent species; T&E species protected at minimum levels.

K - Elk and deer habitat capability declines; old growth habitat maintained in Wilderness and habitat networks; sensitive plant habitat impacted; moderate amounts of habitat for snag dependent species; T&E species protected at minimum levels.

A - Elk and deer habitat capability declines in some areas, improves in others; old growth habitat maintained in Wilderness and habitat networks; sensitive plant habitat impacted; low amounts of habitat for snag dependent species; T&E species protected at minimum levels.

J - Elk and deer habitat capability increases; old growth habitat maintained in Wilderness and habitat nteworks; sensitive plant habitat moderately impacted; moderate amounts of habitat for snag dependent species; T&E species protected at minimum levels.

W - Elk and deer habitat capability increases; old growth habitat linked by corridors; sensitive plant habitat protected; moderate amounts of habitat for snag dependent species; T&E species and habitat protected.

D - Elk and deer habitat capability increases; quality and distribution of old growth habitat increases; sensitive plant habitat protected; high amounts of habitat for snag dependent species; T&E species and habitat protected.

L - Elk and deer habitat capability increases; old growth habitat at high levels Forest-wide; sensitive plant species rarely impacted; high amounts of habitat for snag dependent species; T&E habitats and species protected.

ECONOMIC COMPARISONS OF ALTERNATIVES

The economic implications of alternatives are displayed in Table S-3. Variations in costs, benefits, present net value, and cash flows among alternatives are described in this section. These economic indicators could not be reasonably estimated for Alternative NC (No Change) since it is based on a set of assumptions different than those of the other alternatives, and could not be modeled with the current Forest FORPLAN model.

Present net value (PNV) is a quantitative measure of economic efficiency, and thus is a key variable in the comparison of alternatives. It is defined as the difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area. "Discounting" is the procedure used to adjust all future costs and benefits to their present-day equivalent values in order to enable a meaningful comparison of dollar

flows through time. The discounted benefit and cost flows represent the potential net dollar returned for each alternative: the larger the PNV, the greater the potential return.

By providing a monetary, quantitative measure of economic efficiency, present net value is a very useful indicator of differences among alternatives in terms of their total output of public benefits. A full assessment of net public benefits, however, also requires a consideration of primary benefits and costs that have not been assigned a dollar value. Included in this category are outputs such as increased populations of some wildlife species, and physical conditions such as the maintenance of scenery. The value of such outputs and effects cannot be reasonably reflected in dollar terms because the data and/or methodology needed to do so are not available.

Another aspect of describing differences among alternatives and ultimately selecting a Preferred Alternative is the degree of issue resolution. Secondary benefits and costs, such as employment, are often important for understanding the degree of issue resolution.

Table S-3 displays the present net value, total discounted benefits, and total discounted costs for each alternative. Alternatives are ranked in order of decreasing present net value. Change in PNV between alternatives measures the net economic value of the priced outputs that would be forgone if an alternative with a lower PNV were selected.

Variations in present net value among alternatives are due to the wide range of possible costs and benefits represented in the alternatives. Each alternative is designed to produce a unique set of both priced and nonpriced outputs and effects, each of which generates a distinct pattern of values and costs.

Table S-3. Present Net Value, Discounted Benefits, and Discounted Costs[1]

Item	Alternative

[1]Direct comparisons of benefits and costs in millions of 1982 dollars displayed for individual resource outputs provide general indications of relationships but may be misleading because many multiple-use outputs have common costs of production which cannot be reliably separated and attributed to individual resources. Alternatives displayed in order of decreasing present net value.

[2]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. The alternative NC Description under "Alternatives Considered in Detail," of Chapter II in the FEIS describes these differences.

[3]Costs are for the Wilderness and recreation programs.

[4]Includes all timber-related costs except roads.

The principal factors influencing the level of priced benefits, costs, and present net value on the Forest are the amount and timing of timber harvest. Since this activity has relatively large investment costs and dollar returns associated with it, the volume harvested is the primary determinant of the magnitude of the economic criteria in each alternative. The timing of harvest (i.e., the adherence to a nondeclining yield schedule) is also very important. A departure from nondeclining yield accelerates investments and returns, thereby increasing PNV.

Other priced outputs, such as semiprimitive recreation opportunities, anadromous fish production, and fish and wildlife use, cannot compete with timber harvest economically and would not be produced at levels that affect timber harvest volumes or schedules based solely on economic efficiency criteria. Objectives for these resources can only be achieved through the use of constraints, specific prescriptions, or land allocations. To the extent that these objectives reduce the available timber harvest land base or restrict harvest through longer rotations, limits in harvest unit sizes, or other means, a reduction in present net value can be expected.

Economic values associated with potential future production of locatable minerals, oil and gas, geothermal energy or hydroelectric power are not included in alternatives. The possibility of future development of mineral and energy resources on the Forest does exist. However, the timing of development and the magnitude of production are both highly speculative. It is possible that the economic value of these activities will vary by alternative if they are undertaken.

Comparison of total economic benefits to total costs measures the overall economic efficiency of each alternative. Another important consideration is the flow of dollars to and from the U.S. Treasury. In this comparison the important factors are receipts (the portion of total market output collected as fees or payments) and budget costs. The difference between the two is the net cash flow to or from the Treasury. Net cash flows for the 1st, 2nd, and 5th decades for each alternative are also displayed in Table S-3. The major differences among both economic values and cash receipts are due to different levels of timber production. Over 99% of the revenues received by the Forest are from the sale of timber.

The columns labelled "Noncash Benefits" in Table S-3 represent the total estimated dollar value of the nonmarket resources to which values have been assigned. They are presented to give the reader an idea of the relationship between the actual receipts generated by the alternatives and the value of the nonmarket outputs to which values have been assigned.

Differences in noncash benefits to users generally vary inversely with harvest levels because of the relationship between harvest and recreation-related outputs. Thus, within the range of alternatives, noncash benefits increase as net receipts decrease. Second and fifth decade noncash benefits reflect anticipated increases in recreation use which accounts for a general rise in benefits.

MAJOR TRADE-OFFS AMONG ALTERNATIVES

This section summarizes the relationships and trade-offs among alternatives in terms of the selected issues and economic criteria. The purpose is to highlight major economic and noneconomic trade-offs that can be quantified by using indicators of responsiveness to issues as a means of comparing alternatives. Table S-4 displays the results for each indicator by alternative.

The indicators that could be estimated for the No Change Alternative are displayed in Table S-4. Many indicators could not be reasonably estimated because Alternative NC (No Change) is based on a different set of assumptions than the other alternatives, and could not be modeled with the current FORPLAN model.

Most issue indicators follow consistent patterns throughout the range of alternatives. The primary relationship associated with most indicators is the level of timber harvest in an alternative. Levels of economic indicators (present net value, net cash flows, payments to counties, jobs, and income) and of firewood are positively correlated with the amount of timber harvest in an Alternative. The amount of lands allocated for roadless, semiprimitive, and scenic management, and the level of spotted owl habitat and old-growth remaining are complementary with each other and negatively correlated with the level of timber harvest. Higher levels of timber harvest generate higher levels of potential adverse watershed impacts and greater amounts of erosion.

Table S-4 displays the specific data for each issue indicator and alternative.

Table S-4. Tradeoffs of Economic Benefits and Indicators of Response to Issues

Issues	Max PNV Bench -mark	Units	NC	K	A	J	W	D	L
Economics									
PNV	3.8	$MMM	NA[3]	3.5	3.2	3.1	2.9	2.8	1.6

[1]Changes represent the total potential change in the 1st decade as compared to historical averages over the life of the current Forest Plan (1977-1985).
[2]NE = Not estimated, benchmarks were not analyzed as fully developed implementable alternatives.
[3]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Forest FORPLAN model. See alternative Considered in Detail, Chapter II for additional information.
[4]Represents lands allocated to meet this objective.
[6]Percent of total Forest area at the end of the 1st decade in this watershed risk category. See Chapter IV, Water for further explanation.
[6]Represents end of 1st decade conditions.
[7]Units are average annual for 1st decade.

ENVIRONMENTAL CONSEQUENCES

THE RELATIONSHIP BETWEEN SHORT-TERM USES OF THE ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

Long-term productivity gains through use of various management practices on the Forest are of several types. Practices such as the replacement of old slower-growing timber types with younger, productive stands, the use of commercial tree thinning, and the use of prescribed fire to improve wildlife habitat have measurable long-term economic gains.

Wood fiber production will be increased over the long run as some of the old-growth stands are harvested and converted to more productive second growth stands. Opportunities for dispersed recreation use, including hiking, camping, fishing, hunting, snowmobiling, sightseeing, and cross-country skiing will be maintained and increased for future generations.

While some forest practices can cause losses such as temporary increases in soil erosion and temporary displacement of certain wildlife species, on the whole the ecosystem remains in balance with productivity gains exceeding losses in the long-term. For example, timber management activities such as clearcutting and prescribed burning alter the natural appearing landscape and have a short-term adverse impact on the scenic values. These impacts are reduced within several years with vegetative recovery and are mitigated in the long-term by integrating the principles of landscape management into all Forest management practices and activities.

IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

An irreversible commitment of resources results from a decision to use or modify resources that are renewable only over a long period of time, such as soil, or nonrenewable resources such as cultural resources or minerals. The proposed Forest Plan and the alternatives examined are based on the principles of multiple-use and long-term productivity for all resources. Measures to protect natural resources that could be irreversibly affected by management practices are incorporated into Forest-wide standards and guidelines.

Removal of mineral or energy resources is an irreversible commitment of resources. The removal and utilization of rock resources for road construction would be an example of a common use on the Forest.

Soil erosion, as a result of management activities, is an irreversible loss; once the soil particles are removed from the site and deposited into a stream or river, they are no longer available.

An irretrievable commitment of resources is a use of resources that are lost because of land management objectives. This represents opportunities foregone for the time that the resource cannot be used. An example of an irretrievable commitment might be the loss of wildlife habitat where the management objective for an area is developed recreation.

The development of roadless areas would mean an irretrievable loss of the characteristics which qualify these areas for Wilderness designation. On the other hand, not developing roadless areas is an irretrievable loss of opportunities for vegetation management. This could result in lower volumes of timber harvest and forage being produced on the Forest.

Irretrievable loss of timber production could result from stands being designated as old-growth wildlife habitat, reserved for cultural resource protection, or dedicated for other uses such as arterial and collector roads, administrative sites, and developed recreation sites. Insects, diseases and fire can also cause irretrievable losses to vegetation.

PROBABLE ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED

Under any alternative, some adverse impacts to the environment could be expected to occur which cannot be completely mitigated. However, the application of the management prescription standards and guidelines is intended to limit the extent and duration of these effects. Given the limited supply of an undisturbed Forest setting, extensive Forest use will diminish opportunities for a sense of remoteness, naturalness, and solitude in the Forest. Adverse effects of timber harvest, road construction, increased dispersed recreation use and the development of recreation sites include impacts such as disturbance to vegetation, compaction of soil, impacts on water quality, increases in noise levels, and disturbance of game animals and their habitat.

Fire hazard and resistance to control will increase subsequent to logging and thinning operations as a result of increased timber residues. Fire risk also increases as a result of more people using an area during and after management activities.

Air quality will diminish on a local and temporary basis due to prescribed burning.

In unroaded areas, development activities such as timber harvesting and road construction associated with harvest, recreation, or other purposes will have an adverse effect on the potential future management of these areas as designated Wilderness, as Research Natural Areas, or for other purposes requiring natural characteristics.

The disturbance or displacement of fish and wildlife may occur as a consequence of increased human activity on project areas.

The disturbance or destruction of some artifacts and sites is liable to occur as a result of some management activities. This would be especially true for subsurface sites that cannot be located through surface surveys.

SIGNIFICANT CUMULATIVE EFFECTS

The majority of watershed research conducted on the Forest indicates that when the percentage of a watershed in immature timber stands increases beyond 25% to 30%, changes may occur in the quality, quantity and timing of runoff. The ability of a drainage to absorb impacts is determined by a wide range of variables including soils, vegetation, slope, stability, aspect, past and present management including timber harvest, road construction, and use.

A cumulative effect of disturbing artifacts and sites is the loss of information about the prehistory and history of an area. This inhibits the efforts of historians and anthropologists to describe accurately the cultural history of the Forest and its relationship to other parts of the region. As a result, cultural sites and artifacts on Forest land may become more important over time.

As natural settings are altered through timber harvest and road construction, the capacity of the Forest to provide some types of dispersed recreational settings and experiences is diminished. The greater the

shift from unroaded recreation to roaded recreation in the alternatives, the greater the cumulative effect on semiprimitive (motorized and nonmotorized) recreation opportunity settings.
As road construction and timber harvest activities are implemented over several decades, they have the potential to affect an increasing amount of trail mileage.

While a single activity may only affect its immediate surroundings, many activities over several years or decades will diminish the scenic quality of a much larger area. This effect has even greater consequence in areas where private or other public agency land is adjacent to the Forest. Areas with large blocks of intermingled ownership may display these effects most significantly. It is assumed that private landowners having a large timber inventory will harvest timber and will not keep the landscape in a natural appearing condition. This "checkerboard" effect will be most apparent in the North Santiam, South Santiam, and Middle Fork of the Willamette drainages and to a lesser extent in the McKenzie drainage and around the community of Oakridge.

Approximately 22% of the Forest is currently designated Wilderness. This has the effect of natural state preservation of the water, vegetation, soil, and air quality. The nondesignation of suitable lands may result in the development of such land and over time these may become unsuitable for future Wilderness consideration. Another effect on Wilderness is the development, such as timber harvest and road construction, that may occur adjacent to Wilderness boundaries. This effect may result in physical changes that over a period of time can influence the Wilderness opportunity to be provided. Improved access could result in a greater number of visitors entering the Wilderness at more locations, adversely affecting the type of recreation experience currently provided. Each alternative proposes different levels of development for different amounts of the inventoried roadless areas. As roads are constructed and timber sale units are harvested, roadless areas will be altered in size and shape. In addition, roadless areas adjacent to other allocations and landownerships are subject to the external influences of their management. These effects will alter the potential of individual areas to provide Wilderness quality experiences and opportunities in the future.

As natural settings are altered through timber harvest and road construction, the capacity of the Forest to provide some types of Special Interest Area, National Natural Landmark, and Research Natural Area settings is diminished. Changes to vegetation patterns, surface drainage, and soil horizons on land adjacent to established Special Interest Areas, National Natural Landmarks, and Research Natural Areas may over a period of time affect the natural processes of individual areas or result in an eventual loss of research potential.

In general, alternatives which harvest more acres of timber will gradually result in younger age classes, fewer stands of old-growth, and a younger average age of timber stands in the Forest. Along with the younger ages will come smaller average tree sizes. There will be less defect and breakage as diseases and deformities found in mature and overmature tree have less chance to develop in the younger stands. As more stands are harvested and managed for timber production, there will be a gradual decrease in the population of the more shade tolerant climax species, such as western hemlock and Pacific silver fir. Laminated and blackstain root rots may show some increase with intensive management but losses can be minimized by planting and favoring resistant species and timing precommercial thinning to minimize spread of disease by insects seeking out the fresh cut stumps.

The per acre yield of commercial products from the Forest will increase as stands are managed to maintain fast growth rates by controlling competition. Growth will also be enhanced through fertilization, (except in Alternative NC), and genetic selection. Cross-breeding for desirable genetic traits will provide greater increases in successive generations. Care must be taken to avoid reducing genetic diversity which could make the Forest increasingly susceptible to insects and disease. All alternatives meet or

exceed the requirement that the growth rate by the year 2030 be 90% of long-term sustained yield capacity.

ORGANIZATION OF THE DOCUMENTS

The complete set of Willamette National Forest planning documents includes: (1) Final Environmental Impact Statement (FEIS), (2) Appendices to the FEIS, (3) Forest Plan, (4) FEIS Summary, (5) Resource and Alternative Maps, and (6) Record of Decision.

This document organization guide is provided to assist the reader in understanding what information is presented in each of the planning documents. A thorough reading of the FEIS will aid in understanding the implications of the Proposed Action, which is the basis for the Forest Plan.

In addition to the material included in the FEIS, Forest Plan, and supporting Appendices, other information and records are available during regular business hours at the Willamette National Forest Supervisor's Office; 211 East Seventh Avenue; Post Office Box 10607; Eugene, Oregon 97440.

Final Environmental Impact Statement

Chapter I: "Purpose and Need" identifies the laws and regulations which direct the planning process. Chapter I identifies the public issues and management concerns about the land and resource management of the Willamette National Forest.

Chapter II: "Alternatives Including the Proposed Action" presents the seven alternatives selected for analysis, explains their formulation, indicates response of the alternatives to the issues, and provides a basis for choice among the range of alternatives. The alternatives are compared on the basis of their outputs of goods and services in response to the issues. The alternatives selected for display in the FEIS are Alternatives NC (No Change), A, D, J, K, L, and W (Preferred Alternative).

Chapter III: "Affected Environment" describes the environment of the area to be affected by the range of alternatives under consideration. Information includes the physical and biological setting, the social and economic setting, and the current situation of specific Forest resources.

Chapter IV: "Environmental Consequences" discusses the environmental impacts of the Alternatives, any adverse environmental effects which cannot be avoided should the preferred alternative be implemented, the relationship between short-term human uses of the environment and the maintenance and enhancement of long-term productivity, and any irreversible or irretrievable commitments of resources which would be involved in the preferred alternative should it be implemented.

Other Sections of The FEIS

List of Preparers: Identifies the Interdisciplinary Team Members and provides a brief description of their roles, education, and experience.

List of Agencies and Organizations to whom copies of Forest planning documents have been sent.

References: The list of the works referred to in the FEIS.

Glossary: Terms, their definitions and abbreviations.

Index: Provides the page locations of topics discussed within the planning documents.

Appendices to the FEIS

The Appendices present the more technical or detailed information involved in the planning process.

Appendix A presents a chronology of public involvement activities which were used to determine the issues to be addressed. It includes background on issue development, a listing of the various publics contacted and/or consulted, and the issues selected to be addressed in the FEIS.

Appendix B describes the analysis process used in developing the alternatives. It details the quantitative methods used to perform the analysis.

Appendix C provides a description of each of the inventoried roadless areas on the Forest.

Appendix D contains information about the standards and guidelines, and the management area prescriptions which do not apply to the preferred alternative, but which may apply to other alternatives. The M.A. Prescriptions which apply to the preferred alternative are in Chapter IV of the Forest Plan.

Appendix E describes the analysis and study of rivers on the Forest that are designated, under study, or eligible for inclusion in the Wild and Scenic Rivers System.

Appendix F describes the rationale used to determine the appropriate harvest systems implemented in managing coniferous forest stands on the Forest during the next 10 years on those lands where timber production is prescribed.

Appendix G describes the analysis used and considerations in determining how management requirements for soil, water quality and wildlife habitat could be met and the potential effects on various resources.

Appendix H outlines the Best Management Practices that would be used in any of the alternatives to meet water quality objectives.

Appendix I presents a summary of the comments received on the DEIS and Proposed Forest Plan including Forest responses to the substantive comments.

Forest Plan

The Forest Plan contains management direction for the Forest land and resources based on the Preferred Alternative identified in the FEIS. It contains the detailed standards and guidelines for management practices.

Summary of the FEIS

The **Summary** is a brief overview of the material contained in the FEIS.

Map Packet

The **Map Packet** contains the alternative maps which display the allocations of management areas by alternative. It also contains a separate planimetric map of the Preferred Alternative at a 1/2 inch to 1 mile scale displaying management area boundaries and locations.

Record of Decision

The Record of Decision clarifies what decisions are being made and the rationale behind them.

CHAPTER I

PURPOSE AND NEED

INTRODUCTION

National Forest Land and Resource Management Planning is a process for developing, adopting, and revising land and resource management plans for the National Forest System as required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA). The resulting Land and Resource Management Plans (Forest Plans) provide for multiple use and sustained yield of goods and services from the National Forest System in a way that maximizes long-term net public benefits in an environmentally sound manner. The National Forest System Land and Resource Management Planning process is described in Title 36, Part 219 of the Code of Federal Regulations.

The purpose of this Final Environmental Impact Statement (FEIS) is to provide decisionmakers with an environmental disclosure sufficiently detailed to aid in the selection of a Forest Plan, which contains new management direction for the Forest. Equally important, its purpose is to make information available to the public, and to encourage public participation regarding the development and refinement of that direction. This document discloses the planning process and analysis of the significant environmental effects of a proposed action and 6 other alternatives for the future management of land and resources of the Forest.

Each alternative in the DEIS addresses local, regional, and national public issues, management concerns and opportunities (ICOs); provides for use and protection of resources; and fulfills legislative requirements. Every alternative generates a different mix of goods and services from the Forest. In the analysis, outputs and effects are projected for five decades to indicate long-term implications.

The Preferred Alternative is the "proposed action" (40 CFR 1502.14) which provides for a level of multiple-use and sustained yield of goods and services that is judged to best maximize long-term net public benefits in an environmentally sound manner while responding effectively to all the public issues. Net public benefits represents the cumulative net value of all Forest outputs and activities, whether assigned a dollar value or not.

The Preferred Alternative, as modified by the Record of Decision, is the basis for the accompanying "Willamette National Forest Land and Resource Management Plan" which is a separate document. The purpose of the Forest Plan is to direct all natural resource management activities on the Forest. The Forest Service is required to revise the plan within 15 years of its adoption and this revision may establish different long-term goals with different projected effects and outputs. The Forest Plan may also be amended any time during the next 10 to 15 years if changed conditions or monitoring results indicate adjustments are needed.

While the Forest Plan will guide the management of the Forest for the next 10 to 15 years, the analysis in the FEIS covers a planning horizon of 50 years to evaluate and display the long-term effects of actions during the planning period. This evaluation has two purposes. First, it presents a long-term analysis for decisionmakers and the public of the management necessary for each alternative to achieve and maintain the optimum level of regular periodic outputs of various resources. Secondly, the long-term

analysis allows net public benefits to be maximized while responding effectively to all the public issues without impairment to the productivity of the land (16 U.S.C. 531). The analysis also provides an estimate of the level of long-term outputs for each alternative based on an unconstrained budget and maximization of net public benefits, subject to responding effectively to the public issues.

Preparation of an Environmental Impact Statement is required because the Forest Plan is a major federal action which may have a significant effect on the quality of the human environment. Its development follows the direction of the National Environmental Policy Act of 1969 (NEPA) and the Council on Environmental Quality (CEQ) NEPA Regulations (40 CFR 1500-1508). For purposes of disclosure under NEPA, this DEIS and the accompanying Proposed Forest Plan are treated as combined documents.

A list of references cited in the FEIS and a glossary defining terms, units and abbreviations are located at the back of this document. The reader will find it useful to consult the land management allocation maps for each alternative when reviewing this FEIS. The maps are in a separate packet accompanying this document. A complete description of the direction and emphasis for each of the management areas displayed on the maps is in Chapter II, Comparison of Alternatives.

Disposition Of Previous Plans

The Final Forest Plan will incorporate or replace previous land management and resource management plans prepared for the Forest.

The following plans will be replaced by the Forest Plan:

- Multiple Use Land Management/Timber Management Plan (1977)
- Mt. Jefferson Wilderness Management Plan (1977)
- Three Sisters Wilderness Management Plan (1974)
- Lava Fire Management Plan (1978)
- Trail Management Plan (1980)
- Waldo Lake Recreation Area Plan (1962)
- Off-Road Vehicle Plan (1974)

The following plans will be incorporated as part of the Forest Plan:

- Land Ownership Adjustment Plan (1974)
- Lamb Butte Special Interest Area Plan
- Research Natural Area Establishment Reports

Ollalie Ridge (1963)
Gold Lake Bog (1965)
Wildcat Mountain (1968)
Middle Santiam (1979)

- Geothermal Development Plans

  Breitenbush Area FEIS (1978)
  Belknap-Foley FEIS (1981)

- Willamette Pass Alpine Winter Sports FEIS (1985)

- Crale Creek Bald Eagle Management Plan (1982)

- Hills Creek Reservoir Bald Eagle Management Plan (1983)

Upon implementation, Forest management activities will comply with the Forest Plan. Appropriated budgets may alter the schedule of activities. In addition, all permits, contracts, and other instruments for the use and occupancy of National Forest System lands and resource uses must be in conformance with the Forest Plan as soon as possible (36 CFR 219.10(e)).

Changes Between Draft And Final

The Draft Environmental Impact Statement (DEIS) and Draft Forest Plan were released to the public in December 1987. Changes that have occurred since the DEIS are incorporated in this FEIS. Many of these changes are in response to public comments on the DEIS and Draft Forest Plan. Included are revisions and updates to data and technical modeling procedures used in the analysis, as well as modifying alternatives presented in the DEIS and the development and analysis of additional alternatives. A complete listing of the analytical and technical changes can be found immediately follow the introduction to Chapter II of this document.

The final Supplement to the EIS (SEIS) for an Amendment to the Pacific Northwest Regional Guide (USDA Forest Service 1988) was issued in July 1988 and provides Regional guidelines for maintaining viable populations of northern spotted owls. The new management direction was incorporated in the FEIS resulting in changes in the habitat network and standards and guidelines.

The Oregon Omnibus Wild and Scenic Rivers Act of 1988 designated approximately 12.7 miles of the McKenzie River and 42.3 miles of the North Fork of the Middle Fork of the Willamette River as Wild, Scenic and Recreation rivers. The South Fork of the McKenzie River and Blue River were specified as Study Rivers in the Act also.

The Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation (USDA Forest Service 1988) was released since the DEIS. Changes were made to standards and guidelines to be consistent with the guidelines presented in the FEIS and to reflect a reduced emphasis on herbicide use.

All of the changes mentioned above are discussed in greater detail in Chapter II, Changes Between Draft and Final and Description of Alternatives.

Changes specific to Chapter I, Purpose and Need, primarily involve additional information and clarification of the 7 key issues that were identified through initial scoping efforts and displayed in the DEIS. Public comments on the DEIS and Draft Forest Plan are the principal source of these changes. Although the number of comments received were voluminous (over 170,000 comments in 17,000 individual replies), almost of all of them were related to the original issues. While many simply restated earlier input from the scoping process, others helped to clarify specific points or identify new aspects within the broader issues that were not recognized during the scoping phase or have developed in the 4 to 5 years between scoping and the DEIS release. Public response also served as an indicator of the intensity of the individual issues and how this may have changed during the planning process.

In response to the comments, all of the key issues were reviewed to determine if they were current and accurately portrayed concerns raised in public comments in the FEIS. Where necessary, the ICOs have been updated to keep them current and within the scope of the planning process. In addition to the discussion of ICOs in this section of the document, further information is available in Appendix A, *Issues, Concerns and Opportunities* about specific changes and refinements in ICOs between the DEIS and FEIS.

PLANNING PROCESS

To put forest planning in perspective, it is important to have a general understanding of the overall Forest Service planning process. As required by RPA, NFMA, and the related implementing regulations cited above, the Forest Service has a three-level, integrated planning process.

At the national level, the RPA Program establishes long range resource objectives based on the present and anticipated supply of, and demand for, various resources. A portion of each national resource objective included in the RPA Program is distributed to each of the nine Forest Service Regions in the nation.

At the regional level, a Regional Guide is developed. The Regional Guide presents the distribution of its portion of the national objectives to each National Forest. In addition, the Regional Guide establishes Regional management standards and guidelines. The *Regional Guide for the Pacific Northwest Region* of May 1984 provides this direction for the Forest.

At the National Forest level, a Forest Plan is proposed from the analysis of a set of alternatives that reflect a range of resource objectives, outputs, and effects. One or more of these alternatives are developed to meet or exceed the current RPA Program objectives displayed in the Regional Guide. The alternative development process is described in Chapter II.

The RPA Program is submitted to Congress as an aid to determine appropriation and authorization of the agency's annual budget. Since allocations in the annual budget have a major effect on management activities, many of the Forest's actual outputs and environmental effects are ultimately determined in large part by the annual budget. Through implementation of the Forest Plan and annual budget commitments, the planning process is responsive to public issues and resource capabilities of the Forests.

The planning process is a cyclic process. The information from the Forest level flows up to the national level, is incorporated in the RPA Program, then flows back to the Forest level. In this way, the information regarding resource capabilities and demands is incorporated into the RPA Program.

The planning process specified in the NFMA implementing regulations and the environmental analysis process specified in the CEQ regulations were used in developing this FEIS and the accompanying Proposed Forest Plan. The planning steps employed are:

Identification Of Purpose And Need

This first step is focused on the identification and evaluation of public issues, management concerns and resource use and development opportunities. It is the phase in the process where the major issues, concerns, and opportunities to be addressed in the planning process are determined.

Preparation Of Planning Criteria

Criteria are prepared to guide: collection and use of inventory data and information; analysis of the management situation; and the design, formulation, and evaluation of alternatives. Specific criteria are derived from laws, executive orders, regulations, and agency policies; goals and objectives of the RPA Program and the Pacific Northwest Regional Guide; plans and programs of other agencies; ecological, economic, and technical factors; and resource integration and management requirements specified in the NFMA Regulations.

Inventory Data And Information Collection

Current information and inventory data, including maps and graphic material, appropriate for planning and managing forest resources are collected and maintained. This may require special inventories or studies to be prepared to address emerging issues or changes in planning direction.

Analysis Of The Management Situation

The analysis of the management situation is a determination of the ability of the planning area covered by the Forest Plan to supply goods and services in response to society's demands. The purpose of this analysis is to provide a basis for formulating a broad range of reasonable alternatives and includes benchmark assessments to define resource capability ranges within which alternatives can be constructed.

Formulation Of Alternatives

Alternatives are formulated, in accordance with NEPA procedures, that reflect a broad range of resource outputs and effects and are responsive to public issues and management concerns.

Estimated Effects Of Alternatives

The physical, biological, economic, and social effects of implementing each alternative that is considered in detail are estimated and compared. The purpose of this step is to estimate objectively what the effects would be, given implementation of any one of the alternatives considered in detail.

Evaluation Of Alternatives

The evaluation includes an analysis of the aggregate physical, biological, economic, and social effects of the management alternatives and provides a comparative assessment of present net value, social and economic impacts, outputs of goods and services and overall protection and enhancement of environmental resources.

Recommendation Of A Preferred Alternative

The Draft Environmental Impact Statement (DEIS), which identifies the Preferred Alternative, and the Draft Forest Plan, are prepared for public review. This DEIS and the draft Forest Plan are circulated for review and comment, ensuring that environmental information is available to public officials and citizens before decisions are made and before actions are taken. A Final Environmental Impact Statement (FEIS) is prepared and the Preferred Alternative is identified after comments from DEIS are reviewed and evaluated.

Plan Approval And Implementation

The Regional Forester reviews the FEIS and Forest Plan. Upon completion of this review, the Regional Forester makes a decision regarding approval of the proposed Forest Plan. The decision is documented in a Record of Decision (ROD) and is made available to the public, as are the FEIS and Forest Plan.

Upon implementation, the FEIS and Forest Plan will be used for "tiering" in accordance with the CEQ regulations. Tiering means that site-specific environmental analysis conducted for projects arising from the Forest Plan will refer to the FEIS and associated documents rather than repeat information

from those documents. In this way, the environmental documents prepared for a site-specific project will need only to concentrate on issues unique to that project (40 CFR 1508.28).

Monitoring And Evaluating

At intervals established in the Plan, implementation shall be evaluated on a sample basis to determine how well objectives have been met and how closely management standards and guidelines have been applied. Based on this evaluation, revisions or amendments to the Forest Plan may be recommended.

The Forest Plan will ordinarily be revised on a 10-year cycle or at least every 15 years. It also may be revised whenever the Forest Supervisor determines that conditions or demands in the area covered by the plan have changed significantly or when changes in the RPA policies, goals, or objectives would have a significant effect on Forest level programs. In the monitoring and evaluation phase, the interdisciplinary team may recommend a revision of the Forest Plan at any time. Revisions are not effective until considered and approved in accordance with the requirements for the development and approval of the Forest Plan. The Forest Supervisor will review the conditions on the land covered by the Plan at least every five years to determine whether conditions or demands of the public have changed significantly (36 CFR 219.10(g)).

In addition to revisions, the Forest Plan may also be amended (36 CFR 219.10). A Forest Plan amendment may be significant or nonsignificant depending on the scope of adjustment or change that is considered and only changes a specific aspect of the Forest Plan in contrast to a plan revision which revisits the entire set of resource issues and land allocations. Amendments are expected to occur frequently during the life of the plan as monitoring, site-specific analyses or inventory updates indicate specific areas of the Forest Plan that need to be updated or adjusted to reflect current situations. Amendments of limited scope and effects may be done by the Forest Supervisor with a Decision Memo or a Decision Notice.

Additional information and file documents used in the Forest planning process to develop this FEIS and the accompanying Forest Plan are contained in the planning records maintained at the Forest Supervisor's Office, 211 East Seventh Avenue, Eugene, Oregon; they are available during regular business hours.

FOREST OVERVIEW

The Forest is an administrative unit of the Pacific Northwest Region of the Forest Service, U.S. Department of Agriculture, and is located within the Second, Fourth, and Fifth United States Congressional Districts. It lies primarily in Lane, Linn, and Marion Counties, but also extends south into Douglas County, east into Jefferson County, and north into Clackamas County. Figure I-C-1 displays a breakdown of the Forest acreage by county. The Forest headquarters is the Supervisor's Office located in Eugene, Oregon. There are seven Ranger Districts, with offices in Oakridge, Westfir, Lowell, Blue River, McKenzie Bridge, Sweet Home and Detroit. The vicinity map, Figure I-C-2, shows their location, the location of the Forest in Oregon and its relative size.

The Forest stretches for 110 miles along the western slope of Oregon's Cascade Mountains. The western edge of the Forest borders the Willamette Valley from the Mt. Jefferson area east of Salem to the Calapooya Mountains northeast of Roseburg. The crest of the Cascade Range defines the eastern boundary of the Forest.

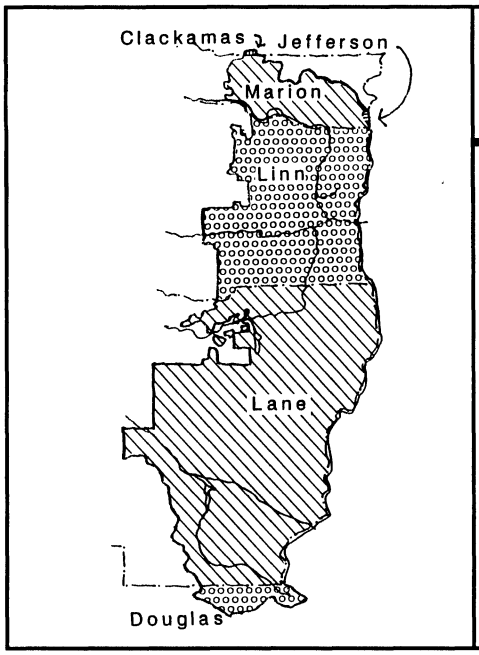
There are over 1.7 million acres within the Forest boundary--1,675,408 of National Forest land and 123,330 acres of land in private ownership or managed by other public agencies. Over 380,000 acres of land within the Forest have been set aside by Congress to preserve Wilderness character and to conserve portions of the Forest's natural scenery, flora, and fauna. Other dedicated areas include the H.J. Andrews Experimental Forest, the Oregon Cascades Recreation Area, the Lamb Butte Scenic Special Interest Area, and four Research Natural Areas.

The landscape of the Forest is divided into two geological provinces, the Western Cascades and the High Cascades. The steep, deeply dissected valleys of the Western Cascades are geologically older than the High Cascades. Elevations range from 900 feet along the Santiam River to over 10,000 feet at the summits of Mt. Jefferson and the Three Sisters. Most of the Forest lies within an elevation range of 2,000 to 4,000 feet. Broad plateaus, broken by a line of inactive volcanoes along the crest, are characteristic of the High Cascades, which comprise one-third of the Forest. Alpine glaciation has left this terrain marked with U-shaped valleys, moraines, and glacial lakes.

Two-thirds of the Forest lies within the Western Cascades and contains some of the most productive forest land in the United States. Diverse forest vegetation provides habitat for a wide spectrum of wildlife. Nearly 300 vertebrate wildlife species inhabit the Forest, including both game and nongame species.

The Forest has approximately 400 lakes and more than 2,700 miles of perennial streams and rivers. An anadromous fishery, including salmon and steelhead, is found in the Forest's main tributaries. Surface water feeds seven major reservoirs that provide flood control, power generation, streamflow regulation, and recreation. Water for domestic use for rural communities and nearly 205,000 metropolitan users in the Willamette Valley also comes from the Forest's system. The main stream systems of the Forest are the Willamette, McKenzie, and Santiam rivers and their tributaries.

A variety of natural resource related products and services are produced on the Forest. Wood, water, wildlife, and recreation are the primary categories of these. Mild climate and abundant rainfall are extremely favorable to growing magnificent evergreen trees including Douglas-fir, western hemlock, and western red cedar. This Forest is the top timber producer of the 156 National Forests in the United States. The Forest produces about 8% of all timber cut on National Forest lands and provides an average of 750 million board feet of timber to the Nation's economy annually.



The amenity and commodity resources of the Forest are important nationally, as well as to the people of Oregon. The lumber and wood products industry is the State's number one manufacturing industry, with agriculture and tourism also playing a significant part in the economy of the State. Most of the timber sold by the Forest is processed in counties adjacent to the Forest. Over 25% of Oregon's population lives in urbanized communities located in Lane, Linn, Marion, Benton, and Polk counties, and a majority of this Forest's recreation users comes from these areas.

During all seasons of the year and at all elevations, the Forest environment provides for a variety of recreational experiences, including sightseeing, hiking, camping, boating, hunting, fishing, mountain climbing, downhill and cross country skiing.

Principal highways providing access to the Forest are State highways 22, 58, and 126, and U.S. Highway 20, all east-west routes. The Forest is within a 1 1/2-hour drive from Portland, and a 1-hour drive from Salem, Albany, Corvallis, Bend, and Eugene-Springfield.

A detailed description of the Forest is presented in Chapter III, "Affected Environment."

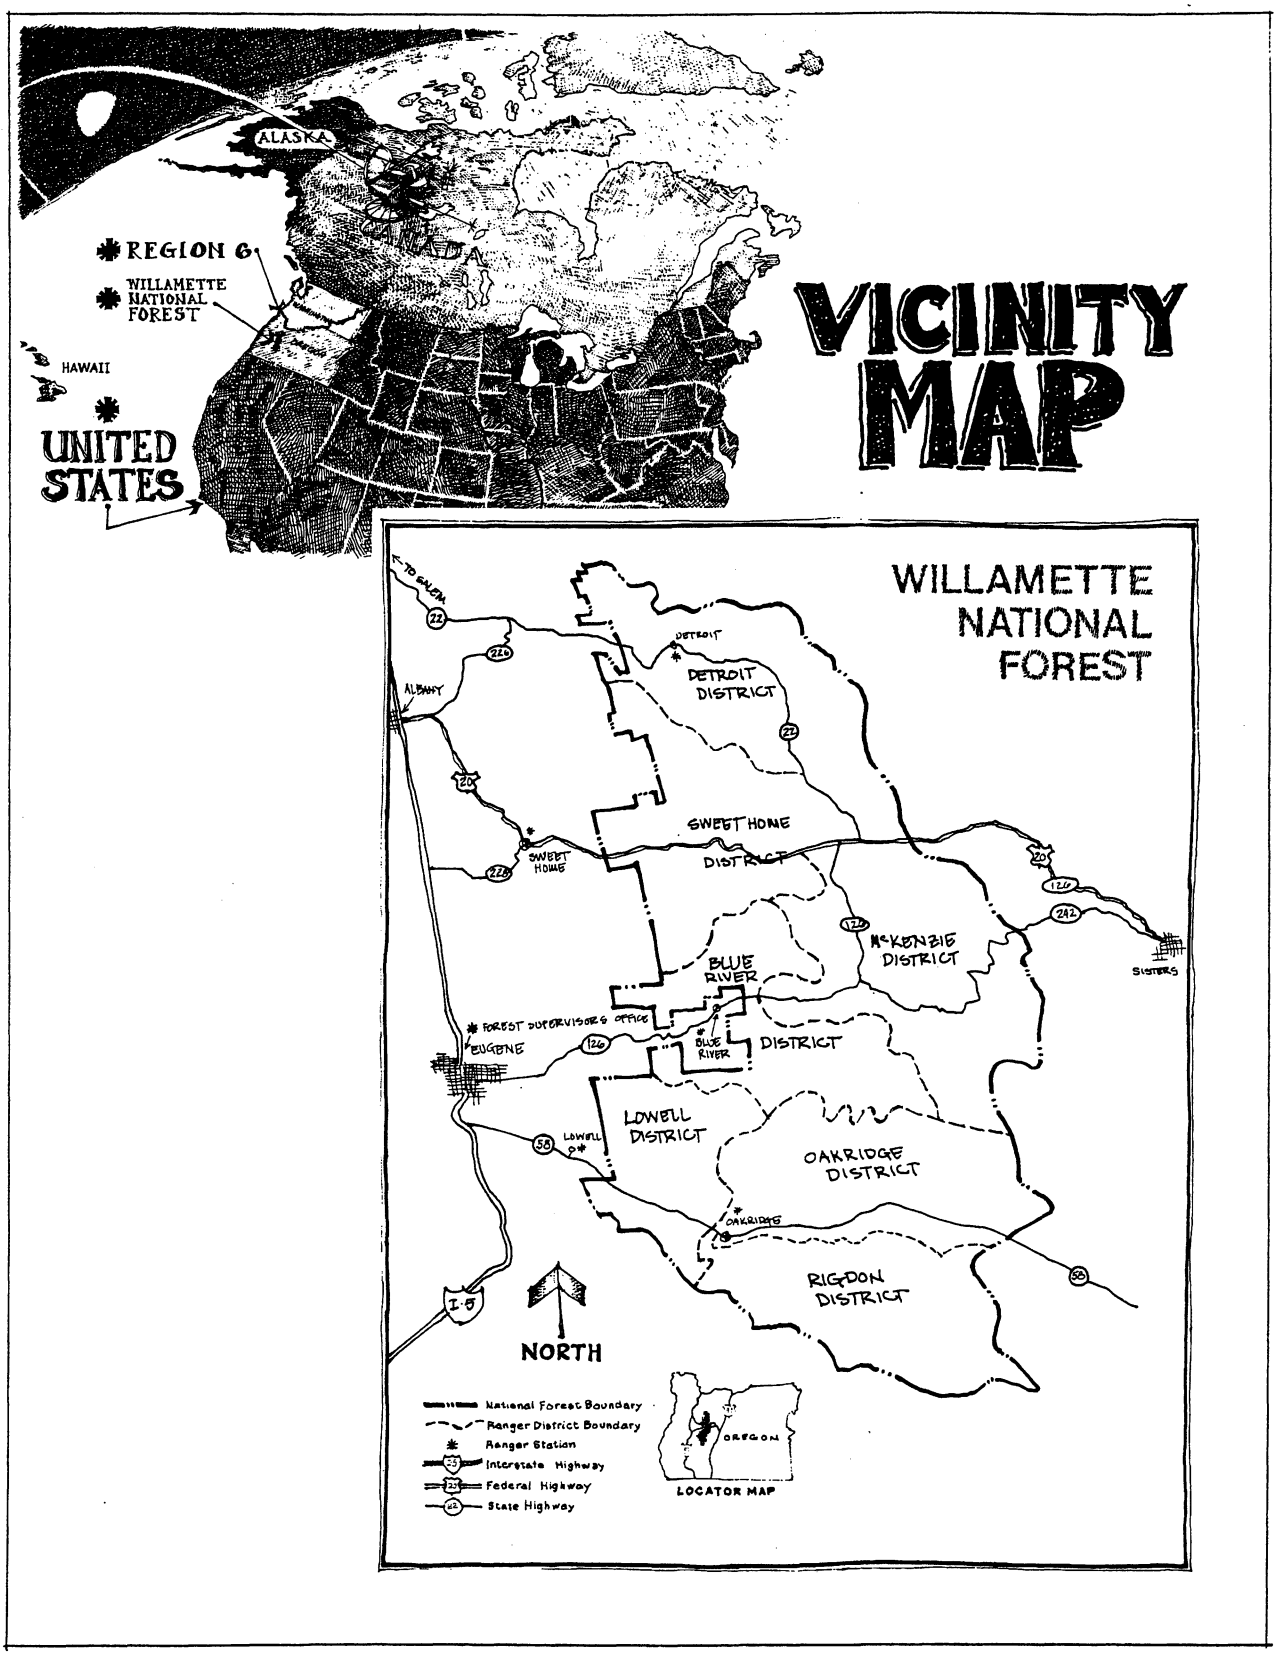


Table T311. Acreage By County (I-C-1)

County	WNF Acres In County	% Of WNF By County	Non-National Forest Acres	Acres Within Forest Boundary
Lane	1,021,941	34.8%	59,233	1,081,174
Linn	465,613	31.7%	56,013	521,626
Marion	136,064	18.1%	8,084	144,148
Douglas	50,296	1.6%	0	50,296
Clackamas	853	0.07%	0	853
Jefferson	640	0.06%	0	640
TOTAL	1,675,407		123,330	1,798,737

ISSUES, CONCERNS, AND OPPORTUNITIES

Introduction

The Forest is composed of complex natural ecosystems that can be managed for various combinations of goods and services, land uses, and environmental conditions. Many of these Forest resources, uses, and conditions are interrelated. Different people and groups prefer to see the Forest managed in different ways. Managing the Forest to emphasize some resources may cause changes in others, and tradeoffs are often necessary. There are practical and natural limits to what the Forest can provide without adversely impacting the quality of the environment.

A central task in Forest Planning is the analysis of a range of alternative ways of managing the National Forest. Alternatives are developed which meet legal requirements, and which address and are based on the important public issues and management concerns. Alternatives represent a blend of different resource emphases and combinations of management practices to produce the goods, services, and environmental conditions that people want. The planning analysis considers both the uses of the Forest, and the implications of these uses in ecological and human terms.

The Forest Planning process is guided by the public issues and management concerns which reflect the different preferences of individuals and groups, and the physical, biological, and legal limits on forest management. A public issue is a subject or question of widespread public interest relating to management of the National Forest System. A management concern is an issue, problem, or a condition which affects the range of management practices identified by the Forest Service in the planning process.

Issue Identification

The identification of public issues and the development of planning questions for the current planning effort began in the fall of 1979. An initial draft of existing and/or anticipated issues, concerns, and opportunities was circulated on-Forest to Rangers, Staff and Zone Engineers for review and comment. These issues and concerns were expressed as objectives and a hierarchy from general to specific was developed for the objectives. Facets of the issues were described from the specific statements in the objectives hierarchy. Following this, a response packet was prepared to solicit public comments. These packets were distributed at Forest offices and public meetings and mailed to concerned citizens and industry groups.

Open house sessions were held to explain opportunities for the public to participate in the Willamette's planning process. The sessions were informal and offered assistance in preparing response forms and answering questions. Response forms were returned by January 1981. There were 291 forms returned. An additional 41 items of correspondence were submitted; these were included in the analysis process as documented in the Planning Record.

Development of the final list of issues for Regional Forester submission and approval was the result of an in-depth analysis of the public responses received in early 1981. The final phase of the analysis had, as its central theme, the goal of validation/revision of the objectives hierarchy in terms of suggested revisions, additions, or comments contained in the public responses. The Regional Forester approved the list of issues in May 1981, and they have been used to guide the Willamette's planning process.

The issues are Dispersed Recreation, Developed Recreation, Wilderness, Visual/Scenic, Cultural Resources (Artifacts and Sites), Wildlife and Plant Habitat, Aquatic Habitat (Fish), Livestock Grazing (Range),

Current and Future Timber Production, Logging Residue (Firewood), Water Quality and Quantity, Air Quality, Minerals, Energy, Individual Well-being, Local Economies, Old Growth, Roadless Lands, Economic Efficiency. The effects of the alternatives on these issues are addressed in Chapter IV.

While all of the issues have been considered during the alternative development and analysis, there are seven major issue areas which have evolved as having the most importance in the selection of the preferred alternative. These major issues are those which have caused the greatest amount of comment in public meetings held by the Forest (see Figure I-D-1), meetings with small groups and individuals, and correspondence received.

The seven most significant public issues are:

1. Dispersed Recreation
2. Old Growth
3. Roadless Lands
4. Scenic Quality
5. Timber Supply
6. Water
7. Wildlife, Fish, and Plant Habitat

The issue identification process is discussed in more detail in Appendix A.

Discussion Of Selected Issues

Most Forest management issues are interrelated. There is information about the issues throughout this document. As you read, look for the key symbols that are associated with each issue subject area. These key symbols identify the important issue related discussions which describe interrelationships with other resource issues, effects, and the resolution of conflicts. Effective resolution of the issues is a goal of the Forest Plan. The lack of compatibility among the resource uses at all levels of output affects the degree of resolution possible for any one issue since it is necessary to find an approach that is responsive to all issues. Therefore some tradeoffs are necessary in each of the issues.

Dispersed Recreation

Overview - The Forest provides a wide range of outdoor recreation opportunities. The Forest provides several developed recreation sites (campgrounds, ski areas, boat launch ramps, etc.), but the primary recreation emphasis for the Forest Service is to manage for dispersed opportunities. "Dispersed recreation" is a term used to encompass all the outdoor recreation activities that occur on the Forest outside of developed sites, such as sightseeing, hiking, fishing and hunting, backcountry camping, and cross-country skiing.

The alternatives analyzed in this FEIS have the potential to affect dispersed recreational settings more than developed sites. Greater public concern has been expressed by users, recreation interests, timber industry, and environmental groups about the effects of management on dispersed recreation than developed, although the total amount of recreational visits (nearly 3 million RVDs per year) to the Forest is about equally divided between the two categories.

The challenge for dispersed recreation is to provide a range of opportunities and areas desired by forest recreationists and at the same time provide for other Forest uses, and products demanded by other segments of the public. Many recreation users would like more dispersed areas, or at least an alternative

to Wilderness. Some would prefer low elevation areas near population centers suitable for year around use. Many who are associated with the timber industry, feel that dispersed recreation should not preclude timber harvest.

Most areas of the Forest supply diverse types of dispersed recreation experiences. A facet of this issue is that some dispersed activities conflict with each other and may be completely incompatible. This conflict is exemplified most clearly between dispersed nonmotorized/motorized uses, such as hikers/trail bikers, and cross country skiers/snowmobilers. Some recreationists would prefer to see snowmobiles and ORVs limited to designated areas apart from other types of use.

An aspect of the dispersed recreation issue that became more apparent from public comment between the DEIS and FEIS, was the role of rivers and river corridors in meeting recreation needs. One result of the increased interest in rivers was the designation of 2 Scenic and Recreation Rivers (upper McKenzie and NF of MF of the Willamette) and 2 Study Rivers (SF McKenzie and Blue River) in the Oregon Omnibus Wild and Scenic River Act of 1988. In addition to these rivers, the Little North Fork of the Santiam River is part of the State Scenic Waterways system. Public comments on the DEIS about the potential recreation and scenic values of other rivers on the Forest prompted a review of other rivers Forest-wide to determine which ones were eligible for Wild and Scenic River designation.

The scope of this issue also includes access and proximity of dispersed recreation opportunities to population centers and points of entry to the Forest. Many users associated with local hiking organizations desire more trails for hiking and other uses that are accessible at low elevation near population centers.

The responsiveness of the alternatives to this issue can be evaluated by considering the demand met and the number of acres that will provide semiprimitive nonmotorized and motorized opportunities. The number of Special Interest Areas provided and miles of trail constructed also indicate response to this issue.

Interrelationships with Other Major Issues

Old Growth: Many people enjoy recreational visits to old-growth forest for wildlife and plant viewing, camping, and solitude. Although large expanses of old growth inhibit some types of dispersed recreation, such as off-road vehicle (ORV) driving and horseback riding, these issues are generally compatible. There would be some interdependence in the amount of old growth retained in the different alternatives to the amount and type of dispersed recreation opportunities that the Forest would be able to provide.

Roadless Lands: The Forest's unroaded areas provide a destination for people who wish to participate in nonmotorized recreation activities outside of Wilderness. They may be closer to populated areas, and receive less visitation than the well-known Wilderness attractions. They offer opportunities for solitude and primitive experiences. Most of the roadless areas remaining on the Willamette are of a terrain and vegetation type that is difficult to access and unsuited for ORV use. Motorized recreation opportunities are limited or nonexistent in roadless lands.

Scenic Quality: The beautiful scenery of the Forest is one of the major recreation attractions. Driving for pleasure, which includes sightseeing, is one of the most popular activities on the Forest. Hiking, camping, and cross-country skiing are enhanced by pleasant visual experiences. In river corridors, scenic qualities of the rivers and adjacent forests are intergral to the recreation values.

Timber Supply: The roads that were constructed for the harvest of timber are now also the Forest access roads that facilitate dispersed recreation. Future timber harvesting could increase access for additional motorized recreation. Timber harvest has some potential to disrupt some recreation

opportunities. For instance, a timber sale may be planned that includes part of an existing trail system. The disruption is generally temporary, as funds are collected under the Knutson-Vandenberg Act for trail and trailhead restoration or replacement. Also, the noise and visual effects from logging operations are unpleasant to some hikers and campers.

Water: Many dispersed recreation activities are water oriented, so water quantity and quality are important to forest users. Maintaining reservoir water levels at historic levels is important to boaters. The supply of clean, cold water for fish habitat is of interest to people who enjoy fishing. There is the potential for very minor impacts on water quality in areas from dispersed recreation activities; two possible impacts might be from inadequate sanitation and erosion from overused trails. The water quality of rivers designated or eligible for Wild and Scenic Rivers is often one of the outstandingly remarkable values that contribute to the recreation experience.

Wildlife, Fish, and Plant Habitat: Dispersed recreationists use areas that are habitat for native species. These uses may have some impact on individual plant and animals living in those areas. There is likely to be little change in the overall habitat as a result of dispersed recreation activities, however, some recreation occurs because of the existence of the diverse Forest habitats, therefore a major change in habitats could affect some types of dispersed recreation. For example, a large reduction in forage and/or thermal cover for big game could reduce hunting opportunities. Logging old growth could disrupt bird watching.

Old Growth

Overview - There is general agreement among wildlife, recreation, and timber interests that some representation of stands of old-growth trees should be retained, but a wide disparity of opinion exists about how much is needed. Current allocations that provide for the preservation of old-growth timber stands include: Wilderness, Research Natural Areas, Old-Growth Timber Groves, and Undeveloped Roadless Recreation areas. Under the current plan, approximately 594,800 acres qualify as old-growth using the definition in the Pacific Northwest Regional Guide (R6 definition). Of this total, approximately 99,300 acres in the current plan are in allocations not subject to future harvest.

Old-growth timber stands are of special ecological concern because they represent a successional stage which provides unique habitat for certain species of plants and wildlife and because of their contribution to the forest gene pool. Some of the Forest's small animal species such as the red tree vole, flying squirrel, and spotted owl are completely or partially dependent on the old-growth canopy as part of their primary habitat. Plant species which have difficulty surviving in other than old-growth forest include certain saprophytes, such as candy-stick and pine-drops, and Oregon's small orchids, such as coral-root and fairy slipper.

Many people using the Forest for recreational purposes enjoy old-growth trees for their aesthetic and spiritual value. They consider old-growth trees as adding to scenic vistas, and providing cool shade, quiet, solitude, and a sense of history of the Forest. Old-growth stands are currently a significant component of both developed and dispersed outdoor recreation settings.

Conflicts arise because the existing old-growth stands contain large volumes of high quality timber which the forest industry in many cases would rather see made available for harvest. There are approximately 495,500 acres of old growth on suitable land which contain about 28 billion board feet of timber that could be available for harvest during the coming decades. Historically, the harvesting of mature Douglas-fir has been the backbone of the timber industry in the Pacific Northwest. Since there is still high demand for timber production from the Forest, the issue then becomes a question of how much old growth, which is not protected under preservation allocations such as Wilderness, should be

retained for recreational, aesthetic, spiritual, or habitat purposes and how much should be allocated for timber harvest.

Comments on the DEIS and activities during the development of the FEIS and Forest Plan indicate an intensification of public interest in the old growth issue. In addition to conflicts over the competing uses of this resource, comments on the DEIS also pointed to the lack of a consistent definition or agreement on what physical attributes of forest stands or criteria should be used to identify old growth. Since the DEIS there has also been increased attention to the specific physical characteristics of old growth and how these might be duplicated in managed stands. "New Forestry" or "New Perspectives in Forestry" are some of the terms that have recently evolved to describe a combination of silvicultural practices and harvest unit location considerations that are designed to maintain some of the ecological functions of old-growth stands throughout a timber rotation.

The responsiveness of the Alternatives to this issue can be evaluated by considering the acres of existing old growth retained on the Forest.

Interrelationships with Other Major Issues

Dispersed Recreation: Building additional roads as part of the harvesting of old-growth stands could increase access to different parts of the Forest, although leaving old-growth stands intact may provide destination points for people who participate in nonmotorized recreation. Stands of old growth provide scenic beauty to both motor and nonmotor recreationists. They provide solitude and quiet to those who walk into them.

Roadless Lands: The most extensive stands of old-growth timber that are outside of Wilderness are located in those parts of the Forest that have not been roaded for timber harvest. There is a strong correlation between these two issues and their resolution.

Scenic Quality: For many people, the appearance of the interrelationship of large trees, fallen trees, light and shadow, smaller plants and ground cover provide intrinsic scenic value. Stretches of old growth may also be attractive when viewed from a distance and add an appearance of texture to the overall scenic appearance of the Forest landscape. At some locations on the Forest, views of distant mountains and lakes may be obscured from travelways by stands of mature trees.

Timber Supply: The timber harvest program directly affects the amount of old growth which remains outside Wilderness and in other preservation type land allocations. With the demand to maintain or increase timber harvest levels, the demand to harvest old growth and to replace old-growth stands with faster growing second growth is likely to increase as well. Conversely, meeting the strong interest in retaining old growth for its scenic and wildlife values could lead to a reduction in allowable timber harvest. The issue of managing forest stands to retain certain structural components of old growth within managed forests, has introduced a potential means of addressing conflicts between timber supply and the ecological functions, and the wildlife habitat benefits of old growth. Values such as scenic quality, recreation and spiritual solitude would still be directly affected by New Perspectives Forestry, however.

Water: Old-growth stands provide high quality water due to the lack of disruptive activities and the filtering and stabilizing effects of the vegetative matter in the overstory and understory. Retaining old growth would have the effect of maintaining the status quo of water quantity (amount of runoff) and quality (no increase in sediment or water temperature) within the affected watershed. Harvesting old growth would have some short term potential for small amounts of change in the water draining from

the harvest area, though harvest impacts would be regulated in a manner to bring the water quality within limits allowed by Oregon Water Quality standards.

Wildlife, Fish, and Plant Habitat: Retaining the old growth will provide habitat for species dependent upon mature or older forest conditions. Old-growth areas contribute large material to streams and the forest floor which is unique to old-growth character forests. Old-growth areas also provide hiding and thermal cover for big game. "New Perspectives" or "New Forestry" concepts may also provide opportuntities to maintain critical habitat components of old-growth forests within a managed landscape.

Roadless Lands

Overview - Prior to the Oregon Wilderness Act of 1984, 294,775 acres of unroaded lands on the Forest were inventoried. As a result of that Act, 78,872 acres received Wilderness classification and 6,122 acres were included in the Oregon Cascades Recreation Area. There are now 380,805 acres of designated Wilderness within the Forest boundary, or roughly one-quarter of the National Forest System land on the Willamette. One area, the Mt. Hagan, 6,036 acres, qualified for further study as proposed Wilderness subsequent to the Oregon Wilderness Act of 1984. (See Chapter III, Section Q, Roadless Lands.)

The 209,845 acres remaining in an undeveloped condition were released to be planned for multiple use management, and the thrust of this issue is which of these areas should remain roadless. The issue surrounding roadless lands is focused on their use for amenity versus commodity values. Many members of the public, including recreationists, conservationists, and environmentalists prefer maintaining more undeveloped land for dispersed recreation use, wildlife habitats, preservation of natural ecosystems, and protection of soil mantles, water quality, and fisheries. Frequently, comments stressed that roadless lands are irreplaceable. Many people expressing concern for jobs, the area's economy, and the need for an adequate supply of wood products, also suggested that there is no need to preserve more roadless land, and that existing Wilderness should be better utilized.

Retaining the unroaded character of these areas provides options for semiprimitive nonmotorized recreation opportunities and possible future inclusion in the National Wilderness Preservation system. Future development options are not foreclosed by leaving these areas roadless during this planning period. Other benefits of maintaining the current character include preservation of the existing wildlife and plant habitat, opportunities for scientific research, and protection of cultural resources.

Allocating areas for roadless recreation limits the capability of these areas to produce some other benefits. Recreationists who rely on roads for access will not be served by these areas. Lack of immediate access hinders resource management activities and general administration as well as adding to the difficulty of controlling wildfires. This limitation may result in decreased economic returns from the Forest.

Road systems developed for timber management result in increased access to existing roadless areas, many of which are adjacent to Wilderness. Increased access could change visitor use patterns in Wilderness. The potential to view and hear timber management activities from the Wilderness could also increase, thereby reducing the quality of the overall Wilderness experience.

The responsiveness of the Alternatives to this issue can be evaluated by considering the acreage allocated to nondevelopment management areas.

Interrelationships with Other Major Issues

Dispersed Recreation: Retaining lands in an unroaded condition limits the ability of the Forest to provide some types of motorized recreation opportunities. Roadless areas provide primarily nonmotorized

recreation, and may decrease pressure for overuse in Wilderness by people looking for primitive experiences.

Old growth: Much of the acreage in the inventoried roadless areas is in an old-growth stand condition; therefore, retaining an undeveloped character in these lands would also preserve old-growth timber.

Scenic Quality: Retention of roadless lands would maintain some unbroken forest expanses which may be seen from overlooks and some distant travel corridors. It would also protect the scenic qualities of the existing vegetation type. There may be locations on the Forest where the development of an unroaded area may produce scenic vistas of mountains, lakes, rock formations, waterfalls, or other scenic attractions.

Timber Supply: If timber is held back from harvest, the pressure to cut in other areas of the Forest increases. Removing the timber in the inventoried roadless lands from the allowable harvest could reduce the potential for the Forest to meet local and national production needs and to support local economies.

Water: Retaining all current roadless areas in an unroaded condition would have little or no effect on water quality or quantity. Transpiration, run-off and sediment rates would remain the same if no development occurs. Development of the roadless areas may result in small amounts of change in water quantity; because of the implementation of protection measures directed by legislation and standards and guidelines, effects on water quality would be within the levels allowed by Oregon Water Quality standards.

Wildlife, Fish and Plant Habitat: Roadless areas provide wildlife habitat by having high snag levels, old-growth habitat, undisturbed riparian areas, and thermal cover. They provide potential sanctuary for sensitive or rare plant and animal species which are dependent on the natural undeveloped forest environment. Unroaded old-growth forest provides less forage for big-game animals than harvested areas, and provides little habitat for species that prefer vegetation in the early seral stages.

Scenic Quality

Overview - The scenic quality of the Forest has been identified as an important dimension of the use of the Forest by recreationists, travelers, and nearby residents. As more people are living near the Forest and visiting for recreational activities, public interest in and values expressed about the appearance of the Forest landscape has increased. Providing for other uses of the Forest, such as timber harvest and utility corridors, may affect the scenic quality of viewsheds which are visible from travelways, homesites, and recreation sites.

The high recreational values of the Forest are directly linked to its beautiful scenery. Resource management activities, including road construction and logging, can open up scenic vistas and routes to natural attractions.

Some segments of the public, and many who recreate in the Forest or are engaged in recreation related or dependent businesses prefer use of methods, throughout the Forest, to maintain scenic resources that are as natural as possible. Most who are concerned about scenic quality want impacts to the scenic resource minimized within road corridors and would like scenic resources maintained in areas of high recreational use. Many members of the public who could be affected by a declining harvest or are associated with the wood products industry feel that scenic quality should not be emphasized to the extent of great cost or the curtailment of timber production; management activities should not be

hidden from public view to meet aesthetic requirements; and that maintaining scenic values should not significantly reduce other resource ouputs or programs.

The responsiveness of the Alternatives to this issue can be evaluated by the acreage allocated to Visual Quality Objective prescriptions.

Interrelationships with Other Major Issues

Dispersed Recreation: Some dispersed recreation activities, (driving for pleasure, photography), are directly related to scenic quality, while others, like hunting, are less dependent on the visual appearance of the Forest. Hikers and campers are generally interested in visually pleasing surroundings. A major change in the observed landscape could change the focus or location of dispersed recreationists, but would not be expected to cause a decrease in Forest visitation.

Old Growth: For the people who prefer to view an unbroken forest canopy, seeing old growth is pleasant. Others may feel that it is dark and foreboding, or that it is blocking distant scenic vistas. Large, individual trees that are characteristic of old growth, are attractive and aesthetically pleasing in many forest settings such as along major travelways, trails and campgrounds. Generally, old growth adds to the overall beauty of the Forest landscape.

Roadless Lands: Access to some scenic attractions in unroaded areas may be restricted by the lack of roads. From scenic overlooks, roadless areas contribute to the appearance of the overall panorama of the Forest.

Timber Supply: Management for the production of wood products has the greatest potential for affecting scenic quality. The road construction and logging that are part of timber harvest change the appearance of the viewshed. In many cases, the most drastic changes of forested to nonforested land is short-term as regenerated stands restore a forested appearance with a few years. Other changes such as height of trees or texture of the canopy between young stands and old growth have longer term effects on visual appearance. Some people who are concerned about possible reductions in timber supply feel that visual concerns should receive less consideration than management for timber production.

Water: Viewing bodies of water as part of the recreational setting on the Forest adds to a pleasant visual experience. A serious degradation of water quality could decrease scenic quality. These two issues are generally compatible.

Wildlife, Fish, and Plant Habitat: There is little conflict between these two issues. Maintaining a variety of scenic landscapes could add to meeting the need for providing a diversity of habitats. The opportunity for viewing wildlife and plants adds to the scenic attraction of the Forest for recreation visitors.

Timber Supply

Overview - The amount of timber harvested each year from the Forest is important nationally as well as regionally. The average annual amount of timber sold, since 1977, has been 778 MMBF (all volume), while the amount harvested has been 672 MMBF. The Allowable Sale Quantity (ASQ) under the current plan (approved in 1977) is about 800 MMBF. This supply of timber supports approximately 16,500 primary and secondary jobs in the Upper Willamette Basin. Millions of dollars circulate through the Federal Treasury, several Oregon counties, and local businesses, that are directly related to Forest timber. Because of its economic significance, the continuation of the flow of this timber supply is of

high interest to the public. There is a detailed discussion of the economic contributions of, and demands for, timber harvest in Chapter III, Social and Economic Environment, and Timber.

Legislation passed by Congress mandates that forests capable of producing commercial timber do so. The amount produced from each forest, however, is determined by the capability of the forest itself. The amount of wood that can be offered for sale each year is based on the amount of land suitable for timber harvest, the amount of volume that the land is physically capable of producing, the other resource uses of the Forest and the intensity of timber management activities.

The instances in which timber harvest may have a perceived negative effect on other resources cause this management activity to be a public issue. The major focus of this issue is the level of timber harvest to be provided during the plan period and in later decades. At the core of the issue is the conflict between harvest levels and the preservation of old-growth timber stands, roadless areas, and wildlife habitats and the maintenance of scenic quality.

Many members of the timber industry feel that measures should be taken to increase timber production and minimize the emphasis on other resources. Some members of this group feel that management of timber resources should be the primary use of the Forest. Many members of conservation and environmental groups believe that there is too much timber harvesting, especially of old-growth timber. They feel that much of the old growth should be preserved, even to the point of encouraging builders to seek alternatives to wood for building materials. Many recreation and Wilderness advocates believe that roadless lands should be maintained in their undeveloped condition as they are irreplaceable. Most wildlife interest groups feel that heavy timber harvest will be harmful to some wildlife, particularly old-growth dependent species such as the spotted owl. Many recreationists would like areas within travel corridors and around recreation sites and areas to remain natural appearing and prefer that the visible effects of timber harvest should be minimized.

Current inventory data and accurately modeling the production capabilities of the Forest are key aspects of the timber supply issue emphasized in public comments on the DEIS. Since laws and regulations concerning Forest Plans are explicit about how allowable harvest levels and the resulting timber supply are determined, there is a high level of concern that the best available information on inventory and production capabilities be used.

The responsiveness of the Alternatives to this issue can be evaluated by considering the Allowable Sale Quantity (net), the Timber Sale Program Quantity (gross), and the number of cords of firewood provided.

Interrelationships with Other Major Issues

Dispersed Recreation: Timber management can be compatible with motorized dispersed recreation, because roads are constructed and maintained to support harvest activities, increasing access to different areas on the Forest. It may be considered in conflict with nonmotorized recreation by some Forest users because of noise, increased traffic occurrence, and a reduction in specific types of recreation opportunities.

Old Growth: Large old-growth Douglas-fir has been a major component of the timber supply from the Forest. Many local mills are tooled for manufacturing wood products from this type of timber. The remaining old-growth forests could contribute a significant quantity toward the Forest's harvest. Harvesting the old growth would reduce habitat for several wildlife and plant species, and reduce some scenic and recreation values associated with that plant community type.

Roadless Lands: Roads constructed in unroaded areas to access timber for harvest and administration purposes would change the roadless character. Timber harvested by aerial logging methods will alter the appearance of the unroaded area. Both of these activities would reduce the potential for future Wilderness designation. Leaving the roadless lands out of the landbase of the allowable timber harvest could reduce the amount of timber supplied from the Forest for wood products.

Scenic Quality: The scenic character of the Forest landscape is changed by road construction and timber harvest. Access to scenic views may be created through harvest activities. Harvest units may be evident from travel corridors, overlook points, and areas of recreational use.

Water: Water quality and quantity can be greatly affected by resource development activities. Consequently, timber harvesting is carried out under regulations, and standards and guidelines for protection. The alternative management strategies considered in this FEIS all provide at least the minimum legally required protection. There may be some variation in water yield and quality related to the amount of timber harvest allowed.

Wildlife, Fish, and Plant Habitat: Big game forage habitat can be improved through the creation of openings in closed stands of timber. The removal of extensive areas of the Forest canopy can reduce thermal cover which big-game animals need for protection. The vegetation manipulation which occurs during timber harvest changes the character of the habitat environment for different species of animals and plants. Habitat quantity and quality may be increased for some species, and decreased for others. Under the Knutson-Vandenberg Act, funds collected from timber sales may be used for projects to improve fish and wildlife habitat.

Water

Overview - The purity and abundance of the water which flows through the Forest is important to other forest resources, to the people who reside in Oregon, and to those who visit the Forest. The water is used for domestic water supplies, irrigation, fishery habitat and fish hatcheries, power generation, and a wide variety of recreation activities. The issue of water quality is primarily focused on long-term effects of suspended sediments (turbidity) and temperature of fisheries habitats resulting mainly from the rate and distribution of timber harvest activities and road construction. Some public attention has also been directed at the possible introduction of chemicals and bacterial contamination into Forest waters. Some domestic water-supply users and many fish and wildlife habitat interests believe that harvest activities adjacent to lakes, rivers, and streams may have adverse effects on water quality. Some from these interest groups feel that new road and trail access to lakes should be prohibited. Many timber industry members feel that current standards governing harvest in riparian zones are adequate for protection of water quality and riparian habitats. They also feel that additional constraints will increase costs, reduce harvest volumes, and ultimately reduce employment levels. Some members of the general public would like to see an end to the use of chemicals to enhance tree growth and control competing vegetation because of potential health hazards, from the risk of contaminating Forest lakes, rivers, and streams. Others feel that the use of chemicals is essential in maintaining annual harvest volumes.

The responsiveness of the Alternatives to this issue can be evaluated by considering the "Adverse Watershed Impact" Ratings and amount of erosion.

Interrelationships with Other Major Issues

Dispersed Recreation: Some dispersed recreation activities may adversely affect water: overuse of trails next to streams could increase sediment in the streams; increased hiking by people and dogs

increases the possibility of the spread of bacterial contaminants such as *giardia lamblia*; overuse of off-road vehicles can cause soil loss and erosion. Water supports many types of dispersed recreation, such as fishing and boating, and adds to the enjoyment of others, such as camping and sightseeing.

Old Growth: The abundant rainfall in the Cascades is a major factor in the existence of large old-growth Douglas-fir and Western red cedar trees. Old-growth stands provide high quality water by preventing erosion and providing thermal cover for temperature stability.

Roadless Lands: These two issues are compatible; the existence of unroaded areas has no adverse effect on the water resource.

Scenic Quality: Water is a major component of the Forest's scenery. The lush vegetation is due to the amount of precipitation. Water features such as rivers and lakes are viewed by most people as positive visual experiences. Management activities designed to enhance scenic quality would generally also be compatible with watershed protection.

Timber Supply: Harvesting trees and the road-building that may accompany logging operations are the resource management activities that have the greatest potential for impacting water quality. There may be a greater amount of water runoff from lands where large vegetation has been removed, as well as increases in sedimentation and water temperature.

Wildlife, Fish, and Plant Habitat: Protection of the water quality and quantity is vital to the protection of habitats for native and desireable nonnative species. The water conditions of the Forest contribute to the diversity and richness of wildlife and plant habitats. The standards which are followed to measure water quality and quantity are designed to avoid adversely affecting aquatic species.

Wildlife, Fish, and Plant Habitat

Overview - The Forest is home to a diverse array of wildlife, fish, and plant species and provides reproductive habitat for over 170 avian breeding species, 64 mammalian species, 30 amphibian and reptilian species and numerous sensitive plant species. Depending on the amount and condition of available habitats, species populations will fluctuate over time. The relationship of these species to their habitat is complex and not every detail is completely known or thoroughly understood. However, biologists do know that the success of a species to inhabit a given environment is dependent on several factors to meet basic survival and reproductive requirements. One such significant factor is the amount extent, condition, and quality of species supporting habitat.

The wildlife, fish, and plants issue is centered on the conflict between timber harvest and providing sufficient habitat, with the desired attributes of extent, condition, and quality, to ensure sustained viable populations of native species.

Most who favor protection of wildlife, fish, and plant habitats believe that timber harvest levels are too high to sustain current habitats for a diverse range of species. Many members of these wildlife interest groups feel that diverse habitats should be provided but that species emphasis should be placed on preservation of habitats of old-growth dependent species. Some from these interest groups also feel that timber harvest is important for big-game species but that connected and undisturbed corridors should be left for old-growth dependent species.

Many members of the public associated with the timber industry feel that Wilderness and other "set-aside" areas provide adequate habitat for old-growth dependent species, such as the spotted owl. They feel that wildlife habitats are enhanced by timber harvest and that sustained yield timber management

will provide habitat adequate to meet wildlife needs. Many others associated with the timber industry feel that timber harvesting is a vital part of the multiple use concept and it should not be excluded to provide for wildlife, fish, and plant habitats and that over-dedication for nonharvest uses could lead to an economic decline.

The responsiveness of the Alternatives to this issue can be evaluated by considering the habitat provided for certain indicator species.

Interrelationships with Other Major Issues

Dispersed Recreation: One of the major components of dispersed recreation is related to enjoyment of fish and wildlife and plants. Many outdoor recreation trips include photography, viewing, fishing, and hunting. Forest visitors may adversely affect some native and desireable nonnative populations by picking rare plants, disturbing nesting sites, or poaching. Managing to provide diverse habitats will generally enhance dispersed recreation opportunities.

Old Growth: This mature forest type provides habitat for many small species of birds and animals and plants that do not thrive in other habitats. It also provides thermal cover for protection of big-game animals. Riparian areas associated with old growth provide high quality habitat for native species; large, stable logs down in streams form pools where fish can live and hide. These two issues are strongly interrelated and are compatible.

Roadless Lands: The remaining unroaded areas on the Forest add to the diversity of habitats of the current condition. They support populations which are dependent on old growth and provide hiding cover for big game.

Scenic Quality: The diversity of habitats on the Forest is part of the varied landscape which gives the Forest much of its visual appeal--from the low elevation old growth, to lush meadows, to the alpine regions.

Timber Supply: Total populations of big game have increased since the last century, as timber harvest has created openings for forage for elk and deer. However these animals also need thermal cover, which exists under a closed forest canopy. Since previous harvest activity has reduced the amount of old-growth forests on the Forest, managing to maintain viable populations of all wildlife, fish, and plant species may cause a reduction in the available timber supply in the future.

Water: The amount of clean, clear water available is a critical part of the range of habitats that exist on the Forest. Abundant rainfall and an extensive stream system support many species of plants and fish. Protection of this resource is as important to the native species as it is to the people who now inhabit the region.

CHAPTER II

ALTERNATIVES INCLUDING THE PROPOSED ACTION

INTRODUCTION

This chapter summarizes the content of the Final Environmental Impact Statement (FEIS). It covers the changes made in the alternatives and their analysis in response to public comments on the Draft Environmental Impact Statement (DEIS), describes the process used to develop a full range of alternatives for the FEIS, describes the goals and management objectives of each alternative, and compares the physical, biological, social, and economic outputs and effects of the alternatives considered in detail.

Chapter II focuses on alternatives and is linked directly to other parts of the FEIS. Alternatives were developed in response to the issues described in Chapter I and Appendix A. Chapter III discusses the environment which would be affected by management of the Forest in the alternatives. Chapter IV discusses the consequences of alternatives on the environmental components in detail. These consequences are represented in part by the outputs and effects presented in Chapter II. The analysis tools and processes summarized here are presented in detail in Appendix B, Description of the Analysis Process.

This FEIS presents in detail seven different alternatives for managing the lands and resources of the Forest. These alternatives explore a variety of ways of responding to the issues identified during the planning process. Each alternative represents a unique combination of land allocations, management prescriptions, activity scheduling, and results in different mixes of goods and services, land uses, and environmental effects result.

The planning regulations (36 CFR 219.12(e) and (f)) require an analytical process which includes an evaluation of various minimum and maximum resource and economic production levels. In addition, a wide range and relatively even distribution of alternatives must be developed to respond to issues and to reflect national goals such as the Resources Planning Act (RPA) program.

In some alternatives the Forest would be managed to emphasize the production of commodities with a market price. Other alternatives would emphasize resources that do not have a market price, such as dispersed recreation, wildlife, and scenery. One alternative, the No Change Alternative, reflects current management direction projected into the future. Another alternative, the No Action Alternative, reflects current management direction projected into the future including NFMA requirements. Two alternatives were developed in response to requests from public interest groups. One alternative was developed in response to public comments on the DEIS.

This broad range of alternatives provides the Regional Forester with the information needed to identify the alternative which comes nearest to maximizing net benefits to the public.

The basis for developing alternatives is outlined in the implementing regulations of the National Environmental Policy Act (NEPA) and the National Forest Management Act (NFMA). NEPA regulations (40 CFR 1502.14) direct agencies to:

- Rigorously explore and objectively evaluate all reasonable alternatives; and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated.
- Devote substantial treatment to each alternative considered in detail, including the Proposed Action, so that reviewers may evaluate their comparative merits.
- Include reasonable alternatives not within the jurisdiction of the lead agency.
- Include a No Action alternative.
- Identify the agency's Preferred Alternative (PA) as the Proposed Action.
- Include appropriate mitigation measures not already included in the Proposed Action or other alternatives.

The implementing regulations (36 CFR 219.12(f)) for the National Forest Management Act (NFMA) contain the following requirements for alternative formulation:

- Alternatives shall be distributed between the minimum resource potential and the maximum resource potential to reflect to the extent practicable the full range of major commodity and environmental resource uses and values that could be produced from the Forest. Alternatives shall reflect a range of resource outputs and expenditure levels; however, potential budgetary limitations do not constrain resource outputs.
- Alternatives shall be formulated to facilitate analysis of opportunity costs and of resource uses and environmental trade-offs among alternatives and between benchmarks and alternatives.
- Alternatives shall be formulated to facilitate evaluation of the effects on present net value (PNV), benefits, and costs of achieving various outputs and values that are not assigned monetary values are provided at specified levels.
- Alternatives shall provide different ways to address and respond to the major public issues, management concerns, and resource opportunities identified during the planning process.
- Reasonable alternatives which may require a change in existing law or policy to implement shall be formulated (if necessary) to address a major public issue, management concern, or resource opportunity identified during the planning process (40 CFR 1501.7, 1502.14(c)).
- At least one alternative shall be developed which responds to and incorporates the RPA Program tentative resource objectives for each Forest displayed in the Regional Guide.
- At least one alternative shall reflect the current level of goods and services provided by the unit and the most likely amount of goods and services expected to be provided in the future if current management direction continues. Pursuant to NEPA procedures this alternative shall be deemed the No Action Alternative.

- Each alternative shall represent to the extent practicable the most cost-efficient combination of management prescriptions examined that can meet the objectives established in the alternative.

- Each alternative shall state at least the condition and uses that will result from long-term application of the alternative, the goods and services to be produced, the timing and flow of these resource outputs together with associated costs and benefits, the resource management standards and guidelines (S&Gs), and the purposes of the management direction proposed.

Alternatives were developed with varying levels of supply potential for the high level of demand for most resources found on the Willamette National Forest (WNF). The ability of the Forest to respond to the levels of demand for the resources was determined through benchmark analysis of key resources. These benchmark analyses identified the range of supply potential possible for both priced and nonpriced resources. Priced resources are those which have a quantified market price, while nonpriced resources are those which are not exchanged through the marketplace. The comparison of alternatives in the latter section of this chapter shows the ability of the alternative to meet identified demand levels.

The planning regulations and agency direction emphasize the use of economic efficiency criteria in the major analytical phases of the planning process. The development of management prescriptions, analysis of benchmarks, management constraints, and alternatives are steps which focus on cost-efficiency and the calculation of economic and resource trade-offs.

CHANGES BETWEEN DRAFT AND FINAL

The DEIS and Proposed Forest Plan documents were available for public review for approximately 5 months (January to May, 1988). The public review process and comments received during the review period are described in the FEIS Chapter I, Appendix A, and Appendix I. After the public comment period had closed and the comments had been reviewed, the Forest interdisciplinary team (IDT) explored ways to respond to the concerns of the public. (A complete discussion of content analysis and Forest responses to substantive comments are in Appendix I.)

Many of the comments suggest:

- Alternatives be modified;
- Alternatives be developed or evaluated that were not given serious consideration in the DEIS;
- Analyses presented in the DEIS be supplemented, modified, or improved;
- Factual corrections be made in information or data used in the analyses.

After reviewing these comments, the IDT and Forest management team agreed on changes that should be made in the FEIS. In some cases, the changes involved analysis methods and data common to all of the alternatives. Other changes involved considering alternatives not analyzed in the DEIS while dropping others that had been analyzed. The new alternatives were developed based on the public response to specific issues and the proposed resolution of these issues displayed in the DEIS. The new alternatives propose different land allocations, management prescriptions, and S&Gs from the set of alternatives analyzed in the DEIS as means of resolving issues.

The IDT updated or reanalyzed all of the alternatives considered in the FEIS. As a result, a new Preferred Alternative (PA) was identified: Alternative W. The Forest Plan was revised to reflect the proposed changes between Alternative J, the PA in the DEIS, and Alternative W. The Plan and the FEIS were submitted to the Regional Forester for review.

Following is a summary of revisions made between the DEIS and FEIS to respond to concerns raised during the public comment period.

Alternatives

- Alternatives B and J-Departure were dropped from the set of alternatives considered in detail. Both proposed a timber sale schedule that departed from long-term sustained yield capacity. Public responses were largely indifferent to the departure alternatives as a means of addressing the timber supply issue. Concerns were raised, however, about the environmental effects associated with the departure alternatives. Environmental effects of the departure alternatives were generally the most adverse of the range of alternatives considered in the DEIS (see Chapter IV, DEIS).
- Alternatives C and I were also dropped as alternatives considered in detail in the FEIS. While there was a moderate amount of favorable public comments on both of these alternatives, other alternatives were proposed and considered in the FEIS that address similar goals and objectives.

- Alternative K was added in response to public comments. Many individuals, as well as timber industry organizations, expressed a desire for an alternative that would maintain the timber harvest near the level in the current plan (1977). Although similar to Alternative I in the DEIS in some respects, differences in specific resource goals and objectives led to developing Alternative K. The Willamette Forestry Council (WFC) played a major role in advising on the development of Alternative K.

- Alternative L was also added in response to public comments that noncommodity uses of the Forest were not adequately represented in the alternatives in the DEIS. Many people were concerned that an alternative proposed by the Oregon Natural Resources Council (ONRC) for the DEIS was not fully analyzed. Alternative L was developed with suggestions from ONRC and affiliated groups.

- Alternative W (PA) was added to the set of alternatives largely in response to comments on Alternative J, the PA in the DEIS. Although the initial thought was to modify Alterative J in response to the criticism, it became apparent that the significance of the changes in specific resource practices as well as overall goals and objectives were as great as the differences between some of the alternatives considered in the DEIS. A new alternative was developed to help the public see and understand the differences.

Modeling and Technical Changes Common to All Alternatives

General

- The FORPLAN model used for DEIS analyses was a Forest-wide model in which similar lands were aggregated across the entire Forest. Reviewers of the DEIS commented that the Forest-wide analysis was not adequate to address critical issues such as water quality. In response to these concerns, a watershed specific FORPLAN model was developed and used in the analysis of alternatives in the FEIS. The revised FEIS model identified 33 major watersheds as the base geographical unit for aggregating similar lands.

- Because of the change in the model design, the way in which many of the resource prescriptions and requirements are modeled were also modified. Refer to Appendix B, *Description of the Analysis Process* for more details on these adjustments. Changes in the management direction or intent of the prescriptions are noted in the following pages.

Timber

- The timber inventory condition classes were updated for the acres of forest harvested or planned to be sold through September 1989. The acres of seedling and sapling stands destroyed in the Shady Beach Fire in September 1988 were also modified in the inventory to reflect the current condition.

- The starting timber yield tables were adjusted to show the expected volume per acre in 1994, approximately the midpoint of the planning period.

- The breakage and defect factors used to determine net volume in the timber yield tables were revised to better reflect the differences between stands of old, large trees and younger, smaller trees. In the DEIS a Forest-wide average for defect and breakage was applied to all condition classes regardless of size and age.

- Young stands in the Douglas-fir/western hemlock inventory component (the predominate timber component by acreage) between the age of 0-40 were stratified into four, 10-year age groups. In the DEIS these stands were combined into 2 groups.

- Old growth and large sawtimber condition classes were treated separately in the FORPLAN model rather than as a single group as was the case in the modeling for the DEIS.

- A prescription for a single application of fertilizer is available for all suitable acres that are predominately Douglas-fir. A maximum of approximately 450,000 acres additional acres were available for fertilization depending on lands available for timber management by alternative. In the DEIS fertilizer availability was limited to soil types that had been tested and shown positive results. A clarification of the Regional policy expanded the availability based on observed results over many soil types in Western Oregon.

- A standard was added to all alternatives that required directional felling of all large sawtimber and old-growth stands on slopes over 30% during harvest operations. This requirement was estimated to reduce volume lost to breakage by approximately 2% in large sawtimber and old-growth stands. The gain in net volume was included in the empirical yield tables.

- A prescription that allows a single, heavy commercial thinning entry as compared to two, lighter entries, was added to the set of prescriptions available in FORPLAN.

- Merchantable sawtimber volume from recent mortality in the empirical yield tables was included in the ASQ projections. This volume was not included in the empirical yield projections in the DEIS. Deductions for wildlife trees have been taken into account in determining this volume.

- The Pacific Northwest Region's *FEIS for Managing Competing and Unwanted Vegetation* was released after the Forest DEIS. Changes were made to management direction to be consistent with the guidelines presented in the FEIS and the intent of the mediated agreement.

Economics

- Timber values were updated to include the average value of stumpage harvested between 1977 and 1988.

- Costs used to determine the Forest budget by alternative were recalculated using the latest unit costs and were organized under the current accounting system.

Old Growth

- The mature and overmature survey (MOMS) of vegetation has been used to calculate acres of old-growth forests for display and analysis in the FEIS. The MOMS inventory utilizes photo-interpreted stand variables such as species, size, density, and stand structure to determine acres of old growth by various criteria. The timber inventory condition classes were used to estimate acres of old growth in the DEIS.

Wildlife

- The size and distribution of Spotted Owl Habitat Areas (SOHAs) were remapped to comply with S&Gs (S&Gs) selected in the Record of Decision for the *Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide, December 1988*. There are 59 SOHAs in the FEIS compared to 62 in the DEIS. The size of individual SOHAs increased from 1,000 to 1,500 acres. The tentatively suitable acres within SOHAs in the FEIS is 62,000 as compared to 46,400 in the DEIS.

- Mapping of the mature conifer habitat managed for wildlife species such as the pileated woodpecker and the marten was adjusted to account for the new distribution of SOHAs. The tentatively suitable acres in the management requirement network for these species in the FEIS is 19,133 as compared to 8,720 in the DEIS.

- Mapping of the mature conifer habitat for species represented by marten as the indicator species was extended to all elevations on the Forest. In the DEIS habitat was not identified and mapped at elevations below 4,000 feet on the southern end of the Forest.

- Big-game evaluations in the FEIS used *A Model to Evaluate Elk Habitat in Western Oregon*. This model incorporates the factors of cover, forage, and animal security to evaluate how well overall habitat conditions meet animal needs.

- Modeling of wildlife trees needed to provide habitat for primary cavity excavators was changed to ensure the management requirement level could be met in each individual stand and at the subdrainage level. Some alternatives have objectives higher than the management requirement. Timber volumes per acre were reduced by about 2 to 10% to reflect the number of trees necessary to provide the management requirement or habitat objectives of each alternative.

Soil and Water

- A data base error in interpreting unsuitable soils in the Soil Resource Inventory reduced the tentatively suited acres in the DEIS by 29,400. The error was corrected and the acres added to the tentatively suitable acres.

- Approximately 11,000 acres were removed from the tentatively suitable land base to meet the management requirements for riparian areas. The prescription for the management requirement level in the DEIS identified 21.5% of riparian acres for removal from the tentatively suited acres. In the DEIS these acres were assumed to occur only on other areas withdrawn from the suitable acres. After a reevaluation of original riparian inventory results, it was revealed that removing 21.5% of the acres evenly distributed across all riparian areas provided a more accurate model representation.

- As a result of public input and management concerns over watershed management and water quality, current practices (Best Management Practices, (BMPs)) designed to protect and enhance water quality are highlighted in the Forest-wide S&Gs in the Forest Plan, in FEIS Chapter IV, and in FEIS Appendix H. This appendix has been included as mitigation common to all alternatives, and as a response to input to the DEIS.

Rivers

- In October 1988, the Oregon Omnibus Rivers Act designated the North Fork of the Middle Fork of the Willamette and the Upper McKenzie rivers as Federal Wild and Scenic Rivers. Prescriptions for either Recreation or Scenic classifications are applied to these river segments in all alternatives.

- The Omnibus Rivers Act also directed that the South Fork of the McKenzie River and Blue River be studied for potential classification and eligibility as Wild and Scenic Rivers. Constraints applied in all alternatives protect the resource values of these rivers and along a 1/4-mile corridor on each side.

- Based on input to the DEIS, a Forest interdisciplinary river review team has evaluated 13 rivers across the Forest for eligibility under the Federal Wild and Scenic Rivers Act. As a result of this review, 10 rivers were identified as being eligible. Prescriptions that protect the outstanding resource values of elgible rivers and the 1/4-mile corridor on each side have been modeled in all alternatives.

Management Areas (MA)

- SOHAs and designated mature conifer habitat for pileated woodpecker and marten indicator species have been identified as individual MAs. In the DEIS these areas of reserved habitat were tracked in the mapping system but were not identified as MAs with individual prescriptions.

- An evaluation of certain prescriptions indicated similar management objectives and S&Gs that could be combined to simplify mapping and reduce repetition in the S&Gs. Consequently, the following MAs in the DEIS have been collapsed into single MAs in the FEIS: MA 4a and 4b, Research Natural Area; MA 5a and 5b, Special Interest Areas; MA 7a and 7b, Old-Growth Groves; MA 12a, b and c, Developed Recreation Areas; and MA 9a and b, Special Wildlife Habitats.

- Wild and Scenic Rivers MA 6 was expanded to MA 6a, Wild Rivers; MA 6b, Scenic Rivers; and MA 6c, Recreation Rivers to provide direction necessary to model designated and eligible rivers under the Federal Wild and Scenic Rivers Act.

- To better reflect management direction for the Hardesty Mountain area on the southwest side of the Forest, the following MAs were added in the FEIS: MA 5b, Hardesty Mountain Ecological Area; and MA 14b, General Forest-Deferred.

- MA 10f, Dispersed Recreation-Lakeside Zones was added. Many of the land allocations in this MAs were in MA 9c and d, Special Lakeside Habitats-Enhancement/Protection, in the DEIS. Since the management direction and objectives in MA 10f are similar to Draft MA 9c and d, these areas were included in the Final MA 10f.

- MA 15, Riparian Areas, was added. The prescription for this MA exceeds the management requirements for streamside management to meet water quality and is not used in all alternatives. Management requirement prescriptions for riparian areas are listed as Forest-wide S&Gs in Appendix D.

Changes Between DEIS Preferred Alternative (PA) (Alternative J) and FEIS PA (Alternative W)

- The FEIS PA recognizes riparian areas as an important feature in the forest landscape for a number of resources. Additional protection has been provided for these sensitive areas by allocating Class I, II, and III rivers and streams, wetlands, and lakeside areas to MA 15 with a prescription of no programmed timber harvest. The width of this no-harvest zone will be located after on the ground reconnaissance but in most cases ranges from 200-400 feet on Class I rivers to 75-150 on Class II and III streams.

- There is increased emphasis on watershed management and water quality. In addition to MA 15 direction, S&Gs have been added to provide protection for Class IV streams in moderately stable and potentially highly unstable soils. These S&Gs provide a no-harvest buffer of 25 to 100 feet to reduce risks of mass soil movement, maintain bank stability, and act as a source of large wood input to the stream channel for sediment control.

- The acres and rate of harvesting have been distributed by subdrainage to minimize potentially adverse effects of peak flow on stream channels.

- Objectives for elk management have been clarified as a result of mapping 212 emphasis areas across the Forest that specify a high, moderate, or low habitat objectives that are linked to a specific set of Forest-wide S&Gs.

- Management emphasis on cavity excavator habitat was reduced. The FEIS PA provides for maintaining 40% of the biological potential by subdrainage rather than 60% Forest-wide.

- A prescription was developed and used in the PA to provide for managed, mature conifer habitat required for pileated woodpecker and marten indicator species in MAs where rotations of 150-200 years were required to meet recreation and scenic objectives. This prescription applies to approximately 20% of the habitat areas for these species.

- Management practices that directly affect the diversity of plants and animals across the Forest have been addressed and a specific group of S&Gs, *Biological Diversity*, has been added to the Forest-wide S&Gs in the PA. This section also includes management direction for categorizing old-growth stands, reducing the rate of fragmentation of the landscape maintaining corridors of mature stands as links across the Forest, and providing large dead wood in all stands.

- Standards and guidelines have been added to MAs with rotation lengths of 150 years and longer to provide for the maintenance of structural features of old-growth stands which would provide old-growth habitat characteristics. Approximately 10 live overstory trees will be left along with down large wood and managed for a diverse species mix.

- Areas managed to protect visual quality were redefined to more closely reflect the areas that can actually be seen from major highway corridors (key viewing points). Overall, the acres allocated to a management emphasis of modification visual quality objective are approximately 77,000 acres less. Partial retention acres are 4,500 less and retention acres are 5,000 less in the FEIS PA than in the DEIS PA.

- More acres are allocated to MA 5a, Special Interest Areas (+9,257 acres); MA 7, Old Growth Groves (+917 acres); and MA 9a, Special Wildlife Habitats (19,988 acres); in the FEIS PA than in the EIS PA. The additional acres allocated to these MAs provide additional protection for special biological, cultural, or geological features that exist on the Forest.

ALTERNATIVE DEVELOPMENT AND ANALYSIS

The following sections describes how the overall themes and resource issues were identified and developed into a range of alternative land allocations and management direction responsive to NFMA, NEPA, and the public. Readers are encouraged to refer to Appendix B for a more complete and technical discussion of the development and analysis process.

Information on the amount and location of resources has been compiled through inventories of timber conditions, recreation use, wildlife populations, soil and water resources, and roads. These inventories were combined in the Geographical Mapping System (GMS) for use in the development and analysis of alternatives. This information was collected on a common map base, with different map layers developed for the various resources and inventory components. This step resulted in the identification of more than 65 layers of resource attributes and management opportunity delineations. This data base was updated between the DEIS and FEIS to reflect changes in land suitability, timber harvest and growth, and a revision of the spotted owl habitat network.

Alternative Development

The alternative formulation process began in November 1984 with a review of Forest issues, concerns, opportunities and resource inventories; resource production capabilities identified in the analysis of the management situation; and applicable planning direction. Based on a review of these items resource management options were developed for nine resource areas: Recreation; Fish and Wildlife; Timber; Range; Soil, Water, and Air; Minerals and Energy; Lands; Facilities; and Protection. Each option was comprised of management direction statements for the important factors for that resource. The resource management options were designed to incorporate issues, reflect a particular level of management emphasis, and serve as a potential building block for Forest management alternatives.

The draft resource management options were reviewed by the public during 1985, with the knowledge that the resource management options would be used as building blocks for alternatives. The public response was evaluated and the resource options were modified to reflect the public comments. The resulting options were used as building blocks in the development of preliminary alternatives.

A review of the options for the nine resource areas indicated that some resources relate primarily to the allocation of land and scheduling of timber harvests for achievement of their objectives (Timber, Recreation, and Fish and Wildlife), while other resources are primarily dependent on program budget and/or administrative action.

Since Timber, Recreation, and Fish and Wildlife are dependent on the allocation of land areas, actions emphasizing one of these resources has a direct effect on the others. The options for these resources were, therefore, compared to each other to determine their compatibility. Compatibility was judged by the Interdisciplinary Team based on the team's knowledge and experience. The six Recreation options, and seven Fish and Wildlife options were compared with each other and were compatible through all 42 possible combinations. These 42 options were then compared to the seven timber management options. Depending on the extent to which Recreation and Fish and Wildlife were emphasized, the timber options were compatible at some levels of production. This comparison resulted in 106 possible combinations of these three resources that could be compatible within an integrated alternative.

Since the range of management options for the resources included output levels close to the minimum and maximum benchmark levels, the preliminary alternatives formulated were by design within the range of benchmark levels, and spread throughout the entire range. Benchmarks are discussed in

additional detail later in this chapter. From these 106 conceivable alternatives, nine preliminary alternatives were identified, based on the following objectives:

- Minimizing the number of alternatives in an array that would still include all of the resource management options,
- Minimizing the duplication of resource options in the array, and
- Maximizing diversity in the mix of resource option combinations.

The resource options for Range; Soil, Water, and Air; Minerals and Energy; Lands; Facilities; and Fire Protection were then compared to the nine preliminary alternatives to determine their compatibility. Most of the options of these six resource areas were found to be compatible with the preliminary alternatives. Options for these resources were then incorporated into each preliminary alternative at a level consistent with the general emphasis of each alternative.

From the combinations of resource option descriptions nine preliminary alternative descriptions were written and rough estimates of some outputs were made. Two preliminary alternatives were dropped due to significant overlap and duplication. These seven alternatives were examined as to how well they resolved major facets of the Forest issues. In doing this the following factors were considered:

- Does the range of alternatives provide an appropriate magnitude of response to the issue?
- What other alternatives should there be?
- Are there inconsistent or incompatible items in the descriptions of the alternatives?

Two alternatives required by NFMA regulations, No Action, and one demonstrating ability to meet the goals of the Resource Planning Act (RPA), were added to the list for consideration at this time. Two additional variations on preliminary alternatives were developed which allowed for departure from long-term sustained yield. Due to significant overlap and duplication, three preliminary alternatives were dropped leaving eight alternatives in the DEIS. In June of 1987 a ninth alternative was included in the array of alternatives in response to decisions made regarding an appeal brought by the Northwest Forest Resources Council. The ninth alternative is referred to as the "No Change" (NC) alternative and is based on the potential yield of the Forest's 1977 Timber Management Plan.

During the review period for the DEIS, many comments were received indicating how well the public felt the key issues were addressed by the alternatives described above. A large number of the commentors expressed the opinion that not all reasonable and viable means of addressing the issues were considered (or at least considered in sufficient detail) in the DEIS. With the comments for direction, the Forest IDT and management team revisited the alternative formulation process used in the development of the DEIS as described previously. The resource options or the management prescriptions and the acre allocations were reviewed and revised. The result of the revisions were three additional alternatives in the FEIS that were not considered in the DEIS.

While developing these additional alternatives, the Forest staff and IDT contacted several groups and individuals that made specific comments concerning alternatives that were not adequately considered in the DEIS. The groups were contacted to clarify their concerns and to help the IDT develop and analyze alternatives that addressed these concerns. Alternative K and Alternative L were developed in this manner. In addition to individual contacts, planning newsletters were sent to all commentors providing them with updates on the development of Alternatives K, L, and W.

The identification of land areas which contribute to the goals and objectives of each alternative was an integral part of alternative development. Working from the management options identified earlier, areas of the Forest were identified as particular MAs and assigned the corresponding management strategy.

MAs are portions of the Forest managed for the same goals and objectives. They are physical units usually delineated on maps, and can be located on the ground. Examples include areas managed to provide specific types of wildlife habitat or particular levels of scenic quality, or intensive timber management. Management strategies (also called management prescriptions) are the direction for activities within MAs, and are detailed in the S&Gs that direct on the ground activities, including rates of timber harvest. A total of 38 management strategies were developed for use in the formulation of benchmarks and alternatives. These combinations of resource objectives were available to be assigned to specific locations on the Forest as necessary to meet the following criteria:

- Cost efficiency,
- Resource trade-offs,
- Resource quality and suitability,
- Planning direction, and
- Resolving issues.

Cost efficiency, which is a requirement of the NFMA regulations (36 CFR 219.12(f)(8)), has been defined as when outputs with assigned dollar values are produced according to their net economic value (i.e., benefits minus costs), or are achieved at specified levels in the least cost manner. For the most part analyses on the Forest consistently show this criterion to be met with the highest level of timber production feasible. Therefore, management strategies were assigned to minimize the impact on the suitable timber land base while still satisfying the other criteria outlined for the alternative.

In some cases resource trade-offs were a factor in addition to the economic trade-offs. Resource quality and suitability were related to the resource trade-offs considered. For example, attributes such as the size of a roadless area or the opportunity for solitude in a roadless area could influence the assignment of a roadless MA. Planning direction influenced MA assignment in some cases, particularly in the No Action and No Change alternatives. Requirements for the No Action and No Change alternatives mandated use of the land allocations in the current Forest Plan (1977) as a guide for MA assignment. Other direction, such as distribution criteria for spotted owl habitat areas, also influenced MA assignments.

The last criterion, issue resolution, had a direct influence on MA assignment in most alternatives. For example, the roadless area issue varies in intensity according to the particular area under consideration. Similarly, scenic corridors along roads are desired to a greater or lesser degree depending upon the emphasis of the alternative.

Data was then assembled and the MA boundaries used for the alternatives were selected. This process combined analysis and judgment to reflect the optimum assignment of MAs and strategies to meet the goals and objectives of the alternatives in both the DEIS and FEIS.

Between the DEIS and the FEIS several of the MAs used to develop the alternatives were also modified. The changes in the MA designations were applied to the alternatives developed since the DEIS

(Alternatives K, L, and W) as well as to the alternatives brought forward from the DEIS (Alternatives NC, A, J, and D). In general, these changes did not affect the goals and objectives of the MAs as described in the DEIS nor the outputs or effects associated with them. The MA changes were described in the section Changes Between Draft and Final.

A complete description of the management strategies for the entire set of MAs used in alternative development can be found in *Comparison of Alternatives, MAs*, later in this Chapter.

The next major phase of alternative development involved selection of silvicultural prescriptions to meet alternative objectives over the Forest and through time. Silvicultural prescriptions represent the potential sets of timber management activities that can be implemented on timber stands of different conditions, including precommercial thinning, fertilizing, commercial thinning and regeneration harvesting. Silvicultural prescriptions are selected in the FORPLAN model, which seeks to schedule activities in a cost-efficient manner. A total of four to eight silvicultural prescriptions were available for selection for each MA, depending upon stand condition. The extent to which FORPLAN selects timber harvest prescriptions determines the timber outputs for each alternative. The role and operation of FORPLAN in alternative development and analysis is described in the following section.

Alternative Analysis

Management prescriptions are sets of activities which represent a specific method of managing particular analysis areas. A group of these prescriptions cover the various ways that different analysis areas can be managed. These prescriptions provide choices which can be made in managing the land. To analyze and present these options, management prescriptions were defined for 15 MAs, each with specific resource objectives. Most analysis areas have the capability to meet the resource objectives of more than one MA. An estimate of economic costs and resource yields associated with the prescriptions was generated for use in the forest planning model (FORPLAN).

Management areas are described in detail at the beginning of Comparison of Alternatives.

Role of FORPLAN

FORPLAN (an acronym for FORest PLANning model) is a linear optimization model that was used to assist in the scheduling of silvicultural prescriptions in order to meet resource and economic objectives; and to assist in the analysis of how well the particular combination of land allocations, management strategies, and silvicultural prescriptions meet the objectives of each benchmark or alternative.

The Willamette FORPLAN model was based on Version 2, with updates designed to assist the interdisciplinary planning team analyze the economic and production trade-offs associated with the recreation, timber, scenery, old-growth, water, roadless, and wildlife resources, and to assist evaluate the extent to which various alternative management scenarios were able to address and resolve the identified public issues.

The FORPLAN model uses analysis areas as the basic building blocks for scheduling silvicultural prescriptions to meet economic and resource objectives. The analysis areas were developed in a two stage process. In the final FORPLAN model areas were first identified with relatively homogeneous characteristics in terms of watershed, silvicultural suitability, timber type (i.e., species group), and timber size class. These delineations were intended to capture the significant social, biological, physical, and economic differences in the way the land responds to alternative management strategies.

The second step was to assign the appropriate management strategy for each analysis area depending on its location, and the resource objectives of a particular benchmark analysis or alternative. A total of 883 preliminary analysis areas were used in the final FORPLAN model. These analysis areas were then combined with the management strategies and processed using a relational data base to reduce the number of unique combinations of analysis areas and management strategies to between 1500 and 2400, depending on the alternative. For a more complete description of the combination collapsing strategies refer to Appendix B.

The scheduling of silvicultural prescriptions is controlled by the management strategy constraints, and the objective function.

Management strategies are represented in the model as constraints on the amount of timber harvest prescriptions which can be selected within analysis areas of a particular MA. For example, where the management strategy is for intensive timber management (such as in the general forest MA), there are no constraints on silvicultural options FORPLAN can choose from. Where the management strategy is to maintain the scenic quality at high levels by retaining the natural appearance of an area (scenic retention MA), the rate of timber harvest allowed within the MA was constrained to less than full yield.

Constraints were applied at two basic levels in FORPLAN. At the broadest level, constraints were applied Forest-wide (e.g., nondeclining yield of timber). At the second level, constraints were applied to a grouping of analysis areas which were included within a particular management strategy. At the third level, constraints were applied to individual analysis areas (e.g., dispersion of timber harvest units). Only the silvicultural prescriptions and timing choices available for a particular analysis area and management strategy could contribute to this type of constraint. FORPLAN could then select and schedule specific silvicultural prescriptions and practices to maximize PNV while meeting all of the objectives for a particular alternative.

In the DEIS FORPLAN model some constraints were applied to specific analysis areas. In the FEIS model the amount of detail included in each analysis area was greatly expanded. Any constraints that may have been applied to a specific analysis area in the DEIS were redesigned to apply to similar grouping of analysis areas in the FEIS.

Constraints were designed to guarantee the spatial and temporal feasibility of land allocation and harvest scheduling choices in order to achieve the multiple-use objectives of a benchmark or alternative. Once the model determined that a feasible solution existed by satisfying all of the constraints, it searched for the set of silvicultural prescriptions and timing choices which permitted it to optimize the solution according to the specified objective function.

The objective function is a mathematical equation which shows how the Forest's objective (maximize PNV for example) is affected by the values explicitly portrayed in the silvicultural prescriptions available for selection.

Two different objective functions were used to drive the Willamette FORPLAN model, these being to maximize PNV and to maximize timber volume. Although there were some differences in scheduling patterns between the two, both resulted in the model harvesting timber within the limitations imposed by the constraints. All final FORPLAN runs for all the alternatives, except the No Change alternative, were made with a timber volume objective function. FORPLAN was not used to analyze the No Change alternative as it was based on a different set of assumptions and mapping.

Other Analysis Tools

Although FORPLAN was the central model in the analysis process, several other models were essential to either prepare data for FORPLAN, or help interpret FORPLAN results. Construction of managed timber yield tables for use in FORPLAN required use of computerized growth models.

The Douglas-fir Simulator (DFSIM), a growth and yield model, was used to simulate a wide variety of growth and harvest patterns over time for the Douglas-fir and Douglas-fir/true fir managed yield tables (Curtis, 1981). With DFSIM, the user can simulate yield regimes for Douglas-fir under different regeneration options (planted or natural), with or without precommercial thinning (PCT), and with or without fertilization. For a given set of investments, the goal was to find the combination of intermediate harvest and final harvest that best met the objective of maximizing volume or PNV (PNV). To search for the combination of thinnings and final harvest over different rotation ages that best met the objective and constraint set would require a great number of DFSIM runs. Dynamic programming was used in conjunction with DFSIM (DP-DFSIM) to automate the search for yield regimes in DFSIM that optimized either volume or PNV. Yield tables were developed to represent each objective for a range of management intensities from "natural regeneration with no intermediate treatments" to "planting genetically improved stock with full stocking level control plus fertilization."

Managed yield tables for other timber types (true fir and mountain hemlock) were developed with the PROGNOSIS model. PROGNOSIS is similar to DFSIM but does not have the dynamic programming option associated with it.

IMPLAN is a Forest Service designed computer model that estimates the expected economic effects of implementing one or more alternatives. IMPLAN is a computer-based system that is based on economic Input/Output (I/O) models. IMPLAN contains national economic data that have been organized into a single predictive model. The basis for prediction can be any single U.S. county or group of counties, any state or states, or the entire nation. Regardless of how the model is constructed (county or multiples of counties), IMPLAN provides a detailed description of the economy in question. The model then provides analytical information about the industries that are present and their relationship to other industries. Thus, changes in any of the industries, as caused by the alternatives, result in measurable changes in the socioeconomic area of influence. The economic effects estimated with IMPLAN are described by parameters typical of input/output studies. They are structural in nature, permitting multiplier effects to be traced throughout the various regional sectors. Direct, indirect, and induced changes in gross outputs, employment, income, and value added are the most representative account of potential regional economic responses. This information was used to portray the Forest Service's relationship to the area economy and to help assess the effects on that economy of alternative management programs.

Other models were designed to provide input to the FORPLAN model, and to analyze the effects of the alternatives on various resources. The VISPLAN model was used to reduce the complexity of the linear programming task while correctly displaying the effects of timber harvest from the management strategies that were limited to 12% or less final harvest per 10-year period. This model was an integral part of the process used to collapse the number of analysis areas, and is described in Appendix B.

A Spatial Disaggregation Process model was used to determine the acres of timber harvest compatible with meeting resource objectives at the subdrainage scale, and to provide FORPLAN constraints for alternative W, increasing the accuracy of FORPLAN estimates of resource outputs.

An economic spreadsheet was used to fully calculate PNV, costs, benefits, and associated measures such as net cash flow.

A recreation model was developed to calculate the effects of the alternatives on recreation visits in each of the Recreation Opportunity Spectrum Classes. A model was set up to estimate the effects of the alternatives on each of the roadless areas. A model was used to assess the effects of various harvest rates on stream conditions and water quality. Several wildlife models were constructed to further interpret FORPLAN results to estimate effects on animal populations. And a transportation model was used to disaggregate FORPLAN timber volumes to areas served by road systems for estimation of road mileages needed for a particular alternative.

Additional computerized methods were used to assess the effects of alternatives on the major resources. These analysis were based on models which are described in more detail in Appendix B.

Management Requirements

The implementing regulations for the National Forest Management Act contain basic direction for ensuring long term productivity of all forest resources (36 CFR 219.27). To assure consistency in interpreting and applying these requirements in forest planning, Regional direction established those requirements which must be met in all alternatives (internal memos dated 2/9/83, 4/16/84, and 8/4/86). These requirements are known as "management requirements" or MR's. In the DEIS they were called "minimum managemement requirements" (MMRs). All alternatives, except the No Change Alternative, comply with applicable laws and regulations. Additional discussion of the how alternative means of meeting MRs were analyzed is covered in Appendix G.

While numerous laws and regulations direct what must be considered in the planning process, the regulations pursuant to NFMA include detailed direction. Of these, four requirements have been analyzed because of the significant effects they have on management of Forest resources. These are:

- *Water Quality* - "Forest planning shall provide for compliance with the requirements of the Clean Water Act, Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State and local governmental bodies with respect to the provision of public water systems and the disposal of waste water" (36 CFR 219.23(d)).

- *Riparian Areas* - Special attention will be given to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes, and other bodies of water...No management practices causing detrimental changes in water temperatures or chemical composition, blockages of water courses, or deposits of sediments shall be permitted within these areas which seriously and adversely affect water conditions or fish habitat" (36 CFR 219.27(e)).

- *Fish and Wildlife* - "Fish and wildlife habitats shall be managed to maintain viable populations of existing native and desired nonnative vertebrate species in the planning area...In order to insure that viable populations will be maintained, habitat must be provided to support, at least, minimum numbers of reproductive individuals and that habitat must be well-distributed so that those individuals can interact with others in the planning area" (36 CFR 219.19).

- *Timber Harvest Dispersion* - When openings are created by the application of even-aged silviculture, individual cuts shall conform to the Regional Guide direction on the dispersion of openings and maximum size limits for areas to be cut in one harvest operation (with some exceptions)(36 CFR 219.27(d)).

Techniques for meeting riparian requirements addressed the need to maintain bank stability and water temperature. The primary methods used were reservation from timber harvest on approximately 20%

of the riparian area which was assessed as inoperable for timber harvest, and reduced harvest rates (extended rotations) on the remaining riparian areas. Another important component of meeting the riparian and water quality requirements are the S&Gs which require implementation of Best Management Practices to control on-the-ground activities. These S&Gs ensure maintenance of viable fish populations including management indicator species of anadromous and resident salmonids.

Wildlife populations were maintained by establishing management indicator species and by providing habitat necessary to ensure continued viability of these species. Dedicated habitats with no timber harvest were provided for the spotted owl, pileated woodpecker, marten, bald eagle, and peregrine falcon. Options were provided for managing marten, pileated woodpecker, and bald eagle habitat. Harvest rotations longer than 150 years were required to provide habitat suitable for reproduction, but younger managed stands would provide habitat for dispersal, roosting, and foraging. Additionally, S&Gs ensure that primary cavity excavator populations will be maintained at or above 20% of biological potential, dead and down woody debris will be maintained in harvested areas, and that unique habitats will be maintained (e.g., cliffs, caves, talus, and meadows).

Timber harvest dispersion was ensured by limiting harvest rates within timber inventory components and within watersheds.

Alternative methods of meeting these requirements were evaluated in the Analysis of the Management Situation (AMS), and in subsequent analysis. During the AMS the impacts of the MRs on timber volume and PNV (PNV) were assessed. Several FORPLAN runs were made with different MR constraints present so that the impacts of the requirements could be determined. These runs evaluated the decreases in volume and PNV as a single MR was added to the base PNV benchmark which had no MR constraints. After the modelling changes for the FEIS were made, the consequences of the MR constraints were again tested. At this stage the effects of the MRs on PNV and timber volume were evaluated by testing how much timber volume and PNV increased as each MR was removed, when compared with a PNV benchmark run which included all the MRs.

Table II-1 shows the results of these runs. Comparisons in this narrative will be in terms of the change in PNV (PNV). Timber volume trade-offs in cubic feet can be determined from the table.

The most significant MR, in terms of effects on PNV, is the spotted owl habitat area requirement (12 % reduction). Riparian area requirements reduce PNV by 3%, mature timber requirements (for the pileated woodpecker and the pine marten) reduce PNV by 3%, and harvest dispersion requirements lower PNV by 6%. The sum of these reductions is 24%. Results of comparisons looking at individual MRs represent the maximum effect of that constraint since the linear program did not have an opportunity to consider any overlapping or interactive effects of more than one MR constraint in its optimization procedures. In the context of a particular alternative, however, the presence of all MR constraints plus additional constraints, allows additional overlapping of constraints and hence lessens the effect of MRs on PNV. Appendix G presents the results of analysis that tests the sensitivity of ASQ and PNV to the management requirements with significant effects.

Table II-1. Minimum Management Requirements - Effects on PNV and Timber Harvest

	LTSY [1]		1st Decade ASQ [1]		PNV [1]		
Description	**MMCF**	**Percent Change**	**MMCF**	**Percent Change**	**$MM**	**Percent Change**	**Comments**
Maximum PNV W/ all MRs	120.2	--	117.3	--	$3,782	--	This benchmark is the basis for comparison.
Dispersion MR	120.4	(+0.2)	119.0	(1.4)	$3,994	(5.6)	Not modeling dispersion allows harvest rates to exceed 25-30 percent of a watershed per decade.
Mature Timber [2]	123.0	(+2.3)	120.5	(2.7)	$3,908	(3.3)	Not modeling this MR adds 18,880 acres to timber production.
Riparian MR	124.0	(+3.2)	121.7	(1.2)	$3,901	(3.1)	Removing this MR adds 11,123 no harvest and 42,742 reduced harvest acres into full yield timber harvest.
Spotted Owl	130.2	(+8.3)	128.2	(9.3)	$4,237	(12.0)	Not modeling this MR adds 70,339 acres to timber production.
TOTAL		(14.0)		(14.6)		(24.0)	
Maximum PNV without MRs[2]	132.5	(N/A)	129.6	(N/A)	$6,073	(N/A)	This data is included as a reference to the DEIS. The percent change information is not valid because many coefficients have changed between the DEIS and FEIS.

[1] These effects are maximum estimates based on benchmarks. Actual opportunity costs are less when MRs are needed in part or totally to meet a resource objective in one or more of the alternatives.
[2] Mature conifer habitat areas for pileated woodpecker and marten.
[3] The maximum PNV without MRs benchmark was not re-calculated using FORPLAN. The information used here is from the DEIS.

Development and Use of Benchmarks

The primary analysis prior to the development of alternatives was the Analysis of the Management Situation (AMS). A comprehensive analysis of resource and economic production capabilities is required in the Analysis of the Management Situation. This was accomplished through individual resource supply and demand assessments, and through FORPLAN computer runs known as benchmarks. The purpose of benchmark analysis was to provide information on:

- The economic implications of complying with legal and policy constraints, including management requirements of 36 CFR 219.27;
- The effects of modeling assumptions;
- The schedule of management activities, resource outputs, effects, costs and PNV (PNV) associated with a single resource or an economic emphasis of individual benchmarks;
- The potential to resolve issues and concerns;
- The need to change current management direction; and
- The range within which integrated alternatives could be developed.

All benchmarks developed in this analysis were designed to be approximately implementable and were not constrained by budgets, except the No Change Benchmark.

All of the benchmarks originally evaluated included provisions to meet the management requirements of 36 CFR 219.27. These included protecting land and resource productivity, meeting air and water quality standards, and maintaining viable populations of fish and wildlife species. The previous section on Management Requirements describes these requirements in detail and presents the opportunity costs of meeting these requirements. Additionally, the results of one benchmark that does not include these provisions is presented in this section.

In addition to the major benchmarks displayed in this section and the analysis of management requirements, analysis was conducted to assess the opportunity costs and resource trade-offs associated with timber harvest policy requirements and economic assumptions. The analysis process and results are explained further in Appendix B. The AMS document, available in the Forest planning records, contains detailed resource supply and demand assessments. Summaries of these assessments are in Chapter III, The Affected Environment.

The analyses described above, in conjunction with the major benchmarks, laid the groundwork for development of the alternatives. The major benchmarks used to facilitate development of DEIS alternative included:

- Minimum Level
- Maximum PNV Based on Established Market Prices
- Maximum PNV Including Assigned Values
- No Action

- Maximum Resource Levels

Changes in FORPLAN model and related yield tables in response to comments on the DEIS would result in different output levels of the major benchmarks. The impact of these changes would be similiar for all benchmarks. The relative effects would be minor. In order to establish a means of estimating the relative affect of the changes on any particular benchmark, the maximum timber and maximum PNV benchmarks were re-analyzed using the FEIS FORPLAN formulation. This revised benchmark analysis can be used to assess the changes in the decision space of the alternatives which can be attributed to changes in the model structure.

A summary of the major results from these benchmarks is contained in Table II-2. A detailed explanation of the benchmarks and the results of the analyses is contained in Appendix B. The analysis of benchmarks provided valuable information about different ways of responding to public issues and management concerns. The maximum and minimum resource levels define the outer bounds, or "decision space," within which integrated alternatives were developed. Relationships among resources and relative trade-offs between resources were also made apparent.

Several of the benchmarks provided the basis for development of a developed alternative as described in the next section, Range of Alternatives.

Table II-2. Outputs, Effects, Activities, and Costs for Benchmarks

Output, Effect, Activity, or Cost	Unit of Measure	Minimum Level	Maximum PNV (Market)[1]	Maximum PNV (Assigned)	Maximum PNV (Assigned) Without MRs	No Action[1]	Maximum Timber[1]	Maximum Recreation
Developed Recreation Use	MRVDs	0	**1,774**	1,774	1,774	***,*****	**1,002**	1,872
Nonwilderness Dispersed Recreation Use

[1]This alternative was recalculated using all of the changes in assumptions and data from the FEIS. The mix of DEIS and FEIS benchmarks is intended to help the reader understand changes that have occured since the DEIS was written.

Range of Alternatives

The range of alternatives considered in this FEIS is represented by the seven fully analyzed alternatives which span the range of issues and opportunities identified in the benchmarks analysis, in the DEIS, and in response to comments on the DEIS.
In the FEIS several new alternatives were developed in response to public comments on the DEIS. A large number of the commentors expressed the opinion that not all reasonable and viable means of addressing the issues were considered, and that other combinations of the resource options should be considered. As a result some of the resource options, management prescriptions, or land allocations were revised, and three additional alternatives were considered in the FEIS.

Additional information on the process used to develop the alternatives is found in the section on Development of alternatives in this chapter.

Several of the alternatives are required by regulation, or regional and national direction. The required alternatives and others developed for display in the FEIS are summarized here. Alternatives eliminated from further detail in the FEIS are summarized in the next section.

Required Alternatives

No Change: This is the No Change Alternative required by Regional and National direction in response to decisions made regarding an appeal brought by the Northwest Forest Resources Council. This alternative would: (1) continue the management of the Forest as defined by existing direction in the Forest's Multiple Use Land Management and Timber Management Plan; (2) maintain timber outputs equivalent to the potential yield of the 1977 Timber Management Plan and to the extent possible produce current levels and mixes of other resource outputs; and (3) continue existing policies, standards and management guidelines; although, *it does not incorporate management requirements directed by NFMA.*

Alternative NC is the No Change Alternative.

No Action: This alternative is required by the Council on Environmental Quality (CEQ) regulations for NEPA (40 CFR 1502.14), and by the NFMA regulations (36 CFR 219.12(f)(7)). This alternative would: (1) continue the management of the Forest as defined by existing direction in approved management plans; (2) continue existing policies, standards, and guidelines; (3) update the current budget to reflect changing costs over time; and (4) to the extent possible, produce current levels and mixes of resource outputs. *Management requirements are incorporated in this alternative.*

Alternative A is the No Action Alternative.

Emphasis on the Current RPA Program: This alternative will determine how the timber targets of the current (1980) RPA Program, which were distributed to the Forests through the Regional Guide, can best be achieved.

Alternative B-Departure is the alternative designed to achieve the Forest RPA targets. Alternative B was analyzed in detail in the DEIS. After a review of public comments on the DEIS and consideration of adverse environmental effects of departure alternatives considered in the DEIS, this alternative was not re-analyzed and considered in detail in the FEIS. The analysis and comparisons in Chapters II and IV of the DEIS remain valid and provide information on trade-offs and management implications

of meeting the 1980 RPA timber targets. Other activity and output targets assigned to the Forest in RPA will be achieved in this or one of the other alternatives.

Emphasis on Market Opportunities: This alternative emphasizes resources that have an established market price. Timber production is the major market commodity on the Forest and is emphasized in this alternative. Management for other resources would be at economically and environmentally feasible levels consistent with the emphasis on timber outputs.

Alternative K emphasizes market opportunities on the Forest. In the DEIS, Alternative I was used to display this management option. Because of some similiarities with Alternative K, Alternative I was not considered in detail in the FEIS. See Chapter II of the DEIS for details on output levels and effects of Alternative I.

Emphasis on Nonmarket Opportunities: This alternative puts an emphasis on water, fish and wildlife, recreation, and other amenity values. Management for other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

Alternative L emphasizes nonmarket opportunities, particularly those related to old-growth preservation, wilderness, dispersed recreation and watershed management. Alternative D provides an emphasis on wildlife values. In the DEIS Alternative C was used to display nonmarket emphasis. Because of similarities with Alternatives D and L, Alternative C was not considered in detail in the FEIS. See Chapter II of DEIS for details on output levels and effects of Alternative C.

Departure Alternatives: In the DEIS, several alternatives incorporated departures from the nondeclining yield policy for timber production. This means that timber harvest schedules were modified to provide more timber in the earlier decades of the planning horizon but less in some of the later periods. The nondeclining yield policy requires harvest levels to remain constant or increase over time.

Two alternatives displayed in the DEIS represented departures from nondeclining yield. As discussed previously, a departure was necessary to meet the RPA timber targets in Alternative B. A departure schedule for Alternative J, the DEIS Preferred Alternative, was also developed to meet the expected future needs of the local timber industry as reflected in the Forestry Program for Oregon and supplemented by additional information from the State Department of Forestry. Alternative J-Departure also analyzed the effects of a departure on forest age-class distribution and possible benefits to other multiple use objectives.

Alternative J-Departure was not re-analyzed and consider in detail in the FEIS because public comments indicated it was not a desireable option for addressing timber supply concerns and that the environmental effects of the accelerated harvest were adverse and did not address other resource concerns. A departure of Alternative W, the FEIS Preferred Alternative, was not considered in the FEIS. Based on a comparison of issues addressed in Alternative J and W, and the effects of Alternative J-Departure displayed in the DEIS, the IDT determined that a departure sale schedule could not be developed for Alternative W that would attain the overall multiple use objectives of the alternative.

Additional harvest scheduling options were also considered for Alternative J in the DEIS that would allow for a smooth transition from current timber program levels to those proposed in the DEIS. These options were not displayed or re-analyzed in the FEIS.

All of the alternatives analyzed in the DEIS as well as the 3 additional alternatives developed for the FEIS in response to public comment were considered by the IDT to evaluate the range of alternatives. These 12 alternatives were evaluated to see how well they were distributed between the maximum

and minimum potentials for resources, if they provided an adequate comparison of resource trade-offs and if they were responsive to public issues and management concerns. As a result of this evaluation, the group of 12 alternatives was reduced to seven because of significant overlaps in one or more resource issues. The IDT also felt that the smaller set of alternatives would provided the FEIS reader with a clearer understanding of the resource issues and trade-offs involved.

Other Alternatives

Additional alternatives were developed by the Forest in response to public issues and management concerns. These also respond to National Forest Management Act Regulations (36 CFR 219.12(f)(1)) which requires that alternatives "be distributed between the minimum resource potential and the maximum resource potential" (the decision space) in order to display the full range of resource outputs that can be produced. Alternatives D, J and W are analysed in this FEIS to provide a wide range of alternatives, and to represent different balances between amenity and commodity oriented issues.

Decision Space

The alternatives developed, except the No Change Alternative, for management of the Forest are designed to be fully implementable under the NFMA Regulations, and focus on the resolution of the identified public issues and management concerns. The limits and reference points identified in the benchmark analyses were used in constructing these alternatives.

The selected harvest system for alternatives in most areas is clear-cutting. In areas managed for scenic retention, partial retention, dispersed, motorized, and nonmotorized recreation both clear-cutting and uneven managed age harvest systems will be used.

In all alternatives the use of herbicides will follow the direction established in the selected alternative of the 1988 EIS on "Managing Competing and Unwanted Vegetation." and the mediated settlement.

All alternative have incorporated the S&Gs from the Regional Guide and the SEIS for spotted owls except the No Change Alternative.

All alternatives include mitigation as described in the following section on features common to all alternatives.

These alternatives assume that there are no budget constraints which result in foregoing economically efficient commodity production opportunities or stated mitigations.

Preferred Alternative

A Preferred Alternative has been identified from the array of alternatives presented in this FEIS. The Preferred Alternative and proposed action in this FEIS is Alternative W.

The Preferred Alternative has been identified after a comparison of the alternatives and consideration of their resource outputs, environmental consequences, implementation costs, and net public benefit.

Alternative W provides direction for management of the Forest to provide a sustainable level of commodity resources, while providing for a wide range of non-commodity uses of the Forest. Wildlife habitats for mature conifer management indicator species will be managed at minimum levels. River and stream corridors will be managed primarily to provide water quality, fish habitat, dispersal of interior wildlife species, and high quality recreation opportunities. Alternative W includes principles of maintaining

old-growth characteristics in areas managed for scenic retention and partial retention, and encourages the use of minimum fragmentation in timber sale design.

Alternative W was developed without budget constraints. The resource activities, effects and outputs displayed in a later section of this chapter, are based on the budget level which is also displayed. The effect of budget constraints on this alternative would vary according to if the constraint was applied uniformly across market and non-market resources or not. Budget constraints might reduce the level of market outputs, increase the effects of timber harvest on non-market resources, and reduce monitoring of the S&Gs.

Alternatives Eliminated from Detailed Study

This section presents alternatives which were considered, but subsequently eliminated from detailed study. This group of alternatives includes benchmarks, preliminary alternatives developed for the DEIS and several alternatives that were considered in detail in the DEIS but were eliminated from detailed study in the FEIS based on public comment on the DEIS and a reevaluation of how the alternatives considered addressed issues, concerns and opportunities.

Benchmarks

Benchmarks were developed as part of the Analysis of the Management Situation (AMS) and were designed to emphasize the production of individual resources, or to define the most cost-efficient combination of prescriptions and land allocations for management of the Forest under certain circumstances. Benchmarks serve as reference points for the purposes of defining the range within which integrated alternatives were developed (the decision space), and for estimating the effects of various objectives and assumptions.

All of the benchmarks discussed in Development and Use of Benchamrks were considered for use as alternatives. However, all but one were eliminated from detailed study. The No Action benchmark became Alternative A, the No Action Alternative. Although the other benchmarks were eliminated from further consideration for a variety of reasons, they were useful as starting points for development of particular alternatives. The minimum level and the maximum PNV benchmarks were used to assess economic efficiency and to determine the economic implications of various harvest scheduling options. The benchmarks to maximize timber and recreation helped to determine objective levels for these resources in various alternatives.

A variation of the No Action benchmark (No Action/Without MMRs) was developed to assess the ability of the Forest to produce goods and services under the land allocations and prescriptions contained in the 1977 Forest Land Management Plan, without including the management requirements of NFMA. Although all resources are addressed in the current plan, the lack of management requirements in this benchmark is contrary to existing law. This benchmark became the No Change alternative.

Other DEIS Alternatives

Several preliminary alternatives were developed for the DEIS to respond to a specific issue or to help provide a wide range of alternatives. These alternatives were developed to varying degrees ranging from formulating a general goal or theme, through analysis of FORPLAN results, but were not presented in detail in the DEIS.

An alternative was developed to provide timber volumes over the first 5 decades that would maintain a steady supply from all ownerships within the three-county area. Achieving this objective required a departure timber sale schedule for the Forest with volumes rising for the first 2 decades and then declining slightly in decades 3 through 5. This alternative was in response to concerns for a Forest timber sale level that would balance timber harvest from all ownerships to provide a stable supply of raw materials for the wood products industry. See Chapter III, Timber for further information on the projected timber supply from other than Forest lands. This alternative was eliminated from detailed study because other departure alternatives considered in detail addressed similiar concerns based on input from the State Department of Forestry through the Forestry Program for Oregon and the 1980 Resource Planning Assessment timber targets.

Another alternative considered, but not studied in detail in the DEIS had an objective to maximize timber management on the suitable timbered land remaining after most of the inventoried roadless lands were allocated to no-harvest allocations. A FORPLAN analysis of this alternative produced an ASQ of 97 MMCF (565 MMBF) annually on a suitable landbase of about 807,400 acres. Like the benchmarks, this information provided a reference point for considering the roadless and timber supply issues, but was not useful as an alternative since it did not adequately deal with many of the major issues on the Forest.

Several preliminary alternatives developed by the Forest for the DEIS, were designed to ensure that all of the issues were being addressed over a broad range of land allocations and management practices. Further evaluation of the entire set of alternatives indicated that several were redundant, did not propose significantly different ways of addressing key issues, and thus were subsequently dropped from further consideration in the DEIS.

During the development of alternatives for the DEIS, several public interest groups developed management proposals for specific areas of the Forest. Rather than develop these proposals as individual Forest-wide alternatives, they were incorporated into Forest-wide alternatives with compatible goals and objectives. The management proposals included in other alternatives involve the Three Creeks, South Fork McKenzie, Fall Creek, and Hardesty Mountain areas of the Forest.

During the development of alternatives for the DEIS, the Oregon Natural Resources Council (ONRC) submitted an alternative that they proposed be considered in detail in the DEIS. After a preliminary analysis of the alternative by the Forest IDT it was dropped from further detailed analysis and consideration. The reasons for not considering the alternative in detail in the DEIS were that it was judged to be outside the range of reasonable alternatives because it did not adequately address key issues such as timber harvests, many of the land allocations proposed in the ONRC alternative were included in other alternatives that were considered in detail, and recommendations within the proposal for additional wilderness designations were not consistent with the direction in the Oregon Wilderness Act of 1984. See Chapter II, Alternatives Considered But Eliminated From Detailed Study, ONRC alternative in the DEIS for further information on analysis and rationale for eliminating this alternative.

Based on comments received during the public review of the DEIS, the Forest reconsidered the rationale for excluding this alternative. After several meetings with ONRC to identify objectives of the alternative (including several modifications of the original ONRC proposal), the Forest developed an alternative in response to their input. Alternative L was the result of this effort and has been analyzed in detail in the FEIS. See the appropriate sections of Chapters II and IV of the FEIS for a complete description, display of outputs and discussion of the environmental effects of Alternative L.

Other Alternatives - FEIS

In response to public review of the DEIS, many comments spoke to alternatives that were either considered or not considered in the DEIS and how well the options for resolving key issues were addressed. In response to the public comments, three new alternatives were developed and considered in detail in the FEIS; Alternative K (developed with input from Willamette Forestry Council (WFC)), Alternative L (developed with input from ONRC), and Alternative W (developed by Forest in response to public comments on Alternative J). See appropriate sections of Chapters II and IV in FEIS for further information on these alternatives.

When these 3 new alternatives were added to the group of alternatives considered in detail in the DEIS, the overall range of responses to issues was similiar to the DEIS. Several of the alternatives considered in the DEIS did not significantly add to the range or were similiar in many respects to the new alternatives. As a result, the following alternatives were not reconsidered in detail in the FEIS; Alternative B-Departure, Alternative C, Alternative F and Alternative I.

Following is a brief summary of the goals and objectives considered in these alternatives. For a more thorough discussion, see Chapter II, Description of Alternatives in the DEIS.

Alternative B-Departure (RPA) The goal of this alternative is to meet the 1980 Resources Planning Act (RPA) Program timber production targets assigned to the Forest in the Regional Guide. Other activity and output targets assigned to the Forest in RPA will be achieved in this or one of the other alternatives.

The level of timber production assigned to the Forest in RPA averages approximately 870 million board feet annually for the 50 year planning period. This volume includes all merchantable timber sold by the forest. Translated in terms of allowable sale quantity (ASQ), or net green volume, the RPA target equals 695 million board feet (128 million cubic feet). This volume is higher than the maximum amount that can be produced on a sustained basis.

The land allocations and acres suitable for timber management in this alternative were similiar to Alternative I in the DEIS. Fish, wildlife, soil and water resources were managed to met management requirements as modelled in the DEIS. The ASQ of Alternative B was 715 MMBF, slightly above the the 1980 RPA target of 695 MMBF. Alternative I, with a nondeparture sale schedule and identical suitable land base had an ASQ of 619 MMBF, several million board feet below the RPA target. Alternative B addressed the major issue of timber supply and demonstrated the effects of meeting the 1980 RPA timber targets. Because of public comment on departures, failure to address other key issues, and overall adverse environmental effects, an alternative designed specifically to meet the RPA timber targets is not considered in detail in the FEIS.

Alternative C - Alternative C emphasized recreation, fish, wildlife, and maintenance of the natural attributes of the Forest. It is designed to provide high levels of recreation opportunities and high quality experiences. The full inventory of roadless areas is maintained in an undeveloped condition with an emphasis on semiprimitive nonmotorized activities. Future demand for developed recreation opportunities would be met. Opportunities for high quality Wilderness experiences would be provided by regulating use. An additional Wilderness is proposed.

All areas of special significance would be managed to protect and enhance desirable attributes. Scenery would be enhanced by managing all areas according to inventoried Visual Quality Objectives and by rehabilitating unacceptable modifications.

The quantity, quality, and diversity of plant and animal habitats would be maintained at high levels. Habitat would be provided for the full inventory of spotted owls. A large variety of allocations are used to protect the soil, water, and air resources of the Forest, well above the Management Requirements, and to retain large amounts of old-growth.

Timber management would be emphasized to the degree compatible with other resource objectives.

This alternative was not analyzed in the FEIS because it was adequately represented by the range of alternatives which were fully analyzed.

Alternative F - Alternative F emphasized a balance of timber production and amenity uses such that historic harvest levels (average of 607 MMBF annually, Timber Sale Program Quantity) are maintained to support the traditional economic base of local communities. Amenity resources would generally be provided at the highest level commensurate with meeting the timber volume objective.

Approximately 41% of the currently unroaded areas would be maintained in a roadless condition to provide semiprimitive recreation opportunities and retain old-growth. Additional old-growth would be maintained to accommodate 74% of inventoried spotted owl habitat areas. Scenery along roads, trails, and attractions would be managed at current levels.

Some user regulation would occur in Wilderness to provide a better experience and help maintain the resource. Additional developed recreation opportunities and service would be provided. Areas currently receiving special area designation would be protected. A moderate emphasis would be placed on soil and water improvements, and fish and wildlife habitat improvements. Fish and wildlife habitat, as well as soil and water resources, would be managed above Management Requirements.

This alternative was not analyzed in the FEIS because it was adequately represented by the range of alternatives which were fully analyzed.

Alternative I - Alternative I emphasized the production of timber. Most of the suitable timber land base is allocated to timber production. Less than 6% of the currently inventoried roadless lands would be kept undeveloped. Old-growth would be retained for wildlife Management Requirements, in areas where roadless recreation opportunities exist, and in timber production areas prior to initial harvest.

Developed recreation opportunities would be limited to sites currently receiving high use. Some protection of the visual resource would occur along major highway corridors. Fish and wildlife habitats, and soil and water resources would be managed to meet Management Requirements. A few areas of special significance would be managed as Special Interest Areas.

Even though these alternatives were not re-analyzed in the FEIS, the relative comparisons of outputs and environmental effects in Chapters II and IV of the DEIS are still valid and were useful in considering the range of options that exist for addressing key Forest issues.

The departure scenario for Alternative J, the Preferred Alternative in the DEIS, also was not considered in detail in the FEIS. There were few comments on this alternative from the public review and many of the comments that were received expressed reservations about the level of environmental impacts associated with a departure. A review of the environmental effects of the departure alternatives considered in the DEIS, Alternative J - Dep. and Alternative B, did indicate generally higher levels of adverse effects in comparison to the other alternatives. See Chapter IV, DEIS for further information. Because of the high level of environmental effects and relative low level of public input for depatures

as a means of addressing the timber supply issue, no departure alternatives were analyzed in detail in the FEIS. See Chapter II of DEIS for discussion of departure opportunities and effects on timber supply.

In addition to the WFC and ONRC input between the DEIS and FEIS on specific alternative proposals, the Sierra Club also proposed an alternative for the Forest. The objectives of the Sierra Club Family Multiple-Use Alternative were to:

- Maintain approximately 60,000 additional acres in roadless condition (as compared to Alternative J).

- Protect all of the remaining "Classic" and "Early Classic" old-growth that was in a timber harvest category in Alternative J. The best available estimate is 126,000 acres which would be removed from timber harvest.

- Minimize further fragmentation of the Forest by using a "triage" concept to identify areas already highly fragmented from those with more coniguity. Harvest opportunities would be emphasized in the fragmented areas.

- Provide a level of timber supply near the historical harvest level for the past 10 years or approximately 520 MMBF.

A preliminary analysis indicated that the timber harvest objective and the roadless and old-growth objectives could not be met simultaneously. Comparisons with DEIS data for Alternative J show an ASQ of about 440 MMBF for the proposed land allocations. Additional analysis of Alternative J and other alternatives for the FEIS indicate that a detailed analysis using the FEIS FORPLAN model would likely result in an even lower ASQ projection. A detailed analysis of the Sierra Club proposal would also be difficult due to lack of a common map to indicate where and more precisely how many "classic" and "early classic" old-growth stands were to be protected. The preliminary analysis was done by correlating narrative descriptions with available Forest data to the extent possible, but mapped information would be necessary for further analysis.

The Sierra Club alternative was not considered in detail in the FEIS for the following reasons:

- Many of the resource objectives proposed were similiar to or were included in other alternatives considered in detail; roadless recommendations - Alternatives D, and L; old-growth - Alternatives D and L; fragmentation - Alternative W; timber supply - Alternative W.

- The "triage" concept failed to produce enough additional timber harvest on the acres identified for high intensity timber management primarily because meeting management requirements for other resources such as wildlife, water and soils did not allow large increases in harvests from these areas. Without the ability of these areas to compensate for decreases due to additional roadless and old-growth protection, the objectives stated for the alternative were not possible.

ALTERNATIVES CONSIDERED IN DETAIL

Introduction

Seven alternatives are considered in detail, Alternatives NC, A, D, J, L, K, and W. These offer various views as to how the land and resources of the Forest could be managed. Each is a combination of land allocations, management practices, and activity schedules which, when implemented, would result in a unique combination of resource outputs and environmental consequences. Together, they present a broad range of possible management alternatives.

The significant land uses, environmental effects, and resource levels are presented by alternative and time period in later sections of this chapter. Chapter IV, Environmental Consequences, describes the causes and relationships of the resource levels and environmental effects in detail.

Features Common to All Alternatives

In this section the features common to all alternatives are described. These features are goals and program levels which are found in all alternatives; inventories and assumptions used in modelling; and mitigation measures which are required to meet Management Requirements. Features which are not included in the No Change Alternative are noted below.

Management activities in each alternative are subject to S&Gs needed to attain the objectives and desired future condition for the Forest and for specific MAs. These standards are often required to mitigate the effects of management activities. S&Gs common to all alternatives (except No Change) are included in Appendix D. Additional S&Gs which apply to the Preferred Alternative are included in the Forest Plan which accompanies this FEIS. Some of these S&Gs are adopted from the Regional Guide for the Pacific Northwest Region, and others were developed by the interdisciplinary team specifically to respond to conditions on the Forest. Mitigation measures listed below are representative of the major types of mitigation found in all of the alternatives. The degree to which they are implemented varies according to the goals and objectives of each alternative, and in accordance with specific site characteristics. In all cases, mitigation measures would be designed at the project level during plan implementation, to fit the site.

Mitigation measures serve to accomplish the following:

- Avoiding impact of an activity altogether by not taking a certain action or parts of an action,
- Minimizing impacts by limiting the degree or magnitude of the action and its implementation,
- Rectifying the impact by repairing, rehabilitating or restoring the affected environment,
- Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action,
- Compensating for the impact by replacing or providing substitute resources or environments.

Timber

With the exception of the No Change Alternative, current information is used including the most recent timber inventory data and yield tables.

Areas which cannot be adequately restocked within 5 years, or with active land slides or risk of irreversible damage to soil and water resources, would be designated as unsuitable for timber production, and would have no programmed timber harvest.

The final determination of timber harvest method would be made on a site-specific level for each project. All alternatives would employ combinations of the silvicultural systems applicable on this Forest. Even-aged and uneven-aged systems, including clearcut, shelterwood, seed tree, single tree selection and group selection harvest methods are all available tools under each alternative. The S&Gs indicate the system generally appropriate for given combinations of site and stand conditions, and management goals and objectives. The FEIS, Appendix F presents a discussion of the various systems, comparisons of their effects, and rationale for uses under different conditions. The final selection of a silvicultural system for a specific site would be left for the silvicultural prescription. This is consistent with the Criterion 6 of Section I-1 of the S&Gs in the Regional Guide for the Pacific Northwest Region. (USDA 1984b).

Logging systems would also be matched to the site specific conditions, with systems selected to meet the resource objectives at the least cost. All systems would be available, including helicopter, and would be used where appropriate. The cost data used in the analysis includes allowances for this mix of logging systems in the timber program. Timber management intensities, which define the levels of practices such as fertilization, precommercial and commercial thinning, etc., were developed to portray different investment levels.

Pest Management

An integrated approach to pest management would be employed that incorporates the Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation. In implementing the Forest Plan through project activities, the Forest would comply with the Record of Decision issued by the Regional Forester dated December 8, 1988, and the Mediated Agreement of May, 1989. Use of all vegetation management techniques is allowed only when other methods are ineffective or would unreasonably increase project costs. Emphasis must be on prevention and early treatment of unwanted vegetation and full public involvement in all aspects of project planning and implementation. Monitoring and enforcement plans to implement specific methods would be developed for site-specific projects and described in the environmental analyses for these projects.

Wildlife

At least two potential nest sites would be managed to meet management requirements and the Pacific States Peregrine Falcon Recovery Plan.

All active bald eagle nest sites would be protected. Additional potential nest sites would be protected to meet the management requirement of 21 active and potential nest areas.

Except for the No Change Alternative, all of the S&Gs concerning Spotted Owl Habitat Areas are based on the direction in the Regional Guide. The Pacific Northwest Region's Final Supplemental Environmental Impact Statement (SEIS) considers a range of alternatives for spotted owl habitat management. The Preferred Alternative in the Final SEIS changed direction for spotted owl habitat management from that described in the Regional Guide. Appendix G displays the potential effects of this change on some of the alternatives described in this chapter.

Many mitigation measures are designed to maintain wildlife habitat. Some roads would be closed to protect threatened and endangered species habitat during critical periods such as the nesting and

breeding season for bald eagles. Access would be controlled to increase habitat effectiveness for deer and elk. The amount of roads with limited entry depend on the elk habitat objectives for the area. Dead, down and defective trees would be protected to meet or exceed management requirement habitat for primary cavity excavator species of birds. Habitat manipulation projects would be undertaken to improve habitat or mitigate habitat loss for wildlife species.

Fish

Increasing the passage of anadromous fish around reservoirs on and adjacent to the Forest would be encouraged by working in partnership with other Agencies, and the public. Rehabilitation and enhancement projects for anadromous fish habitat would be implemented where compatible with other land allocations. Fish population management objectives would be compatible with fish management goals of Oregon Department of Fish and Wildlife, and the Northwest Power Planning Council.

Riparian areas and fish habitat would be protected through mitigation measures which prevent disturbance to streams during spawning seasons, require directional felling of harvested timber, and suspension over stream channels during yarding. When catastrophic events occur, or when preventive measures are insufficient, riparian areas would be rehabilitated by planting grass and tree species with rapid growth characteristics, and by introducing boulders, gabions, or large woody debris.

High quality habitat would be provided for the Oregon Willamette Chub at Buckhead Wildlife Area and Shady Dell campground.

Soil and Water

Management activities in all alternatives would be governed by those S&Gs which include Best Management Practices (BMPs). BMPs are specifically designed to protect water quality, as required by Section 208 of the Clean Water Act. General BMPs would be selected and tailored for site-specific conditions to arrive at project-level BMPs for the protection of water quality. Best Management Practices used on the Forest would meet or exceed BMPs described by the Oregon Forest Practices Act. See BMP Appendix H for a discussion of the process and practices.

Many BMPs are routinely built into ground or vegetation disturbing projects (e.g., timber sales) in order to mitigate adverse effects on soil productivity and water quality. Preventative practices such as log yarding with the entire log or one end-suspended, and burning slash when soil and duff moisture contents are high, have been found to minimize soil erosion and productivity losses. Road construction, reconstruction, and maintenance practices also receive focused attention in project level planning and execution. Road drainage techniques, culvert design, and stream crossing structures are all designed to mitigate the impacts of the Forest road system.

The risk of adverse cumulative effects to water quality vary according to the effectiveness of the selected BMP's and the rates of timber harvest and road construction in subdrainages.

Wetlands and floodplains would be protected according to Executive Order 11990 and E.O.11988. The requirements of the Clean Water Act would also direct the management of wetlands.

Long term soil productivity would be maintained by implementing practices to maintain soil condition. Cost effective soil and water enhancement projects would be undertaken where compatible with other resource goals.

Wild and Scenic Rivers

Except for the No Change Alternative, all of the Alternatives provide for protection of outstandingly remarkable values of 2 designated Wild and Scenic study rivers and portions of 8 rivers determined eligibible for inclusion in the National Wild and Scenic Rivers system. Protection of river values for designated study and eligible rivers is afforded these rivers pending Congressional action or until river segments are determined unsuitable for inclusion into the National System.

Fire and Fuels

A full fire prevention program would be implemented. Three to five lookouts would be staffed. Aerial detection would be provided, as necessary and where cost-effective, after lightning storms and on high risk days. An initial attack program which emphasizes cost-effective presuppression and suppression, while minimizing resource loss would be provided.

Logging residue would be utilized for multiple purposes including nutrient recycling, wildlife habitat, fuelwood, and other commercial products, while achieving reforestation and air quality objectives. Prescribed burning would be limited to times and sites which do not impact high use areas of the Forest and nearby population centers.

The Forest would comply with daily smoke management instructions from the State Forestry Office to mitigate air quality impacts from slash burning. These instructions specify where and when burning is allowed. Other air quality mitigation measures include early and aggressive fire mop-up, increased utilization of logging residue, and public education.

Cultural Resources

Cultural resource management would be accomplished in accordance with appropriate laws, regulations, and policies for both historic and prehistoric properties, and to ensure the rights of Native Americans to practice their traditional religions.

Minerals and Energy

The amount of land available for entry by mineral and energy development would be directly related to the total acres of land in allocations which permit this activity. All energy related applications, notices of intent, or operating plans for locatable minerals would be responded to in a timely manner. Active permits and claims would be administered to established standards to minimize adverse impacts to surface resources. All anticipated major energy projects, mining opportunities and leases, and claims with potential for development would be identified.

Facilities

Utility transmission corridors are excluded from crossing the crest of the Cascades along much of the eastern boundary of the Forest because of designated Wilderness. There are five areas on the crest that are not Wilderness and which are therefore "windows" through which utility transmission corridors could possibly pass. These windows are the areas in the vicinity of Emigrant Pass, Willamette Pass, McKenzie Pass, Santiam Pass, and the North Fork of the Breitenbush River.

A number of avoidance areas would be important considerations in the evaluation of corridors through these windows. These considerations include scenic values, wildlife habitat requirements, and needs and values associated with developed downhill and cross-country ski areas.

If the need arises for utility transmission corridors on the Forest, their establishment and location would be determined through an evaluation of alternatives (including existing corridors), utilizing a project environmental analysis (NEPA) process, with inter-Forest and interagency coordination and involvement.

Roads

The miles of road constructed during the next decade would be in response to needs of the timber sale program for each alternative. Management of existing roads would be responsive to the management objectives of resources appropriate to the MA and alternative.

Lands

All existing special use permits would be administered to established standards. Necessary landline location would be done to support all resource programs. Investments in permanent markers would be maintained. Rights-of-way necessary to support revenue producing resources would be acquired. The desired land ownership pattern in the Forest Plan would be achieved with methods other than purchase.

Law Enforcement

A Forest Service law enforcement agent would make regular patrols in all areas of the Forest. Cases with some possibility of recovering costs would be investigated. Cooperative law enforcement agreements would provide regular weekend and holiday patrols at fee sites and other high use areas from the beginning of fishing season through the month of September. An aggressive cannabis (Marijuana) eradication program would also be maintained.

Firewood

The number of personal use firewood permits issued, amount available per permit, and cost of each would be evaluated and adjusted yearly, based on demand and the cost of administering the program. Firewood cutting areas would also be determined on an annual basis.

H.J. Andrews Experimental Forest

The H.J. Andrews Experimental Forest would be managed for research, according to the objectives of the coordinating agreement between the Pacific Northwest Research Station and the Forest.

Alternative Goals And Management Objectives

This section presents the goals and objectives of the seven alternatives.

Each alternative has a set of goals and output objectives. These are designed to respond to public issues and management concerns identified in Chapter I and Appendix A. Each alternative distributes the lands of the Forest to different MAs. Acreages assigned to different MAs vary from one alternative to another (Table II-3), Comparison of Alternatives). Locations of the MAs for each alternative are displayed on the maps which accompany this document. Descriptions of the MAs are presented in Comparison of Alternatives section in this Chapter.

ALTERNATIVE NC (No Change)

Goals and Background - The No Change (NC) Alternative represents implementation of the Forest's existing Land Management and Timber Management Plan to achieve timber production at potential yield levels.

The No Change Alternative has been developed in response to decisions made regarding Appeal Number 1588, brought by the Northwest Forest Resources Council on May 19, 1986. The appeal centered on a decision by Regional Forester James F. Torrence to "require inclusion of Minimum Management Requirements (MMRs) in the No Action Alternative for each Forest Plan." The substance of the appeal was that a "true No Action Alternative representing current management plans" was not included in the DEIS and is not included in the FEIS. In response to this, a No Change Alternative has been developed to represent the existing timber management plan, and consequently does not comply with all provisions of the National Forest Management Act (NFMA) and regulations promulgated by the Secretary of Agriculture to implement NFMA.

The following provisions of NFMA or other laws or regulations are not partially or fully complied with in the current management plan represented by the No Change Alternative:

> 36 CFR 219.14 - Timber resource land suitability: requires identification of lands not suited for timber production based on risk of irreversible resource damage, lack of assurance of reforestation within five years, or withdrawal by Act of Congress, Secretary of Agriculture, or Chief of Forest Service.
>
> 36 CFR 219.16 - Requires that all alternatives identify decadal timber harvest levels and long-term sustained yield levels, consistent with the requirements of the RPA program and Regional guide. Also specifies conditions under which departure from nondeclining flow will be considered.
>
> 36 CFR 219.18 - Requires that Wilderness management direction be provided, including actions needed to limit or distribute visitor use, and measures desirable to protect the Wilderness or adjacent areas from wildfire, insects or disease.
>
> 36 CFR 219.19 - Provides for viable populations of vertebrate wildlife species, the selection and monitoring of management indicator species, cooperation with wildlife management agencies, and protection of habitat critical to threatened or endangered species.
>
> 36 CFR 219.23 - Requires full consideration of water and soil resources including estimates of current water uses, instream flow requirements, protection of water quality, watershed condition, and protection of wetland and floodplain values.
>
> 36 CFR 219.27 - Identifies specific management requirements to be used in the development, analysis, approval, implementation, monitoring and evaluation of forest plans for activities including: silvicultural practices, resource protection, vegetative manipulation, protection of riparian areas, protection of soil and water, and maintenance of diversity.

The Multiple-Use Land and Timber Management Plan upon which the No Change Alternative is based was developed in 1977. The original plan was based on yield tables and resource relationships which do not reflect the latest scientific techniques and information and do not reflect the standards in the NFMA regulations. The timber management plan has been amended following Congressional designa-

tions (new Wilderness and Wilderness additions), but there has not been reconciliation of the timber management plan with unit plan direction and requirements of NFMA.

The difference in assumptions between the No Change Alternative and the other alternatives is of a magnitude such that some activities, costs, outputs, and effects could not be reasonably estimated or compared to other alternatives. These different assumptions include the following:

- Alternative NC includes 125,000 acres of "marginal" lands programmed at full yield. This results in a suited landbase of 1,064,616 acres. About 60% of the lands in the marginal category are considered unsuited by today's standards. The current plan proposed program recognized the difficulty of managing these lands by scheduling only 7% of the potential harvest on marginal soils, to provide research on management practices.

- Management Requirements are not provided in the No Change Alternative. The most significant requirements included in all other alternatives are providing for maintenance of viable fish and wildlife populations, and dispersion of timber harvest units.

- Timber yields were developed from a different timber inventory, used different growth and yield models, and were based on a different grouping of species and site indices. Fertilization was not included in yield tables for the No Change Alternative.

- Alternative NC uses commercial thinning volume to offset the shortage of mature timber available for harvest in the 6th and 8th decades. As many as six thinnings, spaced ten years apart, are prescribed for some stands with the total yield from commercial thinning accounting for half or more of the volume, thus allowing harvest levels to be maintained at the long term sustained yield capacity.

- Multiple resource objectives were not directly represented in the model used to calculate the potential yield for Alternative NC; areas like streamside zones and scenic corridors had reduced yields to represent these objectives.

These differences prevented use of the current Forest FORPLAN model to evaluate the No Change Alternative.

Recreation - The current mix of public and private sector management of developed sites would remain unchanged. A 108-day managed season for developed facilities would be in effect.

Semiprimitive motorized and nonmotorized dispersed recreation opportunities would be provided from several land allocations including the Waldo Lake Recreation Area and the Oregon Cascades Recreation Area (OCRA). The OCRA is managed to provide motorized use opportunities throughout the year.

Seventy percent of the Forest would be open to off-road vehicles (ORVs); 30% would be either closed or restricted to a specified season of use and/or type of vehicle.

Existing nonwilderness trails, totaling 714 miles, would be retained in this alternative; periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

Increases in future use of Wilderness would be allowed up to user capacity of each Wilderness Resource Spectrum class MA. Trail maintenance, and resource protection and rehabilitation measures would be employed routinely. No additional trails would be constructed.

Nomination of sites to the National Register of Historic Places would be performed as necessary.

The natural and cultural characteristics of four areas (1,813 acres) in the Forest would be preserved as Special Interest Areas (SIAs) in this alternative. These are Monument Peak Botanical Area, Wolf Rock Geological Area, Lamb Butte Scenic Area, and Tumblebug Gorge Geological Area. In addition, this alternative designates 22 specimen old-growth timber groves, totaling 1,237 acres, to provide for recreational use, educational study, and aesthetic appreciation.

Roadless Lands - This alternative would maintain significant portions of 8 inventoried roadless areas and lesser amounts of other inventoried roadless areas in an undeveloped condition. The majority of the Mt. Hagan roadless area would be allocated to multiple-use management, including a Research Natural Area and timber harvest.

Visual Resources - This alternative emphasizes a high to moderate level of scenic quality within foreground zones of all State and Federal highways. The overall scenic quality of Forest viewshed corridors, however, would have a low to moderate emphasis in this alternative.

The foreground areas of all State and Federal highways, selected major Forest roads, and selected trails would be managed to ensure that landscape alterations are not evident from within the area (Visual Quality Objective (VQO) of Retention). In addition, the foreground areas of selected Forest roads and trails are managed to ensure that changes, while noticeable, remain subordinate to the character of the surrounding landscape (VQO of Partial Retention).

Portions of middleground view areas from State Highway 22 and State Highway 126 and from selected Forest roads, are managed to provide a landscape scene where alterations are subordinate to the character of the surrounding area (VQO of Partial Retention).

Old Growth - A minimum of approximately 260,000 acres of old growth (R-6 definition) would be maintained after fifty years in this alternative. These acres are in areas administratively and legislatively removed from development and lands unsuited for timber production. Additional old growth would be present in timber production areas for several decades.

Timber - Timber harvest would be scheduled on a suited landbase of 1,064,600 acres. Approximately 918,700 acres would be managed on rotations of less than 100 years, and 145,900 acres on rotation ages of 100 to 200 years. The Allowable Sale Quantity (ASQ) of 810 MMBF for the 1st decade would be about 30% higher than the average amount sold annually between 1977 and 1989.

Wildlife - Forest-wide, optimal thermal cover would be provided on at least a portion of deer and elk winter range during the first decade. Habitat capability would be provided for a potential population of 3720 elk and 18,600 deer for the first decade. This is the estimated existing population levels.

Twenty-one bald eagle sites would be provided including five active nest sites.

Natural openings would be maintained or enhanced whenever possible. Special attention would be given to the management of natural openings within MAs with timber harvest.

Fish - Improvements would be made on 1,335 acres of reservoirs for resident trout.

Water - Riparian areas would be managed at minimum levels for water quality protection. Water quality would reflect watershed conditions created by managment practices, particularly the cumulative conditions created by high levels of timber harvest and road construction.

Research Natural Areas - This alternative would provide for research needs and opportunities through six Research Natural Areas (RNAs). Of the six RNAs included in this alternative, four are established areas, and two are proposed new areas to meet research needs of the Pacific Northwest Research Natural Area Committee.

ALTERNATIVE K

Goal Statement - Alternative K represents a low emphasis on nonmarket values and a high emphasis on commodity production. The management philosophy of this alternative is one which emphasizes a public understanding of the practices which are undertaken to maximize production of market goods from the forest, under multiple-use principles. The focus is to maintain high levels of timber harvest by making most of the Forest's tentatively suited land available for timber production. The objective is to maintain a timber supply level equal to the historical levels. This Alternative was formulated with input from the Willamette Forestry Council (WFC).

Roadless areas not designated as Wilderness in the 1984 Oregon Wilderness Act would be managed for a variety of multiple use values including timber, except for Bull of the Woods Roadless Area. The visual quality objective would be to allow all types of management activities to be seen in all areas, but the activities would not dominate the views.

Developed recreation would be emphasized, with all existing and inventoried potential developed recreation sites being managed and protected. The Forest transportation system would increase, making larger areas accessible for motorized recreation.

An objective would be to maintain water quality by insuring strict adherence to operational Best Management Practices.

Recreation - Privately managed sites and all publicly managed sites would be maintained and enhanced to meet increased demand for developed site use. In addition, the conversion of old sites to their original form and use; the expansion of other existing sites to increase capacity and diversity of opportunities; and the development of new sites would be employed to meet anticipated increases in demand for developed site use. This alternative also proposes the development of interpretive centers along major travel corridors such as the I-5 route to promote and facilitate use of the Forest. A 108-day managed season for developed facilities would be in effect.

Semiprimitive dispersed recreation opportunities are provided in areas that are unsuitable for timber production. Semiprimitive motorized use opportunities are provided from seven seperate areas in the Forest. Semiprimitive nonmotorized recreation opportunities are provided from three areas. The Oregon Cascades Recreation Area (OCRA) would be managed to provide only nonmotorized use in this alternative except for over the snow use.

Sixty-three percent of the Forest would be open to off-road vehicles (ORVs), 7% restricted to a specific season of use and/or type of vehicle, and 30% closed to ORVs.

Existing nonwilderness trails, totaling 714 miles, would be retained in this alternative. Additional trails would be developed as needed to accomodate increased trail related use. Periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

Management of Wilderness would be accomplished with current budget levels. Increases in future use would be limited to user capacity of each WRS class MA. Trail maintenance, and resource protection and rehabilitation measures would be employed. No additional trails would be constructed.

Nomination of sites to the National Register of Historic Places would be performed as necessary.

Nine areas (2,715) having significant characteristics as either scenic, geologic, botanic, historic, or archeologic Special Interest Areas are included in this alternative. A portion of the historic Central Oregon Military Wagon Road is also included. Also in this alternative, seven specimen old-growth timber groves, totaling 853 acres, are allocated to provide for recreational use, educational study, and aesthetic appreciation.

Roadless Lands - This alternative would maintain significant portions of two inventoried roadless areas in an undeveloped condition. The Mt. Hagan roadless area would be allocated to multiple-use management, including timber harvests in this alternative.

Visual Resources - The central theme of scenic resource management in this alternative is to facilitate visual awareness and understanding by the forest users of all components of Forest management through demonstration of forest management activities. The overall scenic quality of Forest viewshed corridors however have a low to moderate emphasis.

The foreground areas of all State and Federal highways would be managed to ensure that alterations, while noticeable from within, remain subordinate to the character of the surrounding landscape. In addition, the foreground areas of several Forest roads are managed to ensure that alterations, while dominate, possess characteristics of form, line, color, and texture that occur in the surrounding landscape. Management activities within middleground viewing areas of State and Federal highways would also appear dominate but possess attributes of the surrounding landscape.

Old Growth - A minimum of approximately 305,000 acres of old growth (R-6 definition) would be maintained after fifty years in this alternative. These acres are in areas administratively and legislatively removed from development, lands unsuited for timber production, and areas set aside for riparian and wildlife Management Requirements. Old growth would also be present in timber production areas to some extent for several decades.

Timber - Timber harvest would be scheduled on a suited landbase of 932,813 acres. Approximately 797,000 acres would be managed on rotations of less than 100 years, and 136,000 acres on rotation ages of 100 to 200 years. The alternative would achieve about 97% of the "Forestry Program for Oregon" target without departing from non-declining flow. The Allowable Sale Quantity (ASQ) of 650 MMBF for the 1st decade would be about 4% higher than the average amount sold annually between 1977 and 1989.

Wildlife - Bald eagle protection would be provided in 21 areas including five active nest sites. Active nest sites would have site specific management plans prepared, and 30 acres of old growth habitat would be allocated for each potential nest site. All area within 1.1 miles of eleven major water bodies would be considered potential locations for roost, forage, or nest sites.

Management Requirements for peregrine falcon would be met by protecting two potential nest sites.

Suitable habitat would be provided to meet Management Requirements for the northern spotted owl, pileated woodpecker, and marten. Forest-wide habitat networks would be established for each species. This includes 59 spotted owl habitat areas occupied by 60 verified pairs of spotted owls. Approximately

82,782 acres would be specifically dedicated to spotted owl habitat. The remaining spotted owl habitat consists of lands unsuited for timber production. Habitat capability for 35 pairs of spotted owls would be provided in wilderness areas, occupied by 15 verified pairs. Habitat areas managed on 150 year harvest rotations would provide additional suitable habitat for pileated woodpeckers and marten. These extended rotation areas would be distributed and maintained in a pattern meeting Management Requirements for these species.

Effective habitat for deer and elk would be provided by designating High, Moderate, or Low Emphais Areas. Winter range would be 11% high emphasis, 34% moderate emphasis, and 55% low emphasis. Forest-wide, optimal thermal cover would be provided wherever old growth habitat and no harvest allocations overlap. Habitat capability would be provided for a potential population 3720 elk and 17,762 deer, through the first decade.

Created openings contiguous to meadows, talus, cliffs, and caves would not exceed one-third the size of the natural opening perimeter.

Dead and defective tree habitat needed to meet the Management Requirements for primary cavity excavating birds would be provided. Habitat would be distributed to provide for 40% of the potential population forest-wide. Individual harvest units would be managed for 20% potential populations. A minimum of two logs per acre of would be left as large down woody material on at least 10 % of the harvested acres.

Habitat improvement projects would be planned in conjunction with timber sales. Projects would emphasize snag creation, access management, and forage enhancement.

Fish - Improvements would be made on 1,335 acres of reservoirs for resident trout.

Water - Riparian areas would be managed at minimum levels for water quality protection. Water quality would reflect watershed conditions created by management practices, particularly by the cumulative conditions created by high levels of timber harvest and road building.

Research Natural Areas - This alternative would provide for research needs and opportunities through five Research Natural Areas (RNAs). Of the five RNAs included in this alternative, four are established areas and one is a proposed new area to meet requirements of the Pacific Northwest Research Natural Area Committee.

ALTERNATIVE A (No Action)

Goal Statement - Alternative A represents implementation of the Forest's existing Land Allocations with the addition of Management Requirements for wildlife habitat and riparian areas, and updates on inventories of land suitability and timber yield tables. This alternative emphasizes a high level of timber production, with a low emphasis on roadless recreation, and other non-commodity forest uses.

Recreation - The current mix of public and private sector management of developed sites would remain unchanged. A 108-day managed season for developed facilities would be in effect.

Semiprimitive motorized and nonmotorized dispersed recreation opportunities would be provided from several land allocations including the Waldo Lake Recreation Area and the Oregon Cascades Recreation Area (OCRA). The OCRA is managed to provide motorized use throughout the year.

Sixty-one percent of the Forest would be open to off-road vehicles (ORVs); 39% would be either closed or restricted to a specified season of use and/or type of vehicle.

Existing nonwilderness trails, totaling 714 miles, are retained in this alternative; periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

Management of Wilderness would be accomplished with current budget levels. Increases in future use would be limited to user capacity of each WRS class MA. Trail maintenance, and resource protection and rehabilitation measures would be employed routinely. No additional trails would be constructed.

Nomination of sites to the National Register of Historic Places would be performed as necessary.

The characteristics of four areas (1,109) in the Forest would be preserved as Special Interest Areas (SIAs) in this alternative. These are Monument Peak Botanical Area, Wolf Rock Geological Area, Lamb Butte Scenic Area, and Tumblebug Gorge Geological Area. Also in this alternative, 22 specimen old-growth timber groves, totaling 2,730 acres, are allocated to provide for recreational use, educational study, and aesthetic appreciation.

Roadless Lands - This alternative would maintain significant portions of eight inventoried roadless areas and lesser amounts of other inventoried roadless areas in an undeveloped condition. The majority of the Mt. Hagan roadless area would be allocated to multiple-use management, including a Research Natural Area and timber harvest.

Visual Resources - This alternative emphasizes a high to moderate level of scenic quality within foreground zones of all State and Federal highways. The overall scenic quality of Forest viewshed corridors, however, have a low to moderate emphasis.

The foreground areas of all State and Federal highways, selected major Forest roads, and selected trails would be managed to ensure that landscape alterations are not evident from within the area (Visual Quality Objective (VQO) of Retention). In addition, the foreground areas of selected Forest roads, and trails are managed to ensure that changes, while noticeable, remain subordinate to the character of the surrounding landscape (VQO of Partial Retention).

Portions of middleground view areas from State Highway 22 and State Highway 126 and from selected Forest roads, are managed to provide a landscape scene where alterations are subordinate to the character of the surrounding area (VQO of Partial Retention).

Old Growth - A minimum of approximately 337,000 acres of old growth (R-6 definition) are maintained after fifty years in this alternative. These acres are in areas administratively and legislatively removed from development, lands unsuited for timber production, and areas set aside for riparian and wildlife Management Requirements, and as specimen old-growth groves. Old growth would also be present in areas of timber production for several decades.

Timber - Timber harvest would be scheduled on a suited landbase of 874,291 acres. Approximately 743,400 acres would be managed on rotations of less than 100 years, and 131,000 acres on rotation ages of 100 to 200 years. The Allowable Sale Quantity (ASQ) of 608 MMBF for the 1st decade would be about 98% of the the average amount sold annually between 1977 and 1989.

Wildlife - Bald eagle protection would be provided in 21 areas including five active nest sites. Active nest sites would have site specific management plans prepared, and 30 acres of old growth habitat

would be allocated for each potential nest site. All area within 1.1 miles of eleven major water bodies would be considered potential locations for roost, forage, or nest sites.

Management Requirements for peregrine falcon would be met by protecting two potential nest sites.

Suitable habitat would be provided to meet Management Requirements for the northern spotted owl, pileated woodpecker, and marten. Forest-wide habitat networks would be established for each species. This includes 59 spotted owl habitat areas occupied by 60 verified pairs of spotted owls. Approximately 81,075 acres would be specifically dedicated to spotted owl habitat. The remaining spotted owl habitat consists of lands unsuited for timber production. Habitat capability for 35 pairs of spotted owls would be provided in wilderness areas, occupied by 15 verified pairs. Designating 100 marten habitat areas (160 acres each) and 38 pileated woodpecker habitat areas (300 acres each) would meet the Management Requirements for habitat distribution for these species. Additional marten and pileated woodpecker habitat would occur in spotted owl habitat areas, wilderness areas, and in other no harvest allocations.

Effective habitat for deer and elk would be provided by designating High, Moderate, or Low Emphasis Areas. Winter range would be 18% high emphasis, 35% moderate emphasis, and 47% low emphasis. Forest-wide, optimal thermal cover would be provided wherever old growth habitat and no harvest allocations overlap. Habitat capability would be provided for a potential population 4285 elk and 21,425 deer through the fifth decade.

Created openings contiguous to meadows, talus, cliffs, and caves would not exceed one-third the size of the natural opening perimeter.

Dead and defective tree habitat needed to meet the Management Requirement for primary cavity excavating birds would be provided. Habitat would be distributed to provide for 40% of the potential population forest-wide. Individual harvest units would be managed for 20% potential populations. A minimum of two logs per acre of would be left as large down woody material on at least 10% of the harvested acres.

Habitat improvement projects would be planned in conjunction with timber sales. Projects would emphasize snag creation, access management, and forage enhancement.

Fish - Improvements would be made on 1,335 acres of reservoirs for resident trout.

Water - Riparian areas would be managed at minimum levels for water quality protection. Water quality would reflect watershed conditions created by management practices, particularly the cumulative changes in watershed condition resulting from timber harvest and road construction.

Research Natural Areas - This alternative would provide for research needs and opportunities through six Research Natural Areas (RNAs). Of the six RNAs included in this alternative, four are established areas, and two are proposed new areas to meet requirements of the Pacific Northwest Research Natural Area Committee.

ALTERNATIVE J

Goal Statement - Alternative J represents a moderate emphasis on nonmarket resources, and a moderate emphasis on commodity production. The focus is to balance the need for timber supply at levels near historical levels, while maintaining several important roadless areas, important old-growth

areas, and scenery issues in a way that provides some degree of issue resolution for each. This was the Preferred Alternative of the DEIS.

Recreation - All existing sites would remain open under the current mix of public and private management. Existing capacity of publicly managed sites would be expanded. A 108-day managed season for developed facilities would be in effect except where it is cost effective to extend the use season.

Emphasis is placed on maintaining significant portions of the Forest's semiprimitive dispersed recreation opportunities in an undeveloped condition. Areas available for semiprimitive nonmotorized recreation use total 89,458 acres, while motorized opportunities in a semiprimitive recreational setting are provided from 31,291 acres of Forest. The OCRA is managed to provide for motorized use over the entire area during winter, and on designated trails during snow free periods.

Fifty-nine percent of the Forest would be open to off-road vehicles (ORVs), 6% restricted to a specified season of use and/or type of vehicle, and 35% closed to ORVs.

All existing nonwilderness trails (714 miles) are retained in this alternative and 40 miles of new trails would be constructed, with priority given to those trails located in semiprimitive nonmotorized recreation areas. Periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

Management of Wilderness would be accomplished with current budget levels. Increases in future use be limited to user capacity of each WRS class MA. Trail maintenance, and resource protection and rehabilitation measures would be employed routinely. No additional trails would be constructed.

Interpretation of cultural sites and public awareness efforts would be maintained at current levels. Nomination of all Forest historic sites to the National Register of Historic Places would be emphasized.

Twenty-seven areas (22,598) having significant characteristics as either scenic, geologic, botanic, historic, or archeologic Special Interest Areas are included in this alternative. The McKenzie River from Scott Creek to the Forest boundary, Fall Creek, and the South Fork of the McKenzie River would be designated as Special Interest Areas. Also included as Special Interest Areas would be the historic Santiam Wagon Road and portions of the historic Central Oregon Military Wagon Road. 18 specimen old-growth timber groves, totaling 4,096 acres, are allocated to provide for recreational use, educational study, and aesthetic appreciation.

Roadless Lands - This alternative would maintain significant portions of 13 inventoried roadless areas, and lesser amounts of other inventoried roadless areas, in an undeveloped condition. The majority of the Mt. Hagan roadless area would be allocated to multiple-use management, including a Research Natural Area and timber harvest.

Visual Resources - This alternative emphasizes a moderate level of scenic quality within major viewshed corridors.

The foreground areas of all State and Federal highways, major Forest roads, and selected trails would be managed to ensure that landscape alterations are not evident (VQO of Retention). In addition, the foreground areas of selected Forest roads and trails are managed to ensure that changes, while noticeable, remain subordinate to the character of the surrounding landscape (VQO of Partial Retention).

Portions of the middleground areas of State Highways 22, 126, and 58 and U.S. Highway 20 viewshed corridors, and the viewsheds of selected Forest roads, are managed to provide a landscape scene where alterations are subordinate to the character of the surrounding area (VQO of Partial Retention). In addition, the remaining middleground areas of viewshed corridors and the viewsheds of several Forest roads are managed to ensure that alterations, although visually dominant, possess characteristics of form, line, color, texture, and scale that occur in the surrounding landscape (VQO of Modification).

Old Growth - A minimum of approximately 341,400 acres of old growth (R-6 definition) are maintained after fifty years in this alternative. These acres are in MAs administratively and legislatively removed from development, lands unsuited for timber production, and areas set aside for riparian and wildlife Management Requirements. Old growth would also be present in areas in timber production areas for several decades.

Timber - Timber harvest would be scheduled on a suited landbase of 853,389 acres. Approximately 720,000 acres would be managed on rotations of less than 100 years, and 133,000 acres on rotation ages of 100 to 200 years. The Allowable Sale Quantity (ASQ) of 530 MMBF for the 1st decade would be about 85% of the average amount sold annually between 1977 and 1989.

Wildlife - Bald eagle protection would be provided in 24 areas including five active nest sites. Active nest sites would have site specific management plans prepared, and 30 acres of old growth habitat would be allocated for each potential nest site. All area within 1.1 miles of eleven major water bodies would be considered potential locations for roost, forage, or nest sites.

Management Requirements for peregrine falcon would be met by protecting 12 potential nest sites.

Suitable habitat would be provided to meet Management Requirements for the northern spotted owl, pileated woodpecker, and marten. Forest-wide networks would be established for each species. This includes 59 spotted owl habitat areas occupied by 60 verified pairs of spotted owls. Approximately 70,560 acres would be specifically dedicated to spotted owl habitat. The remaining spotted owl habitat consists of lands unsuited for timber production. Habitat capability for 35 pairs of spotted owls would be provided in wilderness areas, occupied by 15 spotted owl pairs. Designating 100 marten habitat areas (160 acres each) and 38 pileated woodpecker habitat areas (300 acres each) would meet the Management Requirements for habitat distribution for these species. Additional marten and pileated woodpecker habitat would occur in spotted owl habitat areas, wilderness areas, and in other no harvest allocations.

Effective habitat for deer and elk would be provided by designating High, Moderate, or Low Emphasis Areas. Winter range would be 35% high emphasis, 26% moderate emphasis, and 39% low emphasis. Forest-wide, optimal thermal cover would be provided wherever old growth habitat and no harvest MAs overlap. An additional 4970 acres of optimal thermal cover would be allocated to site specific high emphasis winter ranges. Habitat capability would provide for a potential population 5709 elk and 28,545 deer through the first decade. The habitat capability would decline through the fifth decade resulting in habitat capable of providing potential populations of 4441 elk and 22,210 deer.

Created openings contiguous to meadows, talus, cliffs, and caves would not exceed one-third the size of the natural opening perimeter. Protection of these special and unique habitats would result in 11,348 acres removed from lands suited for timber production.

Dead and defective tree habitat needed to meet the Management Requirement for primary cavity excavating birds would be provided. Habitat would be distributed to provide for 40% of the potential population within each sub-watershed. Individual harvest units could be managed for 20% potential

populations provided the sub-watershed habitat objective is met. A minimum of two logs per acre of would be left as large down woody material on at least 10% of the harvested acres.

Habitat enhancement projects would be planned in conjunction with timber sales. Projects would emphasize snag creation, access management, and forage enhancement.

Fish - Improvements would be made on 1,335 acres of reservoirs for resident trout.

Water - Riparian areas would be managed at minimum levels for water quality protection. Water quality would reflect watershed conditions created by management practices, particularly the cumulative conditions resulting from the levels of roadbuilding and timber harvest emphasized in the alternative.

Research Natural Areas - This alternative provides for research needs and opportunities through nine Research Natural Areas (RNAs). Of the nine RNAs included in this alternative four are established areas and five are proposed new areas to meet requirements of the Pacific Northwest Research Natural Area Committee.

ALTERNATIVE W

Goal Statement - This alternative is designed to provide a healthy, diverse, and productive ecosystem that would ensure the capability of the Forest to produce a continuous flow of a variety of goods and services to the public over the long-term. Alternative W was formulated to respond to public comments to the Draft Land and Resource Management Plan.

The ability to provide a dependable supply of timber to the market would continue. This alternative recognizes the importance of maintaining old-growth characteristics in some managed stands. Where timber production is either reduced below biological potential or removed from scheduled timber production to provide other resource benefits, this alternative would emphasize the use of these areas to support other compatible goals such as wildlife, dispersed recreation, watershed protection, biological diversity and ecological studies.

Additional recreation opportunities would include expanding activities compatible with areas withdrawn from timber harvesting as well as providing opportunities such as low elevation hiking trails within areas intensively managed for timber production.

A special emphasis of this alternative would be to recognize the role of river corridors and streamside zones on the Forest as critical components in the overall ecosystem. Management activities in these areas would focus on maintaining and enhancing the long term productivity, first, for those uses dependent on rivers and streams and secondly, for other resources. Timber scheduling would be responsive to the cumulative effects of watershed conditions. Very effective Best Management Practices would be used in the area of potentially unstable lands and Class IV streams.

Recreation - All existing sites would remain open under the current mix of public and private management. Existing capacity of publicly managed sites would be expanded. In addition new sites would be identified for development to meet expected demand for developed site use. A 108-day managed season for standard service facilities would be in effect except where it is cost effective to extend the season.

Emphasis is placed on maintaining significant portions of the Forest's semiprimitive dispersed recreation opportunities in an undeveloped condition. Areas available for semiprimitive nonmotorized recreation use total 85,768 acres, while motorized opportunities in a semiprimitive recreational setting are provided

from 36,048 acres of Forest. The OCRA is managed to provide for motorized use over the entire area during winter, and on designated trails during snow free periods.

57% of the Forest is open to off-road vehicles (ORVs), 6% is restricted to a specified season of use and/or type of vehicle, and 37% is closed to ORVs.

All existing non-Wilderness trails (714 miles) are retained in this alternative and 60 miles of new trails would be constructed. In addition all existing and proposed non-Wilderness trails (1,266 miles) are assigned to one of four trail management classes. Each Trail Management Class provides protection to individual trails and trail segments in relation to the amount and type of use, user experiences, public interest, and adjacent management influences associated with each trail segment. Periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

Management of Wilderness would be accomplished with increased budget levels. Increases in future use would be limited to user capacity of each WRS class MA. Trail maintenance, and resource protection and rehabilitation measures would be employed routinely. No additional trails would be constructed.

Interpretation of cultural sites and public awareness efforts would be maintained at current levels. Nomination of all Forest historic sites to the National Register of Historic Places would be emphasized.

Forty-seven areas (31,120) having significant characteristics as either scenic, geologic, botanic, historic, or archeologic Special Interest Areas are included in this alternative. The McKenzie River from Scott Creek to the Forest boundary, Fall Creek, and the South Fork of the McKenzie River are designated as Special Interest Areas. Also included as Special Interest Areas are the historic Santiam Wagon Road and portions of the historic Central Oregon Military Wagon Road. In addition this alternative includes 32 specimen old-growth timber groves, totaling 6,655 acres, to provide for recreational use, educational study, and aesthetic appreciation.

Roadless Lands - This alternative maintains significant portions of 13? inventoried roadless areas, and lesser amounts of other inventoried roadless areas, in an undeveloped condition. The majority of the Mt. Hagan roadless area would be allocated to multiple-use management, including a Research Natural Area and timber harvest.

Visual Resources - This alternative emphasizes a moderate level of scenic quality within major viewshed corridors.

The foreground areas of all State and Federal highways, major Forest roads, and selected trails are managed to ensure that landscape alterations are not evident (VQO of Retention). In addition, the foreground areas of selected Forest roads and trails are managed to ensure that changes, while noticeable, remain, at least, subordinate to the character of the surrounding landscape (VQO of Partial Retention).

Portions of the middleground areas of State Highways 22, 126, and 58 and U.S. Highway 20 viewshed corridors, and the viewsheds of selected Forest roads, are managed to provide a landscape scene where alterations are subordinate to the character of the surrounding area (VQO of Partial Retention). In addition, the remaining middleground areas of viewshed corridors and the viewsheds of several Forest roads are managed to ensure that alterations, although visually dominant, possess characteristics of form, line, color, texture, and scale that occur in the surrounding landscape (VQO of Modification).

Old Growth - Critical components of old growth, such as down woody debris and scattered residual trees are maintained in intensively managed stands.

Approximately 365,200 acres of old growth (R-6 definition) are maintained after fifty years in this alternative. These acres are in areas administratively and legislatively removed from development, lands unsuited for timber production, areas set aside for riparian, special wildlife habitats, management indicator species, and as specimen Old-Growth groves. Old growth would also be present in areas of timber production for several decades.

Timber - Timber harvest would be scheduled on a suited landbase of 774,608 acres. Approximately 689,000 acres would be managed on rotations of less than 100 years, and 85,000 acres on rotation ages of 100 to 200 years. The Allowable Sale Quantity (ASQ) of 491 MMBF for the 1st decade would be about 79% of the average amount sold annually between 1977 and 1989.

Timber harvest design would include:

Maintaining critical components of old growth, such as down woody debris and scattered residual trees, in intensively managed stands;

Minimizing the fragmentation of forest stands, particularly mature and older stands, by utilizing management options of scheduling the location and timing of harvest.

Wildlife - Bald eagle protection would be provided in 24 areas including five active nest sites. Active nest sites would have site specific management plans prepared, and at least 125 acres of old growth habitat would be allocated for each potential nest site. All area within 1.1 miles of eleven major water bodies would be considered potential locations for roost, forage, or nest sites.

Management Requirements for peregrine falcon would be met by protecting 12 potential nest sites.

Suitable habitat would be provided to meet Management Requirements for the northern spotted owl, pileated woodpecker, and marten. Forest-wide networks would be established for each species. This includes 59 spotted owl habitat areas occupied by 60 verified pairs of spotted owls. Approximately 69,045 acres would be specifically dedicated to spotted owl habitat. The remaining spotted owl habitat consists of lands unsuited for timber production. Habitat capability for 35 pairs of spotted owls would be provided in wilderness areas, occupied by 15 verified pairs. Designating 100 marten habitat areas (160 acres each) and 38 pileated woodpecker habitat areas (300 acres each) would meet the Management Requirements for habitat distribution for these species. Some marten and pileated woodpecker habitat areas overlap with visual corridors managed on rotations of 150 to 200 years. Where this occurs, these habitat areas would be managed to meet habitat requirements. Managed marten areas would be 500 acres, and managed pileated woodpecker areas would be 1000 acres. Additional marten and pileated woodpecker habitat would occur in spotted owl habitat areas, wilderness areas, and in other no harvest allocations.

Effective habitat for deer and elk would be provided by designating High, Moderate, or Low Emphasis Areas. Winter range would be 31% high emphasis, 46% moderate emphasis, and 23% low emphasis. Forest-wide, optimal thermal cover would be provided wherever old growth habitat is protected in no harvest MAs, or where MAs have rotations longer than 170 years. Site specific allocation of 4100 acres of optimal thermal cover would be made for high emphasis winter ranges. Habitat capability would be provided for a potential population of 6089 elk and 30,628 deer through the first decade. An additional allocation of approximately 1200 acres of optimal thermal cover would be required to maintain habitat capability through the fifth decade.

Buffers would be provided around natural meadows, marshes, bogs, cliffs, talus, and caves to protect microclimate conditions and overall habitat values of these areas. Protection of microclimate and unique habitats would result in 31,334 acres removed from lands suited for timber production.

Dead and defective tree habitat needed to meet the Management Requirement for primary cavity excavating birds would be provided. Habitat would be distributed to provide for 40% of the potential population within each sub-watershed. Individual harvest units could be managed for 20% potential populations provided the subwatershed habitat objective is met. An average of 8-15 logs per acre would be left as large down woody material on all harvested acres.

Habitat improvement projects would be planned in conjunction with timber sales and through the development of an active habitat enhancement program throughout the Forest. Projects would emphasize a broad spectrum of wildlife habitat projects including waterfowl habitat, osprey platforms, sensitive plant habitat, snag creation, access management, elk forage enhancement, wetland development and enhancement, bald eagle nest, roost,and forage area enhancement, and establishment of peregrine falcon nest sites.

Fish - Improvements would be made on 1,450 acres of reservoirs for resident trout. Riparian areas would be managed to increase levels of Large Woody Material recruited to the stream above current levels.

Water - Management practices would maintain or improve water quality to levels which meet or exceed the needs of the beneficial uses of the water. Riparian areas would be managed above minimum levels for water quality in order to aid in the recovery of current stream conditions, and to meet objectives for dispersion of wildlife between habitat areas, and recreation opportunities. No harvest would be programmed adjacent to Class I, II and III streams. Timber harvest would be designed to minimize risk of debris torrents by retaining trees as needed to provide stability in areas of moderately stable and potentially highly unstable landtypes on slopes adjacent to Class IV streams. Timber harvest would be scheduled at rates which would consider the cumulative effects on peak flows in subdrainages. Because of the importance and uniqueness of the streams and riparian areas, this alternative would stress the need to complete an inventory of these areas and prescribe treatments based on site-specific conditions.

Research Natural Areas - This alternative provides for research needs and opportunities through nine Research Natural Areas (RNAs). Of the nine RNAs included in this alternative four are established areas and five are proposed new areas to meet requirements of the Pacific Northwest Research Natural Area Committee.

ALTERNATIVE D

Goal Statement - Alternative D represents a high emphasis on non-market resources with a moderate emphasis on commodity production.

Habitat for Pileated Woodpecker, Martens, and Spotted Owls would exceed levels required for Management Levels. Many areas would be managed for high quality big game habitat, and many unique special wildlife habitat areas would be recognized.

Dispersed Recreation would be emphasized by maintaining several Roadless areas in their current condition. The scenic quality from many major highways would remain natural.

Riparian areas would be managed to provide input of near-natural levels of large woody material for fish habitat maintenance and improvement.

Recreation - All existing developed recreation sites would remain open. To meet future demand, the existing capacity of publicly managed sites would be expanded through development of new sites. A 120-day managed season for developed facilities would be in effect.

Emphasis would be placed on maintaining the Forest's semiprimitive dispersed recreation opportunities in an undeveloped condition. Areas available for semiprimitive nonmotorized recreation use total 176,484 acres, while motorized opportunities in a semiprimitive recreational setting are provided from 38,245 acres.

In this alternative 54% of the Forest is open to off-road vehicles (ORVs), 5% is restricted to a specified season of use and/or type of vehicle, and 41% is closed to ORVs. The OCRA is managed to provide motorized use over the entire area in winter, and on designated trails during snow free periods.

All existing nonwilderness trails (714 miles) are retained in this alternative, and 68 miles of new trail would be constructed with priority given to those trails located in semiprimitive nonmotorized recreation areas. Periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

Wilderness would be managed for primitive and semiprimitive WRS class opportunities. Areas that currently exceed capacity for these opportunities would be regulated to reduce social and physical resource impacts and enhance user experiences. Future use would be limited to user capacity levels of each WRS class MA. Trail maintenance, and resource protection and rehabilitation measures would be employed routinely. No new trails would be constructed.

On-site interpretation of specific aspects of cultural resource management is featured. Nomination of sites to the National Register of Historic Places would be performed as necessary.

The McKenzie River from Scott Creek to the Forest boundary is allocated as a Special Interest Area in this alternative. The characteristics of 28 of 49 potential Special Interest Areas are preserved by their allocation to a Special Interest Area MA. In this alternative the historic Santiam Wagon Road and the Oregon Military Wagon Road are included as Special Interest Areas. Also 18 groves of specimen old-growth timber, totaling 3,029 acres, would be maintained to provide for such uses as recreation, aesthetic appreciation, and educational purposes.

Roadless Lands - This alternative maintains significant portions of most inventoried roadless areas, and lesser amounts of other inventoried roadless areas in an undeveloped condition. The Mt. Hagan roadless area would be allocated to dispersed recreation, semi-primitive nonmotorized and Research Natural Area prescriptions.

Visual Resources - This alternative emphasizes a high level of scenic quality throughout the Forest.

The foreground areas of all State and Federal highways, major Forest roads, and selected trails are managed to ensure that landscape alterations are not evident (VQO of Retention). In addition, the foreground areas of selected Forest roads, and trails are managed to ensure that changes, while noticeable, remain subordinate to the character of the surrounding landscape (VQO of Partial Retention).

Also, portions of the middleground areas of all State and Federal highways and major Forest road viewshed corridors are managed to ensure that changes remain subordinate to the character of the

surrounding area (VQO of Partial Retention). In addition, the middleground areas of several Forest viewshed corridors are managed to provide landscapes in which physical alterations vary from being noticeable but subordinate, to visually dominant (VQO of Partial Retention to Modification).

Old Growth - A minimum of approximately 368,000 acres of old growth (R-6 definition) are maintained after fifty years in this alternative. These acres are in areas administratively and legislatively removed from development, lands unsuited for timber production, areas set aside for riparian and wildlife Management Requirements, and as specimen Old-Growth groves. Old growth would remain in some portions of areas managed for intensive timber harvest through the planning period.

Timber - Timber harvest would be scheduled on a suited landbase of 719,439 acres. Approximately 639,000 acres would be managed on rotations of less than 100 years, and 80,000 acres on rotation ages of 100 to 200 years. The Allowable Sale Quantity (ASQ) of 476 MMBF for the 1st decade would be about 77% of the average amount sold annually between 1977 and 1989.

Wildlife - Bald eagle protection would be provided in 27 areas including five active nest sites. Active nest sites would have site specific management plans prepared, and at least 125 acres of old growth habitat would be allocated for each potential nest site. All area within 1.1 miles of eleven major water bodies would be considered potential locations for roost, forage, or nest sites.

Management Requirements for peregrine falcon would be met by protecting 12 potential nest sites.

Suitable habitat would be provided to exceed Management Requirements for the northern spotted owl, pileated woodpecker, and marten. Forest-wide networks would be established for each species. This includes 98 spotted owl habitat areas occupied by verified pairs of spotted owls. Approximately 121,248 acres would be specifically dedicated to spotted owl habitat. The remaining spotted owl habitat consists of lands unsuited for timber production. Habitat capability for 40 pairs of spotted owls would be provided in wilderness and roadless areas, occupied by 20 verified pairs. Designating 100 marten habitat areas (160 acres each) and 38 pileated woodpecker habitat areas (300 acres each) would ensure Management Requirements for habitat distribution are met these species. Additional marten and pileated woodpecker habitat would occur in spotted owl habitat areas, wilderness areas, and in other no harvest allocations.

Effective habitat for deer and elk would be provided by designating High, Moderate, or Low Emphasis Areas. Winter range would be 66% high emphasis, 21% moderate emphasis, and 14% low emphasis. Forest-wide, optimal thermal cover would be provided wherever old growth habitat is protected in no harvest MAs, or where MAs have rotations longer than 170 years. A site specific allocation of 7600 acres of optimal thermal cover would be made for high emphasis winter ranges. Habitat capability would be provided for a potential population of 9019 elk and 45,325 deer through the fifth decade.

Buffers approximately 400 feet wide would be provided around natural meadows, marshes, bogs, cliffs, talus, and caves to protect microclimate conditions and overall habitat values of these areas. Protection of these special and unique habitats would result in an estimated 20,000 acres removed from lands suited for timber production.

Dead and defective tree habitat needed to exceed Management Requirements for primary cavity excavating birds would be provided. Habitat would be distributed to provide for 60% potential populations within each sub-watershed. Individual harvest units would also be managed for 60% potential populations. An average of 8-15 logs per acre would be left as large down woody material on all harvested acres.

Habitat improvement projects would be planned in conjunction with timber sales and through the development of an active habitat enhancement program throughout the Forest. Projects would emphasize

sensitive species inventories as well as wildlife habitat projects including waterfowl nesting habitat, osprey platforms, sensitive plant habitat restoration, snag creation, access management, elk forage enhancement, wetland development and enhancement, bald eagle nest, roost and forage area enhancement, and establishment of peregrine falcon nest sites.

Fish - Improvements would be made on 1,450 acres of reservoirs and streams. Riparian areas along Class I and II streams would be managed to provide near or above natural levels of input of large woody material for fish habitat.

Water - Riparian areas along streams, lakes would be managed above minimum levels for water quality. No timber harvest would be scheduled along Class I and II streams, and timber harvest along Class III riparian areas would be based on 200 year rotations. Timber harvest would be designed to protect areas of potentially unstable landtypes upslope and adjacent to Class IV streams. Water quality would reflect watershed conditions created by management practices.

Research Natural Areas - This alternative provides for research needs and opportunities through eight Research Natural Areas (RNAs). Of the eight RNAs included in this alternative, four are established areas and four are proposednew areas to meet requirements of the Pacific Northwest Research Natural Area Committee.

ALTERNATIVE L

Goal Statement - Alternative L places a high emphasis on nonmarket values, and low emhasis on timber commodity values by preserving areas currently not highly impacted by past management activities in their natural condition and by proposing other areas for natural recovery from the effects of past management. This alternative was formulated with input from the Oregon Natural Resources Council (ONRC).

High levels and quality of recreation opportunities and experiences would be provided. Scenery would be enhanced by managing all areas according to Visual Quality Objectives, and by rehabilitating unacceptable modifications.

The full inventory of roadless areas would be maintained in an undeveloped condition with an emphasis on semi-primitive nonmotorized activities. Opportunities for high quality Wilderness experiences would be increased by proposing additional areas for Wilderness study and for Wilderness designation.

The quantity, quality and diversity of plant and animal communities would be maintained at high levels. All management requirements for Pileated Woodpeckers, Martens and Spotted Owl would be exceeded, and habitat would be provided for the full inventory of verified Spotted Owl pairs. All areas of diverse habitats, geological significant areas, and millenium old-growth groves would be managed to protect and enhance desirable attributes. Old-growth characteristics would be retained in all managed stands.

Riparian areas would be managed to maintain and enhance riparian dependent species and connective corridors across the landscape.

Recreation - All existing developed recreation sites would remain open. To meet future demand, the existing capacity would be expanded. High levels of recreation opportunities and high quality experiences would be provided. A 120-day managed season for developed facilities would be in effect.

This alternative provides the maximum amount of motorized and nonmotorized areas for semiprimitive recreation opportunities. Emphasis is placed on maintaining opportunity settings in their undeveloped condition. In this alternative, the Oregon Cascades Recreation Area is managed for nonmotorized use year-round.

Thirty-eight percent of the Forest is open to off-road vehicles (ORVs), 3% is restricted to a specified season of use and/or type of vehicle, and 59% is closed to ORVs.

All existing nonwilderness trails (714 miles) are retained in this alternative, and 40 miles of new trail would be constructed with priority given to those trails located in semiprimitive nonmotorized recreation areas. Periodic trail reconstruction and regular maintenance would be done to keep the entire trail system to standard.

All Wilderness would be managed for primitive and semiprimitive use opportunities. High quality Wilderness experiences would be provided by proposed additional Wilderness. Areas that currently exceed capacity for these opportunities would be regulated to reduce social and physical resource impacts and enhance user experiences. Future use would be limited to user capacity of each WRS class MA. Trail maintenance and resource protection and rehabilitation measures would be employed routinely. No new trails would be constructed.

On-site interpretation of specific aspects of the cultural resource, as well as off-site public awareness of management programs is featured. All eligible cultural resource sites would be nominated to the National Register of Historic Places.

The characteristics of all potential Special Interest Areas are preserved in this alternative. However, only 7 areas are allocated to a Special Interest MA prescription. The remaining areas are included in other nondevelopment MAs. Also 24 groves of specimen old-growth timber, totaling 3,056 acres, would be maintained to provide for such uses as recreation, aesthetic appreciation, and educational purposes in this alternative.

Visual Resources - This alternative emphasizes a high level of scenic quality throughout the Forest.

The foreground areas of State and Federal highways, major Forest roads, and selected trails are managed to ensure that landscape alterations are not evident (VQO of Retention). Although these areas are not in each case allocated to Scenic Resource MAs they, however, provide comparable scenic quality levels. In addition, the foreground areas of selected Forest roads and trails are managed to ensure that changes, while noticeable, remain subordinate to the character of the surrounding landscape (VQO of Partial Retention).

Also, portions of the middleground areas of all State and Federal highways and major Forest road viewshed corridors are managed to provide a landscape where physical alterations, while noticeable, are subordinate to the surrounding area (VQO of Partial Retention). In addition, the middleground areas of several Forest viewshed corridors are managed to provide landscapes in which physical alterations vary from subordinate to not evident (VQO of Retention to Partial Retention).

Roadless Lands - This alternative recommends designation of several roadless areas to Wilderness status, and maintains nearly all inventoried roadless areas in an undeveloped condition. About 85% of current roadless lands would be maintained in a roadless condition, with an emphasis on preserving wilderness values and maintaining semiprimitive non motorized opportunities.

Old Growth - This alternative emphasizes the continuation of old-growth characteristics throughout the Forest. Lands of 300 acres and more, where 70% of the trees are mature, would be managed as old-growth reserves, with no-harvest. Areas of at least 300 acres which have not previously been managed for timber production, and where at least 70% of the forest is young, natural stands, would be managed on rotations of up to 240 years, with harvest activity permitted only from the existing road system. Areas on smaller blocks of old growth would be managed with rotations lengths of between 80 and 160 years. In these and other areas 8 to 10 mature trees per acre would be maintained to provide future old-growth characteristics.

Approximately 523,000 acres of old growth (R-6 definition) are maintained after fifty years in this alternative. These acres are in areas administratively and legislatively removed from development, lands unsuited for timber production, and areas set aside for a variety of uses.

Timber - Timber would be managed for commercial use on 553,090 acres of the Forest, with approximately 314,000 acres in rotation ages of less that 100 years, and 239,000 acres in rotation ages of 100 to 200 years. The Allowable Sale Quantity (ASQ) of 150 MMBF for the 1st decade would be 24% of the average amount sold annually between 1977 and 1989.

Wildlife - Bald eagle protection would be provided in 27 areas including five active nest sites. Active nest sites would have site specific management plans prepared, and at least 125 acres of old growth habitat would be allocated for each potential nest site. All area within 1.1 miles of eleven major water bodies would be considered potential locations for roost, forage, or nest sites.

Management Requirements for peregrine falcon would be met by protecting 12 potential nest sites.

Suitable habitat would be provided to exceed Management Requirements for the northern spotted owl, pileated woodpecker, and marten. Forest-wide networks would not be established for each species. The emphasis placed on protection and replacement of mature and old growth forests would maintain habitat capability for the full inventory of verified spotted owl pairs. The full inventory is 219 verified pairs of spotted owls. Habitat capabiltiy for pileated woodpeckers and marten would be above the Management Requirement. Distribution and quality of mature and old growth habitat would not be limited.

Effective habitat for deer and elk would be provided by designating High, Moderate, or Low Emphasis Areas. Winter range would be 41% high emphasis, 42% moderate emphasis, and 17% low emphasis. Forest-wide, optimal thermal cover would not be limiting because of the amount of the Forest in no harvest and extended rotation MAs. Created opening would become limiting and would result in the need to intensively manage natural and created openings for deer and elk forage production. Habitat capability would be provided for a potential population of 7068 elk and 35,340 deer through the fifth decade.

Buffers would be provided around natural meadows, marshes, bogs, cliffs, talus, and caves to protect microclimate conditions and overall habitat values of these areas. Protection of these special and unique habitats would result without a specific allocation reducing lands suited for timber production.

Dead and defective tree habitat needed to exceed Management Requirements for primary cavity excavating birds would be provided. Habitat would be distributed to provide for 60% potential populations within each sub-watershed. Individual harvest units would also be managed for 60% potential populations. An average of 8-15 logs per acre would be left as large down woody material on all harvested acres.

Habitat improvement opportunities planned in conjunction with timber sales would be limited. Projects would emphasize forage enhancement using native plant species and snag creation. Wildlife habitat programs would be oriented more toward inventory and monitoring with reduced need for mitigation habitat loss.

Fish - Improvement projects, for resident fish, would be implemented on 1,450 acres of reservoirs and streams. Riparian management of Class I and II streams would continue near or above natural levels of input of woody material.

Water - Riparian areas would be managed above minimum levels for water quality in order to aid in the recovery of current stream conditions, and to meet objectives for other riparian resources. Full protection of riparian areas along Class III streams would minimize reduction in water quality. Timber harvest would be designed to protect areas of potentially unstable landtypes upslope and adjacent to Class IV streams.

Research Natural Areas - This alternative provides for research needs and opportunities through four established Research Natural Areas (RNAs).

COMPARISON OF ALTERNATIVES

Overview

This section presents the alternatives in a manner designed to facilitate comparison. The aspects of alternatives presented for comparison include:

- Allocations of land to specific management areas;
- Resource management programs;
- Activities, resource outputs, and environmental effects;
- Responsiveness to issues and concerns;
- Economic criteria including costs, benefits, present net value and cash flows.

These items are presented in map, tabular, and written form, with the intent of condensing a great deal of complex information into a format which allows efficient and effective comparison of Alternatives. This section concludes with a discussion of the principal tradeoffs associated with each alternative.

The purpose of forest planning is to identify and select for implementation the Alternative which most nearly maximizes net public benefits while responding effectively to the public issues. Net public benefits are defined as the "...overall long-term value to the nation of all outputs and positive effects (benefits), less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not...consistent with the principles of multiple use and sustained yield" (36 CFR 219.3).

The assessment of net public benefits must include both those outputs which have prices (such as timber and developed recreation) and those to which no price can be attached (such as scenic quality and the maintenance of viable wildlife populations). Thus, net public benefits cannot be expressed as a single, quantitative measure, but rather must be gauged using both quantitative and qualitative criteria. There is no precise formula for determining which Alternative maximizes net public benefits. Indeed, there are often differences of opinion as to whether particular outputs or effects are benefits or costs. Therefore, it is necessary to identify major effects of each alternative separately to serve as the basis for analysis, judgement, and selection of the preferred Alternative. The remainder of this section highlights these effects in a comparative manner to facilitate identification of net public benefits.

Management Areas

Management areas are portions of the National Forest to which a specific set of management practices are applied and for which standards and guidelines have been developed. All of the management areas considered in the alternatives, which provide for all multiple-uses and resources, are briefly described. Although a specific use or resource may be featured or emphasized in each management area, all other uses and resources are provided for in the standards and guidelines established for each management area.

Forest land is managed in accord with the standards and guidelines of the management area to which it is allocated. This assures that potentially adverse environmental effects are avoided, minimized, rectified, reduced, or otherwise mitigated while achieving basic management area objectives. Standards and guidelines were developed by an interdisciplinary team to ensure integration and coordination of the various multiple uses and resource values, and to respond to the specific environmental conditions of the Forest. Standards and guidelines that apply to the entire Forest were also developed, and are displayed in Chapter IV of the Proposed Forest Plan.

The land area of the Forest is allocated to management areas differently in each alternative. Table II-3 illustrates how the allocation of Forest land to management areas differs among the Alternatives. Alternatives are arrayed in this table in order of decreasing vegetation management using suitable acres as an indicator. A detailed prescription for each management area can be found in Chapter IV of the proposed Forest Plan. Following is a brief summary of each management area.

Table II-3. Management Area Acreage of Alternatives

	Alternatives						
Management Areas	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
1 Wilderness	380,805 [1]

[1] Wilderness Resource Spectrum management is not applicable to the No change Alternative.
[2] All alternatives include 1,207 acres of Wild and Scenic River designation (wild classification) in the Waldo Wilderness. These acres are included in Management Area 1.
[3] Includes Existing nest area habitat only.
[4] Acres of network sites that overlap with other no harvest management areas are not included in MA9a, 9b, 9c acres. Refer to Figure II-4 for total habitat acres by alternative.
[5] Riparian acres which are not included in other management areas with no programmed harvest are allocated to MA15. Harvest rates in these Riparian Management Acres differ between alternatives, as described in Chapter II, Riparian. Riparian acres in NC are distributed throughout other management areas.
[6] Alternative L recommends designation of 169,360 acres of roadless area as Wilderness or wilderness study areas.

Wilderness

The goal of managing dedicated Wilderness is to feature naturalness, provide opportunities for solitude, challenge, and inspiration, and within these constraints to allow for recreation, scenic, scientific, educational, conservation, and historical uses. Permitted but nonconforming uses specified in the Wilderness Act would be carried out under restrictions designed to minimize their impact on the Wilderness. The criteria used for conflict resolution would be to preserve and protect the Wilderness

resource. Consistent with providing a range of wilderness opportunities and experiences each Wilderness is divided into the following management areas based on the Wilderness Resource Spectrum.

MANAGEMENT AREA - 1a (Transition)

The Transition Wilderness Resource Spectrum Class that comprises this management area is characterized predominantly by conditions of relatively concentrated use where encounters with other groups are frequent, opportunities for solitude are limited, and user controls may be highly evident. This management area is usually adjacent to major wilderness entry points or day use destination areas.

MANAGEMENT AREA - 1b (Semiprimitive)

The Semiprimitive Wilderness Resource Spectrum Class that comprises this management area includes areas which are characterized by predominantly unmodified natural environments of moderate to large size; concentration of users may be low, but there would often be evidence of other users in the area; minimum on-site controls and restrictions may be present, but are subtle.

MANAGEMENT AREA - 1c (Primitive Trailed B)

The Primitive Trailed-B Wilderness Resource Spectrum Class that comprises this management area includes areas surrounding existing and proposed trails which provide a primitive trail associated Wilderness experience. These corridors are characterized by an essentially unmodified natural environment.

MANAGEMENT AREA - 1d (Primitive Trailed A)

The Primitive Trailed-A Wilderness Resource Opportunity Spectrum Class that comprises this management area includes areas which lie between developed and maintained trail systems that provide primitive Wilderness experiences. The user would have opportunities to travel cross- country, utilizing a maximum degree of outdoor skills, often in an environment of varied terrain and vegetation that offers a high degree of challenge and risk.

Oregon Cascades Recreation Area (OCRA)

The OCRA was established by Congress for the conservation of unique geographic, topographic, biological, and ecological features, to protect wildlife, recreation, and watershed values, and provide a variety of recreation experiences. Two management areas are identified within the OCRA.

MANAGEMENT AREA - 2a (OCRA Motorized)

This area provides the opportunity, within the OCRA, for users to experience a moderate degree of isolation from the sights and sounds of human activity, establish some sense of independence and closeness to nature, and develop a moderate feeling of self-reliance through the application of outdoor skills. These experiences are provided in an environment that offers some challenge and risk to both motorized and nonmotorized use.

MANAGEMENT AREA - 2b (OCRA Nonmotorized)

This area provides the opportunity, within the OCRA, for users to experience a high degree of isolation from the sights and sounds of human activity, establish a sense of independence and closeness to nature,

and develop some feelings of tranquility and self-reliance. Recreation activities associated with this intensity are nonmotorized and nonmechanical in nature except for over-the-snow use.

Experimental Forest

MANAGEMENT AREA - 3 (H.J. Andrews Experimental Forest)

The primary objective of this management area is research and study of the effects of management activities on a wide range of multiple use resources, including watershed, wildlife, and soil as well as the effects of silvicultural practices on growth rates and harvest yields of Douglas-fir.

Research Natural Areas

MANAGEMENT AREA - 4 (Research Natural Area)

The lands within this management area would be managed for preservation of examples of natural ecosystems for comparison with those influenced by human activity; education and research for ecologic and environmental studies; and preservation of gene pools for typical, rare, or endangered species.

This management area includes established and proposed Research Natural Areas (RNA). Establishment of RNAs is an administrative designation requiring approval by the Chief of the Forest Service. Additions to the RNA system proposed by any alternative would not be implemented until approved by the Chief.

Special Interest Areas

MANAGEMENT AREA - 5a (Special Interest Area)

These areas would be managed primarily for recreation use while maintaining unusual recreational, scenic, historical, geological, botanical, zoological, paleontological, or other special characteristics or features in their natural condition. Depending on the nature of the special features, management may be directed either toward protection activities or facility development for interpretation and viewing activities. Road and trail access may be provided in development areas and discouraged where necessary for site protection.

MANAGEMENT AREA - 5b (Special Interest Area-Ecological Area)

The primary emphasis of this management area is to protect and enhance the exceptional ecological values in the Hardesty Mountain - Mount June area on the southwestern border of the Forest. Nonconsumptive resource activities would be emphasized. Access would generally be restricted to roads outside the area and existing trails within the area.

Wild and Scenic Rivers

MANAGEMENT AREA - 6a (Wild and Scenic Rivers-Wild River)

This management area preserves the Wild River characteristics of the portion of the North Fork of the Middle Fork of the Willamette River that lies within the Waldo Wilderness. Emphasis would be on the preservation of the primitive characteristics and scenic qualities of the river segment and the corridor of lands on either side.

MANAGEMENT AREA - 6b (Wild and Scenic Rivers-Scenic River)

This management area would maintain or enhance the condition of the high quality scenery and condition of the generally undeveloped shore line along designated segments of the North Fork of the Middle Fork of the Willamette River and the McKenzie River. Management activities permitted within this area would include river-oriented recreation as well as programmed timber harvests that are compatible with Scenic river management objectives. Programmed harvests would generally not exceed 5% of the total acres per decade.

MANAGEMENT AREA - 6c (Wild and Scenic Rivers-Recreation River)

This management area would maintain or enhance the recreational and scenic values associate with the free-flowing condition of designated segments of the North Fork of the Middle Fork of the Willamette River and the McKenzie River. Management activities permitted within this area would include river-oriented recreation as well as programmed timber harvests that are compatible with recreation river management objectives. Programmed harvests would generally not exceed 7% of the total acres per decade. In Alternatives J and W, an alternate prescription which excludes programmed timber harvest is applied to the Recreation segments of the McKenzie River.

Old-Growth Grove

MANAGEMENT AREA - 7 (Old Growth Grove)

In this management area outstanding, highly accessible specimen groves of old-growth timber types of the Western Cascades are preserved. These areas are established primarily for the education, use, and enjoyment of the public, and they also provide habitat for a wide range of old-growth dependent plant and animal species. No programmed timber harvest is scheduled in this management area. Management activities are limited to those which protect the flora, fauna, and ecological character of the grove, and which provide aesthetic opportunities through the use of interpretive trails and adjacent developments.

T & E Species

MANAGEMENT AREA - 8 (Threatened and Endangered Species-Bald Eagle)

The management area provides for care and maintenance of active bald eagle nest sites in the Forest. Programmed timber harvest is not permitted, however, unregulated harvest is allowed to enhance bald eagle habitat within the management area.

Special Wildlife Habitat

MANAGEMENT AREA - 9a (Spotted Owl Habitat Area)

This management area protects mature and old-growth habitat for the northern spotted owl and other flora and fauna with similar habitat requirements by providing a habitat network for the northern spotted owl, an ecological indicator species. Primary emphasis is on meeting habitat requirements for the spotted owl. Programmed timber harvest is not permitted.

MANAGEMENT AREA - 9b (Pileated Woodpecker Habitat Area)

This management area protects mature and old-growth habitat for pileated woodpeckers and other flora and fauna with similar habitat needs by providing a habitat network for the pileated woodpecker,

an ecological indicator species. Programmed timber harvests are not permitted in designated habitats. In Alternative W, core habitat areas within management areas with 150 to 200 year rotations would have programmed harvests located and scheduled in a manner that meets habitat requirements.

MANAGEMENT AREA - 9c (Pine Marten Habitat Area)

This management area protects mature habitat and old-growth for pine martens and other flora and fauna with similar habitat requirements by providing a habitat network for the pine marten, an ecological indicator species. Programmed timber harvest is not permitted. In Alternative W, core habitat areas within management areas with 150 to 200 year rotations would have programmed harvests located and scheduled in a manner that meets habitat requirements.

MANAGEMENT AREA - 9d (Special Wildlife Habitats)

This management area maintains and enhances special wildlife habitats and small botanical sites which are important to a biologically diverse ecosystem. Examples of the types of areas included are meadow complexes, cliffs, elk wallows, and talus. Only activities that benefit the featured species or habitat would be permitted. Programmed timber harvest is not permitted. Facilities or improvements for recreation or viewing may be provided if compatible with the wildlife objectives.

Dispersed Recreation

MANAGEMENT AREA - 10a (Dispersed Roaded Natural Recreation)

This management area is for dispersed roaded natural recreation opportunities, wildlife habitat, and timber resource values as well as for other multiple-uses and resources. Timber harvest in this management area would occur at a maximum rate of 10% of the suitable/available land each decade. Activities associated with this management area are motorized and nonmotorized in nature.

MANAGEMENT AREA - 10b (Dispersed Semiprimitive Motorized Recreation)

This management area manages areas within the Forest for their dispersed semiprimitive motorized recreation opportunities, wildlife habitat, and timber resource values as well as for other multiple uses and resources. Timber harvest in this management area would occur at a maximum rate of 7% of the suitable/available land each decade. Activities associated with this intensity are both motorized and nonmotorized in nature.

MANAGEMENT AREA - 10c (Dispersed Semiprimitive Motorized Recreation, No Harvest)

This management area manages Forest lands for their dispersed semiprimitive motorized recreation opportunities and wildlife habitat, as well as for other multiple uses and resources. Programmed timber harvest is not permitted within this management area. Timber harvest may be permitted to enhance recreational use within the area. Activities associated with this management area are both motorized and nonmotorized in nature.

MANAGEMENT AREA - 10d (Dispersed Semiprimitive Nonmotorized Recreation)

This management area manages Forest lands for their dispersed semiprimitive nonmotorized recreation opportunities, wildlife habitat, and timber resource values as well as for other multiple uses and resources. Timber harvest in this management area would occur at a maximum rate of 5% of the suitable/available

land each decade. Recreation activities associated with this management area are exclusively nonmotorized and nonmechanical in nature.

MANAGEMENT AREA - 10e (Dispersed Semiprimitive Nonmotorized Recreation, No Harvest)

This management area provides for the management of Forest lands for their dispersed semiprimitive nonmotorized recreation opportunities and wildlife habitat as well as for other multiple uses and resources. Programmed timber harvest is not permitted within this management area. Recreation activities associated with this management area are exclusively nonmotorized and nonmechanical in nature.

MANAGEMENT AREA 10f (Lakeside Habitats)

This management area provides for the management of Forest lakeside areas for their wildlife habitat, recreational and scenic values. Access within and through the areas would be limited to existing roads and trails. Programmed timber harvest is not permitted. Facilities development for recreation would be limited to that necessary for site protection and would be compatible with wildlife habitat objectives.

Scenic

These management areas provide for management of the Forest landscape for its value as a scenic resource as well as for other multiple uses and resources. A broad range of silvicultural practices is permitted.

MANAGEMENT AREA - 11a (Scenic Modification - Middleground)

Management of the area provides that activities within middleground zones of visually sensitive landscapes, as viewed from major travel corridors and use areas, may visually dominate the landscape but must borrow from natural characteristics in the surrounding area. The size and configuration of harvest areas must conform to standards for meeting the modification middleground Visual Quality Objective.

MANAGEMENT AREA - 11b (Scenic Modification - Foreground)

Management of the area provides that activities within foreground zones of visually sensitive landscapes, as viewed from major travel corridors and use areas, may visually dominate the landscape but must borrow from natural characteristics in the surrounding area. The size and configuration of harvest areas must conform to standards for meeting the modification foreground Visual Quality Objective.

MANAGEMENT AREA - 11c (Scenic Partial Retention - Middleground)

Management of the area provides that activities within middleground zones of visually sensitive landscapes, as viewed from major travel corridors and use areas, may be evident but must remain visually subordinate. The size and configuration of harvest areas must conform to standards for meeting the partial retention middleground Visual Quality Objective.

MANAGEMENT AREA - 11d (Scenic Partial Retention - Foreground)

Management of the area provides that activities within foreground zones of visually sensitive landscapes, as viewed from major travel corridors and use areas, may be evident but must remain visually subordinate.

The size and configuration of harvest areas must conform to standards for meeting the partial retention foreground Visual Quality Objective.

MANAGEMENT AREA - 11e (Scenic Retention - Middleground)

Management of the area provides that activities within middleground zones of visually sensitive landscapes, as viewed from major travel corridors and use areas, would not be visually evident to many observers. The size and configuration of harvest areas must conform to standards for meeting the retention middleground Visual Quality Objective.

MANAGEMENT AREA - 11f (Scenic Retention - Foreground)

Management of the area provides that activities within foreground zones of visually sensitive landscapes, as viewed from major travel corridors and use areas, would not be visually evident to many observers. Configuration of harvest areas must conform to standards for meeting the retention foreground Visual Quality Objective.

Developed Recreation

MANAGEMENT AREA - 12a (Developed Recreation Area, Public-Existing and Proposed)

This management area includes areas of land where physical improvements have been provided for a range of developed recreation opportunities as well as lands that are reserved for future study and potential development for a variety of developed recreation facilities.

MANAGEMENT AREA - 12b (Developed Recreation Area, Private-Existing or Proposed)

This management area includes areas of the Forest that are currently under special use permits or have potential as special use sites. Sites under special use permits with facilities, services, and opportunities provided by the private sector would be maintained according to the terms of individual special use agreements.

Special and Administrative Uses

MANAGEMENT AREA - 13a (Long-term Special Use Sites)

This management area applies to those lands where an existing major, long- term special use is currently under permit. These are generally non-recreational facilities such as repeater stations.

MANAGEMENT AREA - 13b (Forest Administrative Sites)

This management area is applicable where facilities and/or resources for the protection, administration, or management of the Forest are provided and maintained.

General Forest

MANAGEMENT AREA - 14a (General Forest)

This management area emphasizes sustained production of timber while meeting multiple use objectives for other resources as outlined in Forest-wide standards and guidelines. In most areas an extensive road network would be required to facilitate the objectives of this management area. Each management

intensity, applied to suited forest land, within this management area represents a specific set of practices, standards, and guidelines which are responsive to individual site capabilities, and include a full range of silvicultural systems and harvest methods.

MANAGEMENT AREA - 14b (General Forest, Deferred)

This area includes approximately 600 acres near Hardesty Mountain on the southwest side of the Forest. No timber harvest is programmed from this area for the planning period to allow additional studies of the relationship of the area to Management Area 5b. Silvicultural activities other than harvesting would occur as needed to meet sustained yield objectives of Management Area 14a.

Riparian

MANAGEMENT AREA - 15 (Riparian)

This management area is applicable to rivers, streams, small wetlands, lakes and the adjacent riparian areas. The emphasis in this area is to maintain the role and function of riparian areas in the overall landscape ecology. Activities within this management area vary by alternative, with no programmed timber harvest is permitted in Alternatives W and L; some harvest along Class III streams in Alternative D; and the MR prescription would be applied in Alternatives NC, K, A, and J. The MR prescription is described in the standards and guidelines of FEIS Appendix D.

MANAGEMENT AREA ADJUSTMENTS, Alternative L

Alternative L, developed with input from Oregon Natural Resources Council, uses several management area prescriptions that vary from the preceding descriptions. Although the specific emphasis for some of the prescriptions in Alternative L differ from the management area prescriptions in other alternatives, the modelling constraints and ultimate effects on other resources are similar in many cases. To make the analysis of Alternative L comparable with the other alternatives, the prescriptions unique to Alternative L for a particular emphasis were evaluated by the IDT for similarities of constraints and effects with existing management area prescriptions. Once similarities were identified, the management area prescriptions in Alternative L were correlated to the existing management area prescriptions and descriptions for comparability in mapping and modelling. In a few management areas the maximum allowable harvest rates by decade were adjusted to meet the intent of Alternative L.

The management area adjustments used to model Alternative L were:

Alternative L	**Management Area Used**
Wilderness-Recommended	1c
Wilderness-Study	1c
Old Growth Reserve	7
Old Growth Management	7
Old Growth Replacement	11f
Wildlife Habitat-Critical	9d
Wildlife Habitat-Sensitive	9d
Watershed-Critical	10c
Watershed-Sensitive	10b
Riparian Reserve	15

Riparian Management	11f
Rehabilitation-Natural	10b
Rehabilitation-Enhancement	10c
Back Country	10e
Scenic Preservation	10c
Timber Management-Extensive	11a
Timber Management-Intensive	14a
Mixed Rotation-No Harvest	7
Mixed Rotation-160 years	11e
Mixed Rotation-80 years	11c
Wild Lakes	10f

Following is a brief description of the general emphasis and intent of the management areas unique to Alternative L.

Wilderness Recommendation (149,203 acres) - Lands that the Forest Service would recommend to Congress for Wilderness classification.

Wilderness Study Areas (20,178 acres) - Areas which would be studied intensively for their Wilderness attributes and characteristics. Generally includes lands with potential Wilderness quality, which require study before appropriate boundaries and recommendations can be determined. Road closures and certain types of rehabilitation could be considered in the study. The actual study would be a separate document from the Final Forest Plan, to be compiled and scrutinized during the life of the Forest Plan itself. The decision as to final allocation would then occur in the "next" Forest Plan. These areas would be managed in their existing condition, and removed from the commercial forest land base.

Wild Lakes (341 acres) - Similar to Back Country for standing water bodies which, because of surrounding development, are not eligible for inclusion in larger Back Country or Wilderness Recommendation allocations. Keeps lakes in status quo or better conditions such as by prohibiting motorized traffic. In general, no additional development or access.

Old-Growth Reserve (136,555 acres) - Specific areas for no-cut management. The old-growth forest would age naturally. The Reserve can be any size and can include Spotted Owl Habitat Areas.

Old-Growth Management Areas (15,102 acres) - Long-rotation management areas, where 10-20% of the potential yield is expected. At least 3/4 of the entire area must actually be in an old-growth forest condition (250 years plus) at any one time. Areas not currently meeting this criteria can be allowed to grow into the desired condition. Cutting would be either by clearcutting (patch-cutting) small areas (40 acre maximum), or by selective systems. Helicopter and balloon systems preferred, with minimal road networks. Roads to be closed after sales.

Old-Growth Replacement - Extended Rotations (98,075 acres) - Long rotation management areas located in blocks of old-growth larger than 300 acres. The timber would be managed on 80 and 160 year rotations, with enough trees at 240 years old to provide functional Old Growth characteristics.

Wildlife Habitat - Critical Areas (192 acres) - Designation which emphasizes the critical nature of these areas in terms of survival cover, winter range, etc, by minimizing disturbance. Timber cutting is not programmed, and very few circumstances would require or allow any cutting at all. No new roads; existing roads may or may not be closed, either within the specific land use allocation decision or later as a consequence of its management plan.

Wildlife Habitat - Sensitive Areas (40,911 acres) - Same as Wildlife Habitat-Critical but applicable in areas where habitat conditions allow some disturbance. Some timber cutting allowed. About 10-15% of potential yield can be expected. No new roads, and road closures may be appropriate.

Watershed - Critical Areas (6,484 acres) - Designation which emphasizes the critical nature of these areas in terms of unstable soils, by minimizing disturbance. Timber cutting is not programmed, and very few instances would require or allow any cutting at all. No new roads; existing roads may or may not be closed, either within the specific land use allocation decision or later as a consequence of its management plan.

Watershed - Sensitive Areas (3,541 acres) - Same as Watershed Critical, but applicable in areas where watershed allows some disturbance. Some timber cutting allowed. About 10-15% of potential yield can be expected. No new roads, and road closures may be appropriate.

Riparian Reserve (3,903 acres) - Streamside areas which would be provided maximum protection by a no-cut, no roads allocation. Can be of any size. Usually would designate at least 250 feet on either side of stream. Adjacent developed land must be "feathered."

Riparian Management Areas (11,945 acres) - Streamside areas with a 100 foot no-cut buffer, (each side of the stream) then 200 feet at 25% yield. Riparian values, including large woody materials and largest conifers, would remain intact. Managed adjacent lands would be feathered to minimize blowdown. The remaining acres of riparian areas are distributed throughout other management areas which have no scheduled timber harvest.

Rehabilitation - Natural (30,587 acres) - Developed lands which would be allowed to revert to a natural condition by simply leaving them alone. May be used to simply recover that site, or help block up a larger expense of otherwise undeveloped, natural land.

Rehabilitation - Resource Enhancement (4,266 acres) - Same as Rehabilitation - Natural, except that more active on-the-ground management for watershed or wildlife habitat improvement. Especially appropriate for devastated pieces of ground where erosion is a serious factor or threat. Examples of activities would be extensive plantings, burning, and gabions.

Backcountry (88,797 acres) - Administratively-protected "wild" areas, which would be managed as Wilderness, but usually excluding grazing and mining. All other multiple uses (except logging) such as wildlife, fisheries, watershed, outdoor recreation, education, and research would be allowed and encouraged. No roads, and usually no ORVs. Proposed management activities following catastrophic evens would be carefully evaluated at the time. Catastrophic entry permitted, but only after careful scrutiny and approval.

Scenic Preservation Areas (27,324 acres) - For the most sensitive visual zones. This allocation allows no programmed harvest, and cutting can occur only in rare situations where safety or visual quality can indeed be improved. Must meet Forest Service Visual Quality Objective (VQO) of Preservation.

Extensive Timber Management Areas (36,474 acres) - Lands dedicated primarily to timber production, but without investments of intensive management techniques other than replanting and thinning. Yield of 85-95% is anticipated.

Intensive Timber Management Area (182,414 acres) - Similar to extensive, but applicable to lands dedicated to timber production. Intensive management techniques include genetic manipulation, more intensive thinning and replanting, irrigation, fertilization, and other methods, if proven to be cost-effective.

Mixed Rotation Management Areas (322,872 acres) - Old Growth islands of 80-300 acres comprise about 20% of this management area and are subject to no harvest. Another 20% provides connecting corridors between old-growth blocks and are managed on 160 year rotation. The remaining 60% of the area would continue on 80 year rotations, with a 10% reduced yield to provide structural old-growth characteristics that carry over into the next rotation.

Timber

Timber Resource Management Information - Management of the timber resource differs by alternative, depending on the mix of suited acres within management areas that allow timber harvest. Management areas with programmed timber harvest are: General Forest; scenic Retention, Partial Retention and Modification; Dispersed Recreation; and Scenic and Recreation Rivers. General Forest provides for the highest level of timber outputs, bound only by broad, watershed level constraints for dispersion, wildlife habitat and water quality. The other management areas emphasize nontimber resource values (e.g., scenic quality and recreation) resulting in lower levels of timber output. The acres allocated by management area are shown in Table II-3.

Lands suitable for timber production are the base from which the Allowable Sale Quantity (ASQ) is calculated. While trees can be cut and removed from some lands unsuitable for timber production in certain specific cases (e.g., to provide forage), the amount does not contribute to the ASQ. Additional volume not reflected in the ASQ includes cull and salvage material. The total timber sale program for the Forest is referred to as the Timber Sale Program Quantity (TSPQ).

The Forplan analysis and projections for future timber outputs use cubic volume measure. Historic volume data and volumes projected for harvest by alternative in the next decade are also displayed in board foot measure. An industry-wide transition from board foot to cubic measure is expected within the next decade, so volumes are shown in board feet for only the first decade. As the mix of species and size classes harvested varies over time, the board foot volume varies even though the cubic volume remains constant. The board foot/cubic foot ratio will decline over time as the average diameter of stands harvested becomes smaller. Alternative W harvests a constant 87 MMCF per year for the first five decades, while the resulting board foot volume declines from 491 MMBF in decade 1, to 440 MMBF by decade 5. This trend occurs under all alternatives.

Timber resource inventory and management data are presented in Table II-4; (note that an explanation of the columns in the display is provided in the following paragraphs). This display is followed by discussions of land suitability for timber production, timber volumes offered for sale, long-term sustained yield, silvicultural activities, and comparisons with the current Plan.

Table II-4 and the following narrative provide an understanding of how and why differences in timber resource data occur and their interaction with other resources as objectives vary from alternative to alternative.

Table II-4. Timber Resource Management Information

Existing Timber Management Plan

Data from the Timber Management Plan (TMP):

a. Potential yield in cubic feet and board feet: 850.4 MMBF (156 MMCF @5.45). This includes 53 MMBF of salvage.
b. Average annual net volume sold during years TMP was in effect: 623 MMBF (77-89), (114 MMCF @5.45).
c. Total acres of standard, special, and marginal lands used to develop the potential yield: 1,064,616 Acres.

[1] Tentatively suitable lands for all Alternatives, except NC: 1,032,100 acres, with a present inventory of 5,835 MMCF.
[2] Percent of long-term sustained yield (LTSY) reached by end of planning horizon (decade 15).
[3] NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Forest FORPLAN model. Section D4b, of Chapter II in the DEIS describes these differences.

Column 1 -- The suitable acres displayed here reflect the difference in land allocations between Alternatives. Alternative NC represents the Current TM Plan and differs from the other Alternatives and benchmarks in managing 125,000 acres of marginal land for full yield and includes no consideration of MRs. This marginal category is no longer used, most of it becoming "unsuited" in the new landbase classification. The other Alternatives are compared as follows: With a few minor exceptions (old-growth groves, research natural areas, etc.), variation in total suitable acres is a function of roadless recreation and wildlife habitat areas. Suitable acres decline from Alternative K, to A, to J and W, due to additional acres in roadless areas. The decline continues from D to L as more roadless areas and Spotted Owl Habitat Areas are added.

Columns 2, 3, and 4 -- The beginning inventory (2) is proportionate to suited acres. The beginning volume/acre (3) increases from Alternative K, to A, to J as low volume/acre roadless areas are removed from the base. From this point the volume/acre decreases to W, L, and D as riparian areas, additional roadless areas, and Spotted Owl Habitat Areas, with higher volumes per acre are removed, thus reducing the volume/acre on the remaining timber base. Alternative L includes a greater proportion of high volume/acre stands than D.

The inventory volume at the end of 150 years (4) is a function of the suitable acres, age class distribution, and management intensities. The Alternatives are generally in the order of suitable acres except for J and D which include different mixes of age classes and management intensities, resulting in slightly more ending inventory volume than the number of suited acres would suggest.

Columns 5, 6, and 7 -- The first decade ASQ (5 & 7) is highly dependent on the size of the suitable landbase. Alternative K has the highest ASQ followed by A, J, W, D, and L. The ASQ as a percent of the beginning inventory (6) depends on the mix of rotation ages which are a function of species and management intensity. Most of the alternatives are at about 2.3%, but J and L, with higher proportions of long-rotation management areas are at 2.1 and 1.7% respectively.

Columns 8, 9, and 10 -- The LTSYC (8) is generally a function of suitable acres, species (as a surrogate for site index), and management intensity. The order of the alternatives is the same as for suited acres. As a percent of the ending inventory (9), LTSYC follows about the same pattern as ASQ % of the beginning inventory in Column 6. Alternatives J and L, with less intensive management due to the higher proportion of long-rotation management areas, harvest a smaller percentage of the ending inventory. Most alternatives reach LTSYC by the 15th decade (10), but three alternatives (K, D and L) fall short by 2 to 3%, due to age class distributions which are still uneven. Alternative NC avoids future volume shortages associated with uneven age class distributions by harvesting over half the ASQ volume in commercial thinnings in the fifth decade and beyond, so that first decade ASQ is equal to LTSYC.

Columns 11, 12, and 13 -- The average annual net growth per acre at the present time (11) is mostly a function of site index and age class on the suited landbase. Five decades in the future (12), the growth rate increases dramatically as most of the existing mature and old growth stands have been replaced by young, fast growing stands. Alternative L has the least growth per acre because of the higher proportion of long-rotation lands, which delays the conversion from existing to managed stands. The total annual growth in the year 2030 (13), reflects the number of acres in the suited landbase.

Columns 14 to 19 -- In total acres of full yield (14), the alternatives follow the same order as total acres of suitable lands, but as a percentage of the suited lands (15), are more variable and depend on the objectives of the alternative. The reduced yield lands which range from 50% to 94% of full yield (16) have a similar pattern except for Alternative L which has a much higher

proportion of reduced yield lands. There are no suitable acres being managed at less than 50% of full yield (18), except in Alternative L which has management areas with rotations as long as 666 years.

Columns 20 to 23 -- The number of acres clearcut (20) are in the same order as the acres in the suited landbase and volume harvested. The only exception is Alternative D, which harvests a higher ratio of small sawtimber, giving it more acres than Alternative W. Regeneration harvest other than clearcut (21) assumes future use of shelterwood and seed tree cutting will be at about the same proportion (7%) as past use. The acres of selection harvest (22) are modeled at zero, although this option is available to be prescribed.

Based on the percent harvested in the first decade (23), the various alternatives would take about 63 to 100 years to cut over the suitable landbase. The actual time will be longer because of harvest rate constraints, which on some areas require a rotation age of up to 666 years, and the increasing amount of commercial thinning volume which will reduce the number of clearcut acres in future decades.

Suited Acres - Table II-5 compares suited lands and timber yield categories by Alternative. There are 1,032,318 acres on the Forest that are tentatively suitable for timber management (See Chapter III, Timber). Removal of 85,513 acres necessary to meet management requirements (MRs) leaves a potential landbase for timber management of about 946,800 acres. The MR acres include Spotted Owl habitat (74,719 acres), and riparian areas that cannot be harvested due to steep and/or unstable soils (10,794 acres). Pine Marten and Pileated Woodpecker MRs are met in some alternatives by managing larger areas on long rotations, so these acres are still part of the potential landbase for timber management. Alternative K produces timber from 99% of the potential landbase, followed by A (92%), J (90%), W (82%), D (76%), and L (55%). Alternative NC which does not include MRs, and schedules harvest on 125,000 acres of "marginal" lands, has a suitable landbase of 1,064,616 acres, 12% greater than the potential landbase for the other alternatives.

Table II-5 also shows the breakdown of the suited acres by percent of full yield expected under the proposed management intensities. Also shown are the rotation ages that go along with the yield constraints. At full yield the rotations vary from 60 to 110 years, depending on species, access for commercial thinning, and response to fertilizer. The acres with 75 to 94% of full yield have 140 year rotations that result from harvest rate constraints that limit the amount of regeneration harvest to 7% of the suited acres per decade. The acres with 50 to 74% of full yield have 200 year rotations resulting from a harvest rate constraint of 5% per decade. Alternative L has additional constraints as low as 1.5% per decade, resulting in rotations as long as 666 years.

Table II-5. Comparison of Suited Timberlands

					Timber Yield Acres with Yield Reductions to Meet Other Resource Objectives					
Alternative	Acres with Timber Yield	% of Tent. Suited -MRs[1]	No Yield	% of Tent. Suited - MRs	Acres of Full Yield [2]	%	75-94% Full Yield	%	50%-74% Full Yield	%
NC (No Change)[3]	1,064,616	112%	0	0	918,657	86%	54,000	5%	91,959	9%
K	932,813	99%	13,992	1%	796,974	85%	70,306	8%	65,533	7%
A	874,291	92%	72,514	8%	743,451	85%	71,236	8%	59,604	7%
J	853,398	90%	93,407	10%	719,610	84%	72,556	9%	61,232	7%
W	774,608	82%	172,197	18%	689,229	89%	42,870	6%	42,509	5%

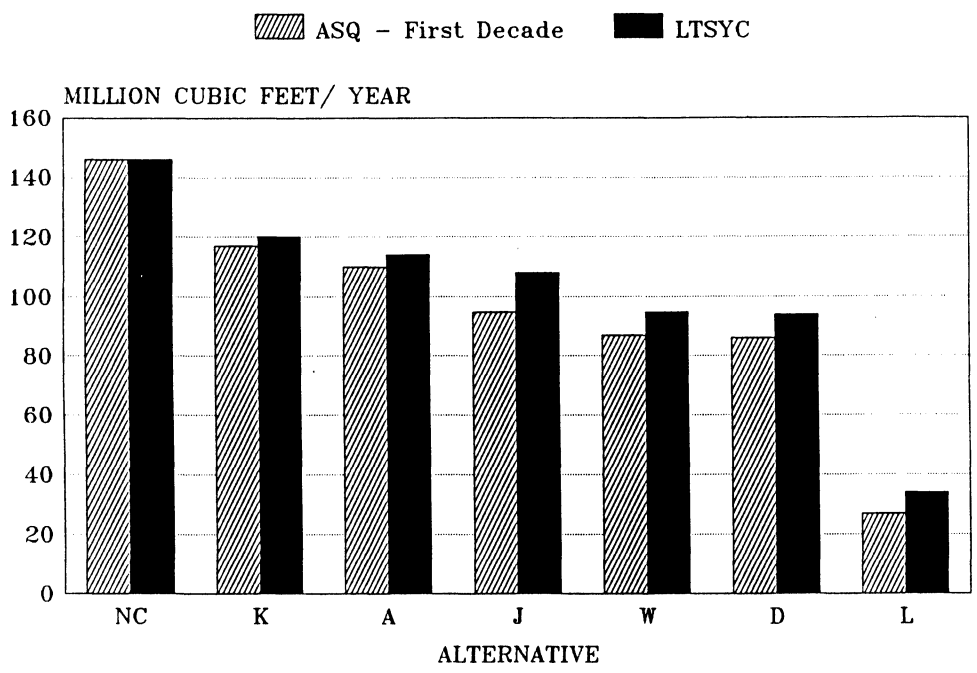
L	553,090	58%	393,715	42%	314,299	57%	74,857	14%	163,938[4]	29%
Rotation Age					60-110 years		140 years		200 years	

[1] Suited acres minus MRs = Total Forest acres (1,675,407) - nonforest acres (146,153) - withdrawn acres (327,501) - roads and unsuited acres (169,615) = 1,032,138 acres tentatively suited - acres required for resource management objectives (36 CFR 219.14 (c)) which preclude timber production (85,513) = 946,805 acres.

[2] Full yield is that developed in a yield simulator, less operational falldown, without further reductions for other resource considerations, and available for harvest at CMAI (or 95% CMAI).

[3] Alternative NC has the same land allocations as Alternative A (No Action) but is based on different land suitability standards and does not include MRs. It also assumes the necessary budget, workforce and technology will be available to produce full timber yields from 125,000 acres of "marginal" land.

[4] This table includes 74,941 acres that are managed on rotations of 330 to 660 years, with timber outputs that are less than 50% of full yield.



Volume - Timber volumes are measured in several different ways to reflect different aspects of the timber program. The Allowable Sale Quantity (ASQ) measures the amount of sound, green or recently dead wood that can be sold in a decade, and is the amount used for controlling the Forest's timber sale program. The ASQ is calculated in cubic feet using FORPLAN. The cubic foot measurement is used because it is a more accurate measure of total merchantable volume, especially over the long term. It reflects the increasing utilization of the tree much better than is possible with board foot measures. The long-term sustained yield capacity (LTSYC) is also measured in cubic feet and calculated using FORPLAN. Alternative NC, developed under the current plan, used a computer program called Timber RAM (Resource Allocation Method) to calculate ASQ and LTSYC.

Long-term sustained yield capacity measures the amount of volume that can be grown and harvested on a sustained basis from future stands. Figure II-1 displays the long-term sustained yield capacity and ASQ in cubic feet for the alternatives. In addition to the ASQ, volume from cull material, salvage sales, and miscellaneous materials and products is also sold by the Forest. This additional volume was determined by averaging the annual volumes from the past decade. The total volume sold, including the ASQ, is termed the Timber Sale Program Quantity (TSPQ). Figure II-2 displays the TSPQ and ASQ in board feet for the alternatives. Firewood availability is measured by the potential cords of

available cull material from timber sales. Figure II-3 shows the potential firewood available for the Alternatives.

All four of these measures follow the same pattern in the alternatives, and vary directly with the number of suitable acres. Alternative NC, with the largest landbase, has the highest ASQ, TSPQ, LTSYC and most cords of firewood available. Alternative K has the next highest levels of outputs, followed in order by Alternatives A,J,W,D and L.

[1] Projections for firewood supply are based on historical proportions of cull volume used as firewood and do not include the piling unmerchantable material (PUM) or other potential sources such as precommercial thinning slash.
[2] NA= Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Forest FORPLAN model. Section D4b, of Chapter II in the DEIS describes these differences.

Silvicultural Activities - A mix of silvicultural treatments is applied to the acres which are suited for timber management. The silvicultural activities used in the alternatives include reforestation, release, precommercial thinning, fertilization, commercial thinning, and regeneration harvest. The difference between alternatives is the number of acres to which these treatments are applied, which reflects the number of suitable acres and how many are accessible for commercial thinning. These activities are displayed in Table II-6.

Table II-6. Annual Silvicultural Treatments

		Alternatives						
Treatment (M Acres)	**Decade**	**NC**	**K**	**A**	**J**	**W**	**D**	**L**

	5	NA	2.8	1.3	10.1	6.8	6.1	4.9

[1]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Forest FORPLAN model. Chapter II (Timber) in the FEIS describes these differences.

Comparison of Past, Present, and Projected Future Outputs - Table II-7 provides a comparison of the current Timber Management Plan potential yield, average volume sold, average volume cut, and the proposed alternatives for the Forest Plan. This table also breaks out the various components of the Timber Sale Program Quantity (TSPQ) for each of the alternatives.

Table II-8 compares the Forest situation from the Potential Yield of the Current Plan in 1977, to the No Action Alternative which incorporates NFMA regulations, and finally to the Preferred Alternative (W). The following discussion explains the differences found in these comparisons in two steps. The first step compares the Current Plan (Alternative NC) to the No Action Alternative (A) under NFMA, to highlight the changes due to implementation of the NFMA regulations. The second step compares the No Action Alternative to the Preferred Alternative (W), to highlight the changes in response to the issues facing the Forest today.

The potential timber yield of the Current Plan was 897 million board feet (MMBF) in 1977. This amount was amended twice to 850 MMBF due to the addition of new wilderness in 1980 and 1984. In addition, 40 MMBF of salvage was removed to provide comparisons based on net green volumes. This results in a Current Plan potential yield of 810 MMBF (Alternative NC). By comparison, the potential first decade yield for the Current Plan, as it would be implemented under the NFMA planning process, is 608 MMBF (Alternative A). The difference of 202 MMBF can be attributed to two factors: fewer acres suited for timber management; and less productivity per acre.

The biggest factor (72%) is the drop in suited acres from 1,064,616 to 874,290 which accounts for 145 MMBF at the average Forest productivity rate of 761 board feet per acre per year. The difference of 190,330 acres is due to changes in land suitability definitions, additional nonforest acres due to more detailed timber typing, and wildlife and riparian MRs.

The remaining factor (28%) is the reduction in Forest productivity. This is due to a combination of yield table differences and management intensities. The overall productivity dropped from 761 board feet/acre/year in the current TM Plan to 695 board feet under the new calculations, and accounts for a drop of 57 MMBF on 874,290 acres. Even though individual yield tables dropped by as much as 12% from those used previously, the loss was offset somewhat by the addition of fertilizer to stands with at least 60% Douglas fir.

The discussion thus far has examined the effects of implementing the Current Plan under the NFMA regulations. The second step is to compare the Current Plan under NFMA (Alternative A) with implementation of the Preferred Alternative (W). The Preferred Alternative allocates an additional 99,690 acres to no-harvest categories (e.g., riparian habitat, dispersed recreation, special interest areas, old-growth groves, and special wildlife habitat) to deal with the issues facing the Forest today. This amounts to a 69 MMBF drop in potential yield. There is also an additional 48 MMBF drop due to changes in management intensity. These changes reflect more restrictive harvest rate constraints to meet resource objectives. The total of 117 MMBF is the volume reduction from the Current Plan (NFMA) potential yield of 608 MMBF to the Preferred Alternative potential yield of 491 MMBF. The total drop from the Current Plan (1977) potential yield (810 MMBF) to the Preferred Alternative (491 MMBF) is 319 MMBF. About 63% of this total drop is due to implementing the NFMA regulations, and 37% is due to land allocation changes in the Preferred Alternative to deal with Forest issues (See Table II-8).

The Current Plan proposed harvest level, excluding salvage, was set at 605 MMBF per year in 1977 and reflected a lack of funding, work force, and technology to realize the full potential yield. This volume has been revised downward periodically to account for changes in the land base due to Wilderness, and increased periodically for the earned harvest effect of intensive management above the level planned. This earned harvest effect results from the accomplishment of more acres of intensive management (pre-commercial thinning, etc.) than was planned, which increases the amount of future volume available for harvest, and in turn, increases the volume that can be harvested now without violating non-declining yield. The earned harvest effect has more than offset the decreased land base and the most recent adjustment shows the proposed harvest for the Current Plan at 645 MMBF annually. The actual amount sold has averaged 623 MMBF (97%) and the amount harvested 538 MMBF (83%) from 1977 through 1989.

The reason the amount harvested was less than the amount sold was because of the 1980s recession. A severe depression of the housing market and a general slowdown in the economy caused timber prices and demand to decline sharply. Timber harvest on the Forest fell to 370 mmbf in 1982, the lowest level since 1952. In order to remain competitive, mills harvested only the lowest priced National Forest timber, and increased harvest on private lands. The average selling price on the Forest from 1977 to 1985 was $192/MBF. However, the value of the timber actually harvested over the same period was only $135/MBF. The private harvest level in the Eugene Timbershed went from 350 MMBF in 1980 to 500 MMBF in 1983, after declining steadily from 630 MMBF in 1972 (Oregon Department of Forestry). For the last three years (87,88 and 89) the volume harvested has exceeded the volume sold, but the planning period average remains about 17% less than the allowable harvest level.

The potential yield for the Preferred Alternative is also the ASQ. The potential yield for the Current Plan (810 MMBF) was never offered for sale. A major concern of some of the public is that we will

continue to offer significantly less than the potential yield. However, the Forest expects to sell 100% of the potential yield of the Preferred Alternative over the planning decade for the following reasons: (1) more accurate delineation of suitable timber land; (2) more realistic assumptions regarding silvicultural intensities; (3) more accurate calculations of harvest reductions to meet other resource goals; and (4) with more accurate planning, full funding is expected. When planning assumptions are correct, targets should be obtainable within the standards and guidelines. However, ASQ and annual targets are secondary to standards which will not be violated to achieve annual targets (Regional Forester, 2430/1920 Letter, March 22, 1990).

Managed Yield Tables - The following discussion provides more information about the difference in the managed timber yield tables between the Current Plan (Alternative NC) and the other alternatives. This difference results from the following changes in inventory techniques, yield models, management intensities, and philosophies (Knapp, 1983):

Inventory techniques -

Site tree selection - The previous inventory allowed selection of an appropriate tree outside of the plot area. The present inventory required selection of the site tree in the plot, resulting in a more accurate measure of site quality.

Site Index Conversion - The site indices from both inventories use McArdle's Douglas-fir site index based on 100 years total age. The DFSIM model used for construction of managed yield tables uses King's site index based on 50 years at breast height age. Conversion to King's site index is a source of minor difference.

Land Stratification - Under the Current Plan the Forest was stratified into working groups (based on species, age and site class) after the inventory. The new plan stratified the Forest before the inventory (by species and size class) and sampled each working group as necessary to achieve a sampling error of less than 10%. The effect of the different methods on Forest-wide ASQ is not known, but working group level yields are more accurate with the new inventory.

Table II-7. Comparison--Past, Present, and Alternatives Timber Outputs (MMBF)

Output	Existing TM Plan	1977-89 Annual Average Timber Sold/Cut	Alternatives						
			NC [1]	K	A	J	W	D	L
I. ALLOWABLE SALE QUANTITY (ASQ) -- The allowable sale quantity is composed of those volumes resulting from the yield projections of FORPLAN. ASQ is obtained from lands designated as suitable for timber production under NFMA standards, and meets the utilization standards in the Regional Guide. When sold, the volume is called "chargeable," and is used to determine achievement of planned allowable sale quality goals.									
Potential Yield [1]									
Green	797	623/538	797	634	594	517	479	465	147
Salvage	53		13	16	14	13	12	11	3
TOTAL Allowable Sale Quantity	850	623/538	810	650	608	530	491	476	150
II. OTHER SAWTIMBER -- Meets utilization standards in Regional Guide, but is not considered "chargeable" against the planned allowable sale quantity goals.									
A. Sawtimber from lands designated unsuitable for timber production--this volume is estimated based on the incidental volume of timber that will be sold from lands that are not designated for timber production.									
Green		2/2	2	2	2	2	1	1	1
Salvage									
TOTAL Sawtimber Volume From Unsuitable Lands		2/2	2	2	2	2	1	1	1
B. Dead sawtimber from lands that are designated suitable for timber production, but which was not included in yield tables.									
		24/20	29	22	21	18	17	16	5
TOTAL -- Other Sawtimber		26/22	31	24	23	20	18	17	6
III. SUBMERCHANTABLE VOLUMES FROM ALL LANDS -- The estimated timber volume that does not meet the utilization standards in the Regional Guide, but which could be utilized for products other than sawtimber. It is not considered "chargeable" against planned allowable sale quantity goals.									
Fuelwood		30/25	39	28	27	23	22	21	7
Other (including cull)		100/87	133	97	90	79	73	71	22
TOTAL Submerchantable Volume		130/112	172	125	117	102	95	92	29
TOTAL NET MERCHANTABLE SAWTIMBER (I + II)		649/560	841	674	631	550	509	493	156
TOTAL NONCHARGEABLE (II + III)		156/134	203	149	140	122	113	109	35
TIMBER SALE PROGRAM QUANTITY (I + II + III) -- The timber sale program quantity includes the allowable sale quantity for the 1st decade and estimated additional volume planned for sale during the 1st decade, such as fuelwood.									
		779/672	1013	799	748	652	604	585	185

[1]The assumptions that were used in the existing timber management plan to calculate potential yield differ from those that were used to calculate Allowable Sale Quantity. While potential yield represented a level that could be produced, allowable sale quantity represents a timber objective and program for achievement of planned levels. However, both the potential yield and allowable sale quantity do represent a ceiling on the amount of chargeable timber volume that could be sold for a given decade. In this context, the two terms are comparable.

Table II-8. Volume Comparison of Alternative NC, A, and W

Description	Potential Yield MMBF	Comments
Alternative NC (No Change)	897	Landbase = 1,125,500 acres (current Plan-1977 without NFMA Requirements)
Adjustments:		
Landbase	-10	French Pete Additions (1980) 15,000 acre reduction of suited land
	-37	Oregon Wilderness Act (1984) 45,880 acre reduction of suited land
Salvage	-40	Removes salvage volume
Alternative NC (No Change)(1984)	810	Potential yield. Includes only net green and salvable dead. Landbase = 1,064,620 acres.
Alternative A (No Action) (current Plan with NFMA Requirements)		
Adjustments:		
Landbase	-145	190,330 acre reduction for nonforest, unsuited and MRs
Forest productivity	-57	Reduction due to differences in yield tables and management intensities.
Alternative A (No Action)	608	Potential yield. 25% decrease represents the Current Plan land allocations implemented under NFMA. Landbase = 874,290 acres.
Alternative W (Preferred) (Proposed Forest Plan with NFMA Requirements)		
Adjustments:		
Landbase	-69	99,690 acre reduction for additional no-harvest allocations to deal with current Forest issues.
Forest productivity	-48	Additional drop from No Action Alternative due to more restrictive harvest rate constraints to meet resource objectives. This results in a 9% decrease in productivity.
Alternative W	491	Potential yield. This is a 19% change from the Current Plan under NFMA, (No Action). Landbase = 774,600 acres.

Managed Timber Yield Models - The Current Plan used the Managed Yield (MGYLD) computer program to make yield calculations. The new plan uses two models, DFSIM for low elevation timber types and Prognosis for high elevation types. Further discussion of timber yield models and yield table development can be found in Appendix B, Section C.5., and in the planning records. The major differences are summarized in Table II-9.

Table II-9. Comparison of Managed Timber Yield Models

	MGYLD	DFSIM, Prognosis
Height growth:	Increase of six Site Index points for stocking level control (PCT).	Both use height function for stocking level control.
Height curve:	Used McArdle's SI curves.	DFSIM uses Bruce's height curve which is generally lower than McArdle's in first half of rotation. Prognosis uses local height curve.
Average tree:	Assumed site index tree represented the stand average tree.	DFSIM uses a stand volume function and assumes the average tree is the tree of mean volume. For Prognosis, the average tree is less than the site index tree.
Model influences:	Volume is highly sensitive to timing and number of thinnings.	Volume is relatively insensitive to timing of thinnings, number of thinnings and initial stocking levels.

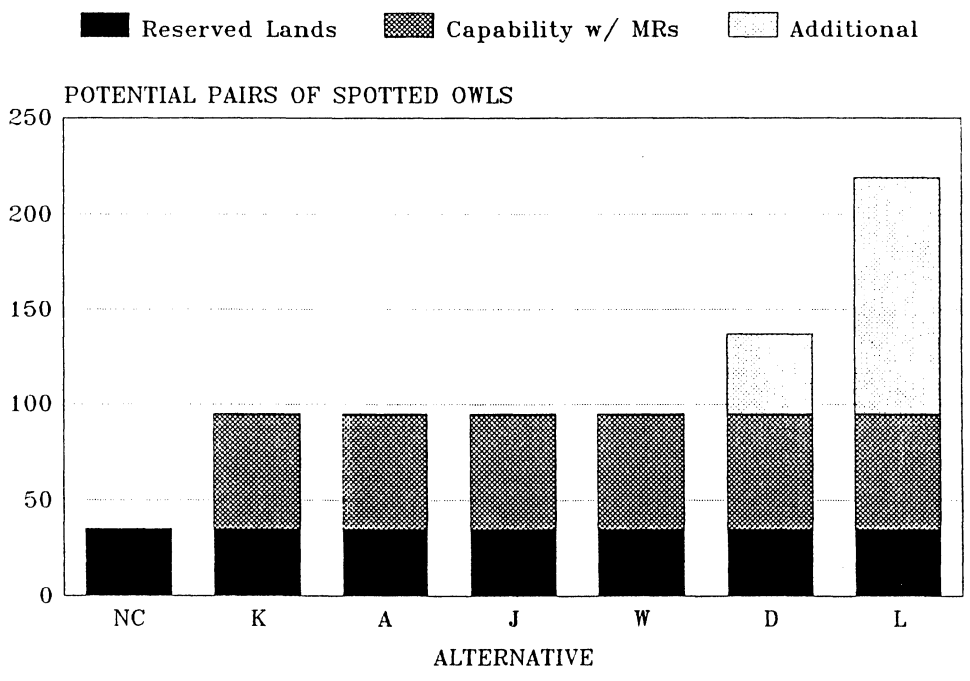
Management Intensity -

Precommercial Thinning (PCT) - The Current Plan assumed a 49% increase in yield for PCT. The new yield tables show an increase of 21% for PCT.

Commercial Thinning (CT) - The Current Plan allowed thinning on a 10 year cycle beginning at age 34 (9-inch d.b.h.), with up to six entries. As much as 41% of the suited landbase was scheduled for CT in a single decade.

In the Proposed Forest Plan, CT is constrained to a 20 year cycle beginning at age 47 (12-inch d.b.h.), with a maximum of two entries. The result is a maximum of 28% of the suited landbase scheduled for CT in any decade. These constraints are based on resource, economic and operational considerations that take into account impacts on other resources, reasonable expectations of work force, and funding situations.

Genetics - The Current Plan does not include an increase in yields for planting genetically superior stock. The new tables use a 10% increase for all working groups.



Fertilization - The Current Plan assumed fertilizer would not be available for use. The Proposed Forest Plan assumes fertilizer will be applied once (at the rate of 200 pounds of nitrogen/acre) to acres which are stocked with at least 60% Douglas fir. This represents about 80% of the suited landbase. Fertilizer increases yields by an average of 7% at culmination of mean annual increment.

Management Philosophy - During the development of the Current Plan, the emphasis was on what *could* we produce with a given level of management. In the Proposed Forest plan the question is what does the Forest anticipate *will* be grown in response to a certain level of management? The first perspective is on the *potential*, the second is on the *expected*.

Wildlife

Spotted Owl Habitat - The Management Requirement (MR) network of spotted owl habitat areas (SOHAs) will be maintained in all of the Forest Plan Alternatives except for the No Change Alternative. Alternatives D and L provide habitat capability above the MR level. All alternatives provide an equal amount of habitat capability for reserved lands. All land designated for protection of spotted owl habitat will be considered unsuited for timber production. Figure II-4 illustrates the habitat capability to support pairs of northern spotted owls provided in each alternative.

Figure II-4. Spotted Owl Habitat Capability

	Alternatives						
Pair Capability	**NC**	**K**	**J**	**A**	**W**	**D**	**L**
SOHA Level[1]	NA[2]	60	60	60	60	60	60
Additional Provided [3]	0	0	0	0	0	42	124
Capability in Reserved Lands[4]	35	35	35	35	35	35	35
TOTAL CAPABILITY IN PAIRS	35	95	95	95	95	137	219

[1]Verified pairs of spotted owls located within the MR SOHA network of 59 areas.
[2]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the Draft EIS describes these differences.
[3]Verified pairs of spotted owls protected above MR levels; based on habitat capability in Alternative L and additional SOHA designation in Alternative D.
[4] Potential pairs of spotted owls based on capability in wilderness.

Pileated Woodpecker Habitat - Figure II-5 displays the long term habitat capability for pileated woodpeckers on the Forest by Alternative. The combination of reserved lands, spotted owl habitat areas, and pileated woodpecker habitat areas provide the quality, quantity, and distribution of habitat required to meet or exceed the Management Requirements for pileated woodpeckers in all alternatives except No Change. Habitat capability on reserved lands is the same for all alternatives.

Figure II-5. Habitat Capability for Pileated Woodpeckers[1]

	Alternatives						
Habitat Capability	**NC**	**K**	**J**	**A**	**W**	**D**	**L**
Pileated Woodpecker Habitat Areas	NA[3]	38	38	38	38	38	--[2]
SOHAs	NA[3]	118	118	118	118	274	355
Reserved Lands	83	83	83	83	83	83	83
Total Habitat Capability	83	239	239	239	239	395	438

[1] Habitat capability is expressed as potential numbers of individual pileated woodpeckers.
[2] No specific allocation of pileated woodpecker habitat is needed to meet MR levels for habitat quality or distribution; capability is maintained by the existing condition.
[3]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the Draft EIS describes these differences.

Marten Habitat - Marten utilize a broader range of habitat than either spotted owls or pileated woodpeckers. All vegetation series with mature and old-growth Forests are used as habitat. Marten habitat will be provided at or above Management Requirements in all the alternatives except for No Change. Because marten use similar mature and old-growth habitat as spotted owls and pileated woodpeckers, a combination of reserved lands, spotted owl habitat areas, pileated woodpecker habitat areas, and marten habitat areas will contribute to meeting Management Requirements. Habitat areas designated specifically for marten occur wherever quantity, quality, or distribution of habitat appear limited. All alternatives provide the same habitat capability within reserved lands. Figure II-6 displays the habitat capability for marten provided in each alternative.

Figure II-6. Marten Habitat Capability [1]

	Alternatives						
Habitat Capability	**NC**	**K**	**J**	**A**	**W**	**D**	**L**
Marten Habitat Areas	NA[3]	100	100	100	100	100	--
Martens in PWHAs	NA[3]	38	38	38	38	38	--
Marten in SOHAs	NA[3]	118	118	118	118	274	438
Marten in Reserved Lands	459	459	459	459	459	459	459
Total Habitat Capability	459	715	715	715	715	871	897

[1] Habitat capability for marten is expressed as potential population of individual martens.
[2] No specific allocation is needed to meet MRs for habitat quality, quantity or distribution.
[3]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the Draft EIS describes these differences.

Bald Eagle Habitat - Five pairs of bald eagles are known to nest on the Forest. Bald Eagle Management Plans exist for two of these pairs. The areas included in the Management Plans are located near Hills Creek Reservoir and Lookout Point Reservoir. Existing Bald Eagle Management Plans must be revised and new plans prepared for all known nesting pairs during Forest Plan implementation regardless of the alternative selected. Management of all nesting pairs will comply with the Bald Eagle Recovery Plan. All alternatives consider lands within 1.1 miles of eleven major water bodies to be potential nest, roost, and forage sites for bald eagles. Table II-10 displays the Bald Eagle Recovery Plan objectives for the Forest as part of four alternatives, including the No Change Alternative. Additional sites have been designated in the remaining three alternatives.

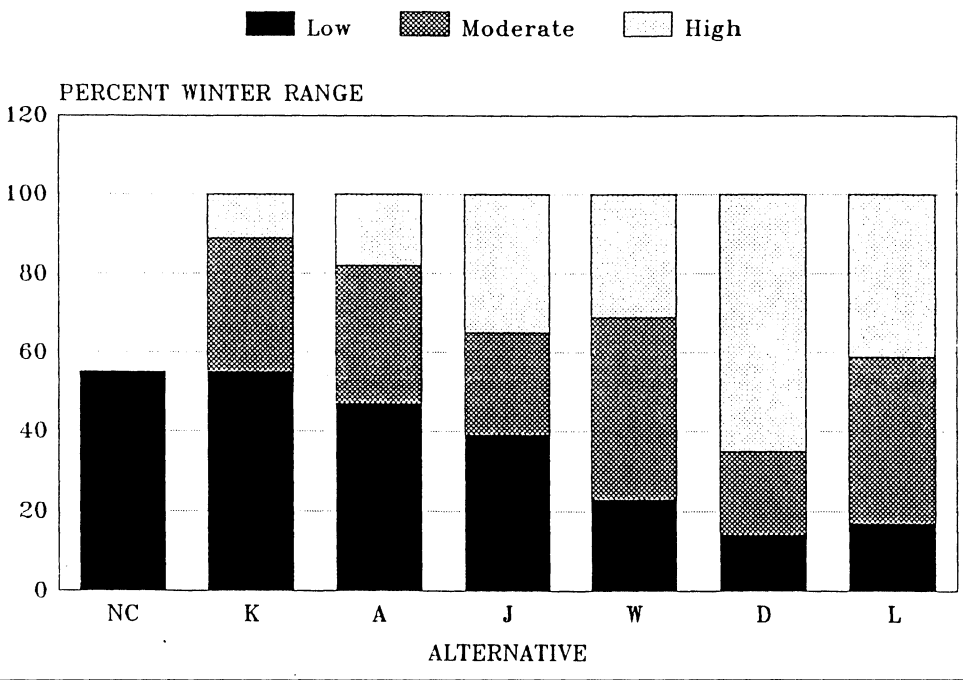


Table II-10. Bald Eagle Habitat

	Alternatives						
Acres of Habitat	**NC**	**K**	**J**	**A**	**W**	**D**	**L**
Existing BEMAs [1]	1472	1472	1472	1472	1472	1472	1472
Potential Nest Sites [2]	725	725	725	725	2250	3000	3000
TOTAL	2197	2197	2197	2197	3722	4472	4472

[1]These acres reflect nest, roost, and forage habitat designated through development of bald eagle management plans for Hills Creek and Lookout Point.
[2]Habitat identified is within 1.1 miles of major water bodies surveyed. Management plans are being developed for three known nest sites that are included in this category.

Deer and Elk - Habitat conditions on winter range are considered a limiting factor influencing survival of wintering deer and elk populations. The manaegment emphasis placed on winter range habitat effectiveness determines potential deer and elk populations. A total of 605,367 acres of winter range have been delineated on the Forest. Habitat objectives set for each level of management emphasis include summer range as well as winter range. Deer and elk populations occurring on the Forest are migratory, thus management of the entire range will be required to maintain healthy, productive populations. Figure II-7 displays the habitat effectiveness emphasis levels for winter range provided by each alternative.

Figure II-7. Optimal Cover on Deer and Elk Winter Range

	Alternatives						
Percent Cover	**NC**	**K**	**J**	**A**	**W**	**D**	**L**
Optimal Cover	NA[1]	31	33	34	36	37	41

[1]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the Draft EIS describes these differences.

Primary Cavity Excavators - All alternatives except No Change provide habitat capability to meet or exceed the Management Requirements for primary cavity excavators. Snag habitat would be maintained at or above levels required to support 40% potential populations within each subwatershed. Figure II-8 displays the percent potential populations managed for in subwatersheds and harvest units by alternative.

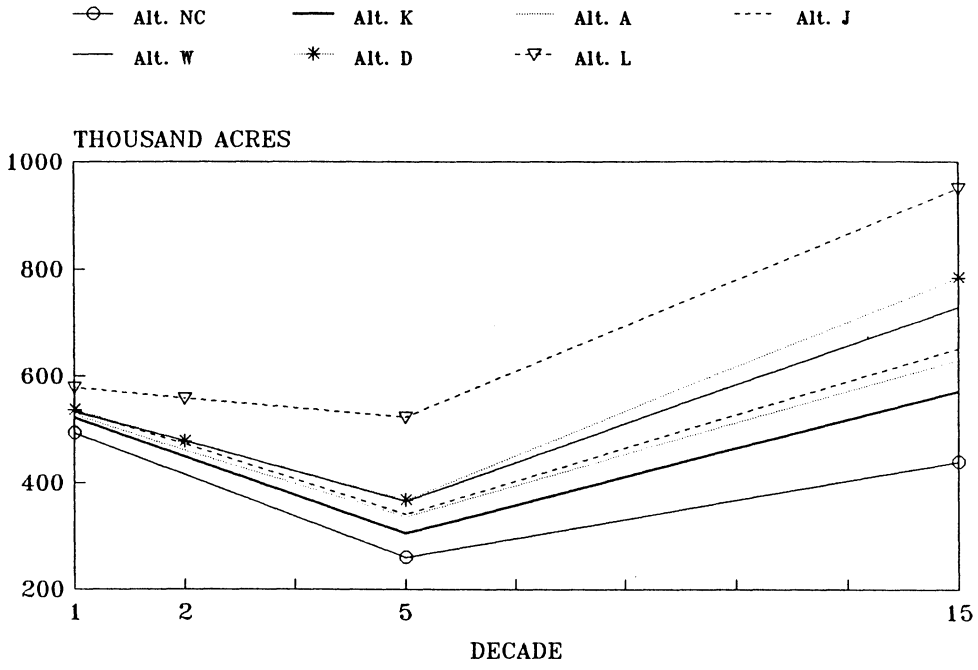
Figure II-8. Primary Cavity Excavator Habitat Capability[1]

	Alternatives						
% Habitat Capability	**NC**	**K**	**J**	**A**	**W**	**D**	**L**
Within Harvest Units	NA[2]	20	20	20	20	60	60
Within Subwatersheds	NA[2]	40	20	40	40	60	60
Reserved Lands	100	100	100	100	100	100	100

[1]Habitat capability is calculated for pairs of birds and is based on the needs of the red-breasted nuthatch, which has the smallest territory on the Forest.

[2]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the Draft EIS describes these differences.

Old Growth



Old-growth timber is characterized by large old trees, multi-layered canopies, standing snags, and large logs in streams and on the forest floor. In the Douglas-fir region of western Oregon, old-growth forests begin to develop at between 150 and 250 years of age (Spies, 1989). Managed stands may begin to show these characteristics earlier by leaving large standing green trees and snags, and large woody debris on the ground. These stands may provide some of the needs for wildlife and plant species that are associated with old growth as early as 60 to 70 years after regeneration of the site following harvest activities. Existing young stands that are to be managed on long rotations can be commercially thinned to wider spacings in order to stimulate the development of multi-canopy stands. Alternatives J, W, D and L manage long rotation areas by leaving 10 large green trees, in addition to wildlife trees, to enhance the development of old growth habitat. All of the alternatives have the option of thinning existing young stands to a wider spacing to enhance understory development in areas of long rotations.

Fragmentation of old growth stands reduces the quality of the habitat for several reasons: 1) the edges of old growth stands are poorer quality due to increased disturbance and climatic extremes; 2) small stands are not suitable for species who require larger home ranges; and 3) animals and plants moving between widely spaced old growth habitat are subjected to higher rates of mortality. Long-term viability of populations of some species may be lower in landscapes where their habitat is highly fragmented. Minimizing fragmentation by grouping harvest units closer together is an option for maintaining the remaining large blocks of old growth habitat for a longer period of time. This option is available under all alternatives, where compatible with other resource objectives.

Because of the current concerns about global warming and increasing levels of carbon dioxide in the atmosphere, it is appropriate to discuss the role of forests in cycling and storing carbon. Carbon dioxide is one of the radiatively active gases that may be involved in the "greenhouse effect". Forests account for about 60% of the stored carbon on the earth's land surface, and old growth forests store significantly more than managed forests, even when considering repeated rotations (Harmon, et. al., 1990). The net reduction in stored carbon when converting from old growth to managed stands is about 150 tons per acre. The effects of the alternatives do not differ much and are not significant by themselves, when comparing against the regional levels of carbon storage. Long-term monitoring and research is needed to determine cumulative effects.

As a result of the Mature and Overmature Survey (MOMS), there are currently about 594,800 acres of old-growth stands that meet the Region Six definition of old growth (see Vegetation, Chapter III). Figure II-9 displays the amount of old-growth timber remaining at the end of decades 1, 2, 5, and 15+, for each alternative. For each alternative the lowest amount provided over time occurs in the fifth decade. Declines in old growth acres from decade 1 to 5 reflect the rate of timber harvest. Increases in old-growth stands after the fifth decade represent timber stands in no-harvest allocations, currently in a young or mature condition, that in the future will begin to exhibit old-growth characteristics. The figure for decade 15+ represents the potential amount of old growth for each alternative, barring catastrophic events.

Figure II-9. Old-Growth Acres Over Time

	Alternatives [1]						
	NC [2]	K	A	J	W	D	L
Decade 1 (M Ac.)	494.0	522.4	528.4	534.9	533.4	537.2	578.3
Decade 2 (M Ac.)	NA	449.7	460.9	473.6	479.1	478.4	558.1
Decade 5 (M Ac.)	259.8	305.1	337.0	341.4	365.2	367.8	523.1
Decade 15+ (M Ac)	440.1	571.7	630.2	651.1	729.9	785.1	951.4

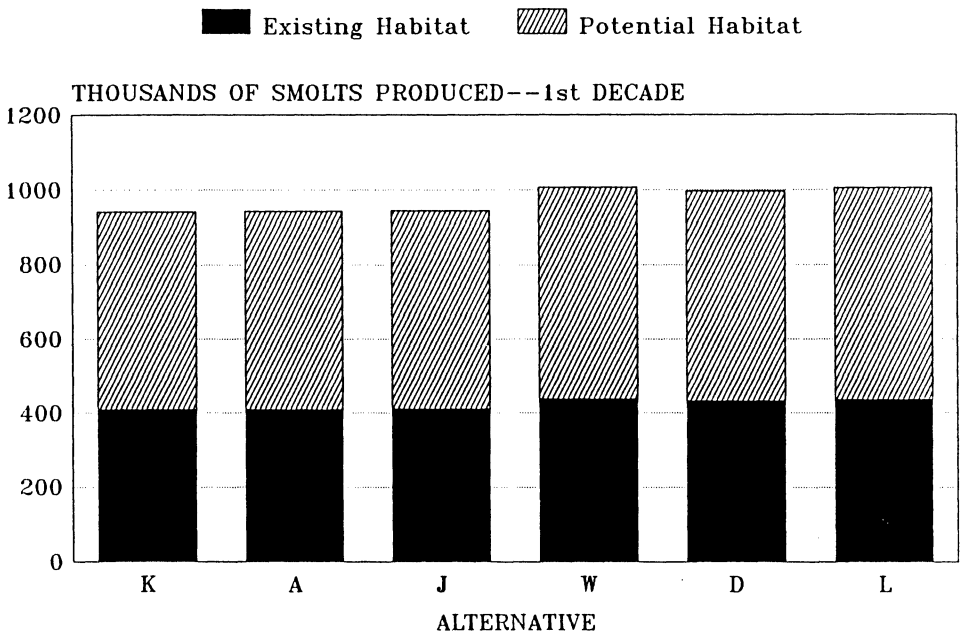
[1]Acres of old-growth timber, in all allocations, remaining at the end of each decade. Decade 15+ values show potential old growth on forested no-harvest allocations, assuming no catastrophic events.

[2]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Forest FORPLAN model. Differences are described in Chapter II, Description of Alternatives.

Fish

Anadromous and resident salmonids are Management Indicator Species for stream habitat. The estimated number of anadromous smolt is dependent on the number of returning adults, and the quantity and quality of habitat.

The numbers of spawning adults will be influenced by stocking programs and fishing regulations established by Oregon Department of Fish and Wildlife (ODFW). The Forest will aid in enhancement of population levels through management of smolt incubator boxes. These, and other improvement projects are conducted in cooperation with the volunteer program, Salmon and Trout Enhancement Program (STEP).



Changes to the quality of existing habitat during the next decade is influenced by habitat improvement projects, and the effects of timber sale projects. Approximately 60 miles of existing anadromous habitat, will be scheduled for habitat improvement projects in all alternatives. Increases in smolt from these projects will not become apparent for 3 generations of returning adults, thus will not be seen until the second decade.

Changes to the quantity of habitat available during the next decade will be largely dependent on the success in providing passage for spring chinook around four major reservoirs; Green Peter, Foster, Blue River, and Cougar. Minor increases in the quantity of habitat may be acheived around smaller barriers to passage on the Forest. The Forest Service will work in partnership with ODFW, Army Corps of Engineers (ACE) and other agencies to facilitate passage around these reservoirs. Habitat improvement projects would be made in approximately 30 miles of this additional habitat.

Timber sales effect the capability of streams to produce smolt in approximately the same proportion of acres harvested, with particular influence from practices which effect riparian areas, and slope stability.

Estimates of outputs are shown as Smolt Habitat Capability Index in the Figure II-10. This is intended to show relative differences between alternatives and other practices influencing smolt production.

Figure II-10. Smolt Habitat Capability Index

	Alternatives						
Smolt Produced [2]	**NC [1]**	**K**	**A**	**J**	**W**	**D**	**L**
FIRST DECADE

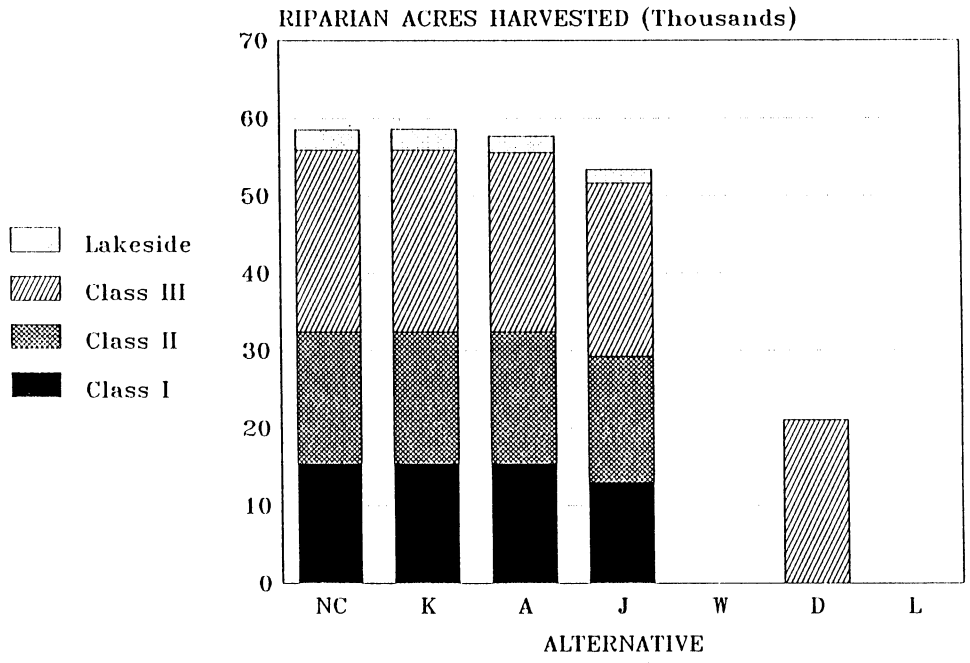
[1]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Differences are described in Alternatives Considered in Detail, Chapter II.



[2]Calculated with coefficients described in "Anadromous Fish Planning Coefficients" 1920 Memo, May 1, 1987. Index numbers indicate thousands of smolt.

Riparian

Timber harvest is scheduled from riparian areas in Alternatives NC, A, K, and J. In these alternatives harvest is scheduled at 5% per decade for Class I and II streams, and 7% per decade for Class III streams. Alternative D proposes no harvest on Class I, and II streams, and 5% per decade on Class III streams. Alternative W and L propose scheduling no timber harvest from areas adjacent to any of these perennial streams. Figure II-11 displays riparian acres by stream class which are scheduled for some level of timber harvest in each alternative. Where the estimated rate of harvest is lower than the rates described above, the acres are in allocations with reduced harvest rates.

Harvest rates within the riparian areas have effects on many resources. Riparian dependent resources, such as water, fish, terrestrial and amphibian species will be influenced. Management of vegetation in riparian zones has the potential to effect the availability of optimal thermal cover for big game animals, and habitat for birds which are primary cavity excavators. These areas have the potential to provide important corridors for dispersion of interior species across the landscape, and to provide quality recreation opportunities for visitors to the Forest.

Figure II-11. Comparison of Riparian Area Management

[1]Total riparian acres in management areas with scheduled harvest in thousands of acres.
[2]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Forest FORPLAN model. Differences are described in Chapter II, Description of Alternatives.

Roadless Lands

Roadless lands are defined as inventoried areas of undeveloped Federal land within which there are no improved roads maintained for travel by motorized vehicles intended for highway use. The roadless area inventory does not include areas designated by Congress (Wilderness, the Oregon Cascades Recreation Area which comprise 23% of the Forest), or other areas of less than 5,000 acres.

In the Forest, current roadless lands in parcels larger than 5,000 acres or adjacent to Wilderness, comprise 172,007 acres in 31 inventoried areas. The alternatives vary in the amount of roadless land they maintain in an undeveloped condition. Each alternative proposes management of these lands for uses that range between full commodity production and recommended Wilderness. Table II-11 displays the percent of each roadless area to remain in an undeveloped condition in each alternative.

Table II-11. Percent of Roadless Land Retained in an Undeveloped Condition

	Alternatives

[1]This area is divided into several parts for purposes of description in Appendix C.

Scenery

The alternatives have varying effects on scenic quality as a result of the type and distribution of the proposed management areas and their associated activities. In general, alternatives emphasizing timber harvest and supporting road construction provide less Forest area managed for high levels of scenic quality.

Figure II-12 provides a Forest-wide comparison of alternatives and their effect on scenery as measured against inventoried Visual Quality Objectives (VQOs). There will be an increase in the amount of area managed for preservation as a consequence of implementing any of the proposed alternatives. However, lands to be managed for retention, partial retention, and modification VQOs will decrease from inventory levels in all alternatives, except in Alternative L where management of lands for retention will exceed inventory levels by 2%.

Table II-12. Forest-wide Effects on Inventoried Visual Quality Objectives

Visual Resource Inventory			Alternatives [1]

[1]Expressed as percent of Inventoried Visual Quality Objective acres.

Recreation

The design of each Alternative, through the use of management areas, determines the number and type of recreational settings to be provided as well as the magnitude and nature of its recreation program. Each Alternative establishes the availability and distribution of recreation settings, miles of trail, and use levels of both developed and dispersed recreation opportunities, and thus determines the capability of the Forest to meet present and future demand for a wide range of recreation experiences. The capacity of recreational settings to sustain projected levels of demand is measured in capacity and anticipated demand for each Alternative, and Table II-12 shows the amount of each recreation opportunity setting to be provided by Alternative.

Figure II-13. Total Dispersed Recreation Use

Wild and Scenic Rivers

All of the alternatives provide for protection and management of free-flowing conditions and "outstandingly remarkable values" of designated Wild and Scenic Rivers and designated Study Rivers in accord with the Wild and Scenic Rivers Act. Also, all of the alternatives, except the No Change Alternative, provide interim protection for all rivers determined eligible for inclusion into the National Wild and Scenic Rivers System. Interim protection of free-flowing conditions and "outstandingly remarkable values" of designated Study Rivers and all eligible river segments is provided at the highest river classification for which they qualify. Interim protection of both designated Study Rivers and eligible river segments is maintained until a river segment is determined unsuitable for inclusion into the National System. The management status, river mileage, and corridor acreage of Forest rivers for each alternative is displayed in Table II-13.

Table II-13. Wild and Scenic River Protection Status

[1] The Little North Santiam River, McKenzie River, South Fork of the McKenzie River, and the North Fork of the Middle Fork of the Willamette River are also designated as State Scenic Waterways.

Wilderness

The Wilderness Act of 1964 states that Wilderness is to be managed in such a manner "devoted to the public purpose of recreational, scenic, scientific, educational, conservation and historical use" only to the extent that the essential Wilderness character of the area is protected. However the accommodation of any use of Wilderness is likely to result in some effect on it's resources or character. A Wilderness management system known as the Wilderness Resource Spectrum (WRS) is the primary method used to assure objectives of the Wilderness Act are realized. The WRS is divided into four management classes that are applied to areas within Wilderness based on such factors as use density, resource conditions, user experiences, and location of camping sites and trails. The alternatives vary widely in how they propose to accommodate human use and protect essential Wilderness character as required by the Act. Each alternative responds differently to this requirement, primarily, through the amount and distribution of WRS Classes and application of their respective standards and guidelines for management of human use and resource conditions. The amount of each WRS Class and projected visitor use, by class, for each alternative is displayed in Table II-14.

Table II-14. Wilderness Resource Spectrum Acres and Visitor Days

		Alternatives 1						
WRS Class	**Units**	**NC[2]**	**K**	**A**	**J**	**W**	**D**	**L**
Pristine	Acres	--	299.3	299.3	299.3	299.7	299.3	411.2
	RVDs	--	16.7	16.7	16.7	16.7	16.7	16.7

	RVDs	--	66.0	66.0	24.6	22.1	0.0	23.0
TOTALS	Acres	380.8	380.8	380.8	380.8	380.8	380.8	550.2
	RVDs	330.7	352.1	352.1	368.0	318.1	207.2	370.5

[1] Recreation Visitor Days are 1st decade outputs only.
[2] Wilderness Resource Spectrum Classes are not applicable to the No Change Alternative.

Special Areas

The Forest includes many areas that exhibit unique ecological, biological and geological characteristics as well as other areas that offer opportunities for a wide range of recreation activities within a semiprimitive setting. These lands are inventoried to identify their recreational, scientific, scenic, geological, botanic, historical, and cultural values and where appropriate are designated to protect their special features and qualities and to foster public use, enjoyment and study. The alternatives vary in the type and number of areas they propose to protect and maintain in an essentially undeveloped condition as well as in the amount of area they dedicate to these special areas. Areas inventoried as having potential or value as Special Interest Areas, Old Growth Groves, or Semiprimitive Recreation Areas but are not specifically designated as such are allocated to other uses that could, depending on the alternative, alter their suitability for special designation. The number and acreage of Special Interest Areas, Old Growth Groves, and Semiprimitive Dispersed Recreation Areas that are included in each alternative are displayed in Table II-15.

Table II-15. Special Recreation Areas

		Alternatives						
Type of Area	**Units[1]**	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Special Interest Areas	Areas	4	9	4	27	46	29	7
	M Acres	1.1	2.8	1.1	22.6	31.1	15.2	3.4
Old Growth Groves	Areas	22	7	22	18	34	18	24
	M Acres	2.8	0.9	2.8	5.0	6.7	3.1	3.1
Semiprimitive Rec. Areas [2]	Areas	18	11	18	20	24	40	22
	M Acres	94.9	52.9	94.9	104.5	104	110.0	166.1
TOTALS	Areas	44	27	44	65	101	87	53
	M Acres	98.8	56.6	98.8	132.1	143.2	128.3	172.6

[1] Acreages are in thousands of acres. Variation in acres from those reported inManagement Area Acreage of Alternatves are due to overlap with Special Habitat Management Areas.
[2] Includes the Oregon Cascades Recreation Area (6,058 ac.).

Research Natural Areas

The alternatives vary in their response to research needs through the designation of new Research Natural Areas. In some of the alternatives potential research opportunities would be foregone through development of some areas for resource utilization, and some areas would be subject to the influences and potential effects of adjacent management activities. The effects on potential RNAs allocated to uses other than research is based on whether or not the selected allocation or use would result in development of area resources or that specific uses would affect baseline conditions of an otherwise undisturbed environment. The degree of development effects on RNAs in each alternative is displayed by development category in Table II-16.

Table II-16. Effects on Research Natural Areas[1]

	Alternatives[2]						
Development Categories	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
No Development	79	69	79	94	100	96	94
Limited Development	7	1	7	2	0	0	1
Full Development	14	30	14	4	0	4	5
TOTAL	100	100	100	100	100	100	100

[1]Includes Middle Santiam RNA within the Middle Santiam Wilderness, the western portion of the Torrey-Charlton RNA within Waldo Lake Wilderness, and a portion of the McKenzie Pass RNA within the Three Sisters Wilderness.
[2]Values are in percent of total acres of potential and established RNAs.

Soil and Water

The potential effects of the proposed activities on soil are highest in those alternatives with the highest timber harvest and road construction levels.

Proposed activities are expected to maintain soil conditions so that less than 20% of an area is not in detrimental soil conditions, such as compacted, displaced or eroded. Soil rehabiliation projects will be implemented where needed to reduce compaction, and establish soil cover.

The risk of loss of soil productivity due to erosion or displacement of the soil profile will be highest where trees are yarded with ground-based equipment, and where fuel treatments include broadcast burning. The extent to which these practices occur is determined during project design. The potential acres to be broadcast burned varies by alternative, but is directly related to acres clearcut. The effects of each burn are largely dependent on the climatic conditions at the time of burn. The potential production of sediment is closely correlated to the acres of regeneration timber harvest. Table II-17 displays these acres by Alternative.

Table II-17. Primary Activities Affecting Soils

Activity	Units	NC [1]	K	A	J	W	D	L
Road Construction	Miles							
	Decade 1	NA	550	500	450	400	300	120
	Decade 2	NA	90	130	70	70	50	40
	Decade 5	NA	40	50	40	20	10	10
Final Harvests [2]	M Acres							
	Decade 1	144	121	125	102	91	99	33
	Decade 2	NA	121	126	100	92	100	27
	Decade 5	NA	116	118	82	81	85	23

[1]FORPLAN was not used with this Alternative. NA means the information is not available. Road construction miles are estimated to be similar to Alternative B-Departure.
[2]Final harvests include clearcuts and shelterwoods only.

The quantity and timing of water flow is expected to vary only slightly between alternatives.

The quality of water, and the stability of the stream channels is described in terms of risk of adverse cumulative effects to these resources. Alternatives J, W, D, and L increase the risk of adverse changes to water quality and of stream channel condition when compared with a continuation of current direction (Alternative A), Alternative K or the NC alternative. All alternatives increase the risk of adverse cumulative changes to water quality and stream channel conditions when compared with the average natural conditions. The relative differences in risk between alternatives is shown in the Table II-18.

Table II-18. Cumulative Watershed Effects Summary

	Alternatives[1]						
Risk Category [2]	**NC [3]**	**K**	**A**	**J**	**W**	**D**	**L**
High Risk	NA	29	28	18	0	12	0
Moderate Risk	NA	27	25	17	0	10	0
Low Risk	NA	44	47	65	100	78	100

[1]Values presented are the percent of the Forest in each category in the 1st decade.
[2]See Chapter IV and Appendix B for description of risk.
[3]Data is not available. Alternative NC would be expected to produce greater effects than Alternative B-Departure (DEIS).

Mineral Resources

Regulation of mineral and energy related activities on National Forest System lands is shared with the Bureau of Land Management (BLM). Regulation of mineral and energy exploration and development are indirectly influenced by the proposed land use allocations and their associated management prescriptions. Factors that determine the degree of mineral exploration and development that may occur are the availability of access, the objectives for each management area, the demand for minerals, and geologic potential. Access and management area objectives are the factors that vary by alternative.

The Forest will recommend to the BLM that land allocations that place a high emphasis on the protection of resources such as visual quality, recreation, wildlife habitat, and special or unique areas, be withdrawn from mineral entry. In other cases, restrictions such as use periods, surface protection measures, and rehabilitation requirements may be required. Access for exploration may also be limited because of the lack of existing roads and other resource developments.

Management prescriptions affect the availability of the land for mineral exploration and development. All Forest lands are in one of three levels of availability; open, restricted or withdrawn.

Open lands for locatable minerals and energy development or leasing are in areas where management designations do not require special mitigative measures, although restrictive lease stipulations or operating plan conditions may be required to mitigate for situations such as unstable soils or visual sensitivity. In general, standard field practices for mining and mineral lease activities can be used.

Restricted lands are available for locatable minerals and energy development or leasing with specific requirements that significantly affect access and ground disturbing activities. This includes management areas where resource considerations require special mitigative measures.

Withdrawn lands are unavailable for locatable minerals and energy development and/or leasing because of other resource values or investments. The Bureau of Land Management reviews all agency withdrawal recommendations and makes recommendations to the Secretary of Interior.

Table II-19 shows the effect of the alternatives on accessibility for exploration and development of locatable minerals. The mineral resource program on the Forest is compared among the alternatives by determining the acres available for mineral exploration and development activities and in terms of regulatory constraints.

Table II-19. Acres Withdrawn, Restricted or Open For Minerals

	Alternatives						
Availability of Minerals	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Withdrawn							
Nondiscrectionary[1]	402,252	402,252	402,252	402,252	402,252	402,252	571,602
Discrectionary	29,789	149,951	137,131	168,807	190,796	209,300	329,249
Restricted	92,273	50,637	89,116	104,389	154,066	258,592	208,183
Open	1,097,110	1,072,580	1,046,921	999,972	928,306	805,276	566,376

[1] Includes existing and proposed Wilderness, H.J. Andrews Experimental Forest and the Oregon Cascades NRA.

The Alternatives propose varying levels of lands open to minerals developments ranging from 43% of the Forest landbase in Alternative L to 65% in Alternative NC.

About 44,600 acres on the Forest have moderate potential for locatable minerals with the remaining 1,630,800 acres having low or unknown potential. Of the acres with moderate potential, 8,319 are legislatively or administratively withdrawn.

Approximately 18,344 acres on the Forest have moderate potential for geothermal resources, 178,550 acres have low potential and 1,478,510 acres with no know potential. Of this, about 491 acres are legislatively or administratively withdrawn.

The USDI Bureau of Land Management has not classified the Forest as to its prospective value as an oil and gas producer. Currently there area about 20,700 acres in leases for oil and gas. The alternatives affect oil and gas exploration and development much in the same way as locatable minerals are affected.

The Forest Service has total management responsibility for the disposal of salable minerals which include minerals such as sand, stone, gravel, cinders, pumice, pumicite, and clay.These minerals are extracted from surface and subsurface layers and are used mostly for road construction and maintenance. Restrictions on this category are similiar to those described for locatable minerals.

Energy

Table II-20 shows the estimated net energy balance for each Alternative. The table shows the difference between the estimated energy requirements and the energy outputs for each Alternative. The values in the table are all negative which indicates that implementation of any Alternative would consume more energy than it would produce. Existing and potential hydropower as well as potential geothermal energy production were not included in the estimates. These production levels would be constant across all Alternatives. Examples of items which were used to calculate energy input are:

- Timber - Logging, construction and reconstruction of roads, transport to mill, processing.
- Fuels - Fuel treatment
- Recreation - Developed recreation construction, operation and maintenance, and recreational travel.

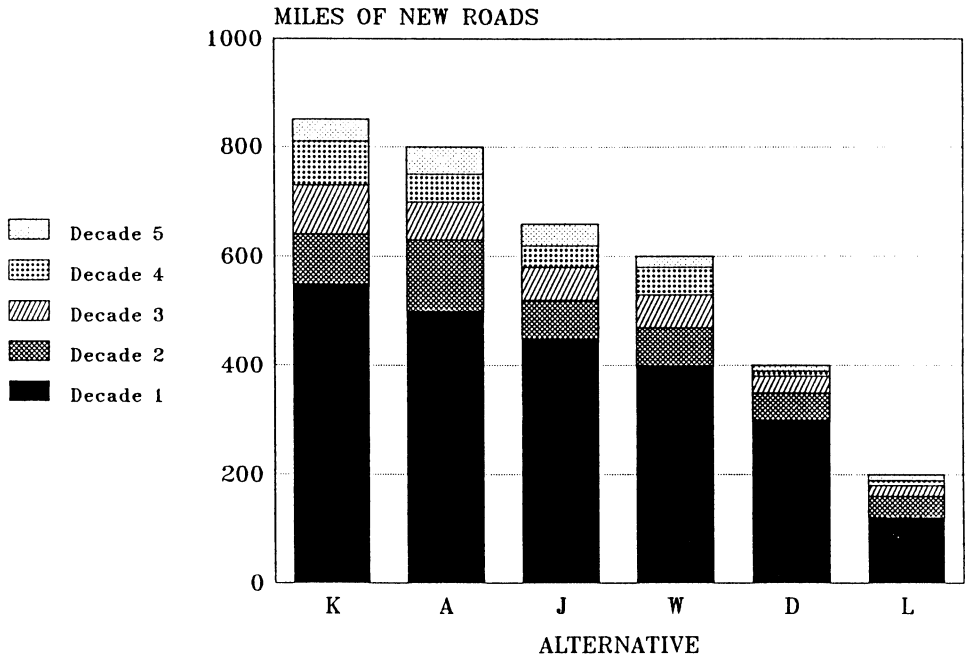
In general, alternatives with higher levels of timber harvest would have higher levels of energy consumption. Increased emphasis on developed recreation and motorized dispersed would also tend to increase total energy consumption, however, this varies less among the alternatives than the energy consumed in timber harvesting and related activities.

Table II-20. Average Annual Net Energy Balance

	Alternatives						
Decade	NC	K	A	J	W	D	L
1st	-13,300	-13,517	-13,300	-12,375	-10,774	-8,523	-7,261
2nd	-13,255	-13,681	-13,255	-12,469	-11,007	-9,344	-7,933
5th	-10,610	10,894	-10,610	-10,219	-8,549	-7,594	-6,411

Roads

The road transportation network currently consists of 6600 miles of road. Most present and future transportation needs are accomodated with the current system.



Additional access would be needed during the planning period to accomplish timber, recreation, and administrative objectives in all alternatives. The miles of new road construction would vary by alternative in direct proportion to the level of timber harvest.

The Forest road system would be at least 97% complete for all alternatives by the end of the second decade. Beyond that, additional access needs will diminish.

Roads would be reconstructed, maintained, and managed to meet objectives for recreation, water quality, wildlife management, and other resources. Roads which are no longer needed for present or future access would be permanently closed, stabilized, and revegetated.

Figure II-14 shows the new road construction for each Alternative. The amount of miles in each of these categories is directly proportional to the amount of timber scheduled for harvest.

Figure II-14. Road Construction by Alternative

			Alternatives						
Output	**Unit**	**Decade**	**NC [1]**	**K**	**A**	**J**	**W**	**D**	**L**
Road Construction	Miles	1	NA	550	500	450	400	300	120
		2	NA	90	130	70	70	50	40
		3	NA	90	70	60	60	30	20
		4	NA	90	70	60	60	30	20
		5	NA	40	50	40	20	10	10
Total			NA	850	800	700	600	400	200

[1]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model.

Residue Treatment

All alternatives would require the treatment of some woody residues following timber harvest. Fire would be used as the primary management tool in all alternatives to reduce levels of residues from timber harvest to meet resource objectives. Such objectives would be the reduction of wildfire hazard, increasing the success of reforestation activities, and occasionally to create conditions favorable to the establishment of wildlife forage. The primary method of treatment would be broadcast burning, although underburning and pile burning would also be used.

The number of acres burned would be dependent on the number of acres with timber harvest (See Timber section), the type of timber harvested, and other resource objectives. Where old-growth timber is harvested, approximately 80% of the acres would require some residue reduction. Harvest of second-growth stands results in less residues, and approximately 50% of these harvest areas would be treated.

The number of acres treated annually would also be dependent on timing restrictions needed to meet objectives for air quality, soil, and water resources. Currently, to meet air quality regulations, no burning in done between July 4 and Labor Day. Prescriptions for protecting soil and water resources require that areas would be treated with "cool" burns, thus limiting the number of days suited to burning to those when particular climatic conditions occur. The number of acres burned would also be dependent on the amount of time when fuels are dry enough, and be influenced by precipitation patterns.

In those alternatives with fewer harvest acres, fewer acres would be treated with fire.

Resource Outputs, Environmental Effects, Activities And Costs

The quantitative resource outputs, environmental effects, activities, and costs associated with each Alternative are presented in Table II-22. These results have been grouped by resources. For most resources the acres allocated the activities scheduled, and the outputs or effects are reported. Costs and other economic estimates appear at the end of the table. The alternatives are ordered across the top of these Tables in the sequence of decreasing acres suitable for timber management. Unless otherwise noted, output and effect figures represent total results: direct, indirect, induced, and cumulative. All numbers represent average annual totals for the indicated decade.

The qualitative effects of the Alternatives are presented in Table II-21. Please note that the entries in Table II-21 are brief, simplistic summaries of qualitative effects that are generally quite complex. Reference to the detailed discussions in Chapter IV is needed to gain full understanding of these effects.

Many of the outputs and effects displayed in these Tables are derived from the analysis described in Appendix B. Detailed coverage of many of the results of this analysis can be found in Chapter IV. Consult these sections for further information regarding analytical procedures, results, and interpretations.

Footnotes for Table II-21.

[1] NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. Section D4b, of Chapter II in the DEIS describes these differences.
[2] Approximately 7% of these acres would be shelterwood harvests
[3] TSI includes release from competing vegetation, precommercial thinning, and fertilization.
[4] Includes net green volume plus salvage, cull, unregulated, and miscellaneous convertible products. The average annual amount of timber sold 1977-1986 was 784 MMBF, and the amount harvested was 607 MMBF.
[5] Includes only live, sound wood.
[6] Historically the firewood supply has come from a portion of the cull material, and is included in the Timber Sale Program Quantity above.
[7] Old growth based on the Pacific Northwest Regional Guide definition.
[8] Includes both existing and potential habitat areas.
[9] Areas include contributing habitat from SOHAs and/or pileated woodpecker habitat.
[10] Population Trend Index; Population trend values by decade are compared to a current level of 1.00.
[11] Recreation visitor day use for the No Change Alternative was developed from previous inventories and yield tables and does not incorporate the latest methods of calculating RVD outputs.
[12] RVD outputs for the No Change Alternative are available for total dispersed use.
MRVDs = Thousands of Recreation Visitor Days
PAOT = Persons at One Time
M Acres = Thousand Acres
MWFUDs = Thousand of Wildlife and Fish User Days
M Smolt = Thousand Smolt (Young Anadromous Fish)
PTI = Population Trend Index%/bio-pot = Percent of Bio-potential
AUMs = Animal Unit Months
MMBF = Million Board Feet
MMCF = Million Cubic Feet
M Ac-Ft = Thousand Acre-Feet
Cu. Yds/Yr = Cubic Yards per Year
Additional information about these terms is included in the Glossary

Table II-22. Qualitative Resource Outputs, Environmental and Social Effects

1. The rate of change in scenic areas on the Forest.	
NC	Most areas of high scenic importance will change rapidly from natural appearing, slightly altered, and moderately altered landscapes to a condition that appears heavily altered.
K	Most areas of high scenic importance will change dramatically from natural appearing, slightly altered and moderately altered landscapes to a condition that appears heavily altered.
A	Most areas of high scenic importance will change rapidly from a natural appearing, slightly altered or moderately altered appearance to a landscape condition that appears moderately to heavily altered.
J	Most areas of high scenic importance will change gradually form natural appearing and slightly altered landscapes to landscape conditions that appear moderately to heavily altered.
W	Most areas of high scenic importance will change gradually from a natural or slightly altered appearance to landscape conditions that range between slightly altered and moderately altered.
D	Most areas of high scenic importance will change slowly. Areas that now appear moderately or heavily altered will,in time, recover to conditions that appear slightly altered. Other areas will remain or become natural appearing.
L	Most areas of high scenic importance will change very slowly in appearance from current conditions due to management activities. Changes in many areas of the Forest will be the result of natural processes. Areas that currently appear moderately to heavily altered will in time recover to a natural or slightly altered appearance.
2. Diversity of recreation opportunities.	
NC	Provides a wide range of dispersed recreation opportunities with an equal emphasis on semiprimitive motor and nonmotorized activities. Provides a high degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open. The current trail system is maintained.
K	Emphasis is placed on Roaded Natural and Roaded Modified recreation opportunities with a minor amount of area provided for semiprimitive opportunities. Provides the highest degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open and new sites would be developed to keep pace with user demand. The current trail system is maintained.
A	Provides a wide range of dispersed recreation opportunities with an equal emphasis on semiprimitive motor and nonmotorized activities. Provides a high degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open. The current trail system is maintained.
J	Provides for a wide range of dispersed recreation activities with a moderate emphasis on both semiprimitive motor and nonmotorized opportunities. Provides for a moderate degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open and several new sites would be developed 3o meet increases in demand. The current trail system is maintained and forty miles of new trails is proposed for development.
W	Provides for a wide, yet balanced, range of dispersed recreation activities with a moderate emphasis on both semiprimitive motor and nonmotorized opportunities. Provides for a moderate degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open and new sites will be developed to meet increases in public demand. The current trail system is maintained and sixty miles of new trails are proposed for development.
D	Provides a balanced range of dispersed recreation activities with a major emphasis on maintaining semiprimitive opportunities. Provides for a modest degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open and new sites would be developed to meet increases in future public demand. The current trail system is maintained and 68 miles of new trails are proposed for development.

Table II-22 Cont. Qualitative Resource Outputs, Environmental and Social Effects

L	Provides for a wide range of dispersed recreation activities with a major emphasis on maintaining semiprimitive recreation opportunities. Also provides for the designation of selected areas as Wilderness, and Wilderness Study for others. Provides for a modest degree of off-road vehicle access to Forest lands. All existing public and privately managed developed recreation sites will remain open. The current trail system is maintained and forty miles of new trail is proposed for development.
3. Diversity and distribution of wildlife habitat.	
NC	Lowest rating for diversity and distribution of wildlife habitat. Landscape highly fragmented, special and unique habitat highly impacted.
A	Low rating for diversity. Mininum distribution met for Management Requirements. Habitat for interior forest species becomes isolated in islands with forest landscape highly fragmented. Special and unique habitats highly impacted.
K	Low rating for diversity. Mininum distribution met for Management Requirements. Habitat for interior forest species becomes isolated in islands with forest landscape highly fragmented. Special and unique habitats highly impacted.
J	Low to Moderate rating for diversity. Minimum distribution met for Management Requirement. Dead and defective tree habitat above MR. Interior forest habitat becoming fragmented and isolated in islands. Moderate impact to special and unique habitat.
W	Moderate to High rating for diversity. Minimum distribution met for Management Requirement. Dead and defective tree habitat above MR. Fragmentation of interior forest habitat delayed. Emphasis on providing corridors for connectivity between habitat islands reduces potential for isolation. Low impact to special and unique habitats.
D	Moderate rating for diversity. Distribution exceeds Management Requirements. Dead and defective tree habitat above MR. Interior forest habitat becoming fragmented and isolated in islands. Low impact to special and unique habitat.
L	High rating for diversity. Excellent distribution of habitat exceeds Management Requirements. Dead and defective tree habitat a highest level. Interior forest habitat maintained, fragmentation reduced, connectivity of interior habitats maintained or restored. Low impact to special and unique habitat.
4. Lifestyles	
NC	Jobs will be up considerably, especially timber related employment. Reduced opportunity for semiprimitive and roaded natural recreation types. Demand for hunting and fishing opportunities will be allowed to increase.
K	Jobs will increase from historic levels, especially timber related employment. Develop recreation opportunities will increase considerably, with reduced opportunities in semiprimitive and semiprimitive nonmotorized recreation types. Overall scenic quality will be low to moderate.
A	Jobs will increase from historic level, especially timber related employment. Developed recreation and dispersed recreation will continue to increase for 2 decades. Overall scenic quality will be low to moderate.
J	Overall jobs will increase somewhat from historical levels, but timber related employment will decrease. Recreation and leisure activities would remain about the same as the No Action Alternative with more unroaded recreation opportunities. Overall scenic quality will be moderate to high.
W	Overall jobs will increase slightly from historical levels but timber related employment will decrease. Jobs related to recreation will increase offsetting the loss of timber related jobs. Increase opportunities for all developed and dispersed recreation activities is expected with the exception of a slight decrease in semiprimitive nonmotorized. Overall visual quality will be moderate to high.
D	Timber related jobs would be relatively low within the range of Alternatives. Jobs related to recreation will offset the loss of timber related jobs somewhat but a net loss of jobs is expected. Potential hunting and fishing activities will increase as well as developed and dispersed recreation opportunities. Overall scenic quality will be high.

Table II-22 Cont. Qualitative Resource Outputs, Environmental and Social Effects

L	Jobs will decrease considerably, with timber related jobs the lowest for any Alternative. All types of recreation opportunities will increase. In addition, all roadless areas will be maintained in an unroaded condition.
5. Community Infrastructure	
NC	Increased timber receipts to fund county road and school systems.
K	Increased timber receipts for 4 decades but then decreases slightly. Small expected effect on county road and school systems.
A	Slight increase in timber receipts for the first 5 decades which would keep county road improvements and school funding at or near present levels.
J	Funding for county infrastructure projects would remain above historical levels but funding would vary (increasing then decreasing) for the first 5 decades.
W	Timber receipts will increase for 4 decades starting above historical levels; however, funding for county infrastructure will remain lower than current levels for the first 4 decades.
D	Timber receipts near historical average.
L	Drastic reduction (about three-quarter) of timber related receipts to counties. County infrastructures would be negatively affected as less money would be received from Federal timber receipts.

Response To Issues And Concerns

One of the primary reasons for developing Alternatives is to provide a variety of responses to the issues and concerns affecting the Forest and the public. Each Alternative represents a unique approach to issue resolution. While all Alternatives address the entire range of issues and concerns, none can successfully resolve all of them concurrently. This is because the issues and concerns reflect the full range of desires for, use of, and outputs from, a limited land and resource base. Some of these outputs and uses are competitive or mutually exclusive, thus creating the need for a variety of issue resolution packages or Alternatives.

Table II-23 displays in narrative terms the responsiveness of each Alternative to the major issues described in Chapter I. The results are presented here in words to assist in interpretation of the Alternatives. Each of the issues also has a set of quantified indicators of responsiveness that are presented in Table II-27 and described in Appendix A. The final section of this Chapter includes a discussion of trade-offs between quantified indicators.

Table II-23. Comparison of Issue and Concern Resolution by Alternative

1. Old Growth - Amount of existing old growth remaining after 5 decades of harvest. There are currently 594,800 acres which meet the Region Six definition of old growth.	
NC	Maintains 44% of existing old growth (259,800 acres).
K	Maintains 51% of existing old growth (305,100 acres).
A	Maintains 57% of existing old growth (337,000 acres).
J	Maintains 57% of existing old growth (341,400 acres).
W	Maintains 61% of existing old growth (365,200 acres).
D	Maintains 62% of existing old growth (367,800 acres).
L	Maintains 88% of existing old growth (523,100 acres).
2. Dispersed Recreation - Percent of Forest's inventoried potential semiprimitive motor and nonmotorized recreation opporuntities provided.	
NC	Maintains 33% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities; 27% motor and 6% nonmotorized.
K	Maintains 21% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities 6% motor and 15% nonmotorized.
A	Maintains 32% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities 26% motor and 6% nonmotorized.
J	Maintains 39% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities 32% motor and 7% nonmotorized.
W	Maintains 39% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities 31% motor and 8% nonmotorized.
D	Maintains 71% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities 63% motor and 8% nonmotorized.
L	Maintains 66% of the Forest's dispersed semiprimitive motor and nonmotorized opportunities 64% motor and 2% nonmotorized.
3. Roadless Lands - Inventoried Lands to be maintained in an undeveloped condition.	
NC	Maintains 26% (45,400 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
K	Maintains 15% (25,300 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
A	Maintains 35% (59,800 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
J	Maintains 46% (79,700 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
W	Maintains 53% (92,100 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
D	Maintains 80% (136,900 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
L	Maintains 85% (145,900 ac.) of the Forest's Inventoried Roadless Areas in an undeveloped condition.
4. Scenic Quality - Expected future condition of the Forest's 10 major viewsheds.	
NC	One of the Forest's 10 viewsheds will be maintained in a natural appearing condition, 2 will remain or become moderately altered, and 7 will appear heavily altered.

K	None of the Forest's 10 viewsheds will be maintained in a natural appearing or slightly altered condition, 3 will remain or become moderately altered, and 7 will appear heavily altered.
A	One of the Forest's 10 viewsheds will be maintained in a natural appearing condition, none will become slightly altered, 2 will remain or become moderately altered, and 7 will appear heavily altered.
J	One of the Forest's 10 viewsheds will be maintained in a natural appearing condition, however, 3 will be maintained in a slightly altered condition, 5 will remain or become moderately altered, and 1 will appear heavily altered.
W	One of the Forest's 10 viewsheds will be maintained in a natural appearing condition, 4 in a slightly altered condition,5 will remain or become moderately altered, and none will appear heavily altered.
D	Six of the Forest's 10 viewsheds will be maintained in a natural appearing condition, 4 in a slightly altered condition, and none of the areas will appear moderately or heavily altered.
L	Seven of the Forest's 10 viewsheds will be maintained in a natural appearing condition, 3 in a slightly altered condition, and none of the areas will appear moderately or heavily altered.
5. Allowable Sale Quantity - Amount of timber estimated to be sold annually (in million board feet), and the acres suitable for timber management.	
NC	This alternative represents the potential yield of the current TM Plan, with an ASQ of 810 MMBF, 26% above the current Proposed Program. The suited landbase is 1,064,600 acres.
K	The ASQ is 650 MMBF, which is 1% above the current program level, on a suited landbase of 932,800 acres.
A	The ASQ is 608 MMBF, which is 94% of the current program level, with a suited landbase of 874,300 acres.
J	The ASQ is 530 MMBF, which is 82% of the current program level, with a suited landbase of 853,400 acres.
W	The ASQ is 491 MMBF, which is 76% of the current program level, with a suited landbase of 774,600 acres.
D	The ASQ is 476 MMBF, which is 74% of the current program level, with a suited landbase of 719,400 acres.
L	The ASQ is 150 MMBF, which is 23% of the current program level, with a suited landbase of 553,100 acres.
6. Water Quality - Risk to water quality and stream conditions.	
NC	Approximately half of the forest land is at High Risk of adverse effects to water quality and stream conditions, because the levels of timber harvest result in hydrological recovery below the desired levels, because of the cumulative effects of timber harvest in riparian areas of Class I, II, and III streams, and the risk associated with harvest of steep potentially unstable areas adjacent to Class IV streams.
K	Approximately 29% of the Forest is at high risk; 27% at moderate risk; and 44% at low risk. The risk is associated with reasons described for Alternative NC.
A	Approximately 28% of the Forest is at high risk; 25% at moderate risk; and 47% at low risk. The risk is associated with reasons described for Alternative NC.
J	Approximately 18% of the Forest is at high risk; 17% at moderate risk; and 65% at low risk. The risk is associated with reasons described for Alternative NC.
W	All of the Forest is at Low Risk, due to the harvest level compatible with desired levels of hydrological recovery, to full protection of riparian areas along Class I, II, and III streams, and provisions for protection of potentially unstable Class IV streams.
D	Approximately 12% of the Forest is at High Risk, 10% is at moderate risk; and 78% is at low risk. The relatively low risk is associated with protection of Class I and II riparian areas, and the relatively low level of timber harvest.
L	All of the Forest is at Low Risk due to the low level of harvest, full riparian protection on Class I, II, and III streams, and provisions for protection of potentially unstable Class IV streams.

7. Wildlife and Sensitive Plant Habitat - Elk and Deer, Mature and Old Growth Habitat, Plant habitat, Dead and Defective Tree Habitat, Habitat for T&E Species.	
NC	Elk and deer habitat capability declines rapidly leaving existing popualtions at high risk for winter mortality. Mature and old growth habitat isolated within Wilderness and in small isolated islands. Sensitive plant habitat highly impacted. Dead and defective tree habitat poorly distributed with potential loss of many snag dependent species. T&E species protected at minimum levels required by Recovery Plans.
K	Elk and deer habitat capability declines below existing condition with few areas managed for habitat quality. Some existing populations at high risk for winter mortality. Mature and old growth habitat isolated in wilderness and in habitat networks established to meet Management Requirements. Sensitive plant habitat highly impacted as most of the landscape outside wilderness is converted to managed plantations. Dead and defective tree habitat distributed with moderate amounts of habitat for dependent species. T&E species protected at minimum levels required by Recovery Plans.
A	Elk and deer habitat capability declines in some areas and improves in others. Slightly increased potential for populations, but some local populations at high risk for winter mortality. Mature and old growth habitat isolated in wilderness and in habitat networks established to meet Management Requirements. Sensitive plant habitat highly impacted as most of the landscape outside wilderness is converted to managed plantations. Dead and defective tree habitat poorly distributed with low amounts of habitat for dependent species. T&E species protected at minimum levels required by Recovery Plans.
J	Elk and deer habitat capability increases above existing condition with specific areas managed for habitat quality. Optimal cover provided on some winter ranges reducing risk for winter mortality. Mature and old growth habitat isolated in wilderness and in habitat networks established to meet Management Requirements. Sensitive plant habitat moderately impacted as most of the landscape outside wilderness is converted to managed plantations, and only portions of the perimeter of special and unique habitats protected. Dead and defective tree habitat distributed with moderate amounts of habitat for dependent species. T&E species protected at minimum levels required by Recovery Plans.
W	Elk and deer habitat capability increases above existing condition with specific areas managed for habitat quality. Optimal cover provided on some winter ranges reducing risk for winter mortality. Mature and old growth habitat in Wilderness and in habitat networks are linked by corridors managed to protect riparian resources and maintain vegetation diversity. Sensitive plant habitat protected as the landscape outside wilderness is converted to managed plantations. Perimeters of special and unique habitats protected. Dead and defective tree habitat distributed with moderate amounts of habitat for dependent species. T&E species and habitat protected to meet Recovery Plan objectives.
D	Elk and deer habitat capability increases above existing condition with highest amount of area managed for habitat quality. Optimal cover provided on most winter ranges reducing risk for winter mortality. Mature and old growth habitat in Wilderness, and in habitat networks established above Management Requirements to increases distribution and habitat quality. Sensitive plant habitat protected as lands available for timber production is converted to managed plantations. Perimeters of special and unique habitats protected. Dead and defective tree habitat well distributed with high amounts of habitat for dependent species. T&E species and habitat protected above Recovery Plan objectives.
L	Elk and deer habitat capability increases above existing condition with specific areas managed for habitat quality. Optimal cover provided on all winter ranges reducing risk for winter mortality, but reduced forage openings could limit population potential. Mature and old growth habitat provided at high levels forest-wide with increases in long term habitat capability for interior forest dwelling species. Sensitive plant habitat rarely impacted as most of the landscape outside wilderness recovers from past management practices. Most special and unique habitats protected. Dead and defective tree habitat well distributed with high amounts of habitat for dependent species. T&E species and habitat protected above Recovery Plan objectives.

Economic Comparisons Of Alternatives

The economic implications of alternatives are displayed in Tables II-24, II-25, and II-26. A discussion of the variations in costs, benefits, present net value, and cash flows among alternatives accompanies each table. These economic indicators could not be reasonably estimated for Alternative NC (No Change) since it is based on a set of assumptions different than those of the other alternatives, and could not be modeled with the current Willamette FORPLAN model. Additional detail on the differences is in Chapter II, Alternatives Considered in Detail.

Differences in Present Net Value

Tables II-24 and II-25 present information about the Present Net Value (PNV) of alternatives. Present net value is a quantitative measure of economic efficiency, and thus is a key variable in the comparison of alternatives. It is defined as the difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area. "Discounting" is the procedure used to adjust all future costs and benefits to their present-day equivalent values in order to enable a meaningful comparison of dollar flows through time. A discount rate of 4% has been used. An alternative discount rate of 7-1/8%, sometimes used by the Forest Service, was also evaluated. Since relative rankings of alternatives were unaffected with the 7-1/8% rate, only the 4% rate is shown. The discounted benefit and cost flows represent the potential net dollar returned for each alternative: the larger the PNV, the greater the potential return. For a more detailed discussion of PNV calculation and its significance, refer to Appendix B.

By providing a monetary, quantitative measure of economic efficiency, present net value is a useful indicator of differences among alternatives in terms of their total output of public benefits. A full assessment of net public benefits, however, also requires a consideration of primary benefits and costs that have not been assigned a dollar value. Included in this category are outputs such as increased populations of some wildlife species, and physical conditions such as the maintenance of scenery, and clean water. The value of such outputs and effects cannot be reasonably reflected in dollar terms because the data and/or methodology needed to do so are not available.

Another aspect for describing differences among alternatives and ultimately selecting a preferred alternative is the degree of issue resolution. Secondary benefits and costs, such as employment, are often important for understanding the degree of issue resolution. See the section, Major Trade-Offs Among Alternatives in this chapter for a summary of issue resolution.

Table II-24 displays the present net value, total discounted benefits, and total discounted cost for each alternative. Alternatives are ranked in order of decreasing present net value. The change in PNV criteria between alternatives is also displayed. These changes in PNV between alternatives measure the net economic value of the priced outputs that would be forgone if an alternative with a lower PNV were selected. These differences in PNV would have to be compared against the differences in non-priced benefits for the complete comparison of Alternatives.

Table II-25 disaggregates the benefits and costs. It displays the contributions of specific priced outputs to total benefits and assigns approximate costs to major accounting or budgeting categories. Note that it would be incorrect to assume a direct relationship between the dollar benefits associated with a particular output and the cost figure assigned to the same resource. This is because many Forest-wide outputs are produced jointly and the costs associated with producing any single one cannot be accurately disaggregated and assigned.

[1]Direct comparisons of benefits and costs in millions of 1982 dollars displayed for individual resource outputs provide general indications of relationships but may be misleading because many multiple-use outputs have common costs of production which cannot be reliably separated and attributed to individual resources. Alternatives displayed in order of decreasing present net value.

[2]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. The alternative NC Description under "Alternatives Considered in Detail," of Chapter II in the FEIS describes these differences.

[3]Costs are for the Wilderness and recreation programs.

[4]Includes all timber-related costs except roads.

Several of the entries in these two Tables require additional explanation to enhance understanding. Timber benefits are expressed in terms of total pond value (i.e., the value delivered at the mill) rather than stumpage value. This approach was taken to be able to show differences in logging costs between the major drainages within the planning model. Thus, the total discounted benefits shown in Table II-24 and the timber benefits in Table II-25 include the value added by logging. The same thing applies on the cost side. In Table II-25 the total logging costs are referred to as "Purchaser's Costs." The total discounted costs in Table II-24 and Table II-25 include logging costs. Non-market recreation represents priced output used for analysis, but not actually six collected as cash receipts.

This approach does not affect the PNV calculation because the value added by logging is offset by the logging costs. The content of the other cost and benefit categories is explained in footnotes below each Table.

Variations in present net value among alternatives are due to the wide range of possible costs and benefits represented in the alternatives. Each alternative is designed to produce a unique set of both priced and nonpriced outputs and effects, each of which generates a distinct pattern of values and costs.

The principal factors influencing the level of priced benefits, costs, and present net value on the Willamette National Forest are the amount and timing of timber harvest. Since this activity has relatively large investment costs and dollar returns associated with it, the volume harvested is the primary determinant of the magnitude of the economic criteria in each alternative. The timing of harvest of is also very important. Discounting diminishes the contribution to PNV of returns gained in the later decades. This means that harvesting high value timber (such as old growth Douglas fir) at full yield as early as possible will provide the highest market values. This effect is illustrated by comparing the acres harvested in decade 1 between alternatives W and D. Even though Alternative D harvests more acres than Alternative W, Alternative W has a higher timber volume and higher PNV than Alternative D. This is because Alternative W harvests more large saw and old growth Douglas fir/Hemlock in the first few decades than D. See Table II-22, Clearcut Acres, for the acres harvested and Table II-24 for the PNV's. These values must be weighed against the loss of non-priced benefits when comparing any two alternatives.

Differences in the amount and timing of land availability accounts for the primary differences in present net value, benefits, and costs. Nonmarket outputs, such as semiprimitive recreation opportunities, anadromous fish production, and fish and wildlife use, cannot compete with timber harvest economically and would not be produced at levels that affect timber harvest volumes or schedules based solely on economic efficiency criteria. Objectives for these resources can only be achieved through the use of constraints, specific prescriptions, or land allocations. Generally, an alternative designed to achieve objectives related to these types of resources will have lower timber harvest levels but higher recreation and fisheries benefits. As a result, differences in PNV between low-timber alternatives and high-timber alternatives are somewhat smaller than if timber was the only resource having an economic value. Some of these differences can be seen in Table II-25. Note that Alternatives K and L show exceptions to this general trend. Alternative K shows a high discounted benefit for nonmarket recreation even though it has the highest level of timber harvest. This is because of the emphasis placed on developed and motorized recreation in K. Alternative L shows a decrease in nonmarket recreation discounted benefits from Alternative D, even though L harvests less timber than D. This is because of L's emphasis on non-roaded allocations allows fewer acres to contribute toward roaded recreational opportunities. When making comparisons such as these, one must consider the overall desired mix of recreational opportunities, not just the composite discounted value.

The production of some priced outputs is not related to timber harvest but does vary based on different levels of management provided. Outputs in this category include domestic livestock grazing use, wilderness use, and developed recreation use. Some of the administrative and support costs of the agency remain constant across all alternatives. These are included in the cost categories of Table II-25.

In addition to the priced outputs discussed above, there are several major outputs, effects or conditions associated with alternatives to which no monetary value can be reasonably assigned. While these outputs are not directly included in the calculation of present net value, they are an important component of issue resolution and, therefore, net public benefits. These outputs and their relationship to priced outputs and PNV include:

- Visual Quality Objectives - As land assigned to visual prescriptions increases, present net value decreases because of restrictions placed on timber harvest. Visual quality objectives are complementary with other amenity-oriented outputs.

- Roadless Area Acreage - Since retention of roadless lands in an unroaded condition and timber harvest are mutually exclusive, increases in roadless acres usually lead to decreases in PNV given the relative values of timber and semiprimitive recreation use. Roadless area retention is complementary with other amenity-oriented outputs.

- Old-Growth Retention - Increasing the amount of old-growth unavailable for harvest has significant impacts on harvest levels and present net value. Because old-growth distribution goals for wildlife and other purposes often dictate that highly productive and readily accessible areas remain unharvested, this nonpriced output can be particularly expensive in terms of PNV. Old-growth retention is complementary to other amenity-oriented outputs.

- Socioeconomic Indicators - Timber harvest is the activity which has the greatest effect on many of the major socioeconomic indicators such as employment, total income, and payments to counties. Production of other priced and nonpriced outputs generally lead to reduced levels for these indicators if their production leads to reduced timber harvest levels.

Numerous other resource management objectives are achieved through land allocations, activity scheduling, or constraints. To the extent that these objectives reduce the available timber harvest land base or restrict harvest through longer rotations, limits in harvest unit sizes, or other means, a reduction in present net value can be expected. The production of both priced and nonpriced outputs are important in the determination of net public benefits.

Economic values associated with potential future production of locatable minerals, oil and gas, geothermal energy or hydroelectric power are not included in the alternatives. The possibility of future development of mineral and energy resources on the Forest does exist. However, the timing of development and the magnitude of production are both highly speculative. It is possible that the economic value of these activities will vary by alternative if they are undertaken.

Differences in Costs

The discounted costs shown in Tables II-24 and II-25 include Forest Service budget costs and costs to others. Non-Forest Service costs are composed primarily of the stump-to-mill costs associated with timber harvest. These represent between 50 and 60% of the total costs of each alternative.

The budget costs associated with each alternative fall into two distinct categories: capital investments and operations/maintenance costs. Capital investments are expenditures on the Forest's physical plant which are designed to provide long-term returns. Examples include road construction, tree planting, and fish habitat improvement structures. Operations/maintenance costs cover those activities which are necessary to conduct the day-to-day business of the Forest. Such things as road maintenance, timber sale administration, and habitat condition monitoring fall into this category.

On the Forest most capital investment costs are for either road construction or activities associated with timber production. These form a substantial part of the projected Forest Service budget for each alternative. Projected annual budget costs in the 1st decade are higher than current levels for all alternatives except L. This is because of the increased emphasis on increasing programs other than timber harvest. Many of the higher costs are for measures to mitigate the adverse effects of timber

harvest. Other major cost increases are due to plans to achieve a more balanced program of resource outputs for recreation, wildlife, soils, water, air quality, and protection. Costs have also increased significantly for planning and administration of NEPA decisions due to the high level of controversy and appeals related to natural resource management. Even though a budget cost for Alternative NC (No Change) was not estimated, a higher budget would also be needed to implement this alternative due to the high harvest level.

Projected budget levels generally parallel harvest levels. The unit costs of harvest-related activities vary considerably, depending on the characteristics of the area in which they occur. For example, the costs of timber sale preparation, fuel treatment, and silvicultural treatments all increase as difficulty of access increases, while road construction costs vary with slope. The development and use of all costs incorporated in the planning analysis is summarized in Appendix B.

Differences in Economic Benefits and Cash Flows

Tables II-24 and II-25 compare alternatives in terms of PNV based on consideration of all values and costs. There are, however, three subcategories of "value" and two of "cost". Value can be disaggregated into non-market value, market value, and Forest Service receipts (which are a part of total market value). Costs can be disaggregated into Forest Service (budget) costs and costs to others.

Total discounted economic benefits associated with market and nonmarket resources are displayed by resource for each alternative in Table II-25. Market resources include timber, recreation user fees, recreation special uses, minerals, and special uses for which fees are collected. Nonmarket resource values are dollar values assigned to dispersed recreation, Wilderness recreation, forms of developed recreation for which no fee is charged, and recreation generated by fish and wildlife. The purpose of assigning dollar values to these is to reflect full economic value, even though none or only part of the value associated with particular resources is actually collected as fees under current laws and policies.

Comparison of total economic benefit to total cost measures the overall economic efficiency of each alternative. Another important consideration is the flow of dollars to and from the U.S. Treasury. In this comparison the important factors are receipts (the portion of total market output collected as fees or payments) and budget costs. The difference between the two is the net cash flow to or from the Treasury. Net cash flows for the 1st, 2nd and 5th decades for each alternative are displayed in Table II-26. The major differences among both economic values and cash receipts are due to different levels of timber production.

The rows labelled "Noncash Benefits" in Table II-26 represent the total estimated dollar value of the nonmarket resources to which values have been assigned. They are presented to give the reader an idea of the relationship between the actual receipts generated by the alternatives and the value of the nonmarket outputs to which values have been assigned.

As discussed earlier, total benefits and total costs are influenced primarily by the level of timber harvest. The same relationship is maintained for cash receipts. Over 99% of the revenues received by the Forest are from the sale of timber. Revenues from other sources are quite small relative to the value of the timber volume harvested.

Differences in noncash benefits in the 1st decade are generally very small due to the relative shifts in the type of recreation program emphasis within each alternative. Alternatives with high timber harvest levels produce more developed and roaded recreation, while those with less timber harvest produce more unroaded recreation. Second and 5th decade noncash benefits reflect anticipated increases in

recreation use which accounts for a general rise in benefits. See the sections on Recreation in Chapters II and IV of this EIS for more details on the mix of recreational opportunities provided by each alternative.

Table II-26. Average Annual Cash Flows [1]

	Alternatives

[6]Noncash benefits are those not collected as cash receipts.

Major Trade-Offs Among Alternatives

This section summarizes the relationships among economic values, and the responses of the alternatives to selected issues. The purpose is to highlight major economic and noneconomic trade-offs that can be quantified by using indicators of responsiveness to issues as a means of comparing alternatives. A complete understanding of the differences among alternatives requires reading Chapter II, IV, and Appendix B. The issues are discussed in detail in Chapter I and Appendix A.

To provide a partial framework for assessing trade-offs, the long-term resource demands of the nation, region, and local communities are briefly summarized. Selected economic values and quantified indicators of responsiveness to issues are then tabulated. Finally, differences and similarities among individual alternatives are summarized in terms of major trade-offs among competing objectives or responses to issues.

National, Regional, and Local Overview

The 1984 supplement to the Resources Planning Act (RPA) Assessment estimates that total national demands will rise for all goods and services produced by the National Forests. At the same time, there will be a continuing strong desire to protect and enhance the quality of the environment.

The Regional Guide for the Pacific Northwest Region estimates that demands for all outputs of the National Forest will also rise in Oregon and Washington. Recreation use is expected to increase as the population increases and its characteristics change, with the bulk of recreation use coming from residents of the region. Demand for Wilderness recreation is expected to exceed the available supply within the Region's Wilderness Preservation System.

A survey of recreation associated with fishing, hunting, and wildlife (USDI 1988) indicates that more than three of every four Americans pursue some type of fish or wildlife activity. Demand for hunting and sport fishing is expected to increase by one-third between 1985 and 2000. Nonconsumptive uses of wildlife and fish are also expected to increase.

The National Forests of the Pacific Northwest are the National Forest System's primary timber producer, with almost one-half of the current National Forest harvest coming from this region. The quantity of timber demanded regionally in 2000 is expected to be about 1% greater than the 1976 demand level. The stumpage price of timber, however, is expected to rise substantially.

The local situation is generally similar to that of the Region. Many of the Wilderness and non-Wilderness areas providing primitive and semiprimitive recreation opportunities are currently being used at levels which exceed their capacity to provide high quality experiences. The demand for this type of recreation on the Forest is expected to increase over the next 10 to 50 years.

Demand for timber from the Forest is also projected to increase over the next 10 to 15 years due to anticipated reductions in supply from private and other public lands in the central and southern Willamette Valley together with a strong market for wood products and fiber.

Growth in the recreation and tourism sectors of local and regional economies will add to the economic base, while the timber industry will remain a significant component of the area economy. These trends are discussed more thoroughly in the social and economic environment and timber sections of Chapter III.

Economic Values and Response to Major Issues

Alternatives are developed to provide different responses to public issues identified on the Forest. This section summarizes the quantifiable differences among alternatives in terms of economic criteria and responses to major issues. These issues are discussed in detail in Chapter I. A complete discussion of these indicators and their relationship to the major issues can be found in Appendix A, Issues, Concerns, and Opportunities Identification Process. The following presents another comparison of the responsiveness of alternatives to major issues. The issues and associated indicators of responsiveness include:

- Dispersed Recreation

  Land allocated to semiprimitive nonmotorized uses.
  Land allocated to semiprimitive motorized uses.
  Land allocated to Special Interest Areas.
  Trail construction in the 1st decade.

- Old-Growth

  Amount of old-growth/mature timber retained at the end of the 1st decade.

- Roadless Lands

  Acres of roadless areas left undeveloped.

- Scenic Quality

  Land allocated to a retention Visual Quality Objective.
  Land allocated to a partial retention Visual Quality Objective.
  Land allocated to a modification Visual Quality Objective.

- Timber Supply

  Allowable sale quantity in the 1st decade.
  Long-term sustained yield.

- Water

  Forest area with a "High" Risk watershed risk rating.
  Forest area with a "Moderate" Risk watershed risk rating.
  Forest area with a "Low" Risk watershed risk rating.
  Erosion in the 1st decade (debris slides).

- Wildlife, Fish, and Plant Habitat

  Land managed as spotted owl habitat areas.
  Elk population in the 1st decade.
  Deer population in the 1st decade.

Other indicators of both local and national concern include those which reflect the social and economic effects of alternatives. The quantifiable indicators of these concerns include:

- Present net value over 15 decades.
- Change in jobs in the 1st decade.
- Change in income in the 1st decade.
- Change in payments to counties in the 1st decade.
- Average annual net cash flow in the 1st decade.

Table II-27 displays the data for each indicator for all the alternatives.

Table II-27. Tradeoffs of Economic Benefits and Indicators of Response to Issues

[1]Changes represent the total potential change in the 1st decade as compared to historical averages over the life of the current Forest Plan (1977-1985).
[2]NE = Not estimated, benchmarks were not analyzed as fully developed implementable alternatives.
[3]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Forest FORPLAN model. See alternative Considered in Detail, Chapter II for additional information.
[4]Represents lands allocated to meet this objective.
[5]Percent of total Forest area at the end of the 1st decade in this watershed risk category. See Chapter IV, Water for further explanation.
[6]Represents end of 1st decade conditions.
[7]Units are average annual for 1st decade.

Differences and Similarities Among Alternatives

This section describes the major differences and similarities among alternatives in terms of the indicators of responsiveness listed in the previous section. The major factors influencing the economic indicators are described in Response to Issues and Concerns, Chapter II. More details on the outputs and effects of the alternatives can be found in the individual resource sections in Chapter IV. Table II-27 contains data used for these discussions; Tables II-24 through II-26 provide some supplemental information. The alternatives are described in order of decreasing present net value (PNV). The indicators for each issue are discussed sequentially for each alternative. Information for the maximum PNV benchmark is provided only as a reference point. Qualifiers such as low or high used in these discussions are relative to the upper and lower level of each output shown in Table II-27. A more detailed comparison of all the alternatives is found in Appendix B, Section H.

Many response factors show a consistent pattern across the range of alternatives. For example, the level of semiprimitive recreation opportunities are directly correlated with the amount of land suitable for timber harvest and the level of timber harvest in an alternative. This same general pattern of tradeoffs is also seen in the water and old growth issues. For water, increased percentages of the Forest are in the High and Moderate categories as the timber harvest levels increase while the acres of old growth remaining after the 1st decade decrease as the timber harvest level of the alternatives increase. The Roadless, Water and Vegetation sections of Chapter IV describes the relationship of these effects in more detail.

Most of the variation in economic response factors described in Response to Issues and Concerns, Chapter II, can be directly related to the amount of timber harvest in an alternative. This pattern does vary somewhat as a result of the level of recreation oriented benefits provided by an alternative. Alternatives with greater emphasis on recreation have higher levels of recreation benefits. Jobs and personal income variations among alternatives follow the same kinds of patterns as the other economic indicators.

The indicators that could be estimated for the No Change Alternative are displayed in Table II-27, and are described in this section. Many indicators could not be reasonably estimated because alternative NC (No Change) is based on a set of assumptions different than were the other alternatives, and could not be modeled with the current Forest FORPLAN model. Alternatives Considered In Detail, Chapter II describes these differences.

Maximum PNV Benchmark - *PNV: $3.8 Billion* - Opportunity Cost: None (Baseline for Comparison)

The Maximum PNV Benchmark identifies the mix of goods and services with market and assigned values that result in the largest excess of discounted benefits over discounted costs. It meets MRs for resource protection and produces a high level of timber harvest on a nondeclining yield schedule. It is summarized in Table II-27 for comparison purposes.

Alternative NC (No Change) - *PNV: NOT AVAILABLE* - Opportunity Cost: NOT AVAILABLE

Alternative NC would produce the highest level of timber of any alternative (allowable sale quantity of 146 million cubic feet annually). This figure represents the potential yield from the current Forest Land and Timber Management Plan (1977). Although many indicators were not estimated for this alternative, present net value, net cash flows, payments to counties, income, and jobs would all likely be at their highest level with this alternative due to the high level of timber harvest. Conversely, the amount of old growth remaining at the end of the 1st decade would be at the lowest level of any alternative.

Forest land allocations for dispersed recreation, roadless areas, and scenic management areas are those in the current Forest Plan (1977) and are intermediate within the range of alternatives. Since MRs are not a part of this alternative, spotted owl habitat areas would be located only where some other allocation prohibited timber harvesting. Consequently, they are at their lowest level with this alternative. Deer and elk populations were not estimated for this alternative. Although quantitative estimates of watershed impact ratings and erosion were not made for this alternative, the amount of land in the "high" watershed risk category, and the amount of erosion would likely be at their highest level due to the high timber harvest level.

Alternative K (Willamette Forestry Council) - *PNV: $3.5 Billion* - Opportunity Cost: $297 Million as compared to Maximum PNV

With the exception of Alternative NC, Alternative K would produce the highest level of timber of any alternative on a nondeclining yield schedule (117 million cubic feet annually in the 1st decade). This is 29 million cubic feet or 20% less than the harvest level under Alternative NC because of land allocations and application of management prescriptions to meet MRs for water, soil, and wildlife resources. The areas available for spotted owl habitat would increase by 14 for a total of 59 areas in Alternative K. As a result of the lower timber harvest levels, all of the economic indicators are correspondingly lower also. The acres of old growth left at the end of the 1st decade would be 522.4 M acres or 28.4 M acres more than Alternative NC.

The number of Forest acres allocated to dispersed recreation and roadless area retention are similar to Alternative NC, overall. There is, however, an increase in Alternative K of acres managed to meet a modification visual objective. Although watershed risk was not estimated for Alternative NC, based on the rate of harvest it is likely the effects would be similar to Alternative K; 29% of the Forest in the high risk category and 27% of the area at moderate risk of adverse watershed impacts.

Alternative A (No Action) - *PNV: $3.2 Billion* - Opportunity Cost: $319 Million as compared to Alternative K.

Alternative A would continue management of the Forest under the existing Forest Land and Timber Management Plan (1977). However, Forest direction is modified in this Alternative to meet MRs. The timber harvest under Alternative A, 110 million cubic feet, is a decrease of 7 million cubic feet per year from the harvest level under Alternative K. Present net value, payments to counties, and net cash flow drop slightly from the Alternative K level. Income and the number of jobs decrease proportionally with the timber harvest levels. Alternative A would retain 528.4 M acres of old growth at the end of the first decade or 6 M acres more than in Alternative K.

Forest land allocations for dispersed recreation, roadless areas, and scenic management areas (with the exception of Modification in K) are higher in Alternative A as compared to Alternatives K and NC. Spotted owl habitat areas would be protected at the MR level or the same level as Alternative K. Deer and elk populations in Alternative A would show a slight increase over Alternative K. Elk populations increase in Alternative A as compared to Alternative K due to a better balance of cover and forage habitat components and overall habitat quality. The watershed risk levels are similar between Alternatives K and A with over 50% of the Forest at high to moderate risk of adverse watershed effects.

Alternative J (DEIS Preferred) - *PNV: $3.1 Billion* - Opportunity Cost: $124 Million as compared to Alternative A.

Alternative J was formulated to provide relatively high levels of timber on a nondeclining yield basis in combination with production of amenity resources at intermediate levels. Timber harvest would be 95 million cubic feet annually. This level is 15 million cubic feet or 14% less than the first decade annual harvest in Alternative A. The difference in timber harvest between these two alternatives is due to more acres that would be managed for nontimber uses such as dispersed recreation and additional acres of reduced yields such as Retention and Partial Retention scenic objectives. Present net value, net cash flows, payments to counties, personal income, and the number of jobs are less in the first period as compared to Alternative A reflecting the increased emphasis on amenity resources. In Alternative J, 534.9 M acres of old growth or 6.5 M additional acres would remain under Alternative J after 10 years as compared to Alternative A. The amount of existing roadless area allocated to roadless prescriptions is 20 M acres greater in Alternative J than in A. The amount of new trails that would be built in Alternative J is 40 miles over the decade, as compared to no new trail construction in Alternative A.

Deer and elk populations increase slightly in Alternative J reflecting the increased amounts of optimum cover and other habitat enhancements. Spotted owl habitat would be provided at the MR level of 59 areas, unchanged from Alternative A. The lower first decade harvest level in Alternative J results in a 35% of the Forest area in a high or moderate risk category for adverse watershed effects as compared to 55% in the same categories in Alternative A.

Alternative W (FEIS Preferred) - *PNV: $2.9 Billion* - Opportunity Cost: $202 Million as compared to Alternative J.

Alternative W emphasizes the management of both commodity and noncommodity resources on the Forest at levels that would recognize the importance of maintaining intact, functional ecosystems and long term productivity. The timber harvest level in Alternative W would be 87 million cubic feet or 8% less than in Alternative J. Cash flows and payments to counties are only slightly less than in Alternative J, but other economic indicators show significant reductions. Spotted owls would be managed at the MR level of 59 areas, the same as Alternative J.

The amount of the Forest at high to moderate risk of adverse watershed effects decreases to 0%, a significant change from Alternative J. In addition, 12.4 M additional acres would be managed in a roadless condition. The amount of trails to be constructed in the first decade increases by 20 miles over the amount proposed in Alternative J to a total of 60 miles in Alternative W. Overall, the dispersed recreation opportunities in Alternatives J and W are similar. The acres of old growth remaining after 10 years shows a slight reduction (1,500 acres) from Alternative J. Elk and deer populations would increase slightly from Alternative J as a result of increased acres of optimal cover and additional emphasis on habitat management.

Alternative D (Wildlife) - *PNV: $2.8 Billion* - Opportunity Cost: $78 Million as compared to Alternative W.

Alternative D places a high emphasis on the management of wildlife and other amenity resources. This level of management would require reductions in the acres where timber is the primary production goal. The timber sale level under Alternative D is 86 million cubic feet which is similar to Alternative W. First period jobs, personal income, payments to counties, net cash flow, and present net value are

also reduced slightly compared to Alternative W. The old growth remaining at the end of the first decade would be 537.2 M acres or less than a 1% increase over Alternative W.

The increased emphasis on amenity resources would result in more acres allocated for semiprimitive nonmotorized dispersed recreation, scenic zones, roadless areas, and spotted owl habitat areas, as compared to Alternative W. The significant changes between Alternative W and Alternative D are in wildlife and watershed outputs and effects. In Alternative D, the number of designated spotted owl habitat areas is 102 compared to the MR level of 59 in Alternative W. Elk and deer populations would increase by 15 to 20% over Alternative W due to an emphasis on high quality habitat conditions and enhancement projects.

The amount of the Forest in the high to moderate risk category for adverse watershed effects increases from 0% in Alternative W to 22% in Alternative D. This increase is due largely to a harvest level similar to Alternative W on a smaller suitable land base and the decreased emphasis in Alternative D to maintain favorable watershed conditions at the subdrainage level.

Alternative L (Oregon Natural Resources Council) - *PNV: $1.6 Billion* - Opportunity Cost: $1,173 Million as compared to Alternative D.

Alternative L emphasizes the protection of remaining old growth and maintenance of the natural attributes of the Forest. Achievement of these goals would require further reductions in the acres where the primary goal is timber production. The timber harvest level is 27 million cubic feet or 59 million cubic feet less than Alternative D, and is the lowest of all alternatives. All the economic indicators are at their lowest level, reflecting the low timber harvest level. Conversely, Alternative L would retain the greatest amount of old growth at the end of the first decade of all the alternatives with 578.3 M acres or 41.1 M acres more than Alternative D.

Alternative L would maintain all of the current inventory of roadless area in a roadless condition. Approximately 145.9 M acres are allocated to roadless management prescriptions and an additional 169.4 M acres would be recommended for Wilderness designation. The acres that would be maintained in roadless allocations in Alternative L are the most of any alternative. In addition, 184 spotted owl habitat areas, enough to protect the known owl population outside of Wilderness, would be preserved. Deer populations would decrease due to the decrease in forage as a result of lower timber harvest levels. Due to the low level of timber harvest and large amount of land maintained in a natural condition, 0% of the Forest would be in the high or moderate risk category for adverse watershed effects. This is 22% less than the acres similarly rated under Alternative D.

CHAPTER III

AFFECTED ENVIRONMENT

INTRODUCTION

This Chapter describes the environment of the Willamette National Forest that would be influenced by the implementation of any of the proposed Alternatives. The environmental factors discussed are those which are significant and pertinent to issues, concerns, and opportunities. This Chapter, like Chapter IV, is organized by environmental component.

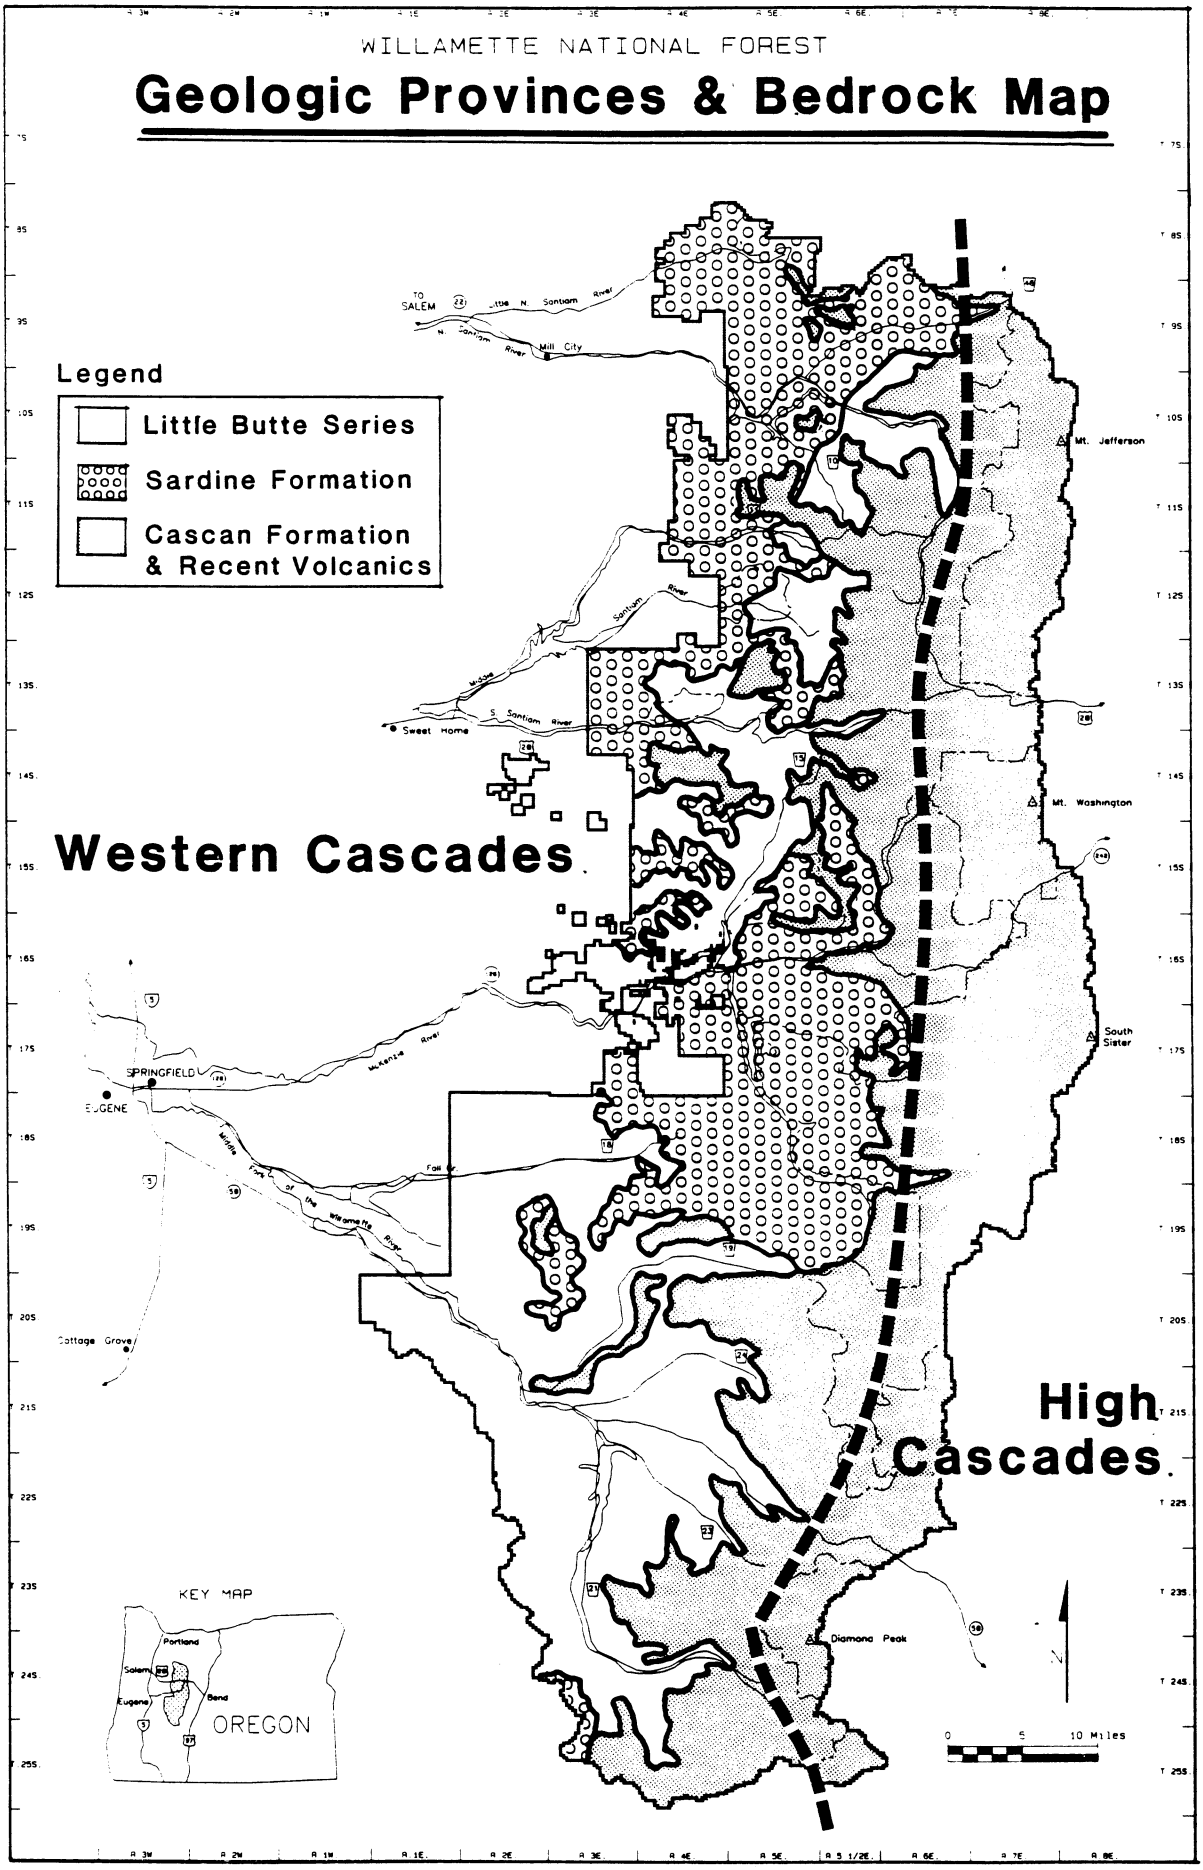
The Chapter begins with general descriptions of the environmental components Climate and Geology, which are followed by descriptions of the other physical, social, and economic components of the Forest. The other environmental components, including those of Water, Vegetation, Wildlife, Timber, and Recreation are described in greater detail to reflect important historic trends, current conditions, and future trends.

The expected changes in the environment that would be generated by implementation of any of the proposed Alternatives are discussed in Chapter IV, Environmental Consequences and summarized in Chapter II, The Alternatives.

GEOLOGY

Knowledge of the geologic characteristics of the Forest provides an understanding of the land's capabilities and limitations for managing the various resources and predicting subsequent effects of management activities. The Oregon Cascade Range of the Forest is divided into two major geologic provinces: the Western Cascade Province and the High Cascade Province (Franklin and Dyrness 1973). (See Figure III-B-1, Geologic Provinces and Bedrock Map).

The geologically older Western Cascades are largely composed of 25 million year old to 45 million year old volcanic and pyroclastic formations, particularly the Little Butte Series and the Sardine Formation. (See Figure III-B-1, Geologic Provinces and Bedrock Map.) The Little Butte Series is dominated by tuffs and breccias that weather relatively rapidly to deep, fine textured soils which can be very unstable. The Sardine Formation, which includes flows of basalt and andesite, weathers slowly and has produced well-drained, coarse, stony soils much less subject to mass movement (Legard and Meyer 1973). A long history of repeated glaciations and active stream erosion has produced the highly dissected topography. Ridgetops are typically about 4,000 to 5,000 feet, with a few peaks nearing 5,700 feet.



The 13 million-year-old and younger High Cascades occupy nearly one-third of the Cascade Range on this Forest, and are adjacent to the older Western Cascades. These formations have built up from a chain of broad, coalescing shield volcanos (predominantly fluid lava flows), that cover the eroded eastern margin of the Western Cascades. They form gently sloping land, beginning at about 3,500 feet and rising up to a crestal plateau near 5,000 feet. Scattered along the crest are many small volcanic cones along with the well known large composite volcanic peaks which rise another 1500 to 5300 feet above the surrounding terrain. Some of these peaks include Diamond Peak, The Three Sisters, Mt. Washington, and Mt. Jefferson. Soils on the High Cascades are usually immature and often developed in volcanic ejecta.

Glaciers have carved the higher elevation areas repeatedly, even as the mountains were forming. During the retreat of ice in the last glacial period, about 10,000 years ago, the topography was modified to include glacially carved rock headwalls, bowl-shaped cirque basins and their associated lakes, steep U-shaped canyons, and widespread deposits of glacial moraines and outwash materials. Distinct peaks that were highly modified by this glacial action include Mt. Washington and Three Fingered Jack. Present day glacial activity is still occurring on the higher peaks of Mt. Jefferson, The Three Sisters, and Diamond Peak.

Since deglaciation, several factors have acted to change the shape of the land's surface, both in the High and Western Cascades. Pumice from Mt. Mazama (Crater Lake), and deposits of ash, sand, and cinders from local cinder cones buried preexisting soils developed in glacial materials, and recent lava outpouring occurred in the McKenzie Pass and Santiam Junction areas. Large scale, downslope mass movements (landslides) have formed new lakes, altered drainages, and created numerous hummocky, uneven land forms, primarily in the Western Cascades.

Slope stability, (the resistance of natural or artificial slopes to failure by mass wasting), is directly related to geology and topography. Gravity is the most important factor--the steeper the slope, the less stable (Sidle 1984). Water is the next major component (both surface and subsurface)--the more water, the less stable (Brunsden and Prior 1984). Generally, on steep slopes, the thicker the soil the more prone the slope is to failure. This is because thicker soils can become more unstable as they are saturated with water. The rock content of the soil also affects the strength and drainage of soils due to both increased friction and improved water drainage (Huang 1983).

Figure III-B-1.

In the Western Cascades, mass wasting is a particularly important slope-forming process because of the generally steep slopes and areas of low strength soils in this geologic province. Mass wasting is the process of removing rock and soil under the influence of gravity; it includes rock falls, rapid debris slides, slow moving earthflows, and soil creep. Slope failures can involve only a few to several hundred thousands of cubic yards of soil and rock. They can range from small bank failures along drainage courses, to debris chutes where a torrent of water, soil, and rock strips stream channels and banks, to a major slump-earthflow that moves an entire mountainside.

In contrast, mass wasting in the High Cascades Province is relatively minor due to younger, stable volcanic rocks; large earthflows are uncommon. Most of the mass wasting in the High Cascades is confined to debris avalanches along glacially oversteepened canyon walls and in the incised pumice canyons.

Vegetation plays a major role in the complex interactions of slope stability, as well as erosion. It acts to intercept and store significant amounts of precipitation, thereby buffering the effects of storm events. The roots of vegetation physically bind soil particles together; the strength of the roots adds strength to the soil; and the roots may grow to bedrock, forming an effective anchor system. Once precipitation enters the soil it becomes available for the vegetation to remove it through evapotranspiration, which decreases the amount of destabilizing groundwater (Swanston and Swanson 1976).

The relationship between bedrock and soil development directly affects vegetation and vegetative growth. The breakdown of the bedrock provides the growth medium, nutrients, and moisture holding capacity for vegetation. The generally cool, moist climate plays a dominant role in forming the types of soils which will be produced by weathering processes.

The formation of soils is a complex dynamic process which depends upon such things as slope, aspect, climate, elevation, slope position, and rates of weathering, mass wasting and erosion. In general, rocks such as andesites and basalts form shallower, coarse, sandy soils with numerous rock fragments. The more easily weathered ash, tuff, and breccia formations produce deeper, more clay-rich, and finer-grained soils. Some locations, such as recent lava flows and some ridgetops, support little vegetation due to the lack of soil development.

Mineral deposits were formed as a result of a variety of geologic processes including physical and chemical decomposition of rocks at the earth's surface; sedimentation, which is the separation, transportation, and deposition of particles broken down from rocks (important in the formation of placer gold); and hydrothermal processes of alteration and/or mineralization, (important in the formation of lode deposits), where metallic elements such as gold, silver, copper, lead, and zinc occur as or mixed with complex compounds distributed within solid rock. Fracture fillings, commonly called veins, within the hydrothermal fluid channels have been sources of gold and silver in the past. Mineralization of the Western Cascades is of limited extent. The patented claims of the North Santiam District, located in the Little North Santiam drainage, produced small amounts of gold and silver and minor amounts of copper, lead, and zinc. The other mining districts (Blue River, Quartzville, and Fall Creek) produced minor amounts of gold and silver (Weissenborn 1969). (See Chapter III, Minerals and Energy.)

The geological processes which influence the Forest affect almost all management decisions in some way. The increasing demand for recreation, cost of road building, accessibility of timber sale areas for cost-effective logging, the control of fires, the need for clean water, as well as other management activities all require a clear understanding of the geologic environment.

For example, the topography of the region affects the complexity of logging operations. Increased cost in felling, bucking, and yarding are directly related to such things as the number of landings available,

the distance from the landing to the unit boundary, slope steepness and suspension requirements. Cost in road construction and maintenance are directly related to the distance required to haul aggregate to the site, excavation in steep or rocky slopes, difficulty of stream crossings, and necessity for structures. Rock for road surfacing and maintenance is considered a nonrenewable resource. Aggregate costs often influence road standards and operating seasons.

Road construction and reconstruction have both direct and indirect effects on slope stability. Road construction causes permanent alteration of the soil mantle/bedrock/water interactions. Studies by Sidle, Pearce, and O'Loughlin (1984) indicate that road construction on any hillslope will inevitably decrease the site stability because of a number of factors. Cuts and fills on side slopes effectively steepen the slopes and decrease the stability. The slopes may be overloaded by embankment fill. Support of the hillside is lost by the cut-slope excavation. Surface and subsurface water drainage paths are altered and concentrated. The road surface is essentially impermeable; thus, during storms more surface water flow occurs. Culverts which become restricted by sediment and debris may be unable to handle runoff, resulting in road failures.

Roads not only affect the stability of the cut and fill slopes, but also the slopes below the road. Culverts sometimes concentrate water where none previously flowed. The drainage water may be routed into potential of inactive earthflows downslope of the road and decrease their stability. Disposal of drainage runoff into slope depressions and other wet areas, especially on steeper side slopes, can also initiate shallow rapid failures on debris chutes. The stabilizing effects of vegetation are removed from the road alignment. The relative importance of any of these influences on slope failure depends on site conditions, construction design, and construction techniques. For example, sidecast road construction on the older roads in the Forest continues to be a major slope stability problem by causing debris chutes.

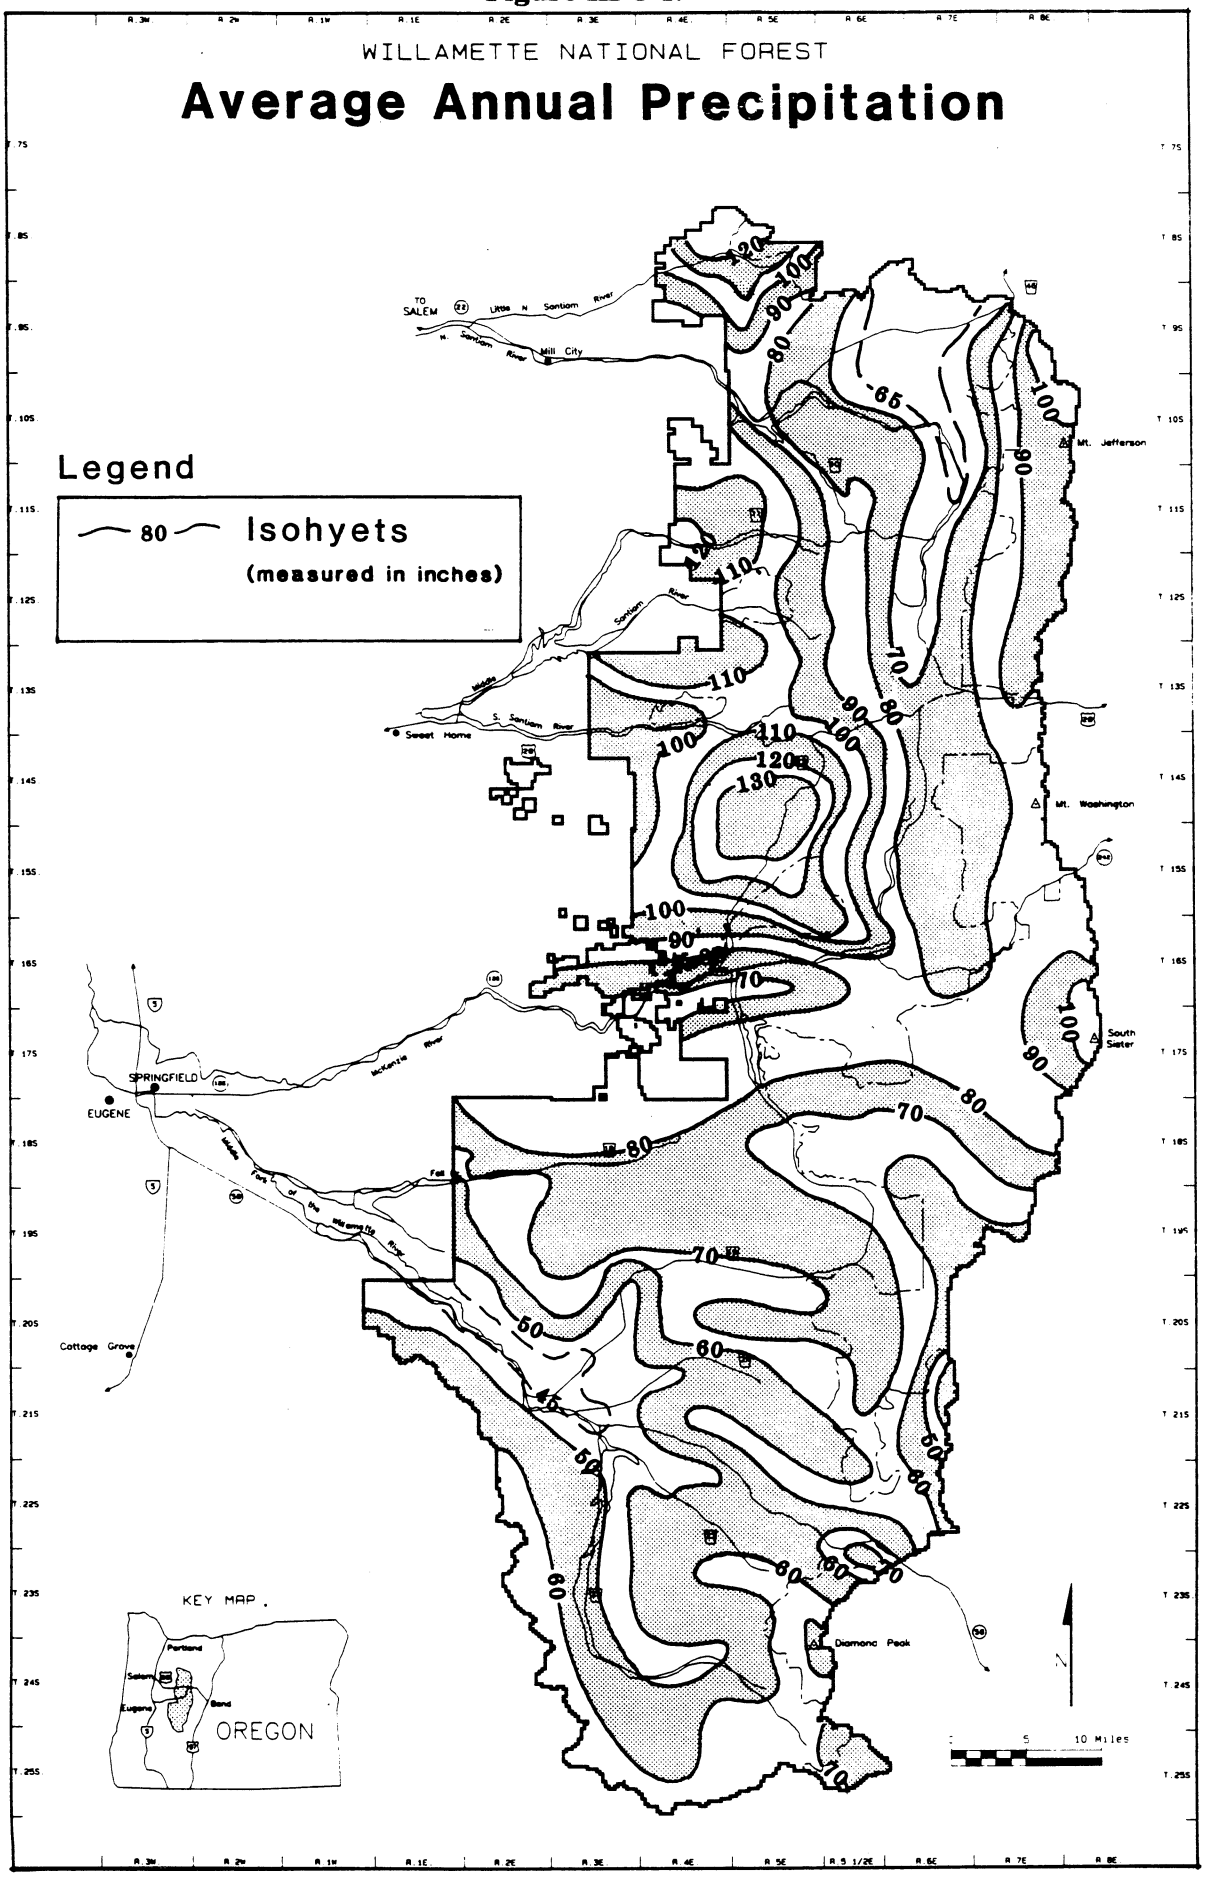
Recreation is also greatly influenced by geology and topography. Areas like Hoodoo and Willamette Pass ski resorts rely on the slopes of the High Cascades for all types of snow skiing. Rock formations like the rock spires of the Menagerie Wilderness, and the peaks of Mt. Jefferson, North Sister, and Mt. Washington provide technical climbing opportunities. Dee Wright Observatory on McKenzie Pass provides an inspiring view of the Cascade Range and recent lava flows. Unique formations such as Tumblebug Gorge and Phantom Natural Bridge reflect nature's sculpturing, while rock cuts in the river channels can provide whitewater recreation.

The sections on Soil and Minerals and Energy also contain information regarding the geological component of the environment.

CLIMATE

Climate is important in the development of the Forest environment and, as a consequence, Forest management. Many aspects of the Forest are influenced by the weather. The winter and early spring seasons supply snow for downhill and cross-country skiing, snowshoeing, and off-road vehicle activity. Melting snow brings the water for municipal use and hydro-electric generation, as well as white water recreation and fish migration. Often, when fog persists in the Willamette Valley during the winter months, the Cascade Mountains are sunny. These sunny periods are an invitation to escape from the fog, go sightseeing or enjoy snow related activities. In the dry summer season, many people again come to the Forest from the valley to seek relief from the heat.

Historic Trends/Current Situation



The climate of the Forest is referred to as Pacific Maritime. It is influenced by several factors including the position and intensity of upper level wind currents, the high and low pressure systems over the North Pacific Ocean, and variations in topography. In the summer, high pressure brings fair mild weather to the Forest. As winter sets in, the high pressure moves to the south, allowing the storms to move across the Forest. These frontal systems bring mild rainy conditions to the valleys and lower elevations of the Forest and heavy snows generally above 4,000 feet elevation (Sterns and Gilbert 1960).

The heaviest precipitation lasts for 3 months starting in December and accounts for 40 to 60 % of the yearly total. Mean average temperatures range from 30 to 40 degrees in January and average in the 60 degree range in August (Legard and Meyer 1973). The Forest receives the least amount of precipitation between June and October, when temperatures are highest. Thunderstorms occur most often during these months. Refer to Figure III-C-1 for average precipitation over the Forest.

This moisture has been one of the primary climatic factors affecting vegetative growth. The Forest has relatively dry cool summers and mild wet winters which are particularly favorable to evergreen conifers (Waring and Franklin 1977). Native conifers are able to carry on photosynthesis through the winter months while hardwoods are dormant. These conditions have created a magnificent conifer forest on the Forest with trees that grow to be some of the largest and longest living plants on earth. These plant formations are known for creating some of the earth's largest accumulations of biomass.

The vegetative patterns of the Forest are strongly influenced by both climatic and topographic conditions. As the elevation increases, the climate becomes more severe. As a result species composition and size decrease in the higher elevation. Another important factor influencing vegetation is that the south half of the Forest is considerably drier than the north half (Hemstrom et al. 1982). (See figures and discussion in Chapter III, Vegetation.) Thorough accounts of vegetation zones and communities on the Forest are in publications by Franklin and Dyrness (1973), Franklin (1979), Hemstrom et al. (1982, 1985).

Figure III-C-1.

Site specific microclimatic conditions are an important aspect of the Forest environment and often directly affect plant and animal habitat. Although meadows, rocky areas and clearcuts are exposed to the weather, riparian zones along creeks and lakes provide shade, lower temperatures and increased humidity. Changes in microclimate are also caused by activities such as timber harvest and road construction. For example, the removal of a stand of trees by clearcutting can cause local wind patterns to shift, lower humidity, and increased solar radiation. Chapter III, Timber and Appendix F both contain discussions of silvicultural treatments used on the Forest. For additional information on wildlife habitat see Chapters III and IV, Wildlife. Climate has played an important role in developing the forest soils. The weathering, decomposition, sedimentation, and overall mineralization caused by ice, snow, rain, wind, sun, cold, and heat are directly related to the breakdown of the bedrock to form soil. Some soils become very unstable with the effect of water saturation and gravity. These soil conditions are discussed in more detail in Chapter III, Soil and in Chapter IV.

When conditions are warm and dry, periodic thunder and lightning storms can result in the ignition of wildfires, but strong east winds often present more critical fire danger. During the summer and fall seasons, these dry, warm winds may be sustained between 30 to 40 miles per hour with stronger gusts over the higher ridges. During these periods, small smoldering embers can quickly ignite large fires requiring major fire suppression efforts, and as a consequence, industrial operations are restricted and prescribed burning activities are curtailed. In extreme cases the Forest is closed to all uses until rain or humidity lowers the danger.

The weather patterns also affect slash burning activity and the subsequent effects of smoke on air quality. Maritime winds provide good mixing and dispersion of smoke into the upper atmosphere and away from smoke sensitive areas in the populated valley bottoms. It is common to have completely different atmospheric conditions in the western valleys as compared to the distant ridge tops. See Chapter III, Air for additional information.

Weather conditions also influence the construction and use of Forest roads. Because of the wet conditions in the winter and spring, roads need to be constructed to a higher standard to alleviate drainage problems. Some roads are not used at all in the winter because of deep snow, mud slides, and fallen trees. See Chapter III, Roads.

Future Trends

An emerging issue that is gaining attention worldwide is global warming. Concern has been increasing as the following data has been gathered by various scientific organizations:

1. The 1980's decade was the warmest in recorded history.

2. The carbon dioxide level in the atmosphere has increased from 315 ppm to 350 ppm since 1958.

3. The rate of increase in carbon dioxide is faster than at any time during the last 100,000 years.

Climatic change and variability along with stresses from existing and new atmospheric pollutants have undetermined impact on the forest and it's ecosystems. Existing historical data are inadequate for predicting future forest responses.

To deal with the scientific uncertainty about the likelihood and signicance of potential climatic changes, Congress is working on a variety of bills (Global Climate Change Prevention Act - S.1610, and the Urban and Community Forestry Act - H.R. 2144) to stimulate research and develop strategies for adapting to and mitigating the impacts of climate change. In addition, the U.S. has joined 70 other

Nations in a "Declaration on Global Climate Change" which identifies improved forest management as one of eight major areas for international funding.

A 1988 USDA Forest Service report, "Forest Health and Productivity in a Changing Atmospheric Environment" identified three broad questions on the effects of physical and chemical climate changes on forest, range and related ecosystems, for which research is needed:

1. What processes in forested ecosystems are sensitive to physical and chemical changes in the atmosphere?

2. How will future physical and chemical climate change influence the structure, function, and productivity of forest and range ecosystems?

3. What are the implications for forest management, and how must forest management activities be altered to sustain forest health and productivity?

A recent study predicted the average global temperature could increase by 1.5 to 5.0 degrees Centigrade over the next 50-100 years. If global warming results in temperature increases of this magnitude, the following changes would be possible in the West Cascades:

1. Vegetation bands could shift upward by as much as 1,000 feet in elevation. The Forest would resemble the present forests of northern California with more Grand fir, Sugar Pine and Ponderosa Pine, and less western hemlock. At lower elevations near the valley floor, the vegetation would likely change to chaparral and oak woodland.

2. Although total annual rainfall would probably be about the same, it would be concentrated in a few severe storms. Summers would be hotter and drier with lower streamflows and warmer water temperatures. The risk of wildfires would be much higher. Trees would be under more stress and increasingly susceptible to a variety of pathogens.

3. Overall productivity of the forest would probably decline, although there might be an increase at some of the mid to high elevations. Some of the highest mountain hemlock types may change to nonforest shrubs and meadows.

There are many unanswered questions concerning the global warming issue. Data is scarce and sometimes conflicting. However, during implementation of the Forest Plan the following strategies should be considered in preparing for possible changes:

1. Emphasize a diversity of species in plantations including hardwoods.

2. Maintain or enhance this mix through the precommercial and commercial thinning entries.

3. Start selecting some trees in the genetic program for their drought resistance instead of height growth.

4. Increased protection of riparian areas to maintain channel stability and cool water temperatures.

The Forest Monitoring Plan will cover reforestation success/failure by habitat types and be able to track changes in vegetation that might be indicators of a climatic warming trend.

SOIL

Soil is a fundamental component of the environment. It is the growing medium for most plants. Soil absorbs and stores water, releasing it slowly over time; it supplies nutrients for vegetation which in turn supplies habitat for wildlife and resources that people use and enjoy. All renewable surface resources of the National Forest are dependent upon soil. Soil is considered a nonrenewable resource because of the length of time required for its formation.

Historic Trends

Soils of the Forest are diverse, reflecting the influence of climate, time, vegetation, parent material, and topography. Parent material of the Forest's soil is almost entirely of volcanic origin and can be divided into two broad classes: hard volcanic rocks, such as basalts, andesites, and intrusions of various kinds; and soft volcanic rocks, such as breccias, tuffs, and volcanic ejecta. Soils with parent materials consisting of hard volcanic rocks may develop at a rate of approximately one inch per thousand years, while soils with parent materials consisting of soft volcanic rocks may develop at much faster rates. Soils can also form on materials derived from other geologic materials and include deposits of glacial outwash and till, alluvium, loess, colluvium and sediments.

Geologically recent volcanic ejecta (pumice, ash, sand, and cinders) have had a major influence on soil formation in the High Cascades region of the Forest. These rock types are generally found at elevations in excess of 4,000 feet, but in the southeastern portion of the Forest, this material occurs at about 3,000 feet and higher. Because of the short, dry, growing season and high snow pack, vegetative growth and microbial activity are restricted. This makes soil formation much slower than in the more temperate lower elevations. These soils are generally not as well developed, or as fertile as those occurring in the Western Cascades. Refer to Section B, Geology, in this chapter for additional discussion of the bedrock and the soil and mineral forming processes.

An inventory of the soils of the Forest was completed and published by Legard and Meyer in 1973. It is entitled "*Soil Resource Inventory (SRI) of the Willamette National Forest.*" This inventory grouped areas of similar soil, parent material, land form, and vegetation into units called landtypes. These landtypes were the basis for the interpretations provided in the report. The inventory recognized 159 mapping units consisting of landtypes, miscellaneous landtypes, and complexes. The objective of the SRI is to provide soils information in a useful form to land managers as an aid to multiple-use management.

Current Situation

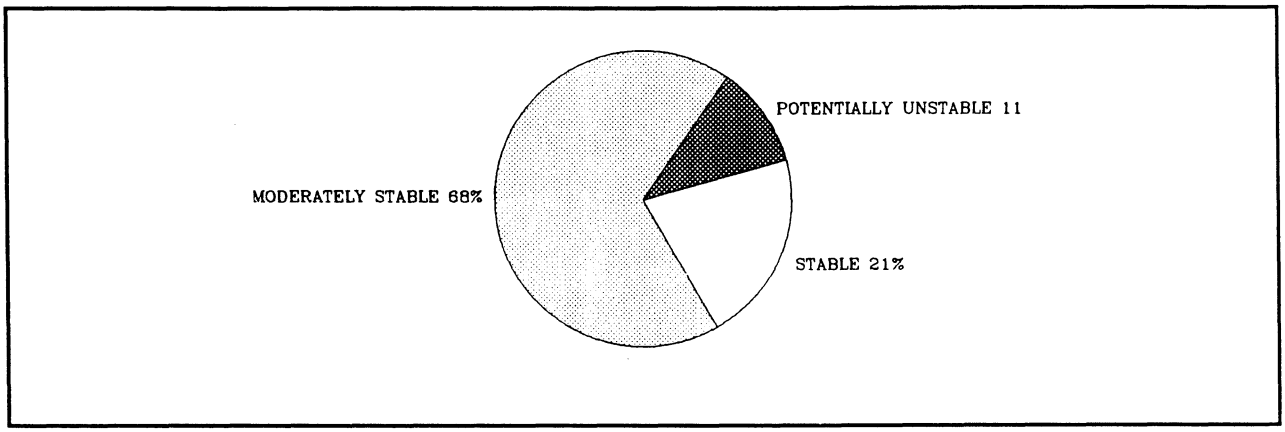
Forest management activities directly affect soil productivity in both the short- and long-term. The concept of productivity includes both the ability to grow vegetation as well as the maintenance of slope stability. The major concerns include the increased risk of soil movement from roading and clearcut timber harvest, reduced growth potential from compaction, nutrient loss from fire, and reduced productivity from loss of large woody material.

Soil productivity varies widely due to varying characteristics such as soil depth, available moisture holding capacity, nutrient status, and site characteristics including elevation, slope, and aspect. The most productive soils for producing wood fiber are found in valley bottoms, toeslopes, and benches.

These include SRI landtypes 14, 15, 22, 23, 25, 35, and their complexes which total approximately 14% of the Forest (Legard and Meyer 1973).

An important component of soil productivity is organic matter content, and related nitrogen availability. Soil organic matter directly affects both water and nutrient holding capacity as well as soil tilth. Organic matter holds many times its weight in water and has a high cation exchange capacity that increases the soil's ability to hold plant nutrients. Organic matter in the form of leaves, needles, and twigs is itself a supply of plant food as it decomposes and releases nutrients, especially in the higher elevation soils. Large woody material (whole downed, rotting trees) supports the life cycle of symbiotic soil fungi which attach to conifer roots, and greatly increase the trees ability to take up nutrients and water. Duff and litter on the soil's surface also act as a mulch and reduces soil erosion due to rainfall impact. Fine rootmats in the surface soil bind the soil together, reducing downslope soil creep and washing. Some Forest soils, for example, have accumulated very little organic matter and are considered sensitive to any organic matter removal by management. These soils generally occur in the upper elevations where the colder climate and short growing season does not generate large amounts of annual vegetative growth.

Timber management can affect organic matter and nitrogen content in several major ways. Logging or wood removal and fuels treatment or prescribed burning can both directly remove organic matter as well as change erosion rates. Surface erosion process are active both during summer drought periods as dry ravel and during winter rainfall events. In timber harvest units, surface erosion rates may exceed natural rates depending on such factors as degree of disturbance, severity of burn, and steepness of the slope. Vegetative regrowth usually forms a protective barrier and binder equal to the original stand within ten years after disturbance (Swanson and Grant 1982). Nitrogen fertilizer, on the other hand, may be applied to soil to increase soil productivity. This results in more and higher quality forage, quicker vegetation responses for shading riparian zones, and more wood fiber in a shorter period of time.



Slope stability is also a fundamental component of soil productivity. Soil stability classes were established for the Forest based on the "Expected Mass Movement as a Result of Man's Activity" rating (Legard and Meyer 1973). Slope stability is also discussed in the Geology section.

Figure III-D-1 shows the relationship of three stability classes to the available land suited for timber production. The three stability classes used in the planning process have been defined as follows:

> Stable--Gentle to moderate slopes (40 to 60%) with hard rocks, and rock with or soil. About 21% of the tenatively suitable forested land is made up of this class.
>
> Moderately Stable--Steep slopes (60+ %) with hard rocks and moderate slopes with soft rocks. About 68% of the tenatively suitable forested land is made up of this class.
>
> Potentially Unstable--Steep slopes and soft rocks. About 11% of the tentatively suitable forested land is made up of this class.

Mass wasting by either debris avalanches or of slump-earth flows are dominate mechanisms for downslope movement of soil. The principal impact of soil movement is on the aquatic environment, but soil productivity is also reduced in the affected area. The delivery of sediment to the aquatic environment is more efficient with mass wasting type processes than it is in surface erosion. This is described in greater detail in the Water section.

Figure III-D-1. Soil Stability Classes for Timber Harvest

Mass wasting can occur on distinctly different land types within the Forest. Deep, plastic, clay soil types formed from tuffs and breccias tend to be dominated by slump- earth flow movement. These types of failures are deepseated by nature and occur predominately on SRI landtypes 25, 33, 35 and their complexes that cover 11% of the Forest. Shallow noncohesive soils over hard bedrock are prone to debris torrents and debris avalanches. These are made up of SRI landtypes 3, 8, 9, 21, 31, 61, 94 and their complexes that comprise about 35% of the Forest. Cost of road construction and maintenance increases within these areas. In some cases, road construction across these landtypes has been prohibited because the risk of resource damage was higher than the benefit. Sidecast of excess excavated material on steep sideslopes (greater than 55-60%) is not considered an option in future road building proposals for any land type, because of the high risk of landsliding.

Future Trends

The demand for the soil resource is that it remain productive. Accelerated surface soil erosion, mass wasting (slope stability), and excessive compaction will continue to be management concerns.

Both total erosion and the delivery of sediment to streams is expected to decrease in the future due to changes in road construction practices and because over 80% of the Forest transportation system is currently in place, although these processes will continue to occur Forest-wide as a result of natural storm events. As previously undisturbed areas of the Forest are entered for timber harvest activities, the slope stability of potentially unstable land flows may be disturbed increasing the potential for mass movement. In localized areas, surges of sediment may exceed average drainage trends. As a consequence, it will become increasingly important to identify, locate, and analyze active and potential slump and debris avalanche areas prior to management activities, and to incorporate site specific analysis in project design and implementation.

WATER

Water draining from the Forest is of high quality and provides many benefits. The Forest furnishes water for municipal and domestic uses, fish hatcheries, electrical power generation, and recreation. Water provides fish and wildlife habitat, and supports one of the most productive vegetative environments in the world. The two basic forms of water on the Forest are surface water, (streams, rivers, lakes, and reservoirs) and subsurface, or groundwater.

The principal issues for water resources on the Forest involve the yield, quality, and use of surface waters, mainly in streams and rivers. Concerns for water quality received the second highest rating in the issue development survey.

Historic Trends

To assess the current condition of Forest water resources, particularly streams, an understanding of the management history is needed. An understanding of the physical and climatic setting is also necessary, particularly as it relates to flood history and potential future, flood occurrence. The infrequent catastrophic floods which occur on the Forest have had considerable influence on current management philosophy and practices.

Before Forest management activities began, natural processes were the sole means of change in the landscape. Catastrophic flood events, recurring at varying intervals, were the dominant forces to change of Forest water resources. In the Cascades, major flood events are caused by storms which deliver large quantities of precipitation in a short time. Rapid snowmelt caused by warm rain also contributes to flood events.

Major flood events occurred in 1861 and 1890 which caused extensive damage in Eugene, Springfield, Salem, and Portland areas. During the 1940s and 1950s, several flood events occurred which also resulted in extensive property loss in the Willamette Valley. The US Army Corps of Engineers conducted extensive flood control studies in the Willamette basin during the 1950s. Subsequently flood control reservoirs were constructed on all the major Willamette River tributaries.

Flood control reservoirs located on the Forest, or controlling the off forest flow of streams are: Detroit (North Santiam River); Foster and Green Peter (South and Middle Santiam River); Blue River and Cougar (McKenzie River); and Hills Creek, Lookout Point and Fall Creek (Middle Fork Willamette River). A reregulating dam on the South Fork of the McKenzie below Cougar Reservoir has been authorized but not funded by Congress. This dam would be called the Strube Dam.

During the winter of 1964/65, two very damaging storm events occurred. The December 1964 event was a 100-year flood (one that occurs on average once in 100 years) on all Willamette basin streams. The January 1965 event was approximately a 50-year flood. Other major flood events occurred in 1956, 1957, 1971, 1974, 1978, 1981, and 1986.

Major damage from the 1964 storms was to roads and bridges totalling approximately $12,000,000 within National Forests in Oregon. Damages to fisheries were extensive, though not calculated in terms of dollar value. Of 725 soil and debris slides reported from Oregon National Forests, 78% were associated with roads or logged areas (54 and 24%, respectively). These proportions are consistent with those found on the Forest, which received the most extensive damage of all the National Forests affected by the storms (Region-6 Storm Damage Report 1966). Although infrequent catastrophic events are the dominant source of change to Forest water resources, management related alterations of a

watershed increase the ability of a flood to cause damage to streams, fish habitat, and improvements (Lyons 1981; Grant 1984). The next 100-year flood which strikes the Forest will have potential to cause more extensive damage than the 1964/65 events, because of the twofold increase in total road miles, as well as increase in acreage harvested. This assertion is evidenced by the $1.3 million in damage to roads, bridges, and culverts caused by a 10-year flood event which occurred in late February 1986 (*Willamette National Forest Storm Damage Report, 1986*). A 10-year flood event occurs on average, once in 10 years and produces about half of the water volume of a 100-year event.

In the late 1940s and early 1950s, extensive timber harvest began on the Forest. Initial road construction practices called for side-cast wasting; material in excess of that needed for construction of the road bed was pushed over the side. The result was an accumulation of loosely arranged material and overweighting of the slope below the road. During the major events of 1964-1965, many of these areas slid, causing sedimentation of adjacent streams.

In the late 1960s and early 1970s the hauling of waste material to stable sites began to be required. This practice, along with stabilization of existing road fills, has greatly reduced the volume of sediment entering streamcourses.

Timber harvest practices have followed a similar history. Initially, little or no suspension of logs was required as they were yarded across the slope or through small, unstable Class III and IV streams. The result was sedimentation of streams and an increase in landsliding in small streams within harvest units. Beginning in the 1970's, more sophisticated logging practices have greatly reduced sedimentation resulting from timber harvest. Partial or full suspension of yarded logs, vegetation left to stabilize soils, and improved tree falling techniques have effected a decrease in sedimentation.

Management practices in riparian or streamside areas have undergone a similar transition. Initial practices did not recognize the need for preservation of stream shading vegetation on fish bearing streams, nor that shade removal on nonfish bearing perennial streams could have a cumulative impact to downstream fisheries due to the increase in water temperature. Several streams had daily peak summer temperatures warmed to the low to mid-70 degrees Fahrenheit (Total Resource Inventory, Aquatic Subsystem files).

Beginning in the mid-1970s, analysis of shade requirements, and leaving of necessary shading vegetation was initiated. As a result of these efforts, as well as shade recovery in older harvest units, recent research and Forest monitoring have documented an apparent drop in peak summer water temperatures in Salmon, Fall and Winberry Creeks (Beschta and Taylor 1986) (Total Resource Inventory, Aquatic Subsystem Files).

Another practice common in the 1960s through mid-1970s was the removal of natural woody debris, or downed logs, from streams in and adjacent to harvest units. This practice was initiated because of extreme amounts of damage to culverts and bridges caused by debris carried by the 1964/65 floods (Part II, Region-6 Flood Damage Report, 1966). As a result, the standard design capacity for bridges and culverts was increased.

The actual function of wood in streams was poorly understood at that time. Research now shows large woody debris is the critical link in fish populations and habitat quality, and that it has a similarly critical role in maintaining channel stability. Downed logs have important functions in dissipating stream energy, storing and routing sediment, and so provide for virtually all of the habitat requirements of anadromous and resident fish (Harmon et al. 1986).

Beginning in the early 1980s, the removal of woody debris was curtailed, except where necessary to protect an existing improvement. It is now a standard management practice to plan for the maintenance of the existing woody debris and to provide a source for future deposits of wood into the streams.

In the past, before management activities began, the Forest's watersheds had the capability of producing consistent flow patterns and valuable fish habitat. As management intensified, it was noted that peak streamflow appeared to be increasing in major rivers draining the Forest (Christner and Harr 1981).

Increased peak streamflow may destabilize a stream by altering the balance under which the stream developed, causing an increase in sediment production and a decrease in bed and bank stability. At any given time, stream conditions are a function of both the volume of sediment and water passing through it and the relative ability of its bed and banks to withstand the scouring effect of the water. As flow volume increases a stream's ability to carry sediment increases, as do bed and bank erosion (Heede 1980).

Peak streamflow increases were suspected to be caused by the rapid melt of snow accumulating in harvest units located between 1,500 and 4,000 feet in elevation. It was found that harvest openings collected a deeper snowpack than surrounding timbered areas, and that the snow melted more rapidly, particularly in the presence of wind and warm rain (Christner and Harr 1983).

In the early 1980s, as a result of these interrelationships, the Forest established a management consideration that watersheds should be maintained at approximately 75% hydrologic maturity, to minimize potential increases in peak streamflow and landsliding (Christner 1982).

Undisturbed areas of the Forest generally have soil surfaces which allow water to penetrate at a rapid rate even during lengthy storms of medium intensities. Under these conditions, overland water flow rarely occurs. Subsurface water typically surfaces in springs, streams and lakes and accounts for nearly all streamflow on the Forest. A portion of the subsurface flow penetrates deeper and recharges porous underground strata called aquifers. The distribution and characteristics of ground water occurring in aquifers are complex.

It is hypothesized that the High Cascades mountains in addition to river confluences, and alluvial deposition areas, contribute to recharge areas for aquifers in the Willamette Valley and portions of eastern Oregon immediately adjacent to the Cascades. A large portion of the precipitation which occurs during the winter months above 4,000 feet in elevation in the High Cascades falls as snow. The recent volcanic area of the High Cascades (see Figure III-B-1, Geologic Provinces and Bedrock Map) is largely composed of porous rock formations. As the snowpack melts during the spring and summer months, it significantly influences the seasonal volume of runoff and groundwater recharge.

Current Conditions

The Forest drains the western front of the Cascade Mountains, from southeast of Eugene to east of Salem. All of the river basins on the Forest are tributary to the Willamette River, which enters the Columbia River at Portland. Total water yield from the Forest is 8.9 million acre feet per year (Hubbard et al. 1983). Major river drainages on the Forest are the North and South Santiam, McKenzie, and Middle Fork Willamette. Figure III-E-1 depicts the major watersheds on the Forest.

The Forest contains approximately 9,300 miles of streams. Streams on the Forest have been classified according to use and/or potential use (FSM 2520). Class I streams (426 miles) are comprised of water used for municipal or domestic purposes, or contain large numbers of fish, both anadromous and resident.

Class II streams (940 miles) either contain or have the potential to contain resident sport fish. Class III streams (1,295 miles) are perennial, non-fishbearing streams and Class IV streams (6,621 miles) flow intermittently. Figure III-E-2 depicts the normal classification hierarchy of streams in a "typical" watershed.

The mileage of streams by class, major watershed, and Ranger District is shown in Figure III-E-3. Streams from the Forest produce the high quality water and physical environment necessary for anadromous and resident fish spawning and rearing. See Figure III-I-2 for the amount and type of fish habitat by major watershed (Fish Section, this Chapter).

There are over 390 natural lakes on the Forest, accounting for more than 11,233 acres (17.6 square miles) of surface area. Most of the natural lakes are located in the High Cascades, above 4,500-foot elevation; 74% (289) of the lakes are within Wilderness. The other 26% (101) are in other land use designations. The lakes on the Forest vary widely in size and productivity, but trout are found in the majority of the lakes over 2 acres in size and 8 to 12 feet in depth (Stewart and Skeesick 1982). There are at least 375 fish-bearing lakes between 2 and 50 acres in size, with 15 lakes ranging in size from 50 to 360 acres (Stewart and Skeesick 1982). The surface stream network in the High Cascades where the majority of the lakes are located, is poorly developed. As a result, few of the lakes have spawning habitat available, and only 10% have naturally reproducing fish populations (Stewart and Skeesick 1982).

The gem of the lake system on the Forest is Waldo Lake, the second largest (6,420 acres) and second deepest (maximum 420 feet) natural, nonalkali lake in Oregon. Waldo Lake is truly a world-class water body, being one of the clearest and cleanest lakes in the world (Lider et al. 1980). The Waldo Lake Wilderness, Waldo Lake Recreation Area, and Torrey-Charlton Natural Area are management units of the Forest contributing to the protection of the water quality and aesthetic setting of the lake, while promoting recreation uses.

Water Use

Several categories of use exist for water originating from the Forest. The first category includes off forest domestic and municipal water supply. Other off forest uses are irrigation, recreation, power generation, and fish hatcheries. Manipulation of water releases from the five largest reservoirs on the Forest assures acceptable water quantity and quality during the summer months in the Willamette River at Albany, Salem, and Portland. On Forest use includes fish and wildlife habitat, recreation, and fish hatcheries. Anadromous fish spawned on the Forest contribute to the Columbia River sport and gillnet fisheries. Figure III-E-4 lists current water use in the major Forest watersheds by Ranger District.

The Forest has 37 surface sources for drinking water supply, including 14 municipalities, 7 unincorporated or private suppliers and 13 campgrounds. As displayed in Figure III-E-5, the Forest is the principal source and is defined as greater than 50% of the watershed area above the point of withdrawal for municipal use is on the Forest. This assumes that all of the land in the watershed contributes equally to water yield as measured at the withdrawal site of drinking water for approximately 204,000 people in the Willamette Valley and surrounding communities. The Forest supplies 82% and 72%, respectively, of the water used by Eugene and Salem, which have a combined population of 185,000. The cities of Albany and Lebanon (combined population 35,000) receive approximately 34% of their water from Forest land.

As defined by the USDA Forest Service (FSM 2543, R-6), the Forest potentially has 21 municipal watersheds. For a watershed on Forest to be classified as a municipal watershed, Forest Service management activity must have the potential for having a significant effect upon the quality of water

at the point of withdrawal. In addition, through the point of withdrawal the watershed must meet one or more of the following criteria:

- Serve at least 25 individuals at least 60 days per year.
- Provide at least 15 service connections.

For this purpose, municipal applies to unincorporated or private utilities, as well as incorporated municipalities.

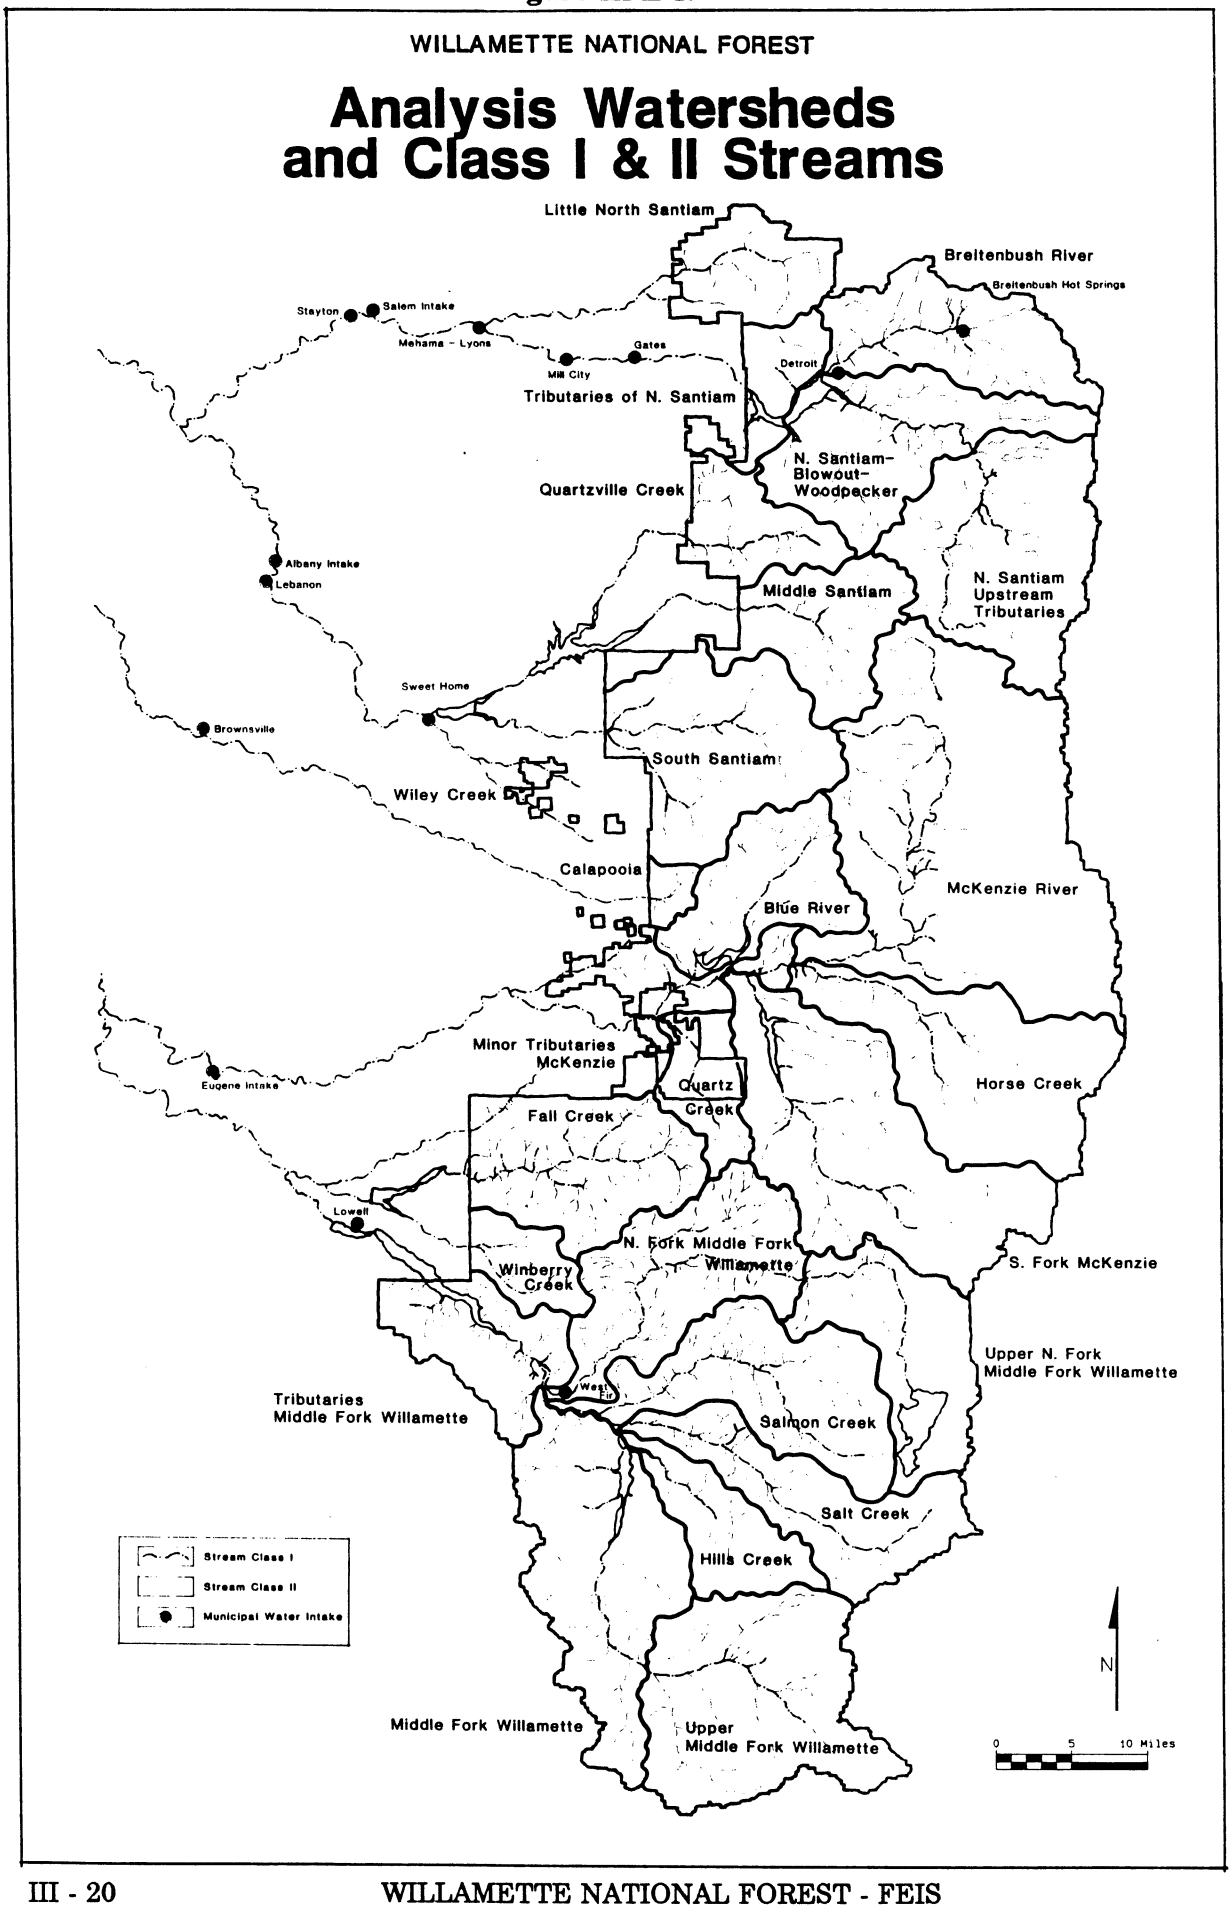
The Forest has no formal municipal watershed agreements, and consequently manages forested watersheds for multiple use purposes and values. None of the watersheds are afforded specific or special management prescriptions for the express purpose of protecting domestic water supplies over and above standard management practices to ensure water quality.

The quality of water delivered to the withdrawal facilities for the watersheds with 100% Forest land has been of sufficient quality that the Forest has not been approached to develop formal municipal watershed agreements. The quality of water delivered to the largest cities; Eugene, Salem, Albany, Lebanon, and Sweet Home depends not only on Forest Service practices, but also several private landowners, the Bureau of Land Management, Oregon State Department of Forestry, and the US Army Corps of Engineers reservoir management programs (see Figure III-E-5).

Currently there are four hydroelectric facilities on the Forest, operated by the US Army Corps of Engineers (COE). These are Lookout Point, Hills Creek, Cougar, and Detroit Dams. Fall Creek and Blue River Dams are being studied for retrofitting with hydroelectric generating capacity. Eugene Water and Electric Board (EWEB) operates a hydroelectric generating system in the upper McKenzie River basin, at Carmen, Smith, and Trailbridge Dams. The Forest supplies greater than 75% of the water used to operate these seven facilities. The combined capacity of the seven facilities generates sufficient power to meet the needs of thousands of households each year.

Passage of the Public Utility Regulatory Policies Act in 1978 encouraged the private development of small power projects. The act requires electric utilities to interconnect with and purchase power from these small sites. Currently one project is on line at Falls Creek on the Sweet Home Ranger District generating 4 megawatts of power. Two additional public projects are operating and three other sites on the Forest are at various stages of study or application for licensing from the Federal Energy Regulatory Commission (FERC). If all of these sites were to be completed, they would produce an estimated 132 megawatts of power.

Figure III-E-1.



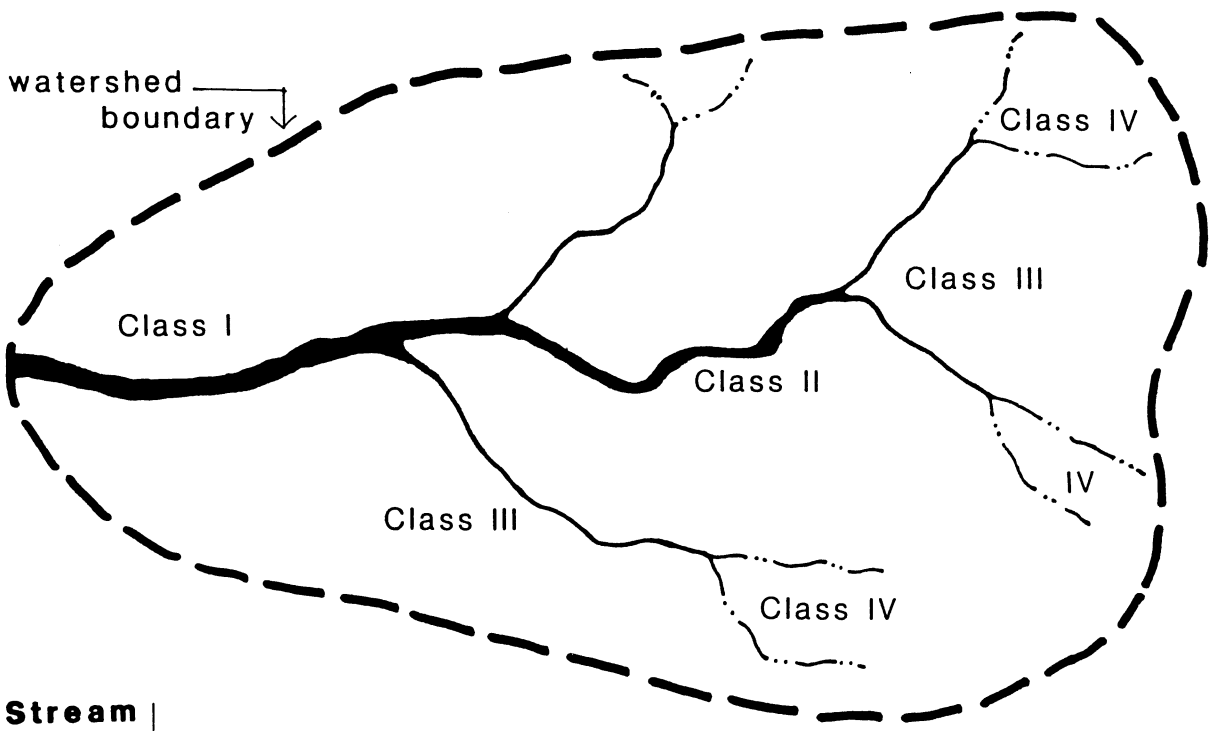


Figure III-E-2 Stream Heirarchy

Stream Class	Qualifying Criteria
I	municipal/ domestic supply, large volume, anadromous fishery
II	resident trout fishery, significant volume to affect Class I
III	perennial stream, no fish present
IV	intermittent flow

The Forest stream classification scheme is based on flow volume and the beneficial uses of a given stream, i.e. municipal/domestic drinking supply, recreation, fisheries.

For a complete discussion see FSM 2526 Willamette Supplement 3 5/81.

There are three fish hatcheries located on the Forest, and five other fish production facilities located within 5 to 15 miles of the Forest boundary (Stewart and Skeesick 1982). The eight facilities consist of seven hatcheries and one catch/release site and were developed either as required mitigation for construction of the flood control reservoirs, or to augment natural fish production. Marion Forks and Willamette salmon and trout fish hatcheries are located on Forest land and operate under special use permits.

Without the suitable quality water produced from the Forest, the eight facilities would not be able to operate in an economically efficient manner and still meet their mitigation obligations (Stewart and Skeesick 1982). The quality of the water at Marion Forks and Willamette salmon and trout hatcheries is directly attributable to Forest practices and land use activities; at the other five facilities the activities of private landowners and the operation of upstream reservoirs also affect the quality of water received.

Approximately 71.5% of Forest recreation is water oriented, generating an estimated value of $17,359,000 annually. Figure III-E-6 lists water oriented recreation use by various categories.

Table T004. Water Related Recreation Use (III-E-6)

	Developed Use (MRVDs)	Dispersed Use (MRVDs)	Wilderness Use (MRVDs)	Total Use (MRVDs)	Percent of Forest Use
Camping	812.8	154.6[1]	60.3	1027.7	35.6
Organized Camping	69.2	--	--	69.2	2.4

[4]Assumes 50% of driving/sightseeing is associated with streamside areas.
[5]All other values represent 100% of the respective activity.

Water Yield

Streamflow from the Forest forms the headwaters of the North and South Santiam, McKenzie, and Middle Fork Willamette rivers, and reflects the precipitation regime of the Pacific Northwest. The regions' maritime climate is characterized by a distinct winter rainy season, when 90% of the 40 to 90 inches of precipitation falls from October to May. Approximately 85% of annual runoff occurs during the 5 months between November 1 and March 31. Annual runoff is measured on the basis of "water years", which begins October 1, runs through September 30 of the succeeding year. Current demand for water in the other 7 months of the year is being met with only 15% of the annual water yield. This includes during the summer low flow period (July-September), when streamflow is less than one-tenth of the average winter flow.

Water yield, or the volume of runoff from the Forest, is the result of the balance between precipitation and physical characteristics of the land. The type, amount, distribution, and timing of precipitation, as well as land form, vegetative cover and soil type influence the volume and timing of runoff. Total water yield from the Forest was estimated at 8.9 million acre feet per year by Hubbard (1983). Annual water yield by watershed is listed in Figure III-E-7.

Table T005. Water Yield by Watershed (III-E-7)

		Area		Water Yield

Water Quality

Protection of water quality and quantity on the Forest is required by the laws which created the National Forests, by the Clean Water Act, the Federal Water Pollution Control Act (FWPCA) and amendments, and most recently by the National Forest Management Act. The FWPCA permits the States to enforce State and local water quality laws on Federal land, and the National Forest Act states that National Forest lands will be managed "to prevent detrimental changes in water flow and water quality." In addition, many Federal and State laws regulate the establishment and existence of water rights on National Forest land. For additional information on relationships with the plans and policies of others see Chapter IV, Water.

Water flowing from the Forest in the four major river basins is generally of high quality, and supports a variety of uses. Principal water quality concerns are water temperature, turbidity, sediment, introduced chemicals, and bacterial contaminations. Specific water quality concerns on the Forest vary by time of year. High turbidity and suspended sediment concentrations are primarily associated with storm runoff, and peak during the autumn and winter months. Water temperature peaks occur during the summer minimum flow period. Peak concentrations of bacterial contaminants generally occur during the summer months in conjunction with warm water temperature and high recreation use. Introduced chemical concentration occurs by chance at virtually any time of the year, either by accident during application or transport on the highways or railroad which bisect the Forest.

Water temperature is a critical parameter for the fish that populate Forest streams, and is directly related to the amount of stream surface area exposed to direct solar radiation. Since water temperature is an important factor affecting the beneficial uses associated with Oregon's salmon and trout fisheries, the State of Oregon has established a water quality standard for water temperature. The standard requires the maintenance of water temperature at 58 degrees Fahrenheit or less, or at existing temperature if naturally greater than 58 degrees Fahrenheit.

The Forest is far enough south that long daylight periods and low summer stream flows may result in critical stream temperatures. Maximum daily water temperatures in July and August in streams draining watersheds with elevations predominantly below 4,000 feet, can reach the mid 60 degrees Fahrenheit to low 70 degrees Fahrenheit. These temperatures may be detrimental to salmon and trout, whose optimum feeding, rearing, and spawning activity takes place between 50 degrees Fahrenheit and 57 degrees Fahrenheit.

Salmon Creek and Fall Creek are two watersheds in which water temperature is of particular concern as compared to most of the watersheds on the Forest. The Oregon Department of Fish and Wildlife operates two hatcheries on water withdrawn from Salmon Creek. Water temperature is critical in terms of optimizing the economic efficiency of the hatcheries; an increase of a few degrees in water temperature can dramatically increase the cost per fish produced. Fall Creek, along with principal tributaries, Little Fall Creek and Winberry Creek, contains an important population of wild winter steelhead trout. The Fall Creek watershed tends to have lower minimum flows than other watersheds of similar size on the Forest. As a result, Fall Creek and its tributaries are more sensitive to activities which remove shading vegetation and potentially increase water temperatures. Past forest management activities and flood events have removed riparian vegetation resulting in increased summer peak stream temperatures in some streams on the Forest. Recent research and Forest monitoring have documented an apparent drop in peak summer water temperature in Salmon, Fall, and Winberry Creeks (Beschta and Taylor 1986), (Total Resource Inventory, Aquatic Subsystem files). This decline is attributed to the shading effect of recovering riparian vegetation.

The most visible characteristic of water quality is suspended sediment which affects the clarity of water. Sediment concentrations and resultant turbidity (clarity), are the water quality attributes most readily and frequently influenced by natural events and human activity. Sediment is primarily eroded soil transported to the stream system, originating from a variety of natural and human-induced sources. There is a natural amount of sediment in streams, which is a necessary and vital part of the aquatic ecosystem. Salmon and trout, for example, require gravel and cobbles of specific sizes and amounts to reproduce.

Sediment is made up of two main components that are defined as follows:

- Suspended sediment--material that the stream carries within the column above the bed or bottom of the stream.

- Bedload sediment--material, ranging in size from sand to gravel and boulders that is moved at or just above the bed of the stream.

The amount of sediment in a stream at any given time is dependent on stream flow and sediment supply. The sediment supply is a function of the amount, type, timing, and location of ground disturbing activities and natural events which expose soil to erosion. Of equal importance is the efficiency of the watershed in transporting the eroded soil to and through the stream system.

High turbidity and/or suspended sediment may cause reduced potability, increased domestic use treatment costs, and reduced aesthetic quality, angler success, and fishery productivity.

Sediment thresholds are difficult to discern, tend to be watershed specific, and are unique to the use in question. The potential significance of sediment elevated above natural levels is well documented by research (Swanston et al. 1986; Triska et al. 1982; Martin et al. 1981).

High bedload and deposited fine sediment may result in reduced fish habitat quantity and quality, reduced pool volumes, fish spawning success, and fish prey base. High bedload and deposited fine sediment may also result in reduced channel stability due to reduced channel capacity; increased water temperature, due to shallower, more readily heated channels; increased rates of sediment deposition in reservoirs, and increased cost of hatchery operations.

For eroded soil to be of consequence to water quality, it must be delivered to the stream channel. All watersheds are not equal in ability to transport eroded soil to a stream.

Thirteen watersheds have areas of channel instability or sediment related effects. They are Fall, Winberry, Quartz, Quartzville, Wiley and Hills Creeks and the Breitenbush, South and Middle Santiam, Calapooia, Middle Fork Willamette, Upper Middle Fork Willamette, and North Fork Middle Fork Willamette rivers. Seven of these watersheds are heavily influenced by other ownerships; Quartz and Wiley Creeks, and the Middle Santiam, South Santiam, Calapooia, Middle Fork Willamette and Upper Middle Fork Willamette rivers. All 13 of these watersheds currently support a wide variety of uses, ranging from domestic water supply to anadromous fisheries (see Figure III-E-4).

The presence or absence of large woody debris such as downed logs and limbs is an important factor in whether sediment inputs affect channel stability or aquatic habitat. If sufficient large woody debris is present, a stream may be able to accommodate an increase in sediment without suffering a decline in fish habitat (Heller et al. 1983).

Large woody debris provides a stream a means to dissipate the waters' energy; store needed sediment and fish spawning gravels; and scour pools (Keller and Talley 1979).

Large woody debris pushes flood water on to adjacent floodplain areas reducing the amount of damage to the stream channel. A stream that is lacking in large woody debris tends to be more uniformly broad and shallow with fewer pools and spawning gravel accumulations and is more prone to channel scour by flood flows (Keller and Talley 1979). A bedrock confined channel without large woody debris may scour down to an underlying bedrock pavement becoming devoid of habitat for most aquatic organisms.

In general, the mature stands of trees along the fish-bearing Class I and II streams on the Forest contain trees of sufficient size to provide large woody debris. Due to past practices, however, the amount of large woody debris within the streams has been reduced. Merchantable wood was salvage logged from streams and/or nonmerchantable material was removed to improve fish passage, minimize bank

erosion, and protect improvements such bridges and culverts. In addition, standing timber and snags, which would have been the most likely to fall into the stream to become large woody debris were salvage harvested particularly if they were in close proximity to a road (Stewart and Skeesick 1982).

As of 1981, approximately 39% or 1,313 miles of perennial Class I, II and III streams were adjacent to harvest units or roads (Stewart and Skeesick 1982).

As a result of these practices, most streams and rivers on the Forest are considered to be deficient in large woody debris volume and distribution. As a consequence, many have experienced channel scour and bank erosion during flooding and have reduced fish habitat quality and quantity compared to natural levels.

The Breitenbush River is currently being studied to determine the effects of past management of large woody debris and the options for future management. The Breitenbush River has a sensitive channel system comprised of small bedload material. Recently the river has tended to migrate across its floodplain, eroding streambanks, and causing damage to property and fishery values.

Two other areas on the Forest have exhibited similar tendencies. In 1983, Lyons and Beschta documented that deposition of sediment in the Upper and Middle Fork Willamette River above Hills Creek had resulted in the destabilization of the channel and that the effects still persisted. Wiley Creek and the Calapooia River have a similar problem; these two drainages contain only small proportions of Forest land.

In the Quartzville Creek, South and Middle Santiam River watersheds, aquatic habitat has been degraded in the main channel as well as in many tributary streams. Stretches of stream with sediment deposition and channel migration are common resulting in greatly reduced pool volume (Stewart and Skeesick 1982; stream surveys in Total Resource Inventory, Aquatic Subsystem Files; DEQ Report 1978).

Fall, Winberry, Hills, and Quartz Creeks and the North Fork Middle Fork Willamette River differ from the other drainages cited in that deposited sediment is not generally evident. In these drainages the presence of bedrock control on the channel, combined with a limited amount of large woody debris, has apparently provided a mechanism by which sediment is flushed from the stream system. These streams have higher turbidity levels and tend to be deficient in pool volume, as well as spawning gravel.

Future Trends

The greatest potential for increasing the usable supply of water at points of principal demand is through the increase in storage capacity of reservoirs. This approach allows for the delay of runoff until the time of greatest demand. The potential for additional water storage on the Forest does exist if new dams were to be constructed.

Existing dams could be upgraded to increase the production of electrical power (Klingeman 1980). In addition, an estimated 2,300 megawatts of power could be available 50% of the time with the installation of low head hydro-projects on many of the Forest's smaller rivers and streams (Klingeman 1979).

Recreation use of the surface waters is expected to increase by 10 to 25%. As a result, a shift in the distribution of experience level would occur because of an increase in the density of recreation users.

Water use potential is contingent upon water supply availability, development of water structures, and changes in the distribution of recreation experience levels. On-Forest water supply is expected to exceed

demand well beyond the planning horizon. Off forest, much of the water has been legally claimed, though it is likely that the claimed water rights exceed the actual use.

AIR

Air directly affects plant, animal and fish habitat, and contributes to the scenic and recreational attributes of the Forest and nearby communities. Clean air is a renewable resource, influenced by a number of factors including the weather, topography, and emission sources. The mountainous Forest lies approximately 80 miles east of the Pacific Ocean, between the Willamette Valley and the desert plateau of Central Oregon. The airshed is generally under the influence of maritime westerly winds.

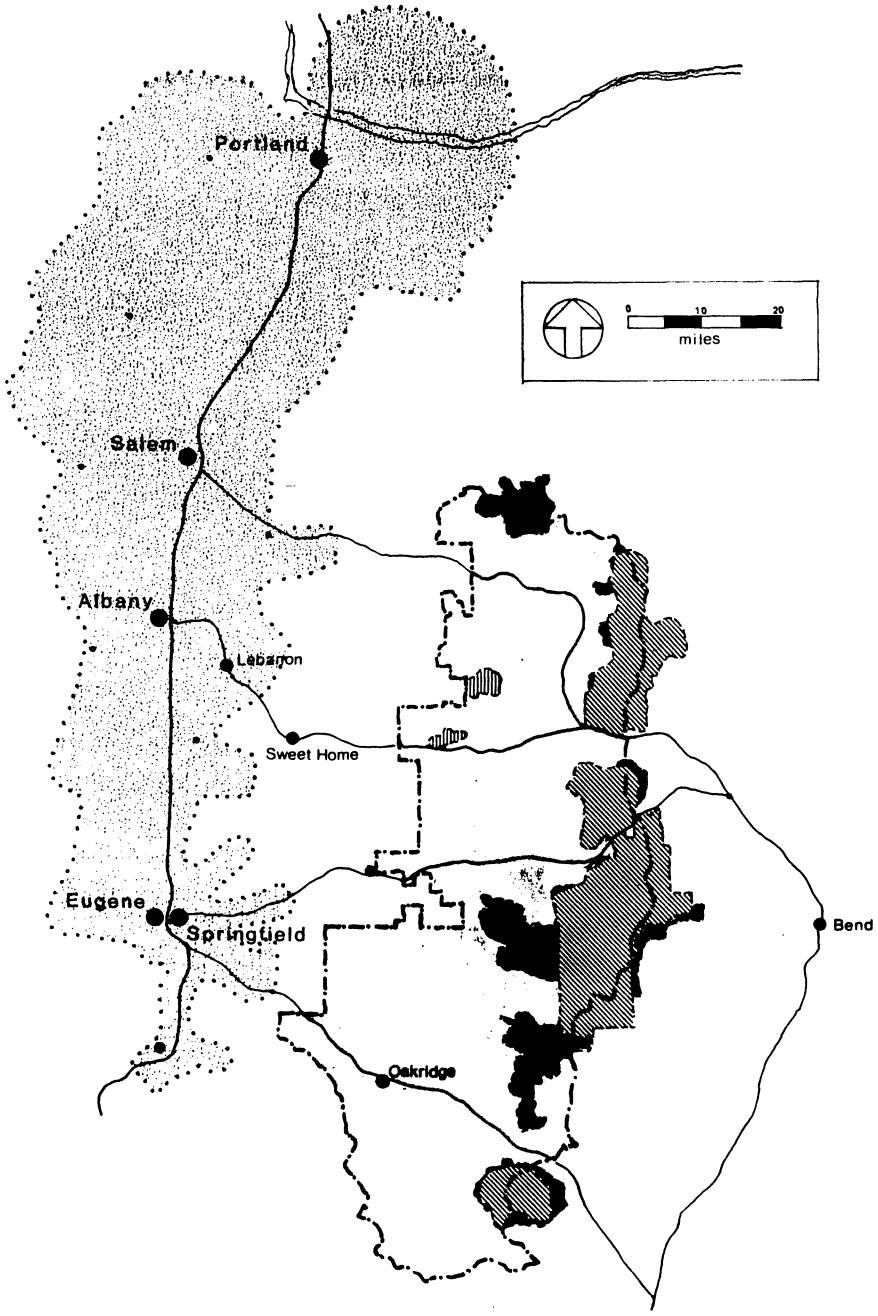
Historic Trends

The condition of the airshed over and adjacent to the Forest has always been affected by smoke and odor from fires and to a lesser degree by dust from roads and unvegetated fields. Early in this century, many of the large catastrophic fires in Western Oregon had their origin in logging slash. In response to these timber operations related fires, the State of Oregon enacted stringent laws requiring private landowners to abate the slash resulting from logging activities. Thus, slash burning became an early forestry practice in Oregon.

Since the 1940s, prescribed fire has been extensively used to dispose of slash created from logging activities on the Forest and on lands adjacent to the Forest. Prior to the 1970s, broadcast burning during the fall was the predominant use of prescribed fire. Burning of machine and hand piled slash was also done to a lesser degree, but there was little use of prescribed fire to meet other land management objectives besides hazard reduction and site preparation.

Residents of the Willamette Valley expressed objections to the reduced air quality in the late 1960s and early 1970s. Burning of grass fields in the Willamette Valley was the original concern, but since most of the Forest slash burning was done in the fall and impacted the air quality of the Willamette Valley, it was also recognized as a contributor to the air quality problem. This concern resulted in State laws and smoke management practices which affected use of prescribed fire on forest lands including National Forest land.

The Oregon Smoke Management Plan was adopted by the Oregon Department of Forestry, federal land management agencies, and the Department of Environmental Quality (DEQ) in January of 1972. The objective of the Plan is "to keep smoke resulting from burning on forest lands from being carried to or accumulating in designated areas or other areas sensitive to smoke." The State Forester is responsible for the coordination and control of the Oregon Forest Smoke Management Plan.



The Clean Air Act designated all National Wildernesses established before August 7, 1977, as Class I. Examples of the Wildernesses that are Class I are Mt. Jefferson, Mt. Washington, Three Sisters, and Diamond Peak. All other lands in the state including any Wilderness additions made after August 7, 1977, are assigned Class II status with the state having redesignation authority. Figure III-F-1 shows the Federally mandated Class I areas, new Wildernesses eligible for Class I re-designation and smoke sensitive areas adjacent to the Forest.

The Clean Air Act, as amended in 1977, directs Federal agencies to comply with state and local regulations directed at preventing and controlling air pollution. The 1977 Amendment includes provisions to prevent significant deterioration of air quality in Class I areas. Class I allows the least increase in air quality deterioration, while Class III allows the pollution levels up to the National Ambient Air Quality Standards to be considered acceptable. The baseline concentrations for particulate matter and sulfur dioxide are being established. There are no Class III areas in the state.

Figure III-F-1.

WILLAMETTE NATIONAL FOREST

Areas of Air Quality Concern

LEGEND

WILDERNESS:
Federally mandated Class I area.

WILDERNESS ADDITIONS:
Federally mandated Class II -- eligible for redesignation to Class I.

WILDERNESS ADDITIONS:
Class II areas 10,000 acres -- not eligible for redesignation.

DESIGNATED AREA:
Oregon Smoke Management Plan

Outside of the Designated Areas populated communities in the Willamette Valley and in Central Oregon are also considered smoke sensitive areas.

The identification of unacceptable impacts is accomplished through the formal process associated with the Prevention of Significant Deterioration requirements of the Clean Air Act Amendments of 1977. This law targets Class I areas for protection and preservation of the area's air quality from fixed point pollution sources. The Air Quality Related Values (AQRVs) are features or properties of a Class I Wilderness that are affected in some way by air pollution. These can include, but are not limited to, odor, fauna, flora, water, and visibility. The Forest has the responsibility to protect these values. Visibility and the deposition of acid rain in the high lakes are currently of concern. Both are being monitored to determine the level of acceptable change associated with protection of AQRVs. Very little information is available about the affects of acid rain on the Forest.

Current Situation

Smoke from prescribed burning causes the most notable impact to air quality over the Forest. Other agencies and private land owners including the Forest contribute to this temporary condition. Although these are recurring activities, the impacts are generally temporary in nature because of the prevailing wind patterns that cleanse the air in the valleys and mountains on a regular basis. Air quality impacts from other Forest management activities are also temporary in nature and may result from dust and vehicular emissions from logging operations, public travel on Forest roads, or chemicals used for the control of insects, diseases and vegetative management. In addition to the impacts generated by Forest activities, the air quality of the area is also impacted by field burning smoke and by wind-borne dust from lands located off Forest.

Figure III-F-2 displays the number of acres treated by burning, the estimated tons of fuel burned, and estimated tons of total suspended particulates (TSP) in the resulting smoke. Since 1979, the amount of fuels treatment has averaged 14,170 acres a year. Since 1981 the decline in acres burned has paralleled the decline in timber harvest. During this same period an increase in spring burning and various specifications for the piling of unmerchantible material have also contributed to a reduction in TSP emissions by reducing the total amount of material burned on harvest units.

Several areas outside the Forest are identified in the Oregon Smoke Management Plan as smoke sensitive or "Designated Areas" within the influence of the Forest. The Smoke Management Plan calls for minimizing smoke intrusions into high population centers of air quality concern such as the Willamette Valley and Roseburg. The Willamette National Forest prescribed burning program is also managed to avoid intrusions into the Bend and Redmond population centers. In addition, during the months from mid-July to mid- September, a priority burning system is implemented in Western Oregon. This reduces the amount of prescribed burning on Forest land during the time when the most acreage of grass seed fields is being burned in the Willamette Valley.

Visibility is monitored on a continuing basis in a cooperative effort by the DEQ, National Park Service, and the Forest Service. It is measured by atmospheric discoloration and change in visual range. Instruments located on Black Butte and near Big Lake monitor visibility for the Mt. Jefferson, Mt. Washington, and the Three Sisters Wildernesses. Air Quality in the Diamond Peak Wilderness is monitored at Cinnamon Butte. Data from this monitoring program indicated that prescribed burning was a significant contributor to visibility impairment. As a control strategy the Oregon State Implementation Plan imposes a prohibition on prescribed burning in the Central Oregon Cascades from Lane County north, except under specified conditions, from July 4 through Labor Day. The Forest has implemented a policy of no prescribed burning during this period without the prior approval of the Forest Supervisor. This prevents significant deterioration of the airshed during the heavy use period in the Mandatory Class I areas.

Table T007. Acres Treated by Burning (III-F-2)

Year	Broadcast Burn Acres	Pile & burn Acres	Total Acres	Tons Consumed [1]	Tons TSP [2]
1979	6,235	10,123	16,358	654,320	16,358
1980	7,038	13,056	20,094	803,760	20,094
1981	7,741	8,781	16,522	660,880	16,522
1982	4,803	7,497	12,300	492,000	12,300
1983	6,939	4,700	11,539	461,560	11,539
1984	6,706	4,171	10,877	435,080	10,877
1985	7,808	3,711	11,519	460,760	11,519
TOTAL	47,270	51,939	99,209	3,968,360	99,209
AVERAGE	6,753	7,420	14,173	566,909	14,173

[1]Based on Forest estimate of 40 tons/acre consumed for broadcast and pile burning.
[2]Based on 50 pounds of total suspended particulate (TSP) emissions per ton of fuel consumed (Ward, McMahon, and Johansen 1976).

Visibility is measured by atmospheric discoloration and change in visual range. Monitoring of the Diamond Peak Wilderness indicates that the visual range is quite good. Median summer ranges of visibility were from 90 to 102 miles. More study is required from this site. The other three Wildernesses showed a median visual range of 92 miles (DEQ 1985). Detailed monitoring data and other information about air quality is available through the DEQ Air Quality Division or at the Forest Supervisors Office in Eugene.

Air quality impacts from woodheating are different than those associated with prescribed burning of logging slash. Most of the wood that is burned as firewood comes from the surrounding forested lands. Wood is made available to residential woodheating users from logging residues, rather than being burned in a prescribed fire. As a consequence, air quality impacts shift to the urban setting. While slash burning generally creates a visibility issue over and adjacent to the Forest, woodstoves contribute to air quality impacts which are a human health concern. Smoke particles emitted from incomplete combustion of wood may have relatively high concentrations of compounds that are known and suspected carcinogens.

Winter air stagnation resulting in air pollution from woodstoves is an increasing problem in the populated valleys of the region. Firewood is usually burned in the winter during periods when colder air and temperature inversions occur. The location of burning shifts from generally higher altitudes, which are more favorable to dispersion and remote from other air pollution sources, to lower elevations with less dispersive conditions and in proximity to other pollution sources.

The Lane Regional Air Pollution Authority estimated that 92,000 cords of wood were burned locally in the Eugene-Springfield area in 1984. This was an increase of 30% over 1982 estimates. Two areas, Oakridge and Northwest Eugene, experienced violation of the secondary Federal standard of total suspended particulates in 1984. In December of 1985, there were violations of the primary standard (health-related). As of July 1, 1986, State law requires stringent emission controls on all wood burning stoves sold within the Oregon.

Future Trends

Since the mid-1970s there has been an increasing interest in utilizing residues as an alternative energy source or for other products. As a result, there has been some criticism of current slash burning practices because the perception is that a valuable resource is being wasted. The fossil fuel equivalent of the slash created on the Forest annually is around 3.4 million barrels of oil, which does represent a significant potential energy resource. In response to this issue and to internal concerns, the Forest, in cooperation with other government agencies and industries has initiated several pilot projects and studies to determine the feasibility and technology necessary to utilize wood residues economically. Utilization of logging residues is expected to increase as it becomes more economically feasible, thus reducing the amount of residue requiring removal. Utilization will continue to be balanced with the need to have vegetative material on site to ensure nutrient recycling and continued site productivity.

The number of acres treated through prescribed fire may be reduced in the future due to limitations imposed by air quality considerations. As a result of a reduction in burning, other more costly treatment methods may be necessary to reduce the amount of logging residues for site preparation and hazard reduction.

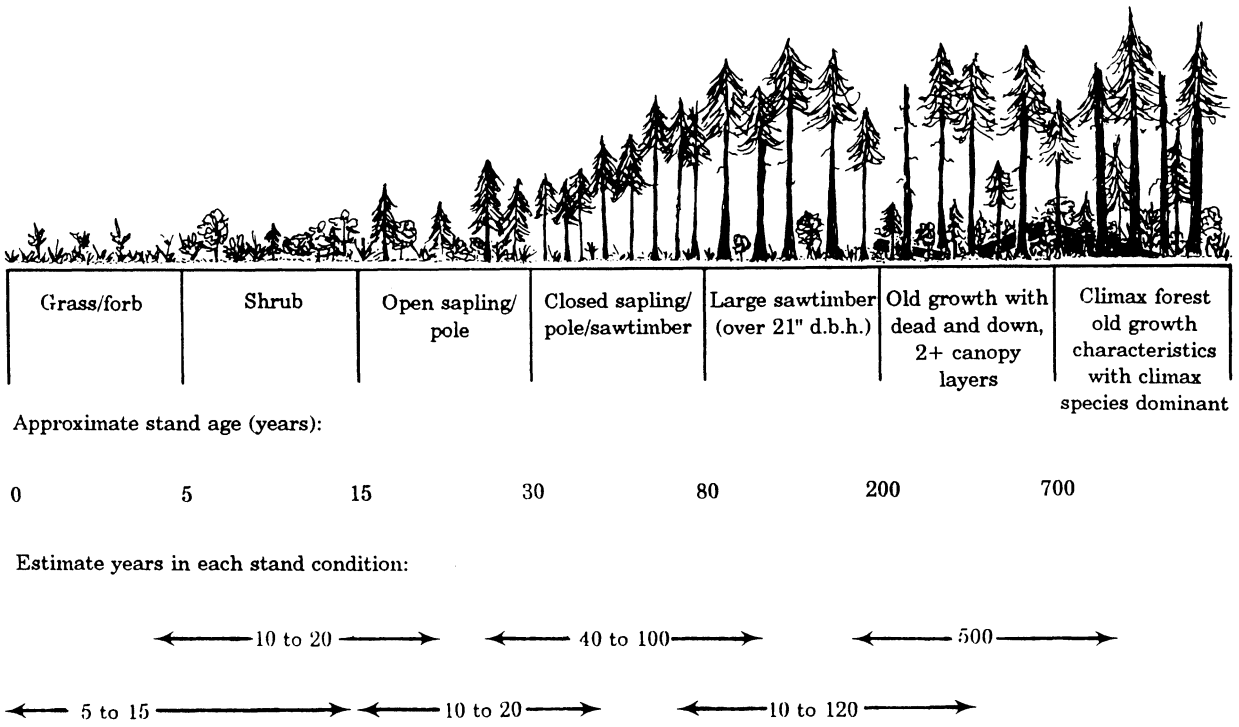
Smoke from residential woodheating will be more of a concern as more people use wood to heat their homes. This wood smoke along with automobiles and industrial emissions will continue to create health hazards during periods of air stagnation.

In the near future, there will be regulations covering fine particulates, redesignation of Wilderness Class II to Class I, inventories of values associated with AQRVs, air pollution source identification, pollution damage determination, and establishment of limits of acceptable change in air quality. Research will determine how to reduce emissions.

Visibility will improve by implementation of current regulations and as regulatory smoke management requirements become more strict. Overall, emissions from prescribed burning are expected to remain at or below current levels.

VEGETATION

The vegetative cover of the Forest provides habitat for wildlife and protection to streams and rivers while stabilizing soil, producing oxygen and humidity, and serving as a vast storehouse of energy. Plants modify the air temperature by providing protection both from the summer heat and the winter cold and wind. The lush richness on the plants on the WNF provide an outstanding array of recreational settings.



Plant populations which have existed on a site for a long period have come into balance with, and are useful indicators of, their environment. Classification of long-term, stable plant communities, combined with soils information, is a tool for evaluating site productivity and determining future implications for management.

This section of Chapter III discusses plant communities, riparian zones, old-growth, and threatened, endangered and sensitive plant species on the Forest. Timber and its use as a commodity resource is described in Chapter III, Timber.

Plant Communities

There are a number of plant communities on the Forest including those within coniferous forests, meadows, subalpine and alpine parklands and wetlands. Succession is the natural process by which one plant community or stand condition changes into another. (See Figure III-G-1, Successional States.) As Forest tree species develop and mature, whether they are deciduous or coniferous, the canopies close and herbs and shrubs that require direct sunlight start disappearing. Temperature, moisture, light, and available nutrients are the factors which determine those plants which can most effectively occupy a site. After a relatively long, disturbance-free period, only those plants which can grow and reproduce in competition with their neighbors remain. On the WNF old growth conditions may develop in undisturbed stands long before development of a climax forest occurs. Unless modified by disturbance, the growth of vegetation continues until the climax stage is reached. Climax forests rarely occur in the Pacific Northwest. Although catastrophic natural disturbances are relatively infrequent pioneer conifer species can be very long lived (Hemstrom 1979, Henderson and Peter 1981, Burke 1979, Morrison 1984).

Figure III-G-1. Successional States

Successional pattern of stand conditions after clearcutting and broadcast burning.

The vegetation of the Forest can be grouped into five major coniferous series and several other series which are dominated by grasses or shrubs. The coniferous series are characterized by both trees and understory vegetation. Within each series, there may be several plant communities or associations. These plant associations are indicators of distinct vegetative response and site productivity. For a detailed description of plant associations and their implications for resource management reference the *Preliminary Plant Association and Management Guide* for the Forest (1987).

The following descriptions of the vegetative series on the Forest rely on Hemstrom, Logan, and Pavlat (1987) and Franklin and Dyrness (1973). Plant distribution is dependent upon a number of factors including species characteristics, precipitation, temperature, and landscape patterns.

The Douglas-fir series occurs on warm, relatively dry sites across the Forest. This series is a northern extension of the Sierran mixed conifer forests common in the southwestern Oregon Cascades, Siskiyou Mountains, and Sierra Nevada Range (Franklin and Dyrness 1973). The Douglas-fir series is rare north of the McKenzie River, occuring only on steep, south-facing slopes with thin, rocky soils (Means 1980). South of the McKenzie River, climax Douglas-fir sites are relatively common at lower elevations on southerly exposures, especially in the Rigdon Ranger District. The major climax tree species include incense cedar and grand fir, but Douglas-fir generally dominates both the canopy and regeneration layer. Western hemlock is scarce or absent. Important species include: Douglas-fir, incense cedar,

sugar pine, ponderosa pine, big leaf maple, oceanspray, poison oak, tall Oregon grape, dwarf Oregon grape, salal, whipple vine, grasses, snow queen, yerba buena, and others typical of Southwestern Oregon.

The Douglas-fir series occupies the driest environments capable of supporting closed forests on the Forest (see Means 1980 for a more extensive discussion). High summer temperatures increase environmental stress. Precipitation is relatively low (45 inches from November to May). Winter snow is usually transient. These factors add up to a long, dry, warm growing season. On the driest sites, conifer canopies give way to open woodlands of Douglas-fir, Oregon white oak, pines, and grasses.

On slightly more moist sites, the Douglas-fir series melds into the western hemlock series. In this transition area, grand fir and western hemlock are co-climax on many sites south of the McKenzie River. This transition area comprises the grand fir series. Franklin and Dyrness (1973) did not consider grand fir climax types separately from the rest of the mixed conifer zone in Southwestern Oregon. Several grand fir plant associations were separated from the Douglas-fir and western hemlock series because grand fir appears to be the dominant climax species and grand fir series have often been described in Southwestern Oregon (Atzet and Wheeler 1984) and east of the Cascade Crest. Climatic information is generally not available, but conditions should be intermediate between the Douglas-fir and western hemlock series.

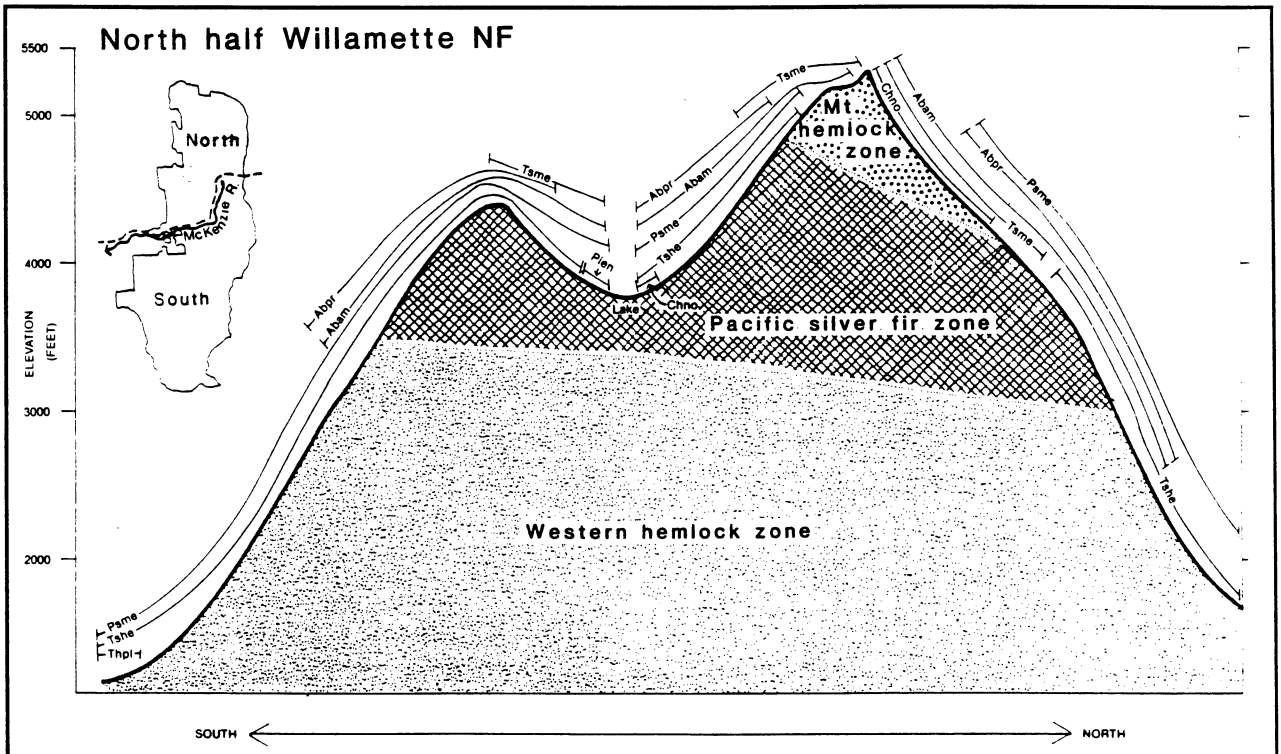
The grand fir series most frequently occurs on relatively dry, south-facing slopes and excessively well-drained river terraces. It extends into upper elevations south of the McKenzie River, where it mixes with the Pacific silver fir series. Important species include a mixture from the Douglas-fir series, the western hemlock series, and the Pacific silver fir series.

The bulk of lower elevation forests fall into the western hemlock series. In the Cascades, the western hemlock series extends from British Columbia south to the divide between the North and South Umpqua rivers (Franklin and Dyrness 1973). Important species include: Douglas-fir, western hemlock, western redcedar, big leaf maple, vine maple, dwarf Oregon grape, salal, rhododendron, swordfern, vanilla leaf, oxalis, twinflower, and redwoods violet.

Climatic conditions of the western hemlock series reflect a strong maritime influence, with mild, wet winters and relatively dry, sunny summers. Temperatures range from slightly below freezing in winter to 90 to 100 degrees Fahrenheit in summer. Precipitation amounts vary from about 60 to over 100 inches per year, mostly falling as rain or snow in the winter. Winter snowpacks are not usually deep nor long lasting.

The Pacific silver fir series occurs on the western slopes of the Cascade Range from British Columbia south to near the southern end of the Forest (Franklin and Dyrness 1973). The Pacific silver fir series dominates upper-slopes (3,000 to 5,500 feet) on the Forest mixing with the mountain hemlock series at the higher elevations. Important species include: Douglas-fir, noble fir, Pacific silver fir, mountain hemlock, western hemlock, lodgepole pine, vine maple, dwarf Oregon grape, big leaf huckleberry, Alaska huckleberry, rhododendron, grouse huckleberry, Cascades azalea, foamflower, false solomon's seal, queencup beadlily, dogwood bunchberry, sidebells pyrola, and beargrass.

Most of the annual precipitation in the Pacific silver fir and mountain hemlock series falls in winter and accumulates as a deep snow pack at upper elevations. Mean maximum air temperatures usually occur in August and range from about 75 degrees Fahrenheit to about 63 degrees Fahrenheit at the transition to the mountain hemlock series. Growing seasons are short at upper elevations and summer frost frequently occurs in openings, particularly on gentle topography (Halverson and Emmingham 1982). Moisture stress can be higher in seedlings planted in cold soils because root growth and function are impeded (Halverson and Emmingham 1982).



Shrub and herb distributions change gradually from the north to the south end of the Forest. Fool's huckleberry and Cascade azalea are uncommon south of the North Santiam River and rare south of the McKenzie River. Devil's club is not widespread south of the McKenzie River (except in the Little Fall Creek drainage on the Lowell Ranger District) but is relatively common on the Detroit and Sweet Home Ranger Districts. Species characteristic of dry sites in the Douglas-fir series are locally common on the Rigdon and Oakridge Districts but rare farther north. Most notable among these are ponderosa pine, sugar pine, incense cedar, tall Oregon grape, poison oak, and whipple vine.

Nonforest types vary from small meadow openings in a forest matrix to rock cliffs, avalanche chutes, and extensive alpine and subalpine parklands. In general, stable nonforest communities indicate extreme environmental conditions: extremely rocky substrates, extremely dry or wet areas, extremely severe winter conditions, etc. Some nonforest openings are the result of disturbance in otherwise forested conditions. In these cases, down logs, abundant charred wood or other signs of the previously existing forest are usually present. Some openings may be the result of heavy domestic livestock grazing; others were caused by humans who controlled the tree or shrub vegetation. Historically their primary use was to feed livestock, particularly sheep (i.e., Mutton Meadows and Rigdon Meadows). Now elk and deer feed in these meadows.

There are two kinds of wetland communities. Soils supporting these communities are saturated with moisture a major part of the year. Herbaceous wetlands have less than 60% woody cover and are generally dominated by rushes, sedges, and grasses. Hardwood and shrubby wetlands have more than 60% woody cover commonly dominated by alder, bigleaf maple, willows, or black cottonwood. The amount of woody vegetation is an important wildlife habitat characteristic. (See Riparian in this section.)

The north half of the Forest has a distinctly different distribution of conifer species from that south of the McKenzie River. (See Figure III-G-2.) At the south end of the Forest, species representative of the Sierran mixed conifer zone (Franklin and Dyrness 1973) become common. Most species shifts relate to precipitation and temperature patterns. For example, vegetation of the Oakridge and Rigdon Ranger Districts reflects significantly drier climatic conditions than those farther north. The Pacific silver fir series is not as widespread on these Districts and is often replaced by grand fir and Douglas-fir series on south-facing slopes. Alaska cedar is restricted to high elevation cirques and cold air drainage areas at the south end of the Forest but is more widespread on the Detroit Ranger District.

Disturbance, or lack of it, may be the determining factor in the development of a plant community toward climax but more often it affects the structure of that community. Wildfires started by lightning and trees blown down by severe isolated windstorms have always been a part of the natural cycle affecting the structure of plant communities on the Forest. Flooding, landslides, volcanic activity, and snow avalanches are other natural disturbances that have significant but more local impacts on plant community structure. Although such events may appear catastrophic at the time they occur, they too are a part of the natural cycle responsible for the plant communities that exist on otherwise undisturbed areas.

In Western Oregon, and on the Forest, the mix of plant communities and stand conditions within communities varies considerably, often over relatively short distances (Maser et al. 1981). Outside of designated Wilderness much of this variation results from timber production and harvest activities.

Human activities have created a mosaic of different aged vegetation and altered plant structure over vast acreages.

The structure of a plant community may be determined either by the physical growth characteristics or by the size and age of plant species making up the community. For example, a grassland plant community provides completely different habitats than does a Douglas-fir community in its mature stage, but the same forest community in the grass/forb condition with fully stocked Douglas-fir regeneration provides habitats very similar to the grass land plant community. Forest plant communities, when altered by timber management programs, exhibit a variety of stand conditions.

Stand condition is the size, density, and species composition of a plant community after disturbance and at various time intervals following the disturbance. The grass/forb stand condition follows clearcutting or intense wildfire; trees such as Douglas-fir, are only 1- to 5-years old. The open sapling/pole stand condition may have many of the same plant species as the grass/forb stand condition, but it has trees larger than 1 inch d.b.h. (diameter breast height) and less than 60% crown cover. (See Figure III-G-1) Also see Figure III-W-9, Tentatively Suited Acres by Size Class, for tree size classification.

The following descriptions of stand conditions and time intervals are based on conditions that normally develop after broadcast burning clearcut units. Modifications of these descriptions may be required when used with other silvicultural treatments or plant communities.

The grass/forb stand condition lasts 2 to 5 years and occasionally 10 years. After timber harvest and/or slash removal, a unit may be largely devoid of vegetation for the first growing season. Resident herbs and new plants quickly dominate the site and give the unit a grass-forb appearance. Invading pioneer species are often non-native plants. The spread and establishment of noxious weed species is often associated with activities which result in the exposure of mineral soil. Shrubs and trees that sprout or are planted are not yet dominant. Seeding for erosion control or forage production may alter the species composition typically found in this stage. The grass/forb stage may also be prolonged where seeding of preferred species occurs. Brush species that colonize disturbed areas from seed may also be reduced.

The shrub stand condition often lasts 3 to 10 years but may remain for 20 to 30 years if tree regeneration is delayed. Shrubs become the dominant vegetation, providing a different habitat type for wildlife. Tree regeneration may be common, but trees are generally less than 10 feet tall and provide less than 30% of the crown cover. Past management has included reducing competitive vegetation to allow conifers to grow. Some shrub species may be pruned to produce more browse during this period.

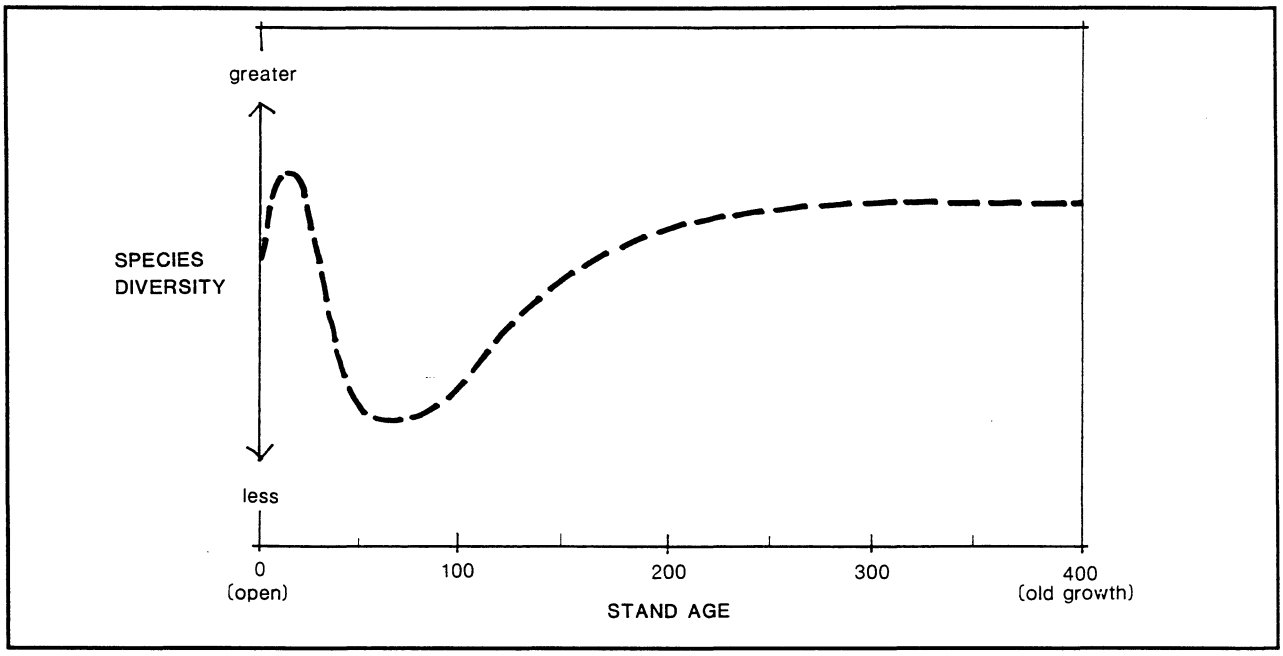
The open sapling/pole stand condition occurs when trees exceed 10 feet in height but still have less than 60% crown closure when they reach 1 inch d.b.h. A dominant shrub understory is common. This open sapling/pole condition is very different from closed sapling/pole where crown closure exceeds 60% at one inch d.b.h. or larger. The open sapling/pole stage may be bypassed if initial tree densities exceed 400 trees per acre. In addition, open sapling/pole can be the first stand condition after overstory removal in shelterwood regeneration. The grass/forb and shrub stand conditions may be bypassed because residual tree cover does not create adequate openings, and broadcast burning is rarely used to set succession back. Thus, little mineral soil is usually present for the establishment of herbaceous vegetation. On the other hand, the open sapling/pole stand condition can be maintained or created with thinning. Length of time in this condition depends on crown closure and subsequent stand treatment. It may last from 8 to 20 years.

Closed sapling/pole/sawtimber stand conditions have one item in common - very little ground vegetation because of a closed canopy. Tree crown closure will exceed 60% and often reaches 100%. Length of time in this stand condition can range from 40 to 100 years. The time is determined by rotation age

and thinning treatment. If stands are thinned and long rotations used, this stand condition can change to large sawtimber or eventually old-growth.

The large sawtimber stand condition is characterized by trees with an average d.b.h. of 21 inches or larger. Conifers usually exceed 100 feet in height, and crown closure is generally less than 100%, permitting the development of ground vegetation. With this stand condition under intensive timber management, diameters of trees may approach diameters of old-growth but the very large snags and high volumes of large down material characteristic of old-growth will be lacking. Natural large sawtimber stands can have nearly as much standing and down woody material as old-growth stands. Duration of this stand condition in managed forests is determined by rotation age and thinning treatments. If mortality and decay are regularly prevented by thinning, this condition lasts for many years; but such a stand will lack the snag component necessary for cavity nesters and the down woody material essential to long term soil productivity and habitat for many wildlife species.

Old-growth stand conditions are characterized by decadence of live trees, snags, down woody material, and replacement of some of the long-lived pioneer species such as Douglas-fir by climax species such as western hemlock. Stands often have two or more layers with large diameter overstory trees commonly older than 200 years. Crown closure is normally less than 100% (Franklin et al. 1981). This definition and reference is consistent with the Regional Guide and is presented in more detail under number three, Old-Growth, later in this section.



Shelterwood cutting generally does not generate the same kind of vegetative response as does clearcuting. A shelterwood is often designed to modify the microclimate of a site by retaining tree cover to enhance tree regeneration. This type of treatment is used more often in the Douglas-fir series where shading and seed fall are important to regeneration; and Pacific silver fir and mountain hemlock series where cold temperatures and soil are limiting. In some cases, advanced tree regeneration of climax species may comprise a majority of the seedlings. The shelterwood overstory is removed before the residual vegetation reaches the open sapling/pole stage, completely bypassing the grass/forb stage. As trees and vegetation grow and develop they display different characteristics. For example: between the open sapling/pole to the closed sapling/pole stage both plant and animal diversity sharply decrease; then as the trees and vegetation reach the large sawtimber and old-growth stages both plant and animal diversity again increase.

Vegetative Diversity

Diversity can be discussed in terms of richness (i.e., the variety of species) and evenness (i.e., the relative population levels of each species). In general, the early successional stages (grass/forbs) have the greatest diversity of plant species, but are dominated by a few species that are adapted to open conditions. The old-growth stands also have a variety of species present, but are dominated by species adapted to that environment. Stands of smaller trees around 50 years old have the least variety of species.

Figure III-G-3 shows the general relationship of species diversity and stand age. As a stand moves from an open condition into the grass/forb/shrub stage, there is an increase in the number of species. As shrubs and young trees begin to dominate, the canopy begins closing and blocks out the sunlight reaching the ground. This results in a fairly rapid decrease in the number of species as the less shade tolerant species die out. Management practices, such as commercial thinning, can mitigate this decrease by opening up the canopy and allowing more light to reach the ground. As a forested stands age and develop into the large mature tree stage, the canopy starts to open up. Diversity increases through this stage and then maintains a consistent, high level through the old-growth stage.

Figure III-G-3. Diversity by Stand Age (From Figure IV-4-1)

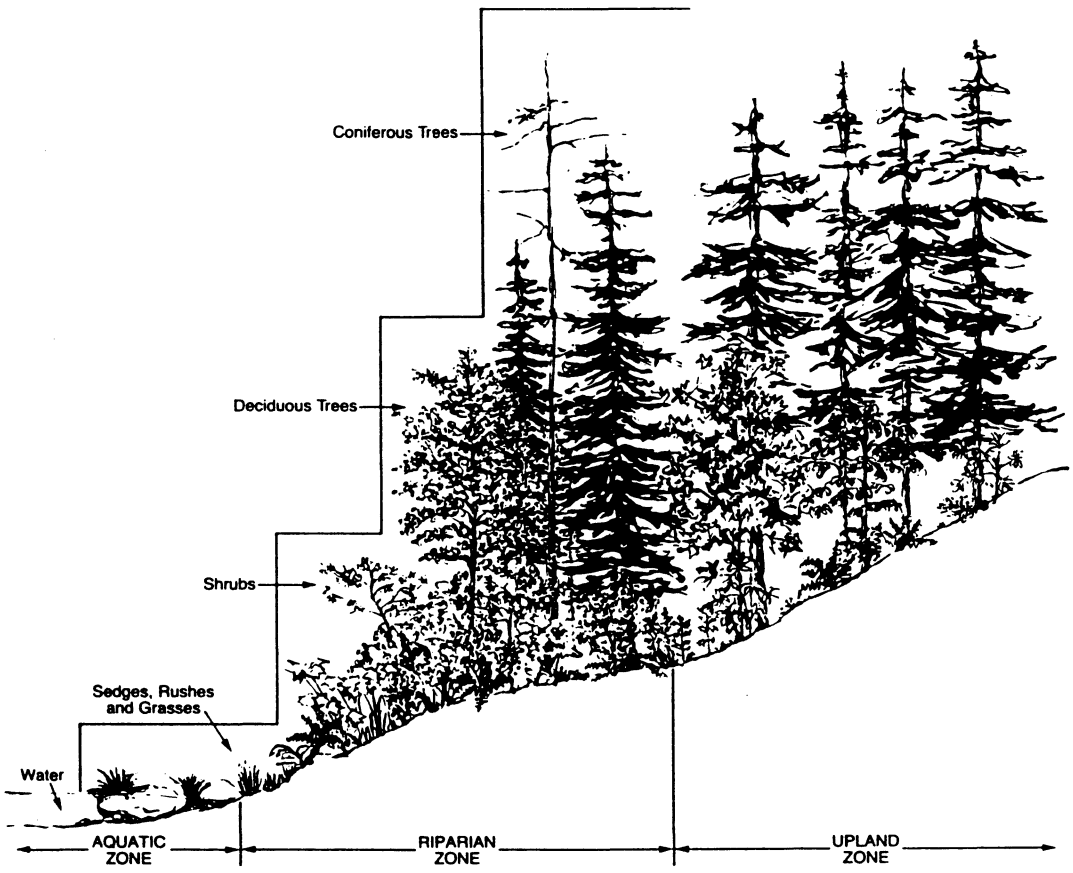
From a forest-wide standpoint, the greatest diversity would occur with a mix of old-growth and forest openings. This would provide habitat for species adapted to old-growth, and species adapted to all other stages, as well as those species that are adapted to the mixed environment of habitat block edges. The current Forest condition has about 36% of the forest in old-growth and mature stands of timber.

Riparian Zones

In the Forest, most riparian zones occur along streams and rivers. Riparian ecosystems, aquatic ecosystems, wetlands, lakeside zones, and floodplains will be jointly referred to as riparian zones. The terms "riparian zones" and "riparian areas" are used interchangeably in this chapter, but by strict ecological definition, they may not be the same in all instances. Figure III-G-4 displays the estimated acres of riparian habitat on the Forest.

Table T008. Riparian Habitat (III-G-4)

Stream Class [1]	Total (Miles/No.) [2]	Average Width (ft.)	Water Surface Area (ac.)	Riparian Width (ft.) [3]	Riparian Habitat (ac.)
I	426	42	2,168	400	20,650
II	940	14	1,595	200	22,800
III	1,295	[4]	[4]	200	31,400
IV	6,621	[4]	[4]	[5]	[5]
Lakes	270/391	--	11,233	150	4,910
Reservoirs	8	--	11,250	[5]	[5]
Wetlands [6]	--	--	--	--	23,950
TOTAL	--	--	26,246	--	103,710



[1] Refer to Chapter III Water for Stream Class descriptions.
[2] Stream miles from FORPLAN data base. Lake length is for shoreline.
[3] Riparian widths were taken from the riparian area process paper, Land and Resource Management Planning, March 4, 1983.
[4] These streams are less than 5 feet in width on the average and no surface area was computed.
[5] Value not determined.
[6] Area of wetlands is taken from the Soil Resource Inventory (SRI) layer the Land and Resource Management Planning Data Base for Soil Resource Inventory, soil type 6.

There are five important elements that define the character and function of the riparian zones. They are topography, vegetation, surface water, soil, and local climate.

Topography often determines the space available for the development of riparian or wetland plant communities. It is a primary indicator of the type, frequency, and magnitude of erosion/deposition processes occurring in an area. It may have a major influence on local climate, particularly sunlight, temperature, and wind. Topography may strongly influence the occurrence and relative effect of various upslope disturbances such as wind-thrown trees, or landslides. Topography also determines the capability of the riparian zone to support many types of uses.

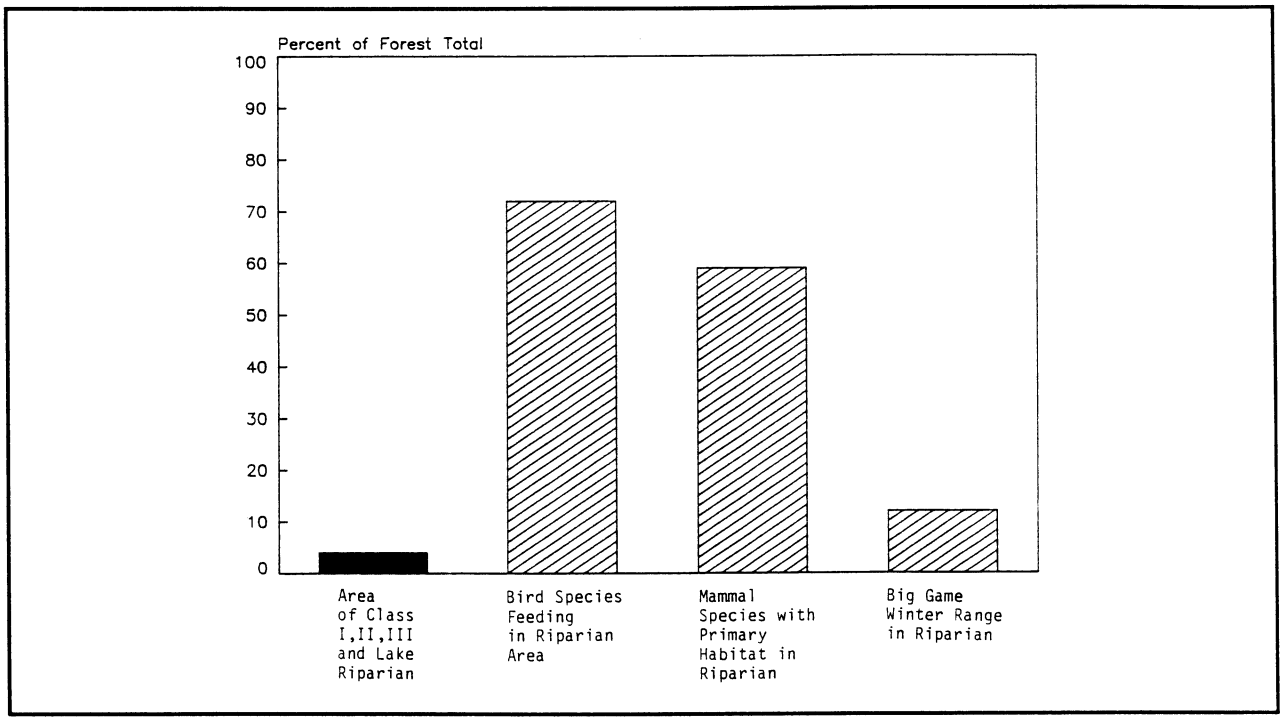
Figure III-G-5 illustrates the structure of riparian zone vegetation. In small streams on the Forest the dense riparian vegetation consists of deciduous shrubs and small trees and develops in 1 or 2 decades. Beyond that point in development, upslope conifers begin to overtop the deciduous streamside vegetation. Stands that are 50 to 150 years old have a dense canopy of deciduous trees with little understory vegetation. Older stands have a multilayered structure, and more light penetrates to the stream. Pioneer species include willows on gravel bars and red alder on mineral soil.

Figure III-G-5. Riparian Zone Vegetation

Riparian zones have vegetation that requires large amounts of free or unbound water and are transitional between aquatic and upland zones.

There is great variability in both the size and vegetative complexity of riparian zones because of the many possible combinations between stream gradient, elevation, soil, aspect, topography, water quantity and quality, type of stream bottom, and plant community (Campbell and Franklin 1979, Odum 1971, Swanson et al. 1981. Walters et al. 1980). Numerous habitats and niches occur within most riparian zones because of these varying conditions. Any of the plant communities found on the Forest can occur in riparian zones. The natural succession of vegetative types following major disturbances such as floods, fires, or logging, determines the kinds of vegetation occurring in a riparian zone at any given time.

Vegetation has numerous functions in riparian zones and wetlands. The number and type of wildlife habitats present in riparian zones are determined to a large degree by vegetative characteristics. For example, where riparian zones are dominated by deciduous vegetation, they provide one type of habitat in late fall and winter after leaf fall, and a different type of habitat during late spring and summer when in full leaf. Such species as the yellow-bellied sapsucker, downy woodpecker, ruffed grouse, and



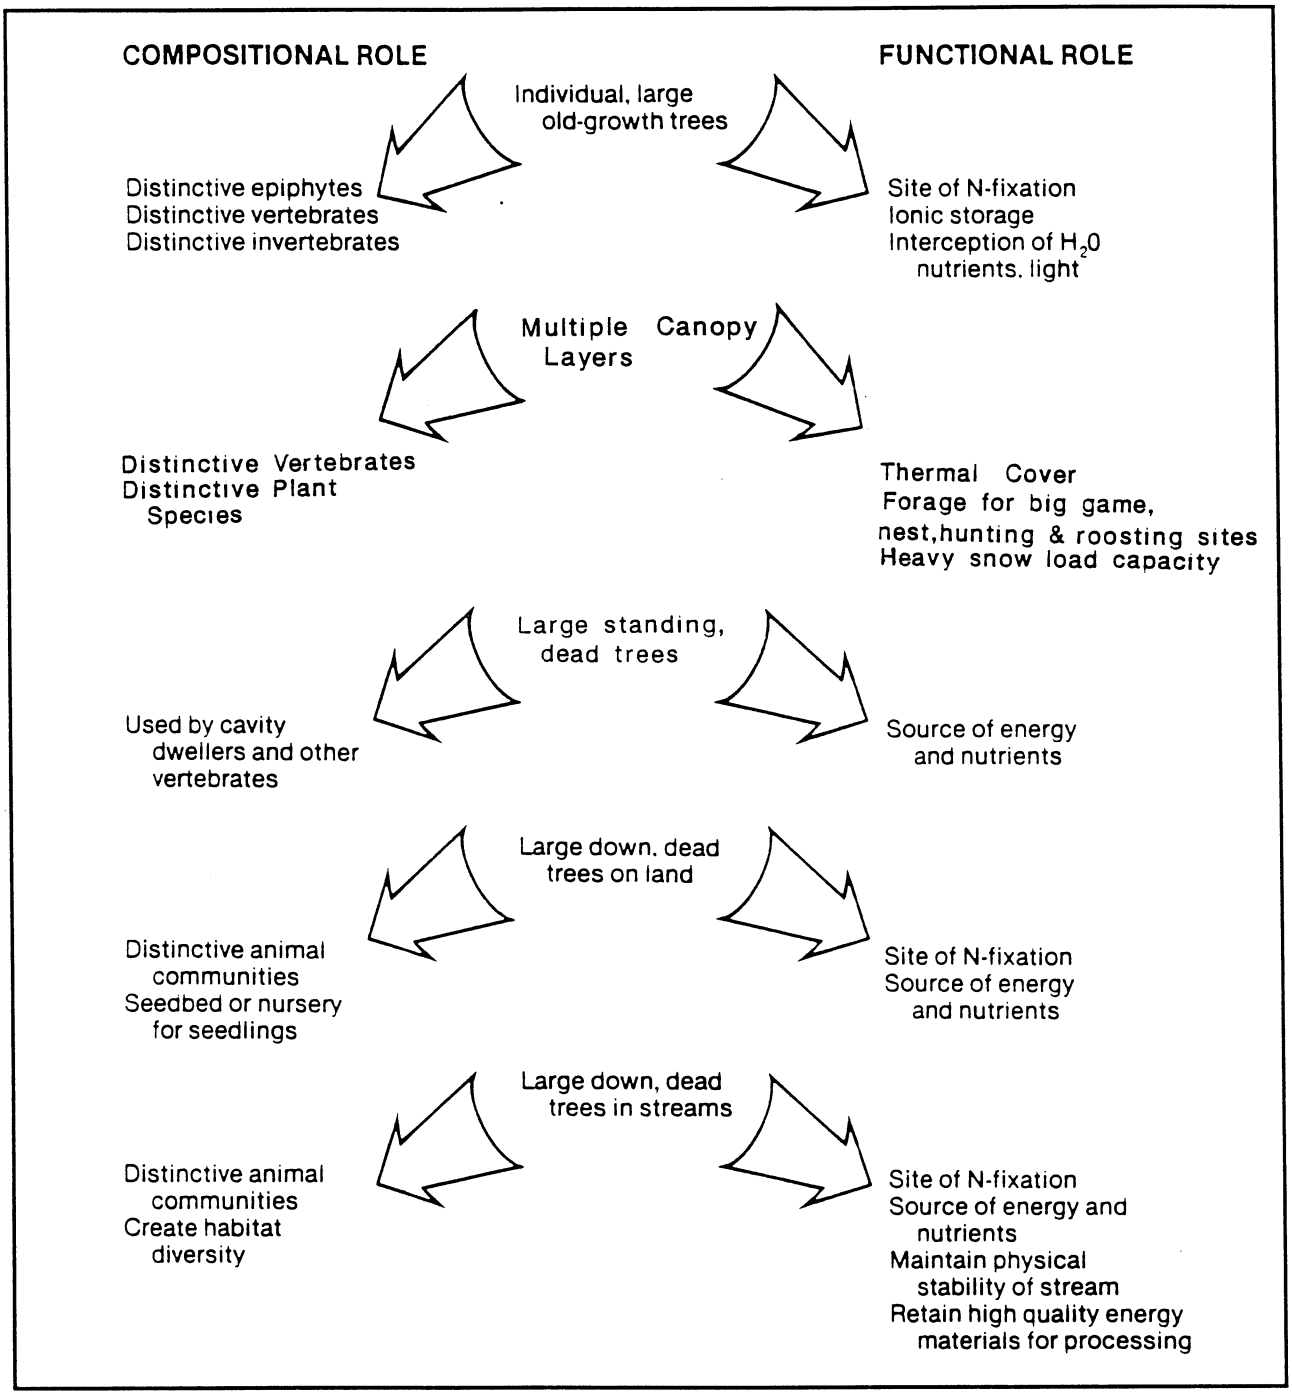
red-breasted nuthatch are highly dependent on deciduous riparian areas. Vegetation also stabilizes soil and streambanks and provides nutrients to the soil. On small to moderate-sized streams, leaves and debris (litter) provide the primary source of energy for the aquatic system (Franklin et al. 1981). Large dead and down trees store nutrients, provide seed beds for various tree species, provide habitat for various wildlife and, when incorporated into the stream, enhance channel stability (Franklin et al. 1981, Swanson et al. 1976). Large downed trees provide a stream a means to dissipate the water's energy; store needed sediment and spawning gravels for fish and, scour pools (Keller and Talley 1979). Large downed trees push floodwater on to adjacent floodplain areas, reducing the amount of damage to the stream channel. Large downed trees are the principal source of aquatic habitat diversity (Harmon et al. 1986). Productive fish habitats and good water quality depend on well-developed vegetative communities in riparian zones.

The presence of surface water during all or part of the year is a common characteristic of riparian zones and wetlands. The character of the surface water--whether standing (lakes, ponds, marshes, etc.) or running (streams and rivers), and whether perennial or intermittent--plays an important role in the function of these areas. The character of surface water directly controls the type of aquatic habitat, the composition and diversity of vegetation, and its potential use by wildlife, livestock, and people. Due to increased humidity, a higher rate of transpiration, shade, and greater air movement, riparian zones have different microclimates from surrounding coniferous forests. These conditions are preferred by some wildlife species, as well as by people, during hot weather.

Although riparian zones occupy only a small part of the overall area of the Willamette National Forest, they are a critical source of diversity within the forest ecosystem. The presence of multiple vegetation layers provides a variety of nesting sites, cover areas, and food sources associated with vertical diversity. Riparian areas often create distinct habitat zones within the drier surrounding areas. In addition, riparian zones are elongated (horizontal diversity) in shape with very high edge-to-area ratios (Odum 1979). They therefore possess a high degree of connection with other habitat types and function as effective transport systems for water, soil, plant seeds, and nutrients to downstream areas (Ewl 1979). Riparian zones also serve as important travel routes for the movement or dispersal of many wildlife species. Wildlife and livestock utilize vegetation in riparian zones more heavily than in other areas because they concentrate here for water, shade, and succulent forage. Figure III-G-6 displays the proportion of wildlife use in riparian areas.

Riparian zones are important for many other types of land use. Highly productive timber sites frequently occur along streams and around wetlands or lakes. Riparian zones are used for road locations, particularly in mountainous, rugged terrain. Rock and gravel for building roads have been taken from streambeds and their banks as well as from floodplains. Recreationists concentrate their use in wetland and riparian areas where scenic values are high. Up to 80% of the Forest's dispersed recreation use occurs in the riparian zone (Clark et al. 1984). Riparian zones are preferred for recreational developments such as campgrounds and summer home sites. Because of these conflicting uses, riparian zones are recognized as critical areas in multiple-use planning.

Figure III-G-6. Proportion of Wildlife Use in Riparian Areas



Old Growth

Each tree within an old-growth stand plays a progression of roles, from the time it matures until the tree becomes a decaying contributor to the forest floor. Examination of the data from the 1988 Mature and Over Mature Survey (MOMS) indicates that about 594,800 acres of the Forest are covered by old-growth under the Regional Guide definition. This accounts for 36% of the total Forest. Of the total acres of old-growth trees, 78% is in the low elevation Douglas-fir type and the remaining 22% is split among the three high elevation types as follows: Douglas-fir/true fir and true fir combines for about 16%; and mountain hemlock equals 6%.

Five structural components are of key importance in an old-growth stand. These are the individual, live, old-growth trees; the multilayered understory of younger trees; the large, standing dead trees or snags; the large, dead, down trunks or logs on the land; and those that are a part of the stream ecosystem. It is these structural features that are unique to an old-growth forest ecosystem, setting it apart from young growth and, especially from managed stands. Most of the unique or distinctive compositional and functional features of old-growth forests can be related to these structural features. (See Figure III-G-7.) These structural components make possible much of the uniqueness of the old-growth forest in terms of flora and fauna (composition) and the way in which energy and nutrients are cycled (function).

Figure III-G-7. Structural Components of Old-Growth

The old-growth ecosystems are represented mostly in the western hemlock series and the Pacific silver fir series. The Douglas-fir old-growth stand is the intermediate stage of the western hemlock series and is the most common form of old growth on the Forest. It is defined by the Regional Guide, R-6 (1984) as any stand generally containing the following characteristics:

1. Two or more species with several age classes.

2. Five or more overmature trees per acre, with at least some Douglas-fir that are bigger than 32 inches in diameter.

3. Stands will usually contain a multi-layered canopy.

4. Two or more conifer snags per acre.

7. Thirty or more tons per acre of down logs.

In addition to stand characteristics, there are other forest characteristics that affect the quality of old growth. Old growth values vary with stand size. Large, contiguous blocks will have core areas that are not affected by edge effects and serve as higher quality old growth habitat. These stands will contain a higher diversity of old growth typical species and will be less susceptible to catastrophic events like blowdown. Small, isolated clusters of old growth serve as important gene pools and seed sources that are site specific. They may also serve as valuable "stepping stones" for wildlife species dispersing from other old growth blocks.

Fragmentation is the increasing amount of edge, loss of contiguity and increasing isolation of habitat patches following disturbance. With old growth this is shown by the number of isolated blocks, the amount of edge/total area within individual blocks and the distance between blocks. Wilderness and roadless areas tend to be less fragmented than general forest, due to limits in logging activities, however the smaller, high elevation timber types found in many wilderness areas on the Forest may be highly fragmented by terrain, extreme weather conditions and other natural disturbances.

A third forest characteristic that directly affects old growth is isolation. This involves the distance between patches and the condition of the intervening stands. Landscape patterns that result in "stepping stones" and corridors minimize isolation. This is important for genetic interchange, wildlife dispersal and movement and increased habitat diversity at the local level.

Large organic debris from old-growth forests has a major influence on the physical characteristics of the small stream (Class IV see Water) systems. Large accumulations of woody debris have resulted in complex aquatic environments of riffles, pools, runs, glides, and side channels. The debris has added stability to stream channels and retarded the rate of downstream flow.

In Class III streams (see Water) large woody debris is common and may cover from less than 25% up to 50% of the channel area. The canopy in the undisturbed state provides continuous shading. Energy of water flowing in the channel is continually dissipated by woody material and vegetation, reducing erosion and leading to deposition of organic and inorganic material. As streams get larger, there is less direct influence of old-growth (Franklin 1981).

Optimum wildlife habitat in old-growth stands as described by Franklin et al. (1981), specifically requires a component of pioneer Douglas-fir mixed with western hemlock. The old-growth Douglas-fir has crown and bark characteristics quite different from western hemlock. These features of Douglas-fir are highly significant as habitat for certain wildlife species (see Wildlife) such as bats and the western red-backed vole.

Harvesting of old-growth stands has been of major importance to the timber industry in the Pacific Northwest for several decades. The challenge of yarding these large logs over steep, mountainous terrain while protecting the other resources like soil and water, has resulted in technological advances

such as long span skyline, balloon and helicopter logging systems. The high value of the old-growth wood makes it feasible to use these expensive systems.

Recreation users of the Forest enjoy old-growth stands of trees for many different reasons. The old trees are aesthetically pleasing and provide a living connection with the past and a visual reference to the natural successional processes of the forest environment. Many people feel that the massive, towering trees in some old-growth stands have a cathedral quality and are spiritually uplifting and inspirational. These stands provide a feeling of solitude and escape from the evidence of human presence. Old-growth stands are also important as a gene pool, conserving the diversity of characteristics which insures the survival of the species against attacks by insects and disease. These stands are also valuable for conducting research on the undisturbed organisms and processes of the forest ecosystem.

Threatened, Endangered, And Sensitive Plants

The 1989 Federal Register Notice of Review does not list any Federally listed Threatened or Endangered plants on the Forest. The Regional Forester has identified 13 documented and 10 suspected plant species on the Forest which are considered sensitive. This list was developed from Oregon Rare and Endangered Plant Program Task Force (OREPPT). An organization ofprofessional (University teachers, Federal and State agency) and lay people (taxonomists and botanists) knowledgeable of the status of the various plant species in Oregon and adjacent areas. The task force has the support of the Native Plant Society of Oregon (NPSO) members (200+). Plant inventory data from public and private land managers is shared with NPSO and Oregon Natural Heritage Data Base (ONHDB) recommendations. The information system that contains plant inventory data from OREPPT.

The Endangered Species Act of 1973 as amended (1978, 1979, 1982) declares that "...all Federal departments and agencies shall seek to conserve endangered species and threatened species and shall utilize their authorities in furtherance of the purposes of this Act."

Prior to 1973 there was an awareness of the need to protect endangered plants when management activities were proposed or implemented. Since 1973 the U.S. Department of Agriculture--Forest Service has established policies to carry out broad responsibilities under the Act through directing the development of management strategies to prevent species from becoming endangered. Such "sensitive species," although not subject to the Act, received special management emphasis to ensure their continued viability and preclude trends toward endangerment which would result in the need for Federal listing. This emphasis eventually resulted in the current USDA Forest Service - Region 6 Sensitive Plant List.

"Sensitive" species are those plant species identified for which viability is a concern. This is evidenced by a significant current or predicted downward trend in population numbers or density. Viability concerns are also indicated by significant current or predicted downward trends in habitat capability that could reduce a species' existing distribution.

The 1989 USDA Forest Service - Region 6 Sensitive Plant List identifies 23 species that are or could be found on the Forest. Typically, those plants are associated with certain types of habitat. The four main habitats usually account for most of the listed plants. These are 1.) bogs and wet/moist areas, 2.) moist, rocky sites, 3.) dry rocky sites, usually ridge tops, and open slopes, fields, meadows. Field inventories are required on proposed activity areas to determine if the plants are actually there. If found, then a determination needs to be made as to the extent of the population and the area occupied, so as to determine the impacts on the plant if the activity should occur and the mitigation necessary to avoid conflict.

Both natural events and human activities can affect a species' viability. Natural causes include catestrophic events and normal succession. Human activities that commonly occur on the Forest include timber harvest, commercial and scientific plant collection, recreation and livestock grazing. Road building and off road vehicle use can impact TE&S plants directly, through habitat loss, or indirectly, by potentially introducing competitive species or noxious weeds to sites that would otherwise have been isolated. Many of these activities are concentrated in specialized habitats such as riparian zones, rock faces or natural meadows. In many cases the TE&S species are uncommon because they are adapted to these unique environments and are habitat limited. This concentrates them in the same sites that concentrate human activities, greatly increasing the potential for conflict.

It should be noted that the effect of both natural and human activity on the species can be positive as well as negative. A few species are disturbance dependant, requiring fire, soil disturbance, increased light or some other alteration in the environment to reproduce or survive. The disturbance may revert the site to an earlier successional stage that is more suitable to the plant's survival. Species that are affected in this manner are responsive to habitat enhancement to improve their survival.

A current list of sensitive species is available in the planning records at the Supervisor's Office, Eugene, Oregon. This list is updated annually. Those plant species listed in the 1989 USDA Forest Service - Region 6 Sensitive Plant List, documented on the Forest, are shown in Figure III-G-8.

No evaluation has been made of impacts to Threatened, Endangered, and Sensitive (TE&S) plants caused by Forest Service programs and activities prior to the 1973 Act.

Table T___. Threatened, Endangered or Sensitive Plants (III-G-8)

Species	Designation	Forest Occurrence
Aster gormanii	Threatened Oregon R-6 sensitive	14 sites identified in the last 10 years
Calamagrostis breweri	Threatened Oregon R-6 sensitive	1 known site
Draba aureola	Oregon and R-6 sensitive	2 sites identified in the last 10 years
Frasera umpquaensis	Federal candidate Category 2 Oregon and R-6 sensitive	3 known sites
Gentiana newberryi	Threatened Oregon R-6 sensitive	1 known site
Hieracium bolanderi	Threatened Oregon R-6 sensitive	1 known site
Lycopodium annotinum	Threatened Oregon R-6 sensitive	1 site in last 10 years
Lycopodium inundatum	Threatened Oregon R-6 sensitive	1 known site
Montia diffusa	Oregon and R-6 sensitive	Numerous sites in Shady Beach fire area
Ophioglossum vulgatum L.	Endangered Oregon R-6 sensitive	3 known sites
Polystichum californicum	Threatened Oregon R-6 sensitive	1 known site
Romanzoffia thompsonii	Oregon and R-6 sensitive	21 sites in last 10 years

FIRE

Fire has played a key role in the development of forest ecosystems in the Western Cascades. Fires influence many segments of the physical and biological forest environment including plant species and communities; insects, parasites, and fungi; and even wildlife habitat patterns and populations. Fires also affect major ecosystems processes and characteristics such as nutrient recycling, energy flow, succession, diversity, productivity, and stability. Factors such as fire frequency, duration, intensity and size all have a bearing on these fire effects.

Historical Trends

At low elevations, most of the Forest was burned by large, lightning-caused fires between 120 and 450 years ago. Catastrophic fire intervals in the upper elevations, including the Pacific silver fir zone, may have been over 500 years apart. Over time, these fires have maintained the Douglas-fir vegetation characteristic of the west side of the Cascades.

Little is known about fires caused by native Indians, but as trappers and settlers moved through the Cascades in the mid-1800's, some fires were intentionally set, and some resulted from campfires left burning, causing an increase in fire frequency. Since the early 1900s fire suppression efforts have affected fire occurrence patterns and, in particular, potential large stand-replacement fires have generally been suppressed at a smaller size. Since 1950, out of more than 2,500 fires, there have been only 12 fires larger than 300 acres; of these, 7 were started by lightning and 5 were human caused.

Fire occurrence on the Forest is characterized by "peaks and valleys", with frequent periods of low fire occurrence and occasional periods of extremely high occurrence. Lightning fire occurrence is far more cyclic here than it is in eastern Oregon. The majority of fires on the Forest are fires of low to moderate intensity and are suppressed at a small size. During the last 30 years, the most lightning fires (316 fires) occurred in 1967 and the fewest number (0 fires) occurred in 1954 and 1988. In the same time period, human-caused fires accounted for 48% of the fires and 45% of the acreage burned. A majority of the human-caused fires have resulted from recreation related fires, e.g., campfires and smoking. The most costly and damaging human-caused fires have occurred from debris burning, industrial operations, and railroad related activities.

Some fire related ecosystem processes have been duplicated and others changed by timber management activities on the Forest. As mature and old-growth stands have been harvested, the timber has been removed from the site, and the remaining slash has been burned. These activities have created a divided mosaic of clearings and older stands. Prescribed fires of low to moderate intensity have changed soil, watershed, and vegetation characteristics less drastically than catastrophic wildfire. Generally, there have been smaller areas burned and, except for short-term slash accumulation during harvest, there has been a reduction of overall forest flammability.

Historically, prescribed burning has been the most common tool used for the reduction of logging residues and natural dead and down debris, and the preparation of sites for reforestation. In the past when prescribed burning was done primarily in the autumn, it was difficult to control fire intensity and duration. Spring and summer burning have increased flexibility to use low to moderate intensity fires to control fire effects and meet resource objectives.

Costs of prescribed burning have risen sharply. Logging is now occurring on steeper ground that cannot be machine piled and burned in winter months when mopup and patrol are not critical. Mop-up and patrol costs in the dryer summer season are much higher than those experienced during the early

spring and late fall when heavy rain aids with mopup efforts. Small, irregular shaped harvest units and the increasing need to meet air quality constraints have also contributed to increased prescribed burning costs.

Current Situation

On the Forest, all fires are suppressed, with an emphasis on the most cost effective suppression response. All fires that escape initial attack are evaluated to determine the strategies that would provide for the least cost for suppression plus the least damage to forest resources.

A wide variety of techniques and practices are currently used to minimize resource loss and suppression costs from debris burning, industrial operation and railroad fires. The Forest maintains three primary and three emergency lookouts, in addition, fire patrol planes are used during the fire season. Due to the extensive road system and sophisticated communication systems now in use, Forest visitors, contractors and permittees are also a significant part of the total detection system. While an increase in use of the Forest setting increases the risk of human caused fires, increased use also contributes to early detection and, in some cases, suppression of small fires.

Prescribed burning is scheduled to avoid smoke intrusions into smoke sensitive areas and to minimize air quality impacts during summer holidays and high use periods, and the State Forester's Office, Oregon Department of Forestry coordinates all forest and agricultural burning in western Oregon. As a result, efforts to maintain air quality have also increased the complexity of prescribed burning on the Forest. For additional information see Chapter III, Air.

On a limited basis, prescribed fire is being reintroduced to both natural and historic meadows on the Forest. Although early settlers managed historic meadows such as Mutton Meadow and Rigdon Meadow with fire, aggressive fire suppression has generally excluded fires from these meadows in recent years. The elimination of fire has caused an encroachment of trees, the loss of natural meadow ecology, and the loss of forage palatability. Prescribed fire can also be used to improve the forage for deer and elk. Fire eliminates old unpalatable forage and in turn adds nutrients to the soil. As a consequence, the new succulent growth is more nutritious.

Future Trends

Both natural and activity fuels need to be managed over time to meet long-term resource management objectives. Regeneration harvest of old-growth timber provides unique opportunities and challenges to establish essential fuel profiles that balance resource objectives such as utilization, hazard reduction, site preparation, and the maintenance of site productivity. In addition, fuel treatments for the improvement of wildlife habitat, the reduction of natural residues on Wilderness and nonwilderness lands, and the reintroduction of fire to Forest ecosystems may increase if treatments are found to be cost effective and funds are available.

Expected increases in public use of the Forest will provide additional opportunities for public contact. To maintain the low levels of human-caused fire incidents fire prevention, cooperative fire prevention efforts with local fire departments and the Oregon State Department of Forestry (OSDF) will continue.

FISH

The fish of the Forest are a diverse number of species adapted to a variety of habitats. Of the 30 species found on the Forest, most are native to the natural streams and lakes of the western slope of the Cascades. A native species is one which has always occurred here, reproducing on its own. Additionally, several species have become naturalized, primarily in lakes and reservoirs. A naturalized species is one that was introduced from other parts of the country or world and has been able to reproduce on its own.

Several native and naturalized species are artificially propagated to meet a variety of fish management objectives. By far the most abundant group is in the Salmonidae family. Fish in this family include anadromous, as well as resident species, and native, as well as naturalized species.

The spring chinook, winter steelhead, and summer steelhead are the most important anadromous species. Anadromous fish spawn and grow to smolt size in forest streams before migrating to the Pacific Ocean where they grow to adulthood. Smolts are juvenile salmon or trout who have undergone physiological changes allowing them to adjust to increased salinity of ocean water. These fish then return to their natal river to rest prior to spawning and completion of their life cycle.

Rainbow, cutthroat, and bull trout (formerly known as the dolly varden) are the most abundant native species of resident trout. Brook trout have been widely distributed in the new Cascade lakes and have naturalized in many areas.

Several salmonid species have limited distribution on the Forest. Native bull trout populations exist only in the upper McKenzie River drainage above Leaburg and in the South Fork McKenzie above Cougar Dam. Although brown trout have not been stocked for many years, naturalized populations persist in Leone and Linton lakes. The population of cutthroat trout found in the Hackleman Creek drainage currently receives special protection while fish systematists compare it to other stocks of cutthroat. Its long period of isolation, caused by lava flows 8,500 years ago, provides an excellent opportunity to study genetic differences caused by isolation.

Several species of resident fish, such as white and black crappie, largemouth bass, and brown bullhead are naturalized warm water game fish that support significant recreational fisheries in reservoirs. Many of the native species such as northern squawfish, largescale sucker, chiselmouth, and a variety of sculpins are either predators on or competition for salmonids. Others, such as redside shiner, brook lamprey, and several species of dace are prey species utilized by various game fish species. The Pacific lamprey is the lone anadromous nongame fish.

The Oregon chub (*Oregonicthys crameri*) is an unusual fish with small, isolated water populations. This 2- to 3-inch long minnow inhabits slough-like tributaries with extensive cover of aquatic plants and woody debris. In the past, the species has been recorded at many locations in the Willamette River Drainages, but its range has dwindled. It is presently found on the Forest at three locations. Because the entire population exists in a 1.5 mile long zone of the Willamette River, it is being proposed for listing as a threatened or endanger species.

The Bull trout is on the Regional Forester's sensitive species list as a consequence of it being on the U.S. Fish and Wildlife Service category-two list for species to be considered for threatened status. It's only known locations on the Forest presently are in the McKenzie River system above the Leaburg dam and in the South Fork of the McKenzie River above Cougar dam. Its presence is suspected in the

Middle Fork of the Willamette River above Hills Creek Reservoir where it was known to exist prior to 1968.

Another species of concern is a unique race of native cutthroat trout (*Oncorhnychus Clarki*). This race of cutthroat trout populates Hackleman Creek year around and when Fish Lake is full of water in the winter and spring the trout occupy the lake as well. To protect this race of trout, the ODFW has ruled that fishing in the creek is not allowed.

The fish habitat available on the Forest includes about 3,400 acres (1,292 miles) of lotic (flowing water) and 22,480 acres of lentic (lake and reservoir) environment (Figure III-I-1). Most of the fish producing streams and reservoirs are located at lower elevations while the natural lake habitat is located in the High Cascades.

This Forest offers diverse settings, species and opportunities for fishing. Opportunities range from fishing by boat or from the shore in reservoirs to hike-in fishing with bait in Wilderness lakes to fly fishing in large rivers such as the McKenzie or Willamette. When converted to dollar value of the commercial catch and sportfishing days, the Forest fish resources are worth an estimated 4.9 million dollars annually.

Fish produced on the Forest contribute to the commercial and sportfisheries both on and off Forest. Spring chinook and both summer and winter steelhead support sport fisheries in the major tributaries draining the Forest and in the lower Willamette River. Spring chinook contribute to the off-shore fisheries of the Pacific Ocean from southeast Alaska to northern California and are a major part of the the lower Columbia River gillnet fishery.

Management of the Forest's fishery resources is a shared responsibility between the Forest and Oregon Department of Fish and Wildlife. The State is responsible for setting seasons and manipulating the populations either through stocking or restrictive gear regulations. The Forest is responsible for maintenance of existing habitat, improving or expanding habitat, and for investigating fish/habitat relationships. The intricate relationships between the animals and the habitat requires continual interagency contact and coordination. Beyond the National Forest boundaries the Oregon Department of Fish and Wildlife assumes the additional responsibility for habitat, and also deals with downstream migrant passage at hydropower facilities.

Historic Trends

Fish habitat on the Forest has undergone significant modifications in the last 4 decades. In the 1950s and 1960s, construction of flood control and hydropower reservoirs isolated approximately 257 miles (925 surface acres) (see Figure III-I-2) of anadromous fish habitat and impaired the productivity of an additional 75 miles (273 surface acres). A total of 11,250 additional surface acres of reservoir water also became available for management of warm and cold water resident species as a consequence of dam construction. There are approximately 119 miles of streams on the Forest which currently produce one or more species of anadromous salmonids. An additional 18.2 miles of anadromous fish habitat exists above Foster and Green Peter Dams on the South Santiam River. This habitat is currently not

being utilized due to fish passage problems over the dams and the possibility of introducing diseased hatchery stock. Current anadromous habitat is about one-third of the historic level.

Fish hatcheries have been established on every major river system draining the Forest, either to mitigate for fish populations damaged by the flood control reservoirs, or to augment the natural productivity of the existing fish habitat. There are seven hatcheries that use water from rivers draining Forest lands. Hatcheries at Marion Forks (North Santiam), Foster (South Santiam), Leaburg (McKenzie) and Oakridge (Willamette) were established specifically to mitigate impacts on downstream migrations of smolt salmon and steelhead. Marion Forks Hatchery near Idanha and Willamette Hatchery at Oakridge are located on the Forest under a special use permit to the United States Army Corps of Engineers who, in turn, contract with Oregon Department of Fish and Wildlife (ODFW) for operation of the facilities.

A significant storm in late 1964 caused heavy degradation of fish habitat in several major resident trout streams, such as Salmon Creek and Middle Fork Willamette River. After undergoing a prolonged period of restabilization, these habitats are now in a recovery mode and should continue to improve. See Chapter III, Water for a detailed discussion of flood events.

The 1950s and 1960s were also decades in which considerable stream habitat for anadromous and resident fish was degraded by road construction and logging practices that increased erosion and removed streambank vegetation. This activity continued into the 1970s, although at a lesser rate. By the end of that decade, approximately 1,075 miles of streams (24%) were adjacent to clearcut units and an additional 238 miles were within 100 feet of a road (Stewart and Skeesick 1981). Culvert installations occasionally isolated spawning habitat for resident trout and prevented juveniles from reaching protected winter habitat.

The late 1970s and early 1980s were periods of increasing awareness of fishery values and need for improved protection of fish habitat. Streamside management unit prescriptions, improved logging methods, better road locations, and improved erosion control techniques significantly reduced the impact of land management activities. By the mid-1980s actual fish habitat improvement projects were being implemented to mitigate previous impacts and to capitalize on the inherent productive capabilities of the various aquatic habitats.

Populations of anadromous fish and resident fish have followed distinctly different trends during the last several decades. Since 1950, the native anadromous fish populations have decreased significantly and have largely been replaced by fish released from the hatcheries. Smolt mortalities associated with Fall Creek Dam, Eugene Water and Electric Board diversions on the McKenzie River, and Foster Dam on the South Santiam River have decreased those stocks considerably. The summer steelhead stocks introduced by the ODFW have become naturalized in the McKenzie River system. The wild smolts in conjunction with continued hatchery liberations have generated an excellent population of summer steelhead using the McKenzie River and its major tributaries.

The overall supply of native resident cold water fish is not known to have changed significantly over time even though populations inhabiting several major streams may have been depressed as a result of the 1964 flood or other habitat distresses. There is some indication that bull trout may now inhabit fewer areas than they did previously.

Fish stocking by the State (Fish Commission) began as early as 1912 in Linton Lake and others. During 1913, the Oregon Fish Commission stocked several lakes with eastern brook trout. To help sustain the relatively intense fisheries on moderate to large rivers, the ODFW has developed a large-scale program of stocking fishing streams with legal-sized fish. Concurrently, they stocked the reservoirs and selected road accessed lakes with both legal-sized and fingerling trout and salmon. Less accessible lakes were

stocked with fingerling trout, first by pack horse, then by fixed-wing aircraft, and more recently by helicopter.

Warm-water fish were introduced into Detroit, Hills Creek, and Lookout Point reservoirs by unauthorized parties; and, brown bullhead, largemouth bass, white crappie, and black crappie naturalized. The white crappie population in Hills Creek Reservoir expanded rapidly and by the late 1970s was supporting a very active spring fishery.

Table III-I-2. Anadromous Fish Habitat

River System	Current Anadromous Habitat (miles)	Lost Anadromous Habitat (miles)

North Santiam	0	35.7
South Santiam	20.5	18.2
McKenzie	56.7	70.1
Fall Creek	35.6	0
Middle Fork Willamette	0	133.3
TOTAL	119.0	257.3

Current Situation

Important fish species on the Forest include those belonging to the family Salmonidae. These include the native species of spring chinook, winter steelhead, rainbow trout, cutthroat trout, bull trout, and mountain whitefish as well as the introduced species of summer steelhead, brook trout, brown trout, and sockeye salmon that have become naturalized. These species support major recreational fisheries on the Forest and contribute significantly to sport and commercial fisheries in the Pacific Ocean, lower Columbia River, and lower Willamette rivers. The current smolt population on the Forest is estimated at 169,000 fish. Anadromous fish spawning population levels are reasonably well documented (Figure III-I-3).

No estimates of abundance of resident cold-water fish have been attempted because of the variability of the productivity of the various habitats and the dependence of many of the water bodies upon regular stocking to maintain population abundance.

The premier fisheries supported by fish produced on the Forest are for spring chinook and summer steelhead. The primary spring chinook harvest occurs in the lower Willamette River between St. Helens and Oregon City. Fish reared in the Santiam, McKenzie, and Middle Fork Willamette subbasins account for 80% of the average 15,000 fish catch. In addition, the lower Columbia River gillnet fishery harvests an additional 8,000 of these, the highest quality of all the salmon stocks.

The summer steelhead stocks are a recent phenomenon based upon proper stock selection and hatchery technology implemented in the 1970s. Adults returning from hatchery releases and natural production support major fisheries in the Santiam, McKenzie, and Middle Fork Willamette rivers just below the Forest boundaries. These fisheries are gaining in popularity as more people learn the proper angling methods and preferred locations to fish.

The stream fishery for resident trout is supported primarily by wild native cutthroat and rainbow trout. The cutthroat are the main contributors in the small tributaries and head water streams while the rainbow are the major target in moderate to larger sized streams. Hatchery augmentation of trout populations in streams has gradually been reduced and is now limited to a few intensively fished areas where the catch rate justifies the high cost. Special fly-fishing only regulations on North Fork of the Middle Fork Willamette River provides a unique opportunity to fish for native rainbow and cutthroat trout at high population levels.

Table III-I-3. Approximate Current Anadromous Fish Spawning Populations [1]

Drainages	Spring Chinook	Summer Steelhead	Winter Steelhead	Coho Salmon
Little North Santiam River[2]	50	30	50	10

[2] In USFS Ownership.
[3] Leeburg Dam Counts.
[4] Fall Creek Dam Counts.

Presently, nearly half of the watersheds in the Forest exhibit high sediment yields, as compared to natural levels, and are considered indicators of lower water quality. Sediment that is significantly elevated above natural levels can reduce fish habitat quantity and quality.

In the recent past, acknowledgment of the importance of providing and retaining large woody debris in streams has resulted in a diversified as well as a reasonably stable condition for fishery habitat Forest-wide. Specifically, attempts to return Fall Creek tributaries to a more natural condition by the addition of in-stream rock and log structures has been accomplished. Initial evaluation suggest efforts have had significant beneficial effects for fish populations.

There are approximately 390 natural lakes with trout populations on the Willamette National Forest. These range from Waldo Lake at 6,410 surface acres down to 2 acres in size. Most of the total acreage (10,924) of lakes on the Forest is located in the High Cascades where stream drainages are poorly developed. Consequently, few of the lakes have natural spawning areas available. Approximately 90% of the lakes are regularly stocked with fingerlings by the Oregon Department of Fish and Wildlife (ODFW) to capitalize upon the productive capacity and to support the recreational opportunities associated with the lakes. ODFW stocks lakes one acre or larger in size. Recently helicopters have been used to improve the reliability of stocking fingerlings in small lakes. However, financial limitations have caused significant interruptions to the program in recent years. Helicopter stocking of remote lakes is normally conducted every other year. The majority of the lakes are stocked with fingerling brook trout with rainbow planted in most of the rest. Cutthroat trout receive limited distribution because of a lack of stocks adapted to lentic environments. West slope cuttroat trout are being stocked experimentally with some success.

Flood control and hydropower reservoirs on the Forest have created 11,250 acres of fish habitat when at full pool (Figure III-I-4). During the flood control season (November through February) that area is

reduced to approximately 4,470 acres. Although the annual fluctuations reduce the value of flood control reservoirs as fish habitat, these reservoirs produce valuable cold and warm water fish.

Lookout Point and Hills Creek reservoirs provide nearly all the significant warm water fish habitat in all of Region 6 (Oregon and Washington). The white crappie fishery in Hills Creek reservoir is a significant spring event that adds measurably to the fishing opportunities on the Forest. Efforts are occurring to identify the proper fish species for use in Lookout Point Reservoir to establish a self-sustaining fishery. Each of the reservoirs, except Lookout Point Reservoir, is stocked with fingerling and/or legal-sized rainbow by ODFW to support the major fisheries that occur there. Lookout Point Reservoir receives annual stocking with juvenile spring chinook.

Several volunteer organizations have been instrumental in helping the Forest develop technology for establishing terrestrial vegetation in reservoir drawdown zones. This vegetation is expected to: provide structural diversity and protective cover for juvenile fish; add organic matter to the reservoir food web; provide big-game winter forage; and improve the visual characteristics of the reservoir slopes.

The demand for fish and fishing opportunities in western Oregon continues at a strong steady level (Lowry 1977, Griggs 1984).

Future Trends

The spring chinook of the lower Willamette and Columbia Rivers will continue to be dependent upon the quality water and habitat conditions of the Forest. Increased supplies of spring chinook and winter and summer steelhead will occur from four sources: hatcheries, habitat improvement, passage improvement, and cooperation with other agencies.

The Oregon Department of Fish and Wildlife is planning to increase the Willamette River spring chinook populations by 25%. Fish passage improvements at Foster Dam, Leaburg Dam, and Willamette Falls (Oregon City) are improving survival rates of naturally produced smolts, leading to greater returns of

adults. Protection of the undammed tributaries of the McKenzie River system will contribute to habitat productivity. These tributaries include streams on the Forest such as Horse Creek, Deer Creek, Lost Creek, and the South Fork of the McKenzie below Cougar Reservoir. Fisheries management of the McKenzie River above Leaburg Dam will focus on Spring Chinook and wild trout. The Northwest Power Planning Council is preparing a critical review of the full production potential for all anadromous fish in the Willamette Basin. The Northwest Power Planning Council program mitigating the effects of hydropower production will, in the longer term, finance projects designed to improve the inherent productivity of stream habitat and may also fund development of fish production facilities. Any production facilities added will rely heavily upon the high quality water produced on the Forest.

When fish passage improvements are provided by the Army Corps of Engineers at the Fall Creek, Foster, and Green Peter Dams; these drainages will support increased anadromous fish production. Recent activity by local organizations is seeking to intensify fisheries management of major salmonid habitat on- and off-Forest to improve economic benefits to local communities (i.e., McKenzie-Willamette Fisheries Enhancement Group sponsored by Lane County Intergovernmental Relations Committee). Maintenance of high quality water and improvement in riparian habitat will continue to strongly influence resident fisheries on the Forest. Although there has been habitat recovery in some drainages such as Fall Creek and Salmon Creek, the ability of the streams on the Forest to produce resident trout in the future is contingent on the continuation of fishery habitat improvements. Historically, the ODFW has supported a put-and-take fishery at selected sites on the streams, reservoirs, and lakes within the Forest boundary. Legal sized trout are intermittently stocked near recreation areas from May to September, to augment fish populations. The high cost of augmenting naturally produced stream trout with legal sized hatchery fish dictates that only a few of the more heavily fished streams will continue to be stocked by ODFW. This practice is being heavily scrutinized and will probably be reduced over time. The high mountain lakes fish populations and fisheries are expected to continue at current levels with the exception of a few non-Wilderness lakes where habitat improvements will be made to improve productivity.

The full development of resident warm-water fisheries at Hills Creek and Lookout Point Reservoirs will be important to future management of the Forest. Currently, Lookout Point has the biggest untapped resident fishery potential of the eight reservoirs on the Forest. Resolution of predation and competition problems will increase both fish production and fishing opportunities. As well, the manipulation of vegetation on drawdown zones of flood control reservoirs will provide bank stability and increase fish productivity. This vegetation will provide forage for animals, a food base for aquatic invertebrates, and serves as a nursery area for young warm water fish.

The Forest expects to invest substantial habitat improvement funds to augment the work of volunteer organizations to capitalize on this opportunity. Fishing organizations and volunteers are expected to play an important role in continuing to improve fish habitat and our knowledge base. The Challenge Grant Program for funding habitat improvements will stimulate investment in those areas where local interest is highest, and organizations other than USDA Forest Service can provide part of the funding. In addition, volunteers will be accomplishing surveys, collecting data, and doing projects to improve the management of the Forest fish resource.

The improvements in anadromous fish habitat and numbers, improvements in the productivity of the reservoirs, and the establishment of a fishery in Lookout Point Reservoir can be expected to have a significant impact of the local economies of the areas where the fisheries occur. For example, a 25% increase in population and catch of spring chinook will add 2,000 fish (31,200 pounds) worth $32,760 (RPA values) annually to the Columbia River commercial fishery and 3,750 fish worth $370,000 to the lower Willamette River sport fishery. This expansion in the population is dependent upon habitat maintenance and continued production of high quality water for the hatcheries, and in-stream production.

WILDLIFE

The Forest provides diverse habitats which support over 260 wildlife species. This includes 170 avian breeding species, 64 mammalian species, and 30 amphibian and reptilian species.

Several important roles are played by wildlife in the Forest. As predators, animals act as natural controls of insect populations, helping reduce the frequency and severity of epidemics. Predators also remove sick and weak individuals, influencing the populations of prey species. Burrowing or tunneling animals aerate the soil and carry the remains of plants and prey to lower levels. All of these smaller animals in turn support a host of larger predators. Animals that feed on plants and their seeds are agents in helping to disseminate seed. Some are pollinators; others browse or clip vegetation for food. As certain animals dig and grub for food in logs they are helping with the breakdown of this larger material that enables quicker decomposition of organic matter. Aquatic animals like the beaver alter water flow patterns, create marshes, and meadows. Beaver ponds also provide excellent habitat for resident trout and young anadromous fish.

Wildlife also contributes to local economies. Communities near the Forest benefit from the tourist income generated from hunting and sightseeing recreationists.

Historical Trends

Habitat conditions are the prime determinants of wildlife abundance both in the number of species and the number of individuals over time. The abundance of most wildlife species is directly dependent upon the condition of available habitat, whether used for breeding, feeding, or resting.

The mosaic of wildlife habitat on the Forest has been continuously changing. Prior to the early 1900s, wildfire was the primary source of disturbance to the Forest environment of the Western Cascades, although floods, landslides, drought, and wind also influenced habitat conditions. Forest management activities tend to alter the stages of plant succession in a similar fashion to wildfire. However, management activities may change the habitat composition and rate of successional development. Another major difference between natural succession following wildfire and Forest management activities is that during activities such as road building and timber harvest nutrients are being actively removed from the system in the form of logs, rock, fill material, and other products.

The relationship between wildfire and succession has been used to predict the effects of Forest management activities on wildlife populations. Habitat management systems affecting Forest management activities and wildlife populations have historically focused on contolling damage to tree seedlings, and maintenance of habitat for game species. More recent research focuses on the retention of snags, down logs, and remnant live trees within managed stands, and landscape patterns created as a result of Forest management activities. These factors are now believed to be an integral part of maintaining biological diversity. (For more information regarding vegetation diversity, refer to the Vegetation Section.)

Species populations adapted to a wide variety of plant communities and stand conditions have been less likely to decline because of the number of habitat options available to them. Examples of these species are deer, elk, and bear. However, as the landscape is converted from natural conditions dominated by old-growth Forest stands into young, managed stands wide fluctuations in deer and elk numbers may occur due to lack of high quality cover resulting in poor winter survival. Other species, such as the northern spotted owl, are more dependent on specific stand conditions. Their populations have been more likely to decline as the amount of Forest lands in late stages of stand development decreases. Some species are affected less by direct changes in vegetation conditions. Peregrine falcons, for example,

are cliff-nesting birds whose productivity has been more strongly influenced by pesticide use, prey abundance, and predation than by the changes to Forest vegetation. Prey populations of peregrine falcons are directly influenced by vegetation diversity which provides for high populations of song birds.

The Endangered Species Act of 1973, as amended, declared that federal agencies shall seek to conserve endangered and threatened species of plants and animals. Two species of birds, the northern bald eagle and peregrine falcon, occur on the Forest and are listed as threatened or endangered in the 1989 Federal Register. Several other species are either proposed or being considered for listing. All federal, state, and regional proposed, threatened, endangered, and sensitive species are listed on the Regional Foresters Sensitive Species List. (See Figures III-G-8, Threatened, Endangered and Sensitive Plant Species, and Figure III-J-1).

All species in a given area must be maintained to assure the continued existence of the populations throughout their natural range. Managing for viable populations of wildlife species reduces the potential for species becoming listed as Threatened, Endangered, or Sensitive (TE&S) or for local elimination of the species.

Table III-J-1. Threatened, Endangered or Sensitive Fish and Wildlife Species

Species	Designation	Forest Occurrence
BIRDS		
Harlequin duck	R-6 sensitive	Habitat exists on forest. Pairs sighted regularly along major rivers and streams.
Ferrugenous hawk	R-6 sensitive	Occasional visitor. Inadequate foraging habitat to support breeding.
Peregrine falcon	Federal/endangered	No known nest sites on Forest. Potential nesting habitat exists. Several sightings have occurred on Forest.
Bald eagle	Federal/threatened	Seven known active nest sites. Utilizes habitat on Forest for winter forage sites.
Greater sandhill crane	R-6 sensitive	Habitat limited to high lake country. Birds breed in marshes of lakes just outside the Forest boundaries.
Northern spotted owl	Proposed federal listing Oregon/threatened R-6 sensitive	Habitat exists on Forest. Known nesting, roosting, foraging sites are identified on Forest.

Table III-J-1Cont. Threatened, Endangered or Sensitive Fish and Wildlife Species

Species	Designation	Forest Occurrence
MAMMALS		
Pacific western big-eared bat	Federal candidate Category 2 R-6 sensitive	Habitat exists on Forest and two known roost sites identified. Other sites on private land within forest and on neighboring lands
White footed vole	Federal candidate Category 2 R-6 sensitive	Habitat exists on forest and 3 known sites identified.
California Wolverine	Federal candidate Category 2 Oregon/threatened R-6 sensitive	Intermittent sightings over the past 20 years on Forest. Majority of sightings in the Wilderness where abundant habitat exists.
AMPHIBIANS		
Red-legged frog	R-6 Sensitive	Habitat exists on Forest and scattered sightings have been reported in past 10 years.
FISH		
Oregon chub	Federal candidate Category 2 R-6 sensitive	Habitat exists on Forest and species occurs at two known sites.
Klamath large-scale sucker	Federal candidate Category 2 R-6 sensitive	Species documented as having occurred on Forest
Bull trout	Federal candidate Category 2 R-6 sensitive	Habitat exists on Forest with distribution limited to the upper reaches of a single drainage.
INVERTEBRATES		
Beer's false penny beetle	Federal candidate Category 2	Species documented as having occurred on Forest
Mt. Hood primitive caddisfly	Federal candidate Category 2	Detroit R.D.
Tombstone prairie caddisfly (*Farula reaperi*)	Federal candidate Category 2	One record from 1965; Sweet Home R.D.
Tombstone prairie caddisfly (*Oligophlebodes mosthento*)	Federal candidate Category 2	Blue River R.D.
Ft. Dick Limnephilus caddisfly	Federal candidate Category 2	One record from 1969; Oakridge R.D.
One-spot caddisfly	Federal candidate Category 2	Rigdon Ranger District

Current Situation

The implementing regulations for the National Forest Management Act of 1976 (NFMA) require the Forest Service to plan the management of wildlife habitats to "maintain viable populations of existing native and desired non-native vertebrate species in the planning area." To facilitate management of all these species, NFMA further requires each Forest to identify management indicator species (MIS) through the planning process and to establish objectives to maintain and improve the habitats of these indicator species. Implementing regulations for NFMA further define viable population management. "In order to insure that viable populations will be maintained, habitat must be provided to support at least a minimum number of reproductive individuals and that habitat must be well distributed so that individuals can interact with others in the planning area" (36CFR 219.19).

Seven species of wildlife, one group of bird species, resident fish, and anadromous fish have been selected as management indicator species to represent the habitat needs for fish and wildlife species present on the Forest. Management indicator species are considered representative of other species with similar habitat requirements for life and reproduction. By managing for viable populations of indicator species and their associated habitat, viability risks for other species found in the same habitats are reduced.

Management indicator species represent either featured species or ecological indicators. Featured species are threatened and endangered plant and animal species on federal lists, species that are hunted, fished, or trapped, species of special concern or interest, and species with special habitat needs that may be at risk due to planned management activities. Ecological indicator species were selected because their population and habitat changes indicate potential effects of management activities on other species dependent on selected habitat types or water quality. Population and habitat recovery objectives for federally Listed Threatened and Endangered species are determined by the U.S. Fish and Wildlife Service and encorporated into Land and Resource Management Plans through development of interagency Management Plans designed to meet site specific needs for habitat protection and enhancement. Usually each nest site or territory has a site specific plan to ensure recovery objectives are met.

Figure III-J-2 lists the species with special management requirements for the Forest, and is followed by a discussion of each species. The selection of these species was based on the following criteria:

1. Endangered or threatened species identified on federal lists for the planning area;

2. Economically important species that are commonly hunted, fished, or trapped; or

3. Species having limited or specific habitat requirements that may be significantly influenced by management practices. Limiting habitats are those habitats which may be subject to reduction by unconstrained management activities below levels necessary to maintain viable populations.

Table III-J-2. Management Indicator Species

Indicator Species	Habitat Feature	Selection Criteria
Spotted Owl	Threatened species; Old-growth and mature conifers	Ecological Indicator, represents limited habitat
Pileated Woodpecker	Old-growth and mature conifers	Ecological Indicator, represents limited habitat
Pine Marten	Old-growth and mature conifers	Ecological Indicator, represents limited habitat
Elk	Winter range	Commonly hunted
Deer	Winter range	Commonly hunted
Cavity Excavators	Dead and decaying trees	Ecological Indicator, represents limited habitat
Bald Eagle	Threatened species (T&E habitat)	Federal Register List of T&E species
Peregrine Falcon	Endangered species; nesting habitat near prey	Federal Register List of T&E species
Anadromous Fish [1]	Water quality	Commonly fished
Resident Fish [1]	Water quality	Commonly fished

[1]Anadromous and resident fish are discussed in Section I, Fish.

Through Region-wide coordination, each Forest identified the minimum numbers, distribution, and habitat characteristics needed to satisfy life history needs for each species or group of species identified as having a Management Requirement(MR). Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service, June 1986. Maintenance of the MRs ensures the viability of management indicator species and the species they represent. MRs are therefore incorporated into all of the Alternatives, except for the No Change Alternative.

Old growth and Mature Conifer Habitat

Old growth and mature conifer habitat provides the feeding, resting, and breeding areas that are required by the northern spotted owl, pileated woodpecker, and pine marten. These management indicator species represent wildlife associated with late seral stages of Forest development. As ecological indicators, these wildlife species represent all species which may be affected by limited amounts, distribution, and quality of mature and old-growth coniferous forests.

Bald Eagle: Threatened and Endangered Species - The bald eagle is listed in the Federal Register as a threatened species. Examination of Forest conditions near nest sites has shown that bald eagles require Forests with old-growth characteristics for nesting (Anthony et al. 1989). The diameter and height of individual nest trees are usually the dominant and largest diameter trees in the stand. Bald eagles require large trees with stout thick limbs to support their large nests which may be up to 10 feet in diameter and can weigh in excess of several hundred pounds (U.S. Department of Interior,

Fish and Wildlife 1982). Perch trees associated with the nest tree need to be tall enough to provide a clear line of sight to the forage area and surrounding terrain. Bald eagles need to feed without interference from human activity (Stalmaster and Newman 1978). All Forested lands within 1.1 miles of the shoreline of major water bodies can be considered potential nesting habitat (U.S. Department of Interior, Fish and Wildlife 1981).

Tenacity to a nest site is weakest in late winter and early spring when a pair first establishes a territory. Disturbance of even limited duration at that time may cause desertion of the site (Fyfe and Olendorff 1976). Nest abandonment, however, can occur at any time as the result of frequent and persistent disturbance.

Bald eagle roosting and feeding areas are usually associated with rivers, lakes, and reservoirs. No communal roost sites have been identified on the Forest. Resident and wintering populations tend to be dispersed within territories around foraging areas. Human activity can adversely affect feeding bald eagles (Stalmaster and Newman 1978). The availability of and access to fish, water-fowl, invertebrates, and carrion becomes critical in nesting season. Young bald eagles are less tolerant of food deprivation than the adults.

Systematic surveys are conducted annually by the Forest Service and the Oregon Department of Fish and Wildlife. There are five known bald eagle nest sites on the Forest. Pairs of bald eagles occupy primary and alternate nest sites along Lookout Point Reservoir and Hills Creek Reservoir (2). Surveys conducted in 1989 confirmed additional nesting pairs at Detroit Resevoir, Clear Lake, and Erma Bell Lakes. Seventeen potential nest sites containing at least 125 acres of nesting habitat have been identified around 11 major water bodies.

When bald eagle nests are found, site specific management plans are prepared in compliance with the USDI Fish and Wildlife Service recommendations and in accordance with the Pacific States Bald Eagle Recovery Plan (1986). Roost sites that are identified in the future will be managed in accordance with the Pacific States Bald Eagle Recovery Plan.

Northern Spotted Owl:Ecological Indicator - The Northern Spotted Owl is listed as a Sensitive Species on the Regional Forester's Sensitive Species List. The spotted owl has been the center of controversy throughout its range. Debate centers on the threat to species viability due to harvesting mature and old-growth forests and silvicultural practices which are designed for harvest rotations of less than 100 years. The northern spotted owl has been proposed and is being considered for listing on the Federal Register for Threatened and Endangered Species.

Old-growth Forests provide high quality habitat for nesting, roosting, and foraging spotted owls. Recent studies have suggested that the northern spotted owl uses habitat areas ranging in size from about 1,000 acres to 3,000 acres. The *Final Supplemental Environmental Impact Statement* (FSEIS 1988) and *Amendment to the Regional Guide* (1989) requires at least 1,500 acres of mature and old-growth habitat for a pair of spotted owls in the Oregon Cascades. All allocated habitat should occur within 1.5 miles of the nest or roost site. Information from the FSEIS for the spotted owl indicates that a larger home range of approximately 6,600 acres, with 2600 acres of mature or old-growth habitat, may be utiliized by a pair of spotted owls.

The principal prey species of the spotted owl are primarily found in mature and old-growth Forests. The northern flying squirrel is the most abundant prey species in spotted owl diets in northwestern Oregon. Prey species may be more abundant and available in old-growth stands than second growth stands. The size of the old-growth limbs are larger and able to support arboreal nests of flying squirrels and red tree voles. Snags and down logs are generally abundant. Foraging perches found in old-growth

stands enhance detection and capture of prey. In addition, many old-growth stands lack the dense understory brush associated with second growth Forests. An open understory may make detection and capture of prey more energy efficient.

Northern spotted owls do not build nests, but rely on pre-existing cavities, broken tops or platform structures as potential nest sites. Large, decadent trees with missing limbs and tops provide these cavities and platforms for spotted owl nests. Selection of old-growth nesting habitat by spotted owls is also influenced by prey abundance. Production of prey biomass is greater in old-growth than that produced in second growth stands. This abundance of prey provides an optimal environment to support food requirements of young as well as adults.

Multi-layered canopies associated with old-growth stands provide favorable roosting habitat that moderates temperature extremes, producing shade during warm weather, and buffering the effects of cold, wet weather and snow. Juvenile spotted owls are dependent on leaning trees and understory trees for climbing off the ground once they have fledged from the nest, but are not yet mobile enough to escape predators. Once off the ground, multi-layered canopies provide hiding cover from predators such as the great-horned owl and goshawk.

The Forest has verified the presence of 219 spotted owl pairs since 1985. During 1989, 156 pairs were reverified. Of these, 15 pairs were located within Wilderness or lands Congressionally reserved from timber harvest.

In compliance with the implementing regulations for the National Forest Management Act of 1976, spotted owl habitat will be provided to ensure existence of a viable population of the species. The Region 6 Planning Guide requires all National Forests within the Cascades Province to maintain 1,500 acre spotted owl habitat areas (SOHAs) with specific guidelines on spacing to ensure distribution across the range of the species.

The process used to establish viable population levels is fully discussed in the Spotted Owl FSEIS and Amendment to the Regional Guide. The Amendment to the Regional Guide estimated current habitat capability of the Forest to be 254 pairs of spotted owls. The 15 year capability to be maintained is 225 pairs of spotted owls. The SOHA network developed under the Regional Guide resulted in establishment of 59 SOHAs protecting 60 pairs of spotted owls. In addition to the 59 SOHAs, 83,680 acres of suitable habitat capable of supporting 35 additional pairs of owls exists within Wilderness and other Reserved areas. The Forest's SOHAs and reserved sites contribute to the Regional MR network for managing spotted owls throughout its range in Oregon and Washington. It should be noted that not all the habitat acres within the SOHAs are on lands suitable for timber harvest. Approximately 10800 acres within the SOHA network (12%) coincides with lands unsuited for timber production.

Pileated Woodpecker:Ecological Indicator - The pileated woodpecker represents those wildlife species which use large, standing dead trees (snags) and mature/old-growth trees when nesting, roosting, or foraging. Downed logs also serve as an important habitat function by providing foraging areas for insect and fungi eating species, as well as habitat for many repitles and amphibians. The diet of the pileated woodpecker consists predominantly of carpenter ants, termites, and other insects found in decaying wood. Foraging surfaces tend to be decayed tree trunks, dead limbs, snags and downed logs associated with mature and old-growth Forests (Mannen 1980). Nesting habitat is most often found in mature and old-growth Forests. The average diameter of a pileated woodpecker nest tree is 25 inches (Brown 1985). The pileated woodpecker is the largest of the woodpeckers, averaging 16 to 20 inches in height. Due to this large size, a pileated woodpecker requires at least a 21-inch d.b.h. nest tree to accommodate itself and its young. Research conducted in Western Oregon suggests that pileated woodpeckers have relatively large home ranges often exceeding 1000 acres in size (Mellen 1987). When

foraging, pileated woodpeckers tend to avoid openings, although they have been observed using shelterwoods on a regular basis (Evelyn Bull, personal communication). Minimum requirements for pileated woodpecker habitat estabished for Region 6 provide 600 acres of habitat per pair. At least 300 acres must be mature or and old-growth Forest.

No systematically collected survey data exists on the Forest for pileated woodpeckers or other wildlife species associated with the habitat features represented by this MR. Existing Forest habitat capability for this species is estimated at 514 individuals based on habitat availability and distribution.

Marten: Ecological Indicator - The marten represents wildlife species dependent on mature and old-growth forests for at least a portion of their life history needs. Marten home ranges often include several seral Forest conditions, ranging from poles to old-growth. Dead, down, and defective trees characteristic of old-growth Forests and seral fire regenerated Forests are critical to marten survival. Downed logs and snags provide potential den sites and access to small mammal prey that are active during winter months (Clark and Campbell 1976). An overhead Forest canopy provides protection from aerial predators (Herman and Fuller 1974).

The recommended habitat area (MR) for marten includes at least 160 acres of contiguous mature or old-growth forest. Home range size of individual marten may be significantly larger (Irwin 1987). Little information is available on home range size or habitat use on the west slope of the Cascade Mountains. The habitat characteristics of primary reproductive or core area habitat for marten are similar to those of the pileated woodpecker and spotted owl. Thus, habitat areas designated for spotted owls and pileated woodpecker MRs will also provide marten habitat.

No systematically collected survey data exists on the Forest for this species. Sighting and trapping records are available to establish general distribution patterns. Current habitat capability for marten is estimated to be 1,138 marten. An estimated 250,018 acres of suitable marten habitat exists on lands Congressionally removed from timber harvest. Lands unsuited for timber production may provide additional habitat, but may be in parcels to small or fragmented to provide suitable habitat to support individual home ranges.

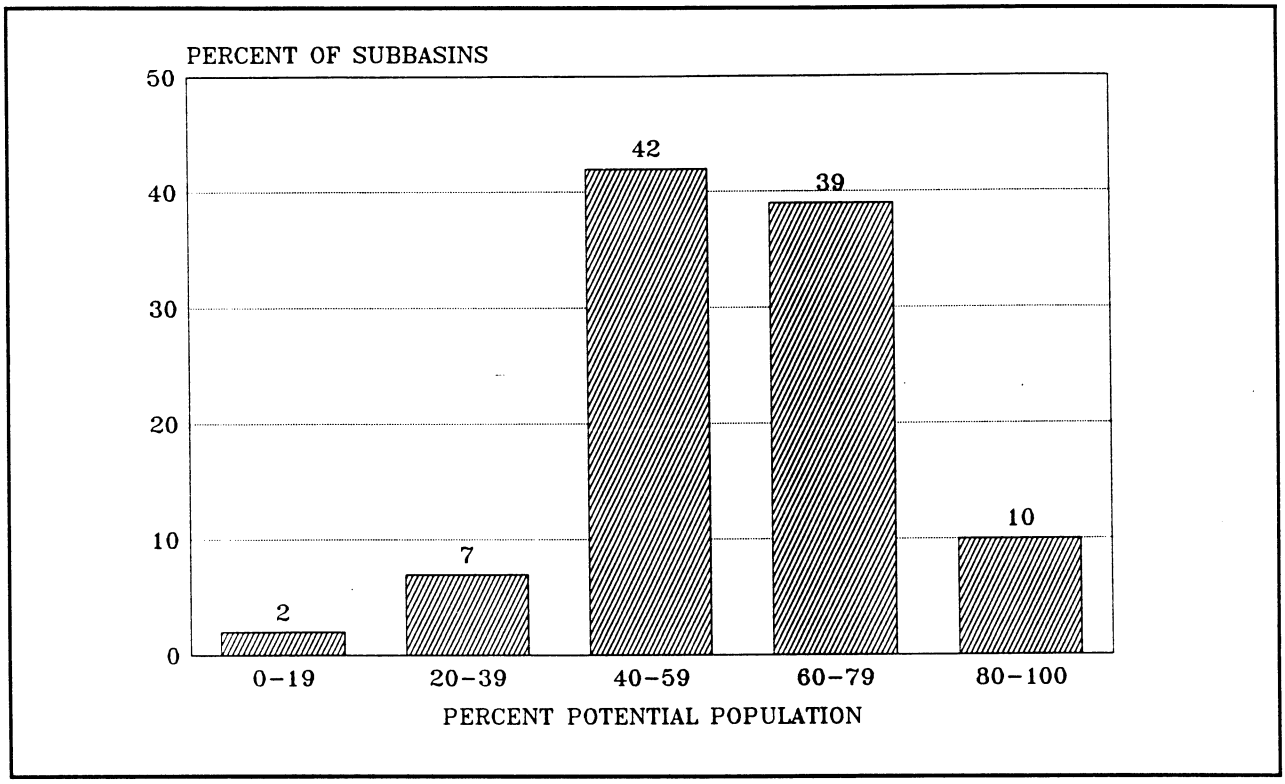
Dead And Defective Tree Habitat

Dead and decaying trees (snags) are a vital component of the Forest ecosystem. Many wildlife species are dependent on these deteriorating trees for nesting, roosting, foraging, and other life functions. Wildlife species dependent on snags are associated with all successional stages of Forest development. Snags are an important source of food production. As the tree's wood fiber decays through time, the bark, cambium layer, and heartwood will serve as forage substrates for a rich supply of insects and bacteria. Some species such as western bluebirds, tree swallows, and violet-green swallows are secondary cavity nesters and use snags located in early seral Forests. Other species are associated with closed canopy stands. On the Forest, wildlife species dependent on dead and defective trees are represented by a group of birds referred to as primary cavity excavators.

Snags and defective trees with heartrot, fungal conks, dead branches, and old wounds are often selected by primary excavators as nest trees. Natural cavities as well as those constructed by primary excavators provide thermally regulated nest sites and over-wintering enclosures for many wildlife species.

Snags are also food storage sites where a variety of birds and mammals cache prey and other food items. Reproductive behavior and territorial defense for specific species may be critically tied to snag numbers and distribution.

Primary Cavity Excavators: Ecological Indicator - Snags, live defective trees, and down logs provide the critical habitat for primary cavity excavators and secondary cavity users.



Primary cavity excavators used as ecological indicators on the Forest are those birds, other than pileated woodpeckers, which require dead and defective trees for nesting, roosting, and foraging. Primary cavity excavators create new cavities each year for roosting and nesting. Cavities constructed and abandoned by primary excavators are used by other species (secondary cavity users) for nest and roost sites.

Species of primary cavity excavators used as ecological indicators on the Forest are the red-breasted nuthatch, northern flicker, hairy woodpecker, downy woodpecker, red-breasted sapsucker, Lewis' woodpecker, black-backed woodpecker, and northern three-toed woodpecker. The amount, size, and distribution of dead and defective trees is a limiting factor in existing managed Forest stands.

No systematically collected survey data exists for primary excavator species or secondary cavity users on the Forest. Figure III-J-3 illustrates habitat capability for primary cavity excavators at the sub-watershed level.

Habitat capable of supporting high populations of insectivorous birds may be needed to maintain biological control of endemic insect population levels. The primary ecological role of these birds in controlling insect levels is moderating epidemic outbreaks.

Figure III-J-3. Subbasin Snag Levels

Deer And Elk Habitat

Deer and elk have been selected as Featured Species because they are important game species on the Forest. Economically, they are important to local communities which benefit from the revenue generated by hunters and other recreationists that like to view and photograph game species.

The historic range of Roosevelt elk, black-tailed deer, and mule deer includes all of the Forest. Long-term viability of these species is not presently a concern, but populations capable of supporting hunting and viewing demands are dependent on biological and habitat conditions.

The Oregon Department of Fish and Wildlife (ODFW) estimated the wintering populations of deer and elk to be 17,762 and 3,720, respectively as of 1987. Planning benchmarks for deer and elk populations have also been established by ODFW. Planning benchmarks provide population estimates needed to maintain current and predicted demand for hunting opportunities. To meet demand for hunting opportunity, ODFW estimates a wintering population of 24,500 deer and 6,200 elk should be provided for on the Forest.

The Roosevelt elk population on the Forest has been supplemented through a transplanting program conducted in cooperation with the ODFW beginning in 1972. Since then, about 280 Roosevelt elk have been released into areas of underutilized habitat.

During the winter months, much of the Forest is covered by deep snow. As a consequence, the herds of deer and elk that range over thousands of acres during the summer months are restricted to significantly smaller range areas for much of the time between November through April. These low elevation areas are referred to as winter range. Winter range habitat must supply deer and elk with optimal cover, an available food supply, and security. Without these habitat features wintering populations suffer high mortality during winter periods and surviving cows and does have a low potential for producing viable young the following year.
Winter range is characteristically at lower elevations and along riparian areas where snow accumulation is not as deep. High quality winter range provides protection from wind, snow, rain, and low temperatures, constant availability of quality forage, and security that limits harrassment and allows for efficient use of energy reserves. This habitat is typically found where large patches of old-growth timber provide optimal cover interspersed with meadows, major riparian areas, and harvest units. Security may be provided by all cover types, but in a managed Forest landscape harrassment and poaching may become a limiting factor associated with open roads and recreation sites.

Over the years, the total acres of winter range has been reduced. In the past few decades, flood control projects, road building, timber harvest, and recreation use have all been intensely focused on winter range on the Forest. The development of eight reservoirs in the late 50's and 60's eliminated over 11,000 acres of prime winter range for deer and elk on the Forest. The development of the reservoirs removed thousands of old-growth trees that served as optimum thermal cover and forage sources. Hundreds of deer and elk were displaced from traditional wintering areas and migration routes changed or were eliminated. As a consequence, current deer and elk populations have access to less winter range habitat than was historically available.

Habitat availability on summer range is not considered as critical or limiting as winter range. Most of the Forest provides summer range. Quality of habitat remains a concern. Summer range habitat conditions ultimately determine the amount of stored fat reserves that animals take into the winter period. Lactating does and cows and breeding bulls require high nutrional levels and efficient energy use while utilizing summer range. Little information exists on the relative quality of forage areas on the Forest.

The past few decades have brought changes in the landscape characteristics of deer and elk ranges on the Forest. The gentler slopes at lower elevation allowed greater accessibility for road building. Harvest of the mature and old-growth Forests was concentrated in these areas through 1960. Steeper terrain has been extensively roaded since 1960, and timber harvest has become distributed throughout the available Forest lands.

Roosevelt Elk: Featured Species - Roosevelt elk, blacktailed deer, and mule deer utilize similar habitats on the Forest. All species migrate using summer and winter ranges. Elk appear to be more sensitive to the effects of Forest management activities and are used to represent the habitat requirements of all three species.

Four habitat variables are recognized as being directly influenced by Forest management activities and as having significant impacts on deer and elk habitat. Forage quality, cover quality, open road density and the distribution and size of forage and cover areas contribute to habitat effectiveness. Each of these habitat variables play an important biological function, and interact at the landscape level to determine habitat effectiveness.

Forage Quality - The quality of forage ultimately determines the amount of energy, protein, minerals, and fiber an animal has available throughout the year. Most techniques used to measure forage quality have been adapted from research on domestic ungulates. Quality rather than quantity of forage is usually more limiting in western Oregon. Quantity may be of concern during specific time periods, winter and early spring, or where competition with domestic livestock occurs for the same forage resource.

Forage requirements for deer and elk can double during the winter months because of increased energy requirements imposed by the weather conditions. Since does and cow elk are normally pregnant during the winter, forage availability and accessibility are also critical. Research has indicated that cow elk having more than 3% weight loss after January and prior to calving produced calves with less than 50% chance of survival (Thorne et al. 1976).

No research has been completed on the Forest assessing the availability and quality of forage species. Research from other areas west of the Cascades has been used to describe the relationships between Forest management activities, successional Forest development, and forage quality (Wisdom et al 1986). Forages capable of providing greater than 6% digestable protein are required for maintenance of body condition. Significantly higher protein levels are required for lactating cow elk and growing young (Sharrow 1985).

Forage areas are described as vegetated lands with less than 60% canopy closure of trees and tall shrubs. The sucessional stages comprising primary forage areas in Forest types are grass-forb, shrub, and open sapling pole. Availability of forage may become limiting in the open sampling pole stands as tree and shrub heights exceed normal browse heights of deer and elk. Meadows, marshes, and bogs are also preferred forage areas.

Cover Quality - The quality of cover increases as Forest development progresses. Hiding cover develops first, and has been described as vegetation capable of hiding 90% of an individual animal at a distance of 100 feet. On the Forest most forested stands more than 15 years old begin providing cover from predators and harrassment. Viewing angle may increase the density and height of vegetation required to achieve effective hiding cover on steep terrain (Lyons 1985).

Thermal cover develops during the mid seral stages of forest development. Stands with canopy closure greater than 70%, stem diameters greater than 8 inches, and canopies at least 40 feet tall provide

thermal cover. Thermal cover offers protection against adverse weather conditions and hiding cover. The closed canopy buffers wind, moderates cold and hot ambient air temperatures, and provides some shelter from rain and snow.

Optimal cover develops late in Forest succession. Stands of optimal cover supply forage and the most effective thermal cover. Quality of cover increases with structural development of several vegetation layers and accumulation of large woody material. Low elevation stands containing old growth Douglas fir have a capacity to hold large amounts of snow in the canopy. This reduces the energy elk must expend to access forage. During periods when Forest openings become inaccessible due to snow, understory vegetation and litterfall are critical to deer and elk survival.

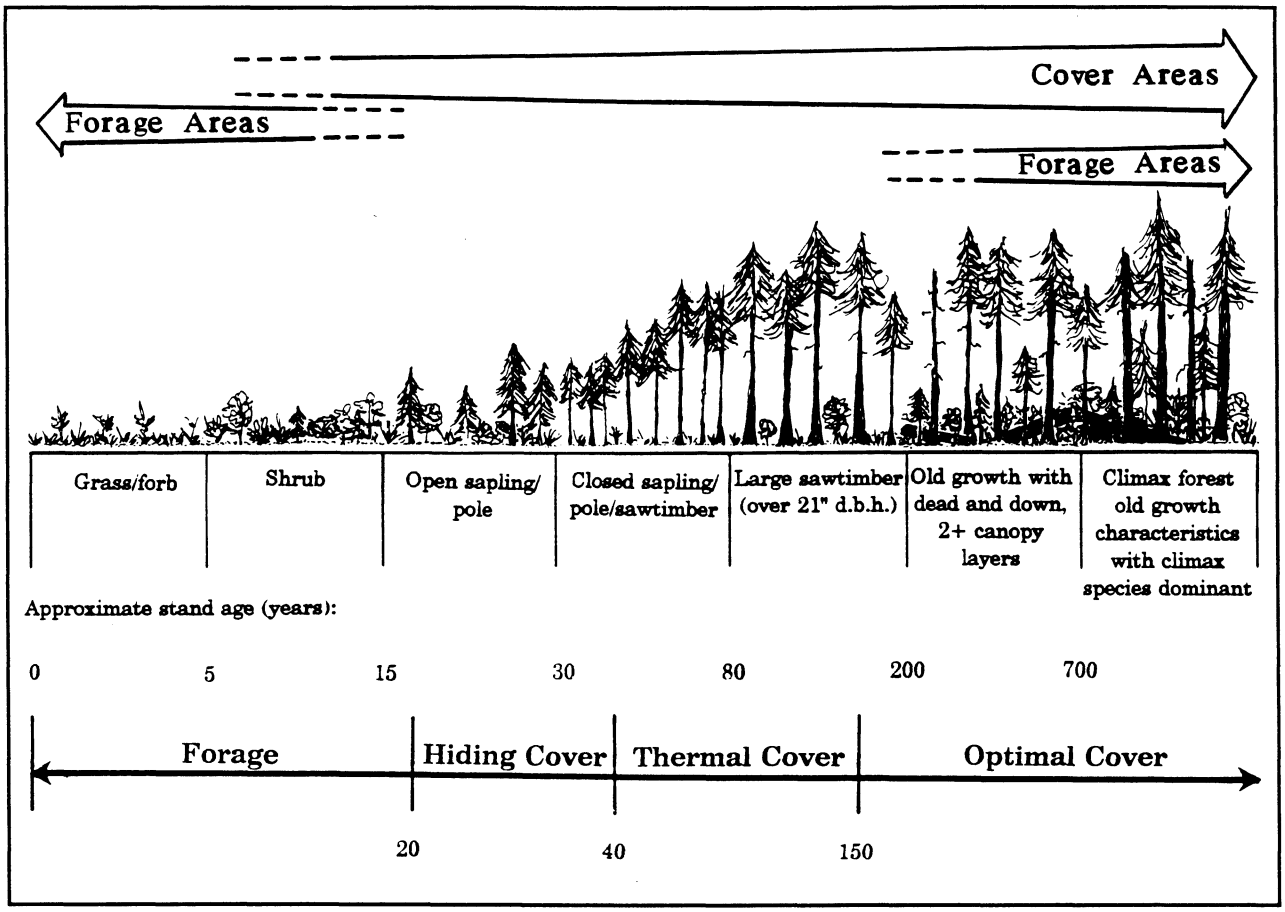
Figure III-J-4 displays the relationship between succession development in Forested ecosystems and deer and elk habitat.

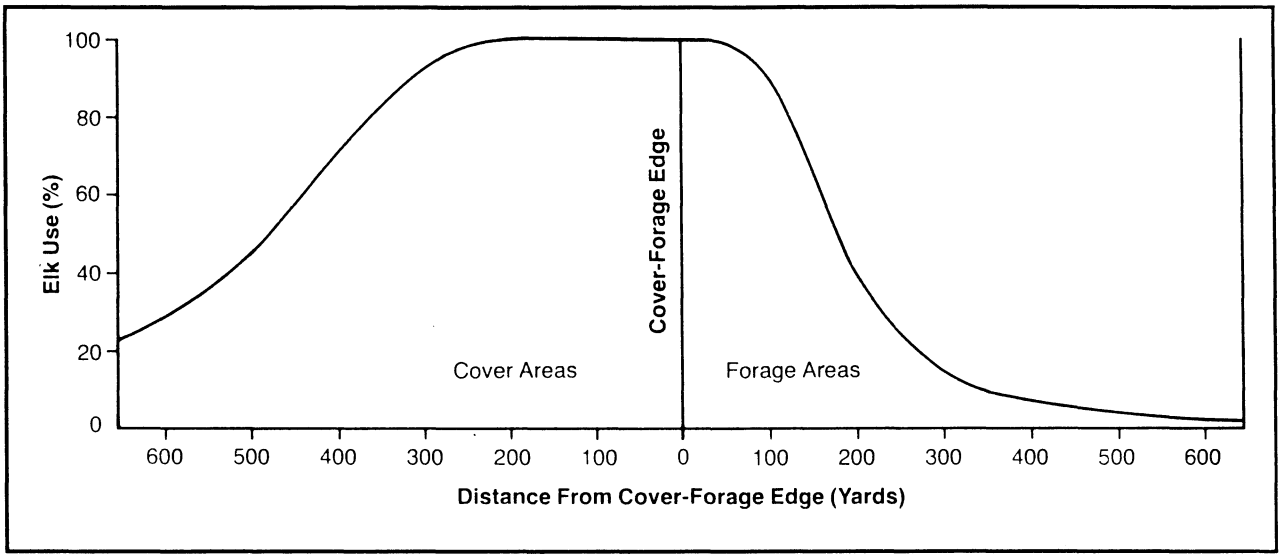
Distribution and Size of Forage and Cover Areas - The distance deer and elk travel into cover or forage areas determines how effective individual stands or landscapes are in meeting habitat requirements. Maximum use of forage with the least expenditure of energy occurs when forage and cover are interspersed. Size of individual openings become less effective as the distance from cover increases. The relationship of stand size and effective habitat distribution can be expressed in terms of distance from edge (Figure III-J-5 displays this relationship).

The current amount and type of cover and forage areas on summer and winter range is displayed in Figure III-J-6. These percentages represent a Forest-wide average. Depending upon the amount of past timber harvest activity, frequency of harvest entry, and size of harvest units within a given subdrainage, amounts and distribution of forage and cover areas varies throughout the Forest.

Rate of timber harvest determines the long-term availability and distribution of forage and cover areas. Natural forage openings comprise only 1% of the Forest. Openings created during timber harvest make up 13% of the Forest. Continued long-term availability of forage openings depends on timber harvest or fire in many areas of the Forest.

Figure III-J-4. Deer and Elk Forage and Cover Areas





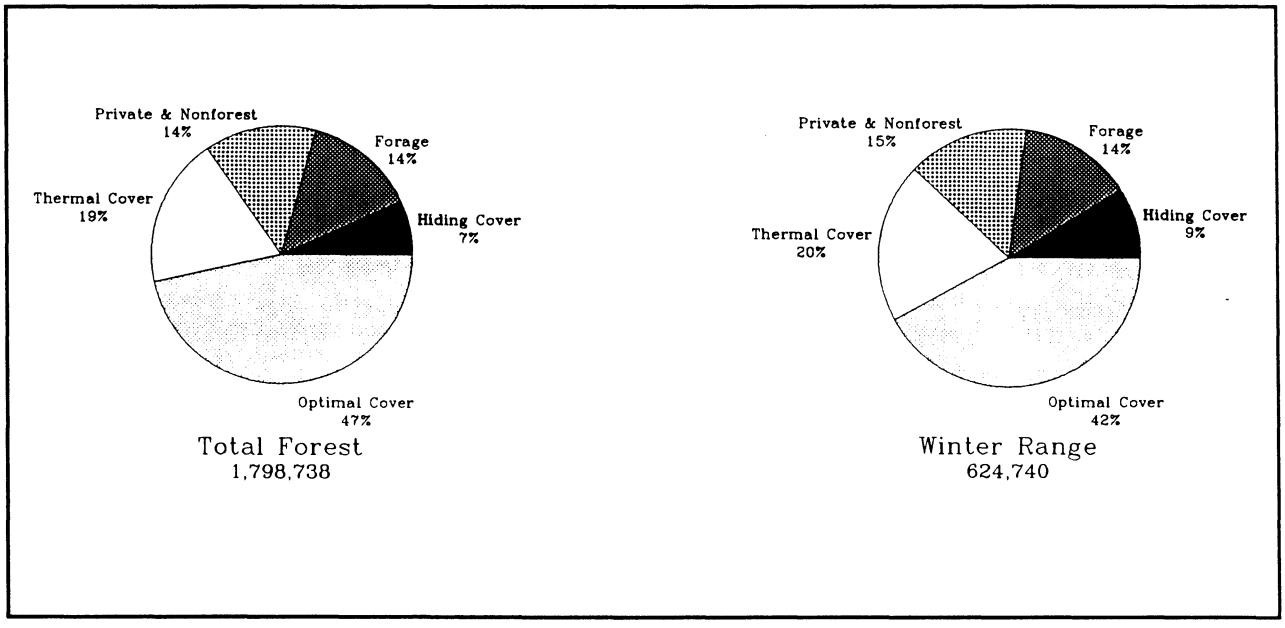


Figure III-J-5. Relationship of Elk Use to Distance from Cover-Forage

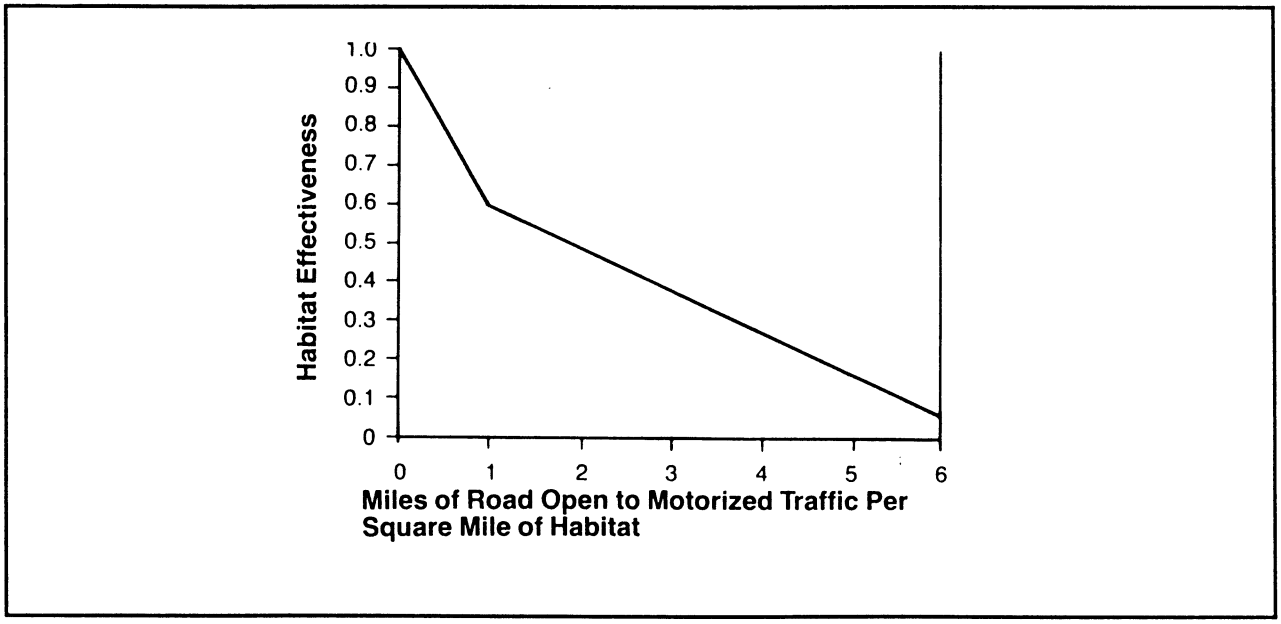
Source: Wisdom et al. 1986

Figure III-J-6. Existing Distribution of Forage and Cover Types



Density of Roads Open to Moterized Vehicles - Elk avoid roads to a greater degree than deer. Roads open to vehicular traffic significantly affect use of adjacent habitat by elk (Lyon 1983, Witmer and DeCalesta 1985). Hunted population show greater avoidance than populations that are protected. The frequency of road use that results in habitat avoidance has not been determined.

Open roads have been identified as a limiting factor in bull escapement during hunting seasons. In addition, ODFW estimates that significant numbers of deer and elk are illegally harvested (TWS 1989). Open roads reduce effective law enforcement capability because of the number of escape routes available to poachers. Because summering populations are dispersed over a larger geographic are, they are less suceptable to poaching. Exceptions occur near key use areas and along migratory routes. Figure III-J-7 displays the relationship between habitat effectiveness and miles of road open to motorized vehicles.

Current estimates are that 6500 miles of road are present on the Willamette. Higher elevation summer ranges contain more wilderness and roadless areas thus have an overall lower road density. Road closures have been implemented and timber sale contracts have been modified in an effort to reduce harassment to elk during winter and calving periods.

Surveys of hunters indicate that the greatest concern associated with current habitat conditions and recreational opportunities is the density of open roads (ODFW 1983). Hunters expressed concern at the lack of "walk-in" hunting opportunities, and the impacts of illegal harvest on opportunities to be successful during designated hunting seasons.

Figure III-J-7 Relationship of density of roads to habitat effectiveness

(Lyon 1983)

Special and Unique Habitats

Special and unique wildlife habitats are found throughout the Forest. These habitats are often associated with natural Forest openings, riparian areas, meadows, hardwood Forests, geologic features such as cliffs, talus, and caves and open water. Meadows provide foraging areas for numerous species including elk, bear, deer, and song birds. Predators including hawks, owls, falcons, coyotes, foxes use meadows and riparian habitats extensively while hunting. Caves are an important habitat element for bobcats, cougars, and bats providing shelter, roost, and den sites and protection from predators. Cliffs provide secure places for a variety of raptors to nest and rear their young. Talus concentrates animals such as pikas, frogs, toads, lizards, snakes, and other small mammals, and provides protection for some species during reproduction and hibernation. Open water provides needed habitat for wintering waterfowl, as well as foraging for eagles, ospray, and other fish eating species. Although these areas are a relatively small part (146,153 acres) of the Forest, they contribute significantly to the diversity of wildlife species.

In the past, some of these special and unique habitats have been altered by timber management and road building activities. The removal of Forest stands adjacent to special wildlife habitats alters food sources, eliminates visual barriers, opens areas to increased human harassment, and changes wind current patterns. Although natural openings such as caves, cliffs, and talus have not been changed to any great extent, the surrounding vegetation which contributes to their microclimatic conditions or usefulness as habitat for certain wildlife species has often changed dramatically.

Peregrine Falcon: Endangered Species

The peregrine falcon is listed in the Federal Register as an endangered species. A systematic inventory and survey for peregrine falcon has not been completed on the Forest. No nesting pairs of peregrine falcons have been found on the Forest, although several sightings have occurred. In 1981, the Forest in cooperation with ODFW identified cliffs meeting nest site characteristics for peregrine falcons. Subsequently, the ODFW conducted an aerial reconnaisance and identified 12 of these sites as having high potential as nest sites, but found no peregrines present. Table III-J-8 displays the locations of potential peregrine falcon nest sites.

Table T013. Potential Nest Sites for the Peregrine Falcon (III-J-8)

Ranger District	Location	Legal
Detroit	Mt. Beachie	T9S R5E Sec. 11/12
	Blowout Cliff	T10S R5E Sec. 23 (mostly private)
	Puzzle Creek	T11S R8E Sec 26/27
Sweet Home	Scar Mt.	T12S R6E Sec. 31/32
	Jumpoff Joe	T14S R5E Sec. 11
McKenzie	Lookout Mt.	T15S R6E Sec. 31/32
	Horse Creek	T16S R6E Sec. 28-34
Blue River	None	
Lowell	None	
Oakridge	Monteith Rock	T21S R4E Sec. 20/28
	Mt. David Douglas	T22S R5E Sec. 24
Rigdon	Balm Mt.	T25S R3E Sec. 23 (with Umpqua N.F.)
	Dome Rock	T24S R3E Sec. 36

In the Pacific states, American peregrine falcons nest almost exclusively on cliffs, usually near water and abundant populations of song birds. Preliminary studies show peregrines prefer nest sites that are sheer cliffs 150 feet or more in height. The cliff usually has a small cave or overhang ledge large enough to contain three or four full grown nestlings (USDI Fish and Wildlife 1982).

The direct use of cliff habitats for nesting and dependence on diverse vegetation conditions for high populations of prey species makes the peregrine falcon a featured species form these habitat types. Many other species of raptors are also commonly found in association with special and unique habitats. The diversity of wildlife species and habitats associated with special and unique features contributes significantly to the long-term recovery potential for peregrine falcons and to maintaining viability of many wildlife species.

Future Trends

Habitat of native and desired non-native species will be maintained at levels capable of supporting viable populations. The use of Management Requirements (MRs) for featured species will provide habitat conditions distributed throughout the Forest to ensure that all represented species exist in viable numbers. This will be accomplished by managing habitats and populations so that limiting factors are reduced and habitat characteristics are provided in the vegetation mosaic throughout the Forest.

Habitat conditions for those species associated with old-growth Forests will continue to decline. Forests managed on rotations less than 150 years will not provide suitable habitat. Only those areas allocated

to no harvest prescriptions will provide suitable habitat for species dependent on mature or older forests conditions.

Although the overall number of species present on the National Forests will remain stable, large fluctuations in the number of individuals within a species will likely occur. Populations are expected to remain viable, but whether the populations are high enough to ensure that the biological function of the species in the ecosystem remains uncertain.

Nesting peregrine falcons are likely to be found on the Forest in the near future. The species has been reported nesting on the adjacent National Forests and suitable habitat exists on this Forest. The Forest will be maintaining the 12 potential nest sites in suitable cliff habitat identified in the 1981 assessment of potential nest sites. When presence of nesting peregrine falcons, is verified, site specific management plans will be developed. All nest sites will managed in compliance with the USDI Fish and Wildlife Service recommendations and the "Pacific Coast Recovery Plan for the American Peregrine Falcon" (1982).

INSECTS AND DISEASE

Insects and diseases play a very important role in the ecosystem. Insects provide food for other insects, animals, and fish and act as plant pollinators. Many insects and disease relationships in the Forest ecosystem contribute directly to the carbon and nutrient recycling process in dead plant residue and to the development of Forest soil organic layers. Insects and disease may have negative impacts on stands of trees. Younger, vigorous trees are more resistant to damage from insects and disease. Mature or old-growth trees tend to have the greatest incidence of disease. Trees inhabitated by insects or disease have reduced sound fiber for utilization as wood products. Other insect-disease relationships are responsible for mortality and retarding growth in Forest stands.

Historic Trends

Historically, the Forest's overall tree mortality from insects and disease has been moderate. However, scattered outbreaks with tree damage have occurred, usually following fire or blowdown. In 1953, 80,000 acres on the Forest were sprayed to control an outbreak of the Spruce Budworm. Insects, diseases, and their hosts have evolved together for centuries, each responding to changes in the other. Though antagonistic to individual plants, many insects and diseases are beneficial to the Forest ecosystem, acting as a natural and necessary component of the system as long as the system is in balance.

Insects, including bark beetles and wood borers, utilize fungi as their primary food base and contribute directly to the dispersal and effectiveness of these decay organisms. In the process of eating the fungi, the insects ingest spores which sometimes survive passage through their digestive tracts (Witcamp 1975). Tree pathogens such as root rotting fungi are dispersed through the Forest ecosystem in this way.

Physical stress, such as lack of moisture, light, or nutrients, predisposes plants to invasion by insects and certain diseases or pathogens. Moisture stress reduces the tree's ability to combat insect attacks. Insects and disease, that attack stressed trees can release the healthier and more resistant trees. The result is similar to a precommercial or commercial thinning.

There are primarily three insects which have caused significant timber losses in the Forest. These are: The Douglas-fir bark beetle (*Dendroctonus pseudotsugae)*; Mountain-pine beetle (*Dendroctonus ponderosae*); and the Balsam wooley aphid (*Adelges piceae*). Douglas-fir bark beetles are occasionally found in down Douglas-fir timber. Mountain pine beetles occasionally kill pines that are weakened by white pine blister rust, poor or changing site conditions. Balsam wooley aphid damage may occasionally be found in the true firs, particularly Pacific silver fir. An aggressive salvage program has kept insect damage at a minimum.

In many instances birds regulate insect populations locally (Buke 1974). Pileated woodpeckers forage for carpenter ants and termites that invade the heartwood of trees, while sapsuckers and hairy woodpeckers prey on larvae and pupae in the cambium layer. Adult bark beetles, spiders and ants are pursued by other insectiverous birds such as the brown creeper, and the white-breasted nuthatch (Evans and Conner 1979). These birds, bats, other small mammals, and microbes help hold insect populations at nondamaging levels or exert some control during early stages of outbreak. The Forest standards and guidelines for wildlife trees will help maintain viable populations of these valuable species throughout the Forest.

In 1984, an isolated and well-established gypsy moth infestation was discovered on about 5,000 acres of white oak, alder, and Douglas-fir on a ridge south of Oregon Highway 58 between Rattlesnake and

Williams Buttes in Lane County. The area is about 15 miles west of the Forest boundary. Some moths were also found on the southwest portion of the Lowell Ranger District. The gypsy moth has not been proven to be a major defoliator of Douglas-fir; its greatest impact will be on south aspects where oaks and other hardwood brush is abundant. On these habitats it has shown the ability to build up to high population levels and is suspected of defoliating minor amounts of needles of Douglas-fir along with the hardwood species (Miller 1986).

Immediately after this infestation was detected, the Oregon Department of Agriculture and U.S. Department of Agriculture Animal and Plant Health Inspection Service (APHIS) established a quarantine area to regulate and restrict the spread of the gypsy moth. Approximately 200,000 acres of the Forest were included in this quarantine area. All Forest products, including nursery stock, Christmas trees, lumber, firewood, and wood chips had to be certified as being free of gypsy moth life stages before being shipped from the regulated area.

Current Situation

All of the diseases that attack timber species in the Douglas-fir region are present on the Forest. Much of the old-growth timber has heavy defect from butt and trunk rots. Root rots often weaken trees making them subject to windthrow. Dwarf mistletoe causes considerable damage, loss of growth, and occasional death in hemlock and true fir stands. White pine blister rust is prevalent in western white pine and sugar pine.

As existing older stands are harvested from lands suited for timber management, the total Forest losses due to defect will be reduced. The biggest disease losses in the regenerated stands are and will continue to be caused by pockets of root rots, such as *Armillaria mellea* root disease, *Phellinus weirii* root rot, and *Ceratocystis wageneri* black stain root disease. Consideration is now being given to planting tree species more resistant to root disease where the root disease pockets have been identified prior to reForestation actions.

Black stain root disease can be spread by bark beetles and weevils which pick up the fungus while feeding on infested trees and transfer it to other trees. This is minimized by scheduling thinning treatments in June and July when the insects are inactive. The stumps then dry out and are not attractive to the beetles or weevils.

Current tree management and silviculture systems provide methods of control of insects and disease. Prescribed management practices include but are not limited to:

- Removal of disease-susceptible or infected trees.
- Introduction of rust-resistant western white pine and sugar pine.
- Salvage of beetle-infested or susceptible trees.
- The use of more resistant species in reForestation programs.
- Cutting and disposal of mistletoe-infected trees to prevent spread of this disease.
- Aerial reconnaissance for and detection of insect and disease problems to assure prompt and timely treatment.

- Timing cultural operations to minimize insect population increases.
- Enhancing habitat for predators that control insect populations.

The potential threat of the gypsy moth outbreak to Oregon's economy was significant. In 1980, the total Oregon timber product value was $4.4 billion. Receipts from National Forest lands in Oregon during 1984 totaled about $350 million. The Oregon nursery industry ranks third in producing woody nursery stock for shipment throughout the Nation and overseas. Nursery sales and Christmas tree sales in Oregon are valued at $215 million annually.

Through the aggressive effort of federal and state agencies, the outbreak was controlled by aerial applications of *Bacillus thuringiensis* (Bt), a bacterium that produces a toxin against the moth.

The quarantine was lifted in 1989 after 3 years of trapping with zero moths captured. Industry was able to adjust to the compliance procedures of the quarantine and the impacts were less than predicted.

Currently there is a small outbreak of Spruce Budworm in the Santiam Pass area, that has apparently spread from the Deschutes National Forest. The population is being monitored closely to see if pesticide use will be necessary.

Future Trends

Major outbreaks of insects or diseases are unpredictable. As timber is harvested, new pockets of disease will be discovered. Prescriptions will be implemented that will reduce the product loss in plantations. Perpetuation of some of these diseases is inevitable. Insects will cause damage in isolated areas and will probably be recurrent on cone crops. Current tree management and silviculture systems will continue as long as there practices effectively reduce loss of wood fiber and protect other resources.

The benefits of salvaging scattered mortality must be weighed against the reduction of wildlife tree habitat and large woody debris. Loss of this habitat along road corridors will require more green trees to be left in harvest units to maintain the overall watershed in an acceptable condition. Trees causing a safety hazard must be felled but their removal is not necessary.

ARTIFACTS AND SITES

Evidence of past human use of the land and resources within what is now the Forest remains in prehistoric (American Indian) and historical sites throughout the Forest. These sites, and scattered artifacts, make up the cultural resources from which information can be learned about former ways of life in the forest setting, of the Western Cascades.

Historic Trends

Human use of lands and resources in and around the Forest extends over an estimated 8,000 years. Previous American Indian inhabitants within or adjacent to the Forest at the time of historic contact include the Molala, Kalapuya, Tenino, and Northern Paiute. The Molala and the Kalapuya peoples wintered at sites along streams in the lower elevations of the Western Cascades and traveled to the higher elevations to hunt game, gather wild plant foods, and to collect toolstone (obsidian) and other necessities of primitive life. American Indian sites are documented throughout the Forest including toolstone quarrie, habitation sites and seasonal camps, trails, food gathering areas, peeled bark trees, rock shelters, and religious sites (Minor et al. 1987).

Euro-American settlers, miners, trappers, and loggers have used Forest lands and resources since the 1800s. Remnants of the historic (1805-1910) Euro-American use include trails, wagon roads, railroad grades, homesteads, cabins, sheep camps, and mines. The physical remains of early Forest administrative sites (1910-1940) include cabins, guard and Ranger Stations, trails, lookouts, and Civilian Conservation Corps (CCC) recreation and administrative structures.

Many prehistoric and historic sites have been lost or degraded due to environmental processes including weathering, erosion, tree fall, and fire. Historic buildings and structures are affected by weathering, insect infestation, moisture, and fire. Archaeological sites are affected by erosion and natural weathering.

Past experience has shown that cultural resources can also be lost directly through development of campgrounds and trail construction, logging and road construction, and indirectly through improving access which increases potential for vandalism and artifact theft. Occasionally, public use may result in the deliberate destruction of cultural properties through vandalism, relic collecting, theft, and carelessness. Losses of this type may increase in the future with increasing use of the Forest for a wide range of activities. The main protective measures used in the Forest have been to maintain the confidentiality of specific prehistoric site locations, to direct public use away from archaeological properties, and periodic monitoring of sensitive areas. Public education has been used to promote awareness and protection of prehistoric and historic sites.

A number of laws have been enacted to ensure the preservation of the Nation's cultural resources. Principal laws affecting the Forest are:

Preservation of American Antiquities Act of 1906
Historic Sites Act of 1935
National Historic Preservation Act of 1966
National Forest Management Act of 1976
National Environmental Policy Act of 1969
Archeological Resources Protection Act of 1979
American Indian Religious Freedoms Act of 1978
Federal Land Policy and Management Act of 1976
Executive Order 11593 (1971)

Guidelines in 36 CFR 800; 36 CFR 60, 63, 66; and 7 CFR 3100.
United States Forest Manual, Part 2360.
Historic Preservation Handbook

The National Historic Preservation Act, as amended, directs that cultural resources on federal lands be inventoried and evaluated. Project inventory, cultural site evaluations to determine *National Register of Historic Places* and various kinds of investigations including archeological data recovery evaluations are completed annually on the Forest. Enhancement and interpretation of cultural resources has not been accomplished as a regularly scheduled activity. Limited interpretation or enhancement has been accomplished for prehistoric properties to date. Future study will be done of both prehistoric and historic sites as regular program of activities.

Current Conditions

Over 1100 cultural resource sites have been identified in the Forest as of January 1990. Figure III-L-1 summarizes this data by Ranger District. One historic site, Independence Prairie Guard Station, is on the *National Register of Historic Places*. Some 200 evaluated historic and archaeological sites eligible for addition to the National Register. In addition, prehistoric and historic land use patterns suggest a high probability for the occurrence of other significant cultural resources within the Forest.

The Forests CCC era administrative and recreational structures are currently in the process of being nominated to the National Register of Historic Places. Included in this process are: Longbow, Trout Creek, and Clark Creek Organization sites; Breitenbush and Marion Forks Guard Stations; Fish Lake Remount Station and Santiam Lodge; Olallie Mt. and Carpenter Mt. Lookouts; and White Branch Lodge. In addition, the two historic wagon roads (Santiam Wagon Road and The Oregon Central Military Wagon Road) in the Forest are eligible for nomination to the National Register of Historic Places.

There are no known Native American burial sites located in the Willamette National Forest. The Confederated Tribes of The Warm Springs, Grande Ronde and Siletz, and The Cow Creek Band of The Umpqua are regularly consulted regarding Forest activities that are known or likely to affect prehistoric and historic sites. To date, no groups have expressed strong interests about specific prehistoric or historic sites or traditional use areas on the Forest.

The Forest has undertaken a program to identify, evaluate, protect, enhance, and mitigate adverse effects on prehistoric and historic resources within the Forest. The program has expanded from preliminary inventory of known significant prehistoric and historic resource sites to include field surveys of any areas in which proposed management will result in ground disturbance or an exchange of property. Cultural resource inventories consist of project area reconnaissance surveys to identify the presence or absence of cultural sites. The Forest currently inventories approximately 23,000 acres per year. The scientific or historical value or "significance" of all identified cultural resources is determined by evaluating the properties against the National Register criteria for evaluation (36 CFR 60.4). When there is insufficient information present to evaluate a prehistoric site, the Forest archaeologist coordinates a testing program usually consisting of subsurface excavation and scientific collection of artifacts.

Cultural resource compliance procedures, mandated by federal laws and regulations require on-going consultation with the State Historic Preservation Office (SHPO), and the Advisory Council on Historic Preservation and the Keeper of the National Register of Historic Places (National Park Service). When appropriate situations arise, the Forest also coordinates its cultural resource activities with those of adjacent federal land-managing agencies such as the National Park Service, the Bureau of Land Management, and the Army Corps of Engineers.

Table T015. Cultural Resource Information (III-L-1)

Ranger District	Number of Sites		Sites Tested[1]	Sites Eligible to NR [2]	Site Impacts Mitigated[3]
	Prehis-toric	Historic			
Rigdon	134	16	30	16	5
Oakridge	120	58	8	3	0
Lowell	98	37	13	10	1

Detroit	251	35	12	6	5
TOTAL	1,169	189	112	75	21

[1]Denotes sites where either full acheological testing or historic archival research occurs to determine the importance or "National Register" significance of site(s).
[2]National Register of Historic Places
[3]Adeverse affects to cultural sites by project activities are usually mitigated through project redesign and "avoidance". This figure denotes only those cultural sites subject to scentific "data recovery" excavations or historical recording as mitigation measures prior to partial or total site destruction by ground disturbing projects.

Future Trends

As the dimension of land development increases on private and public lands, a correspondingly greater proportion of the physical remnants of our American heritage and a large source of scientific and historical data will be irrevocably lost. As a result, the value of cultural sites on National Forest lands will increase with time. This intensifies the need to protect and manage this irreplaceable resource.

The anticipated demand for identification and use of cultural resources will likely be a function of four factors: 1. intensified timber management activities; 2. recreational use; 3. Native American religious or cultural use; 4. and the development and expansion of archaeological and historical research. The probability for loss of cultural resources increases as lands are allocated to uses involving land modifying activities. The degree of loss will depend upon the location and extent of land alteration.

Timber harvest can result in significant ground disturbance caused by roads, skid trails, and landing construction, yarding of logs, slash piling, and tree planting. At the same time, timber harvesting provides opportunities for identification and evaluation of previously unknown cultural properties. Field reconnaissance for cultural resources accelerates proportionally to the number of acres scheduled for harvesting. In heavily vegetated environments, the removal of understory and forest duff may provide the only means of locating archaeological sites.

Cultural resources will continue to be identified as more of the Forest is inventoried according to the Forest's inventory plan. This plan will enable archaeologists and cultural resource technicians to concentrate their inventory efforts in areas of high probability for the occurrence of artifacts and sites. Current efforts to identify where cultural resources are likely to be found in the Forest are documented

in a forest-wide inventory of occurrence probability. Figure III-L-2 displays the relative occurrence probability of artifacts and sites by landscape feature.

Table T016. Occurrence Probability of Artifacts and Sites (III-L-2)

Landscape Feature	Occurrence Probability			
	High	Moderate	Low	Total Acres
Water Related	218,675	--	--	218,675
Saddles/Knolls/Ridges/ Benches	78,110	--	--	78,110
Meadows/Ecotones	12,627	--	--	12,627
Valley Floors	12,307	--	--	13,307
Aspects - S, SE, SW	--	145,471	--	145,471
Other	--	--	1,208,217	1,208,217
TOTAL ACRES	321,719	145,471	1,208,217	1,675,407

Evaluation of cultural properties will likely remain constant in the near future, while mitigation, including site avoidance, will increase as more ground disturbing projects will be planned for areas with identified cultural properties. Enhancement and interpretation of prehistoric and historic resources has become a high priority in recent years (since 1987) as Forest inventories come near completion and as site evaluation and mitigation accelerate. A large body of information about the prehistoric and historical human use of the Western Cascades has been amassed as a result of these efforts. Consequently, in concert with broader Forest efforts, the Forest has embarked upon a program to enhance and interpret important and represenative cultural sites for public education and enjoyment (See activity schedule for enhancement and interpretation projects, Appendix D of the Forest Plan). This program will likely increase in importance in future years along with the Forest's recreational opportunities.

There are currently few data sources available to determine recreational use of cultural resources on the Forest. Enhancement and interpretation of historical properties would likely increase the demand for recreational use. An effort by th

RECREATION

The Forest offers a diversity of recreation settings ranging from developed sites to Wilderness. People participate in a wide range of recreation activities throughout the year. The most popular recreation activities in the Forest are camping, driving for pleasure, fishing, and boating-related activities. In 1982 participation in these four activities represented approximately two-thirds of the total recreational use in the Forest. Next in popularity were swimming, picnicking, hiking, and resort use.

The dispersed and developed recreation resources of the Forest serve to meet the varied recreational needs of its residents and are an important aspect of the area's economy.

Dispersed Recreation: Forest recreation that takes place outside of developed recreation sites is referred to as dispersed recreation. Areas of dispersed recreation opportunities are available throughout the Forest from a spectrum of landscape settings that range from the densely forested West Cascades to the meadow and lake dotted Cascade Crest. This spectrum of recreation opportunity settings provides the basis for users to engage in a variety of activities, including fishing, hiking, horseback riding, hunting, off-road vehicle (ORV) use, cross-country skiing, driving for pleasure, gathering Forest products, and nature study.

Developed Recreation: Opportunities are considered developed when a particular activity utilizes a structure, facility, or site that has been developed for recreation purposes. These opportunities are provided from an array of developed sites that vary widely in their degree of environmental modification and development. Sites range from downhill ski areas, to campgrounds where facilities are provided for the convenience and comfort of users, to primitive campsites where environmental modification is minimal and facilities are provided only for the protection of basic resources.

Recreation use is measured in Recreation Visitor Days (RVDs) which are used to quantify the amount of participation in various recreation activities. An RVD is equivalent to 12 person hours spent recreating on National Forest land; e.g., 12 hours spent by one person, 6 hours spent by two people, etc.

The primary purpose of managing recreation resources is to provide a range of opportunities from which National Forest users can obtain satisfying recreation experiences. To fulfill this purpose the USDA Forest Service uses a land classification system to inventory and describe a range of recreation opportunities called the Recreation Opportunity Spectrum (ROS). This system seeks to identify recreation settings of varying characteristics that range from large, remote, undeveloped areas to small, easily accessed highly developed sites. These settings are described in terms of five ROS Classes. (See Figure III-M-1 for a description of Classes.) Within this management framework, the traditional concepts of developed and dispersed, motorized and nonmotorized, and trail and nontrail recreation opportunities are interwoven.

Table III-M-1. Recreation Opportunities Spectrum Descriptions [1]

ROS Class	Descriptions
Primitive	Area is characterized by essentially un-modified natural environment of fairly large size. Interactions between users is very low and evidence of other users is minimal. The area is managed to be essentially free from evidence of human induced restrictions and controls. Motorized use within the area is not permitted. Extremely high probability of experiencing isolation from the sights and sounds of humans. Independence, closeness to nature, tranquility, and self-reliance through the application of of outdoor skills in and environment that offers a high degree of challenge and risk.
Semiprimitive Nonmotorized	Area is characterized by a predominately natural or natural-appearing environment of moderate-to-large size. Interaction between users is low, but there is some evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present, but are subtle. High probability of experiencing solitude, closeness to nature, tranquility, self reliance, challenge and risk. Access and travel is nonmotorized on trails, primitive roads, or cross country. Vegetative alterations; sanitation salvage units to be very small in size and few in number, widely dispersed and not obvious. No on site facilities except limited signing, sanitary and safety needs in native or rustic materials. Minimal to no site modifications. Interpretation through self discovery. Some use of maps, brochures, and guide books.
Semiprimitive Motorized	Area is characterized by a predominately natural or natural-appearing environment of moderate-to-large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present, but are subtle. Motorized use is permitted. Moderate opportunity for solitude, tranquility, and closeness to nature. High degree of self reliance, challenge and risk in using motorized equipment. Vegetation alterations very small in size and few in number, widely dispersed and not obvious. Limited facilities for signing sanitary and safety needs in native or rustic materials. Minimal site modification for facilities. Interpretation through very limited on-site facilites. Use of maps, brochures and guide books.
Roaded Natural	Area is characterized by a predominately natural-appearing environment. Interaction between users may be low to moderate, but with evidence of other users prevalent. resource modification and utilization practices are evident, but harmonize with the natural environment. Conventional motorized use is provided for in construction standards and design of facilities. Opportunity to affiliate with other users in developed sites but with some chance for privacy. Self reliance on outdoor skills of only moderate importance. Little challenge and risk. Some obvious on-site control of users. Access and travel is conventional motorized including sedan and trailers, RVs and some motor homes. Moderate site modification and amount and complexity of facilities for comfort and convenience of user. Interpretation through wayside exhibits. Use of primarilly native-like or rustic material with some refinement in design. Some casual interpretation from Forest staff.
Roaded Modified	Area is characterized by substantially modified natural environment. Resource modification and utilization practices are to enhance specific recreation activities and to maintain vegetative cover and soil. Sights and sounds of humans are readily evident, and the interaction between users is low. Facilities may be provided for special activities. Moderate densities of use are provided for away from developed sites. Opportunity to get away from others but with easy access. Feeling of independence and freedom but with little challenge and risk. Substantially modified natural environment where roads, landings, slash, and debris may be strongly dominant from within, yet remain subordinate from distant sensitive roads and highways. Conventional motorized access including sedan and trailers, RVs & motor bikes. Little on-site controls of users except for some gated roads. No on-site facilities except signing at major road junctions and occasional sanitary facilities for user health protection. Interpretation by simple wayside signs of native or rustic materials may be provided.

Historic Trends

To determine the most likely rate of change in future recreation use it is necessary to examine trends in historical data. The primary source for visitor use data for the Forest is the Recreation Information Management (RIM) System. RIM files contain use data for specific activities and sites in the Forest. Similar RIM activities were combined into appropriate categories for analysis and display.

Analysis of RIM data from these activity groupings for the period 1980-89 revealed an average annual growth rate in recreation use for all activities of about 2.7%. See Figure III-M-2 for dispersed/developed use trends and Figure III-M-3 for trends of all activities. Although some fluctuations in use were noted between 1980-1989, clear trends of continued growth are evident in the data.

Figure III-M-2. Recreation Use in Thousands of RVDs[1]

Type of Use	1980	1981	1982	1983	1984	1985	1986	1987	1988[2]	1989[2]

[1]Source: USDA Forest Service, Recreation Information Management System (RIM).
[2]Includes use attributed to Wilderness.
[3]Source: Estimates of Forest use based on historical use patterns.

During the 1980-1989 period, participation in most recreation activities increased at varying rates with some noticeable peaks, valleys and plateaus in the trend lines. It seems evident from the figures that recreation use was affected by such variables as weather and travel costs. Although use in most activities showed some decline during the 1980-1989 period total use has increased steadily. Total use did not change from 1981-1982. This may be due in part to the econmic resession the region was experiencing, although there was dramatic increases in use for some activities.

Two activity groupings show a decrease in participation over the 10 year period: organized camping and resort use. Hiking and picnicing use dropped dramatically in 1982 and have only recently regained their 1982 participation levels. Swimming use follows a similar pattern. Between 1982 and 1985, swimming use decreased significantly. Since that time, it has risen to approximately the 1981 level and has shown increases over the last four years.

Current Situation

Access to the Forest is provided by four highways, U.S. Highway 20 and State highways 22, 126, and 58. From these highways, Forest roads branch out to the many points of interest and recreation opportunities. From the Forest roads many trails provide access to remote, undeveloped recreation opportunities.

People from many western Oregon counties, other states, and even other nations visit the Forest. Lane, Linn, and Marion County residents are the most frequent users of the Forest, although Benton, Polk, and Yamhill counties, the Portland metropolitan counties of Clackamas, Multnomah, and Washington, as well as Deschutes County to the east, all contribute many recreationists.

Total recreation use in the Forest is split almost evenly between developed sites and dispersed areas (including Wilderness). The wide variety of sites and settings available provides opportunities for everyone to participate in many different activities and have meaningful recreational experiences.

Recreation Activities: Approximately 80% of the Forest's camping use occurs at developed sites. Nearly one quarter of all developed recreation site use occurs at Detroit Lake State Park, a site managed by the State of Oregon under special use permit. Other high use campgrounds include Paradise, Coldwater Cove, Ice Cap Creek and Big Lake.

About half of the driving and sightseeing activities occur on the major Forest roads in the High Cascades of the McKenzie and Oakridge Ranger Districts. The mountain pass roads are extremely popular for this type of activity.

Some of the reservoirs in the Forest receive heavy boating and swimming use during the summer months. Over 40% of reservoir boating use occurs on Detroit Lake with another 30% on Hills Creek Reservoir. Lakes receiving heavy boating use include Big Lake, Clear Lake, and Lost Lake in the McKenzie Ranger District. These reservoirs and lakes also receive a large portion of the swimming use, both at developed sites and nondeveloped areas along the shore. The remainder (over 40%) of the swimming activities takes place along the rivers and streams flowing through the Forest. The Fall Creek area in the Lowell Ranger District accounts for over half of this type of use. Fishing use in the Forest is divided almost equally between lakes/reservoirs and rivers and streams. Heaviest river and stream use occurs in the Detroit (North Fork of the Santiam and Little North Fork of the Santiam River), Rigdon (Middle Fork of the Willamette), and McKenzie (McKenzie River) Ranger Districts. Lake and reservoir fishing use is heaviest on Detroit Lake and the high elevation lakes on the McKenzie District.

Over 80% of the hiking in the Forest takes place on the Forest trail system. Much of this occurs in the Detroit and McKenzie Districts which together contain 65% of the Wilderness and 30% of the nonwilderness trail mileage in the Forest. Over half of the general undeveloped area hiking occurs in the Rigdon and Blue River Districts. Cross-country hiking without trails makes up about 20% of the hiking experiences on the Forest.

An emerging dispersed recreation activity on the Forest is Mountian Bike use. Mountian Bike enthusists are becomming organized as an group with a desire to cooperate in identifying Mountian Bike use opportunities on the Forest. Currently several trails have been identified as being ideal for this use.

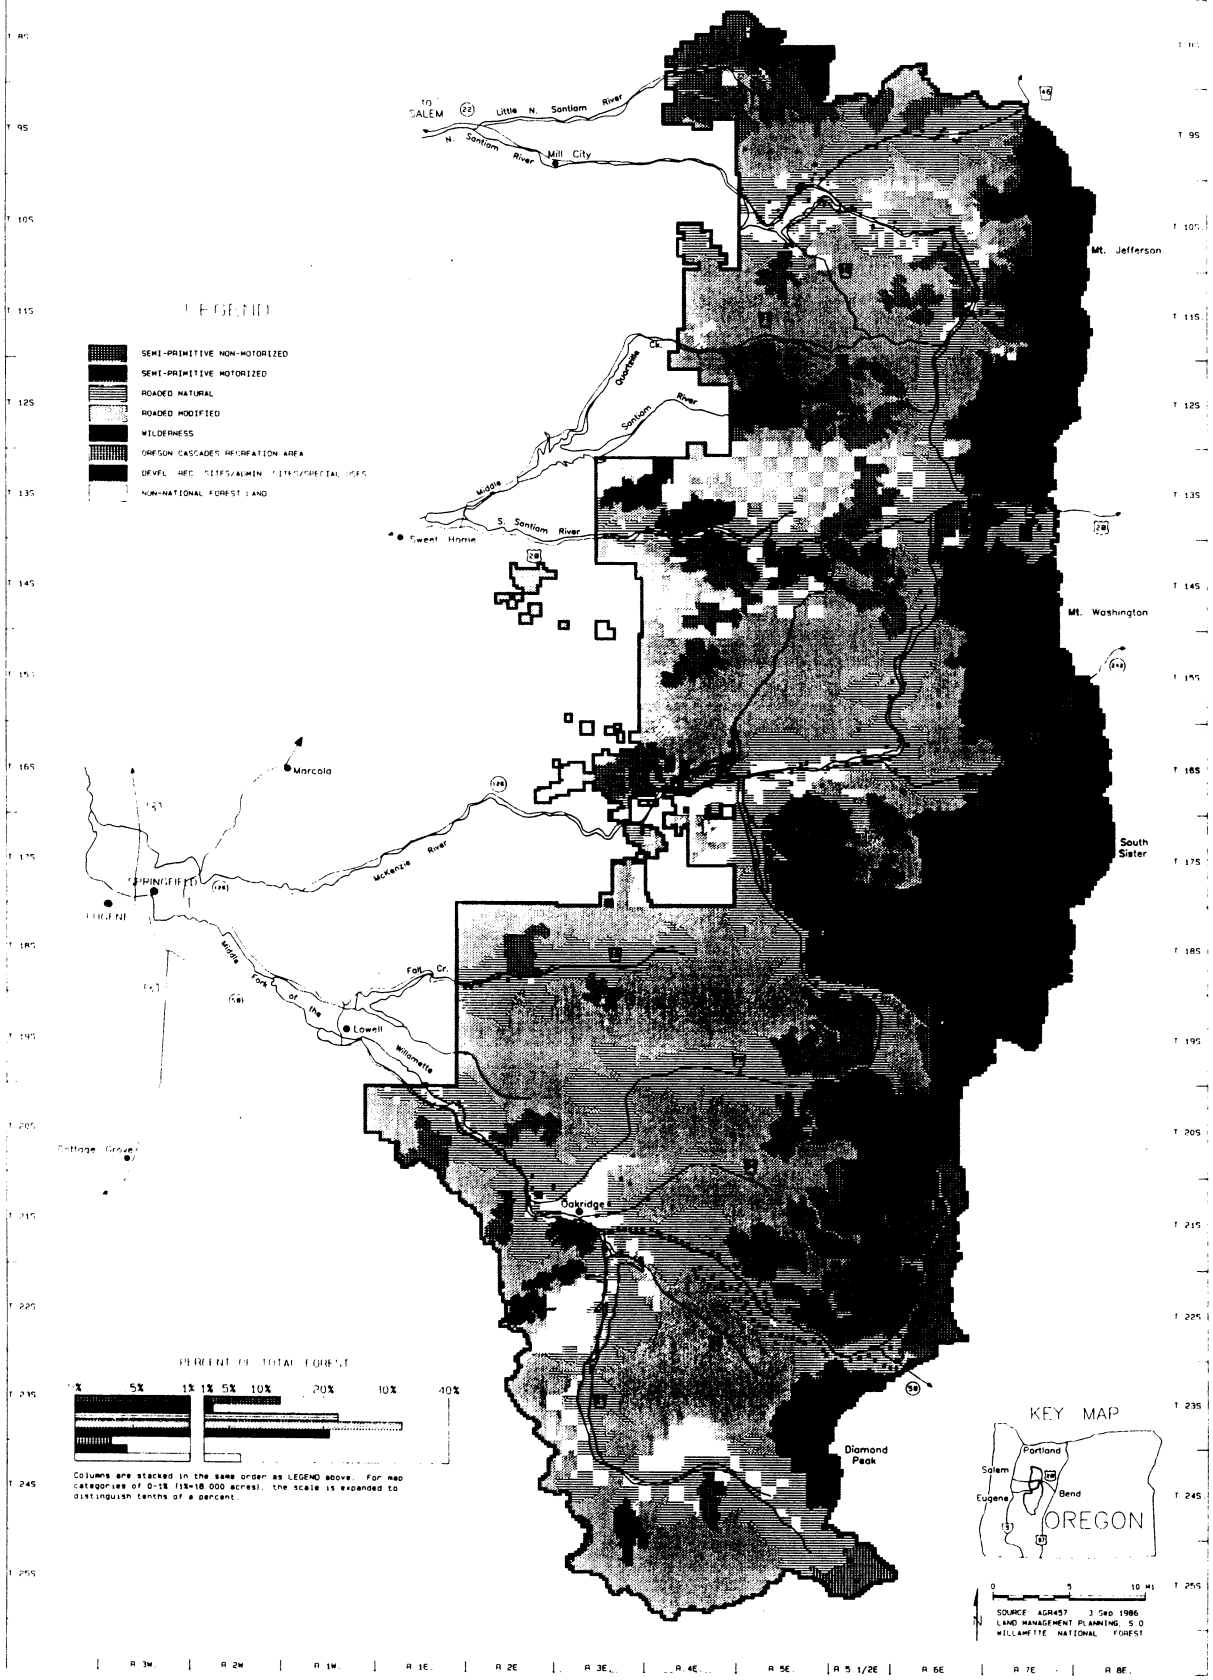
Nearly 65% of all hunting in the Forest is for big-game animals--primarily deer and elk. Another 20% is for small game with the remainder for upland birds and waterfowl. Two-thirds of the big-game hunting occurs in the Detroit, McKenzie, and Oakridge Districts while nearly 70% of the small game hunting occurs in the McKenzie District.

Many of the other recreational activities in the Forest take place at specialized developed sites. Picnicking, resort use, downhill skiing, visitor information services, and much of the cross country skiing fall into this category. Others activities such as horseback riding, nature study, mountain climbing, and gathering Forest products occur primarily in dispersed areas.

Dispersed Recreation: Opportunities for dispersed recreation are available from nearly all land and water areas within the Forest. The type and quantity of dispersed nonwilderness recreation opportunities have been identified through the Recreation Opportunity Spectrum (ROS) inventory process. The inventory, through the use of specific criteria, classifies the Forest landscape into categories that identify a spectrum of recreation opportunity settings. In Figure III-M-4 a summary of acreages, trail miles, and Recreation Visitor Day (RVD) capacity is displayed for each recreation opportunity settings located in the Forest. The spatial distribution of these opportunity settings is illustrated in map form by Figure III-M-5.

Of the four recreation opportunity types that occur in the Forest, the semiprimitive motor and nonmotor are in shortest supply, as they comprise 19% of the Forest's nonwilderness dispersed recreation opportunities. These opportunity types are coincident with Inventoried Roadless Areas and other unroaded lands. Inventoried Roadless Areas, discussed later in this chapter, together with other unroaded lands (less than 5,000 acres in size) comprise the land base from which the Forests semiprimitive dispersed recreation opportunities are derived as illustrated in Figure III-M-5.

Table III-M-4. Nonwilderness Dispersed Recreation Opportunities [1]



Data Categories	Primitive	Semiprimitive Nonmotor	Semiprimitive Motor	Roaded Natural	Roaded Modified	Totals
Acreage [2]	0	205,335	43,300	437,615	600,120	1,286,370
Trail Mileage	0	280.7	60.5	248.3	124.2	713.7
RVD Capacity	0	125,084	67,378	2,954,146	1,686,858	5,833,466

[1]See Planning Records for documentation of ROS Inventory criteria and process.
[2]Acreages include the Oregon Cascades Recreation Area but exclude developed recreation sites, special use and administrative sites and designated Wilderness.

Figure III-M-5.

WILLAMETTE NATIONAL FOREST

Dispersed Recreation Opportunities

Oregon Cascades Recreation Area: One unique nonwilderness area in the Forest which provides semiprimitive recreation opportunities has been reserved by Congress for recreation purposes by the Oregon Wilderness Act of 1984. This area spreads over adjacent lands of the Deschutes and Umpqua National Forests.

The Oregon Cascades Recreation Area (OCRA) was established by Congress ". . . to conserve, protect, and manage, in a substantially undeveloped condition, certain National Forest System lands in the State of Oregon having unique geographic, topographic, biological, ecological features and possessing significant scenic, wildlife, dispersed recreation, and watershed values . . . within the Umpqua, Willamette, Winema, and Deschutes National Forests . . . "(Oregon Wilderness Act of 1984).

The Forest portion (6,122 acres) of the OCRA (84,278 acres) is located in the Timpanogas Basin about 45 miles southeast of the city of Oakridge. This area includes the headwaters of the Middlefork of the Willamette River and ranges from 5,200 to 7,664 feet in elevation. Most of the area is a true fir/mountain hemlock forest type dotted with numerous small lakes.

Both dispersed and developed recreation opportunities exist in the basin, consisting of two nonfee campgrounds and 20.2 miles of developed hiking trails. Both developed campgrounds, Indigo Lake and Timpanogas Lake have a use season of June 15 to October 15 with peak use occurring in August and September. Timpanogas Lake (10-unit campground) is accessible by a high standard gravel surface road while Indigo lake (two units) requires a 1.5-mile hike.

Dispersed recreation in the OCRA is primarily confined to the trail system consisting of both hiker and off-road vehicle uses. Much of the use originates from either Timpanogas Lake Campground or the Pacific Crest Trail. Motorized use in the OCRA is limited to the existing trail system except for over the snow vehicles.

The OCRA is being managed under a seperate management plan prepared in accord with and subsequent to enactment of the Oregon Wilderness Act of 1984, which has been in effect since February 2, 1989.

Wild and Scenic Rivers: The Forest also provides for a wide range of dispersed recreation activities within two designated Wild and Scenic Rivers: the McKenzie River, from Clear Lake to Scott Creek and the North Fork of the Middle Fork of the Willamette River from Waldo Lake to near West Fir, Oregon. These designated rivers were established by congress in the Oregon Ominbus Wild and Scenic Rivers Act of 1988. Both river corridors provide for extensive hiking opportunities, dispersed and developed site camping, white water boating, fishing, hunting, and other natural resource appreciative activities. A complete description of these and other potential Wild and Scenic Rivers are included in the Wild and Scenic Rivers section in this Chapter and in Appendix E of the FEIS.

Trails: The Forest trail system is the basic off-road facility that dispersed recreationists, such as hikers, horseback riders, hunters, and motorized trail bikes and mountian bike enthusiasts utilize to access and traverse many areas of the Forest. The Forest's trail system includes a total of 714 miles of nonwilderness trails. Three National Recreation Trails, and portions of the Pacific Crest National Scenic Trail are included. Figure III-M-6 displays Forest trail mileages by trail type.

The capacity of the Forest to provide additional trail facilities and enhance trail related use in nonwilderness areas is represented by an 81% expansion potential of the existing trail system mileage. Refer to Figure III-M-6 for a display of potential trail mileage.

Table III-M-6. Nonwilderness Trail Mileage

Trail Type	TRAIL MILEAGE		
	Existing Trails	Potential Trails	Total Miles
Forest Trails	644.1	569.1	1,188.8
National Recreation Trails[1]	46.3	7.5[2]	53.8
Pacific Crest National Scenic Trail[1]	23.3	0.0	23.3
TOTAL	713.7	576.6	1,265.9

[1]Trail segments occurring outside of established Wilderness areas.
[2]Both the Breitenbush and Fall Creek NRTs are proposed to be extended.

Off-Road Vehicles: Off-road vehicle use opportunities are currently available from 71% of the Forest. The remaining 29% is closed to or restricted from ORV use due to topography and safety, potential disruption of wildlife habitats or damage to basic natural and cultural resources, or conflicts with other existing or potential uses. ORV use opportunities are generally available within Roaded Modified, Roaded Natural, and Semiprimitive Motor ROS Class categories. Much of the area identified in the ROS inventory of dispersed recreation opportunities may not be desirable for certain types of ORV use due to slope, dramatic terrain variations, vegetation density, or lack of trail access. ORV opportunities within these ROS Classes may be subject to further adjustment based on these consideration. ORV use is allowed on 63% of the nonwilderness trail system mileage in the Forest. This type of use is projected to increase, which will result in the need for more ORV dispersed recreation opportunities.

Developed Recreation: Existing opportunities for developed recreation are available from 174 Forest Service managed sites and 30 sites managed by the "private sector" under Special use permits. The 204 total sites have the combined capacity to accommodate 2,538,714 Recreation Visitor Days (RVDs) annually. These sites have a combined estimated capacity to accommodate 25,318 persons-at-one-time (PAOT). The distribution of sites by ROS Class is illustrated in Figure III-M-7.

Potential developed recreation opportunities can be made available from a wide variety of sites within the Forest. These potential sites have been identified by field specialists from each Ranger District utilizing such criteria as accessibility, slope, attractiveness, and proximity to water, as well as to other attractions or use areas. This inventory process identified 193 sites with an estimated capacity of over 3.5 million RVDs. Sites from this inventory provide the basis to increase use opportunities for site types that may reach capacity before the year 2040.

Table III-M-7. Developed Sites by ROS Class[1]

Kind of Site	Number of Sites by ROS Class					Total No. of Sites

Future Trends

Future recreation use in the Forest will likely be affected by changes in various socio-economic indicators (e.g., population growth, disposable income, leisure time), the availability of opportunities, technology, weather conditions, and other variables. Due to large uncertainties about the variables affecting future use, use projections become more tenuous as they are extended further into the future. Studies which have developed future growth projections for recreation cannot anticipate fluctuations in weather patterns nor predict events such as a world energy crisis or economic recession. Their projections generally assume that an underlying demand is present and will increase with a growing population that has an ever-increasing awareness and appreciation of recreation values. Based on these factors and the general trends in past use in the Willamette Forest, it seems appropriate to assume that future participation in all activities in the Forest will increase as long as opportunities are provided.

To determine future participation rates for all activities in the Forest, recreation activity projection rates of three separate studies were reviewed. During prreparation of the DEIS projection rates of the State Comprehensive Outdoor Recreation Program-Oregon; Projections of Future Forest Use, USDA Forest Service, 1979; and Pacific Northwest River Basins Commission, 1979 were compared. The annual growth rates for recreation use developed in the River Basins Commission study were selected for making use projections in the development of the DEIS and Draft Forest Plan because they most closely approximated trends in the Forests historical (1973-1982) use data. They were also the highest projection rates of the three studies and thus, indicated the upper level of use which could be expected in the year 2000.

However, since release of the DEIS and Draft Forest Plan, more recent studies of user preferences and use projections for a wide range of recational activities have been completed. In addition historical

use data for the Forest has been updated for more accurate comparisons with use projections of recent studies. In 1987 the Pacific Northwest Outdoor Recreation Study (NORS) was completed and in 1988 a draft of the State Comprehensive Outdoor Recreation Plan (SCORP) for Oregon was issued. The NORS study is a regional approach to integrated recreation planning and management among public agencies and is directly related to SCORP processes of participating states. The NORS study included the states of Washington, Oregon and Idaho.

The SCORP for Oregon utilized NORS results from the Oregon Survey portion of the study. Further Oregon's SCORP subdvides the state into geographic regions for purposes of recreation planning. The Willamette Natonal Forest is included in the State's Mid-Willamette Valley Region (Region 8). Oregon's SCORP provides recreation use projection rates for activity groups for each of it's regions. Average annual growth rates for activities within SCORP Region 8 for 1991 to 2010 are displayed in Figure III-M-8.

The annual growth rates for recreation activities presented in the draft SCORP and developed through the NORS study were selected for making use projections for the Forest's FEIS and Forest Plan. Use projections for the Mid-Willamette Valley, SCORP Region 8, closely approximate the Forest's historical use trends for the period 1980-1989. They were selected for use because they exceed SCORP projection rates on a state-wide basis, are specific to the Forests primary area of influence, are the most current projection rates available, and are also the highest projection rates of all studies reviewed and thus, may show the upper level of use expected in the year 2010.

Selecting an appropriate growth rate for recreation participation beyond the year 2010 is more difficult since there are few projections of the underlying factors affecting these activities. An annual average rate of 1.4% for the period 2011-2040 is assumed for the Forest. This rate represents an extension of Bonneville Power Administration (BPA) forecasts of electricity consumption in the Pacific Northwest (Appendix I, Economic/Demographic Projections, May 1982), projected population growth rates for the Pacific Northwest and the State of Oregon.

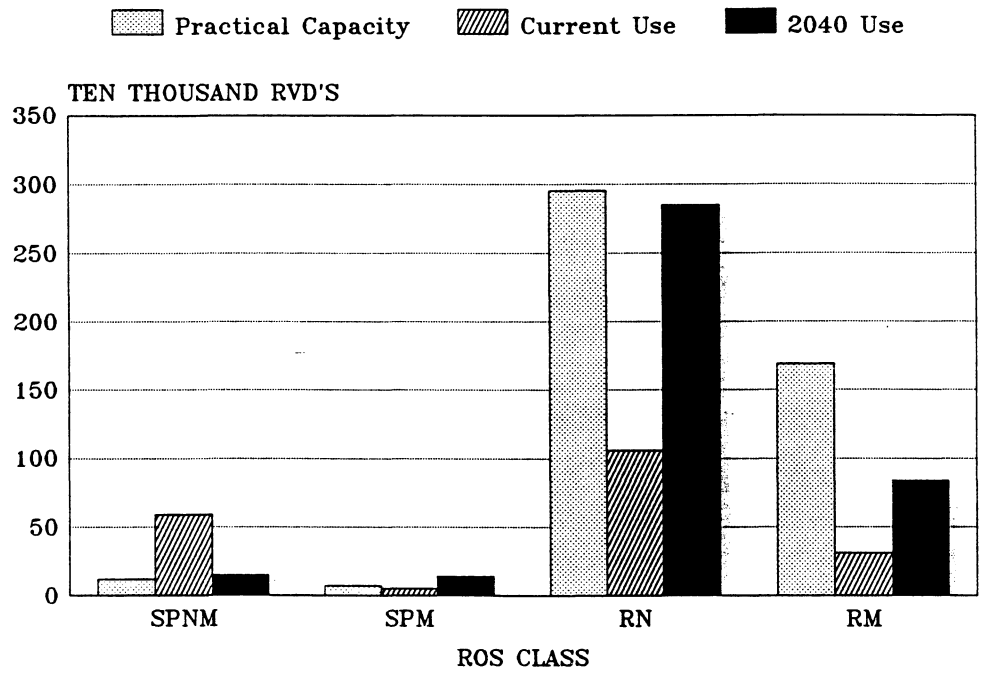

Table III-M-8. Recreation Projection Rates

Activity Group	1991-2010 Rate[1]	2011-2040 Rate[2]
Cammping	3.7	1.40
Driving/Sightseeing	4.9	1.40
Hiking/Walking	4.1	1.40
Picnicking	3.8	1.40
Boating/Waterskiing	5.5	1.40
Swimming	4.2	1.40
Horseback Riding	1.7	1.40
Downhill Skiing	2.6	1.40
Cross Country Skiing	2.8	1.40
Other Snow Activities	3.1	1.40
Organized Camping	1.0	1.40
Resort Use	1.0	1.40
Visitor Information	2.5	1.40
Hunting	2.5	1.40
Fishing	2.5	1.40
All Other Activities	2.5	1.40

[1]Source: Oregon State Comprehensive Outdoor Recreation Plan (SCORP)-Draft 1988. Activity groupings listed in SCORP were grouped according to the categories shown above. Projection rates for this time period represent a moderate scenario of future use for SCORP's Mid-Willamette Vlley Region 8.
[2]Source: Bonneville Power Administration 1982. Forecasts of electricity consumption for the Pacific Northwest.

Dispersed Recreation: Use of nonwilderness dispersed recreation areas has averaged 41% of the total recreation use in the Forest over the past decade. In the past there have generally been adequate use opportunities in terms of quantity of various ROS settings for most dispersed activities. Demand for dispersed recreation is estimated by applying growth projection rates to dispersed activities to obtain total use by time period. The subsequent disaggregation of total dispersed use to ROS Classes is based on observed patterns of activity participation in relation to Forest recreational settings. Although the science of estimating or proportioning demand by ROS Class is somewhat less than exact it affords comparison with existing and potential supply categories. Figure III-M-9 compares the practical RVD capacities by ROS Class for the existing inventory of dispersed recreation areas with 1989 and 2040 projected use.

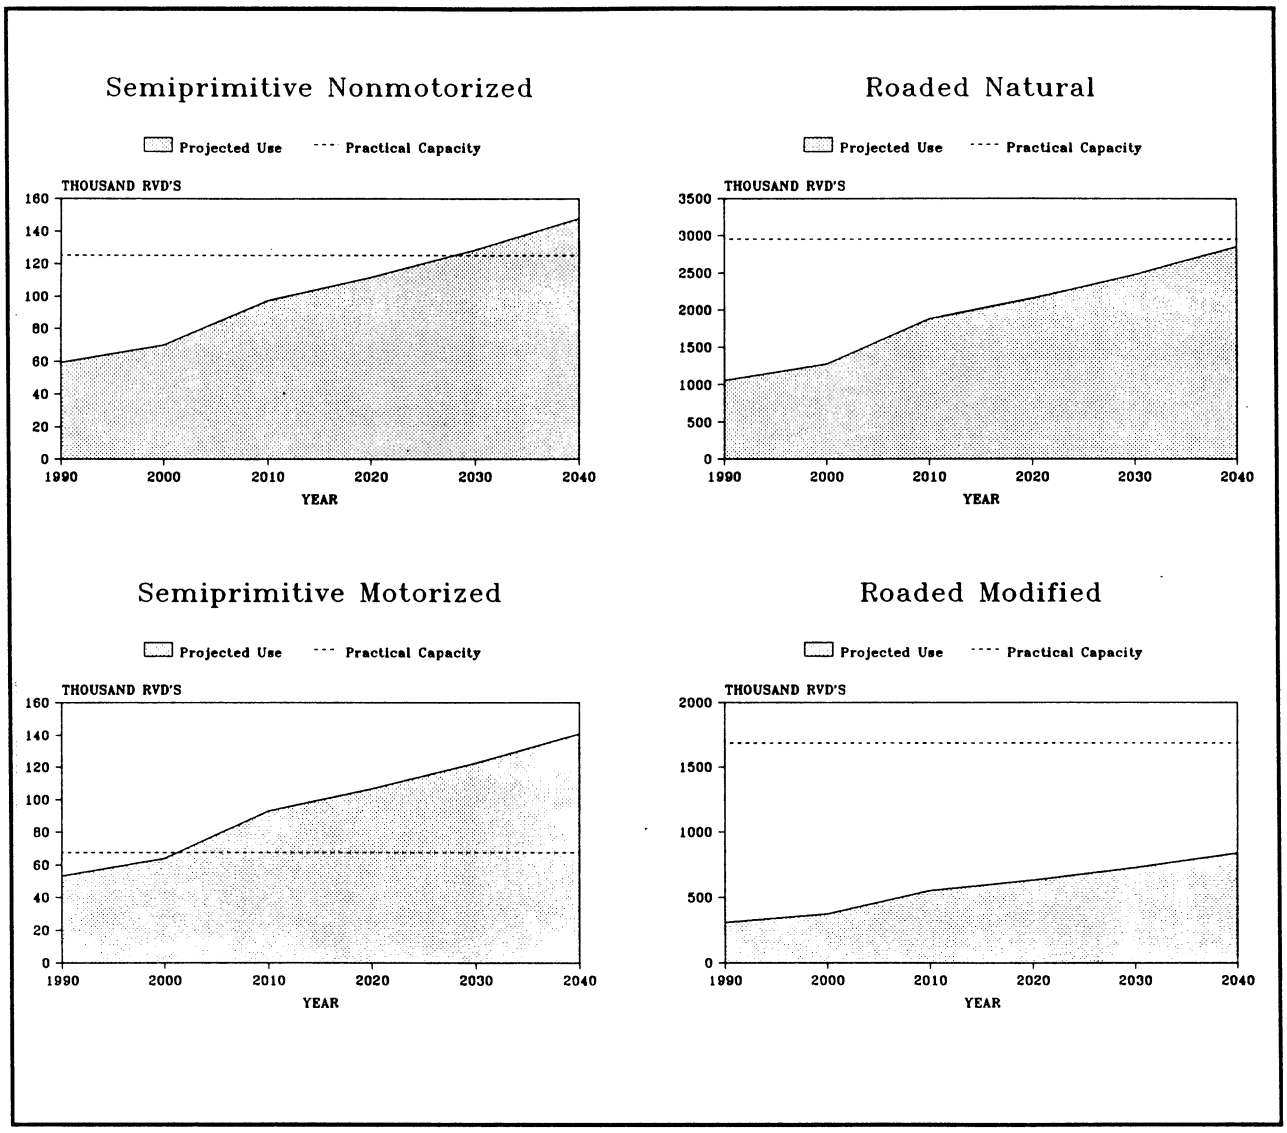

Table III-M-9. Comparison of Dispersed Recreation Capacity and Use

ROS Class Use	Acres	Practical RVD Capacity	Current RVD Use	2040 RVD USE
Semiprimitive Nonmotor	205,335	125,084	59,300	147,800
Semiprimitive Motor	43,300	67,378	53,100	140,900
Roaded Natural	437,615	2,954,146	1,056,300	2,852,700
Roaded Modified	600,120	1,686,858	311,600	839,200
TOTAL	1,286,370	4,833,466	1,480,300	3,980,600

Total dispersed practical capacity for the Forest far exceeds projected total use levels through 2040. This relationship, however, is not consistent among all ROS Classes. Uses which depend upon a semiprimitive setting face a decreasing supply of opportunities as lands are converted from an unroaded state. Unroaded areas which undergo intensive timber harvesting and accompanying road construction will lose those attributes that provide the solitude and undisturbed environment associated with semiprimitive recreation experiences. Even if existing inventories of semiprimitive opportunities were maintained, future demand is expected to exceed capacity by the year 2010. Figure III-M-10 displays projected recreation use by ROS Class and provides an indication of when future use may exceed practical capacity for the Forest.

Figure III-M-10. Projected Dispersed Recreation Use by ROS Class

Developed Recreation: Developed recreation opportunities are provided through a wide variety of site types in the Forest. The practical capacity for each site type in the Forest is compared with projected use in Figure III-M-11.

Developed recreation use for twelve types of sites, and for the Forest as a whole is expected to exceed existing practical capacity before the year 2020. Of these twelve site types, two are supplied primarily by the private sector: resort hotel/lodges, and private organization sites. The demand for organization sites can be met from the potential supply in the Forest regardless of whether they are managed by the public or private sector. There are also enough potential resort hotel/lodge sites in the Forest to meet future demand. However, these site types would be developed and operated almost exclusively by the private sector. At this point, it is difficult to predict if economic conditions will exist to make future investments in these sites attractive.

Table III-M-11. Developed Site Capacity and Use in RVDs

Site Type	Existing Practical Capacity	Projected Use in Year 2040	% of Use Supplied
Observation	39,052	52,201	75
Boating	263,036	463,298	57
Swimming	32,840	250,800	13
Trailheads	111,186	245,200	45
Campgrounds - Family	1,212,904	2,265,255	54
Campgrounds - Group	34,332	51,908	66
Picnic	133,510	333,509	40
Hotel, Resort, Lodge	54,340	176,500	31
Organization - Public	18,980	22,000	86
Organization - Private	81,160	87,600	93
Concessionaire	17,248	54,175	32
Recreation Residences	158,660	158,660	100
Ski Areas	238,096	117,100	203
Winter Sports Area	97,456	61,300	158
Visitor Information Services	45,914	141,800	32
TOTAL	2,538,714	4,481,300	57

Of particular importance is the demand for downhill skiing facilities as expansion plans for one area have received intense public scrutiny. As shown in Figure III-M-11, increases in downhill skiing use do not exceed the total practical capacity of the Forest's two ski areas -- Hoodoo Bowl and Willamette Pass. This relationship holds true for each area individually as well as on a combined basis.

The theoretical capacity for ski areas is determined by skiable acres times skier density by level of skiing ability. It is assumed that a ski area is operating at capacity for the entire use season. Ski area use, however, is not even throughout the week. On peak use days (i.e., weekends and holidays) overuse can occur, with the limiting factor usually being the uphill or lift capacity of the area. Thus, if lift capacity becomes limiting on too many days of a particular season, the theoretical capacity may be an overstatement of the actual use capacity.

Therefore, rigid use of theoretical capacity limits may not be entirely appropriate to determine when expansion should occur for some ski areas. The projected use shown in Figure III-M-11 is in visitor days. The privately operated facilities base their planning more on the number of people, or in the

case of a winter sports area the number of skiers, at one time rather than the number of visitor days that can be provided.

Typically a skier visit includes six or fewer hours of actual skiing during their normal visit to a ski area. Since in most cases the uphill lifts are only operated for about seven hours per day the actual capacity of a winter sports area is more likely to be about 30% of the theoretical capacity, rather than the 40% figure that is provided in Figure III-M-11. Therefore, in order to realize the projected 117,100 visitor days use shown for the year 2040 in Figure III-M-11, the two ski areas on the Forest would need a total number of visits that exceeds 235,000 skiers during a season.

Ski areas also expand to disperse skiers more evenly, as well as to capture periodic increases in use. Accessing new terrain may attract new skiers to the area, permit longer operating seasons, and provide some protection against years with limited snow. These and many other supply and demand related factors (e.g., costs, revenues, and effects on local communities) are carefully evaluated by both the private investor and the Forest Service before any development decision is made on public land.

The service level or types of amenities provided at a developed site can affect demand. While demands exist for all different types of services, there appears to be a growing desire from a more urban-oriented population for facilities which provide more than the basic amenities including the opportunity to participate in multiple and varied activities.

For developed recreation, future use levels can be accommodated to varying degrees by expanding existing capacity for specific types of sites which are likely to experience the projected increases. The availability of substitutes off forest is not taken into account in the projections. This, plus quality-related and other management variables such as the length of managed use season, types of service provided, public versus private sector management, and the charging of fees at public sites can all affect the amount of future use.

The point in time when future use will exceed capacity, if at all, will be different for each site type. This implies that the supply of some site types can and should be increased at various points during the 50 year planning horizon.

Dispersed and developed recreation areas and resources interact with, and are affected by, other resource management activities and natural events. Some management activities, such as wildlife habitat and riparian zone management generally have no adverse effect on recreation settings. In fact, these activities can provide long term beneficial effects to the recreation resource such as improved fishing and wildlife viewing opportunities. However, other activities such as timber harvest, road construction, and fire management may have an opposite affect on recreational settings.

Wildfire suppression activities, such as the construction of firelines, can introduce human modifications into dispersed recreation settings. On the other hand, fire can have a beneficial affect by reestablishing or perpetuating plant and animal diversity within recreation settings.

Trails are affected most by industrial operations and road construction. Logging operations can inhibit trail travel and make it an unpleasant experience. Another important interaction is between different types of trail users. Large groups are generally incompatible with individuals seeking isolation and quiet. Firearms and dogs can be offensive to many users. Off-road vehicle (ORV) users can affect other types of recreation use. Their use can produce noise impacts over large areas and their mobility increases potential to encounter groups and other users unexpectedly. Their use in high elevation Forest zones may also cause damage to vegetation and fragile soils.

Developed recreation is least compatible with Forest industrial operations such as logging and mining and most compatible with Forest management that emphasizes other resources such as wildlife, water, and scenery. Developed sites are vulnerable to vandalism and to the effects of increasing use. Budget reductions may inhibit maintaining facilities for the levels of use they may receive, resulting in increased site compaction, loss of vegetation including large trees, and a general worn-out appearance of facilities. Potential sites are affected most significantly by other Forest uses that may permanently alter the suitability or availability of an area for recreation development.

SCENERY

The landscape of the Forest is composed of dense coniferous vegetation, varied terrain, an abundance of geologic features, lakes and rivers, wildlife, and snow-capped mountain peaks which together form an outstanding scenic resource. This resource provides a broad range of natural and managed scenic experiences for both local and distant visitors.

The quality of the Forest's scenic resource is important to the local tourist industry as well as the Pacific Northwest. Many residents of the southern Willamette Valley, and beyond, through their recreational pursuits, seek an overall natural appearing landscape in contrast to their normal surroundings of urban streets and agricultural lands. The scenery of the Forest is an important asset to the local communities which are attempting to diversify their economic base in an effort to recover from recent declines in the wood products industry.

Historic Trends

The scenery of the Forest is characterized by two distinctive geologic provinces or landscape character types; the Western Cascades and the High Cascades. Each landscape character type is a broad geographical area that exhibits throughout its extent similar features of landform, rock form, vegetation, and water form. Although landform is usually the most significant feature, all features combine to create a certain visual image of the character type.

The Western Cascades landscape character type is oriented in a north-south direction and occupies the western two-thirds of the Forest. The High Cascades character type, also oriented in a north-south direction, occupies the eastern one-third of the Forest. A map of the geologic provinces of the Forest is located in Chapter III, Geology.

The Western Cascades type is characterized by a general conformity in ridge crests separated by deep valleys with moderately steep, highly dissected, side slopes. In the southern portion of this type, the major valleys are V-shaped. Glacial features are evident, but not pronounced throughout the area. Some rock cliffs and rock outcrops exist. Vegetation is characterized by dense stands of large trees including western hemlock, Douglas-fir, and true fir. Most areas have a continuous cover of overstory and understory vegetation. Deciduous species such as alder and maple are often intermixed along drainages. Some meadows are found in both lower and upper elevations.

A wide variety of rock formations exists in the area but most are hidden by the dense vegetative cover. Some extensive bare rock ridges and volcanic plugs stand out above the vegetation, and old volcanic lava flows are sparsely vegetated. Water bodies, particularly lakes, ponds, and marshes are scarce within this character type. Other waterforms consist of streams and major rivers, all of which drain into the Willamette Basin.

The visual experience of Forest visitors in this landscape type is characterized by views that are focused or directed at points or features in the landscape by road and trail side vegetation or landform structure. To a lesser extent, visitors will also experience landscape spaces enclosed by a continuous physical barrier of trees, hills, or mountains.

The High Cascades landscape character type consists of a volcanic plateau capped by shield volcanoes, cinder cones, and other volcanic forms such as lava flows of various ages. All these landforms are in various stages of disintegration. It is essentially an area of rolling terrain, but interrupted at intervals by glaciated channels in the major drainages. The area is dotted with a chain of volcanic peaks and

cones which rise above the surrounding landscape. Much of the landscape is mantled with pumice and volcanic ash. Vegetation is characterized by both dense and open stands of conifers. Usually with sparse understory, western portions are dominated by Douglas-fir, hemlock, and true fir while eastern portions have mostly mountain hemlock and lodgepole pine. In higher elevations there are meadows with lush stands of alpine and subalpine vegetation.

Rock forms are numerous and significant in the landscape. Most rock forms are volcanic in origin, either glaciated volcanic peaks, lava flows, or talus slopes. Some deep, glaciated canyons exhibit extensive rock cliffs on their steep side walls. A wide variety of water bodies dot the landscapes including marshes, lakes, streams, and rivers. Many of the lakes and small streams are the headwaters for rivers flowing west to the Willamette basin.

The visual experience of Forest visitors in this landscape type is characterized by broad panoramic views encompassing considerable distance, also dominated by a single landscape feature or group of features. Visitors will also experience, however to a lesser extent, areas of open space enclosed by a continuous physical barrier of trees, hills, or mountains.

Change in the Forest's landscapes in recent centuries was due primarily to wildfires, but since the early 1900s, noticeable change has been due to a variety of land and vegetation altering activities, such as road and railroad construction, timber harvesting, and dam building, as well as wildfires. Human-caused changes are most apparent in the Western Cascades character type, as evidenced by a mosaic of harvest areas in various stages of regeneration. In the face of this landscape change, Forest managers recognized and sought to manage portions of the landscape for its scenic value by establishing water and travel influence zones.

However, not until recent years have the quality and the characteristics of the scenic forest landscape actually been described and inventoried. Since 1973 the visual resources of the Forest have been described through the use of four inventories integral to the National Forest's Visual Management System (VMS) including: Viewshed Corridors (VSC); Visual Resource Inventory (VRI); Visual Absorption Capability (VAC); and Existing Visual Condition (EVC).

The Visual Management System (VMS) is the primary means for planning and management of the Forest's scenic resources. Through use of this system, project designers seek to maintain the visual quality of the Forest's scenic resources, based on their inherent value, prominence, and public interest. Now adopted throughout the U.S. Department of Agriculture--Forest Service, the VMS enables Forest managers to integrate the principles of landscape management into multiple-use resource planning. The system sets forth procedures that enable managers to identify and classify the visual characteristics of the Forest landscape establish scenic resource objectives and simulate and analyze the visual effects of proposed resource management actions.

To meet the public's long-term expectations for scenic quality, the rate at which change is introduced into the Forest landscape is regulated; management activities are carefully located through viewshed corridor planning; and activities are designed to assure that effects on form, line, color, texture, and scale in the Forest landscape are minimized.

The public's desire for scenic quality has increased over the years. As resource management activities have extended into previously undisturbed and undeveloped areas the public has become more vocal about protecting scenic values. Groups and individuals have actually become involved in the design, location, and scheduling of activities. The public's increasing desire for scenic quality in the Forest is partially reflected by increased demand for recreational opportunities in which scenic quality is an integral part, such as driving for pleasure, hiking, camping, and fishing.

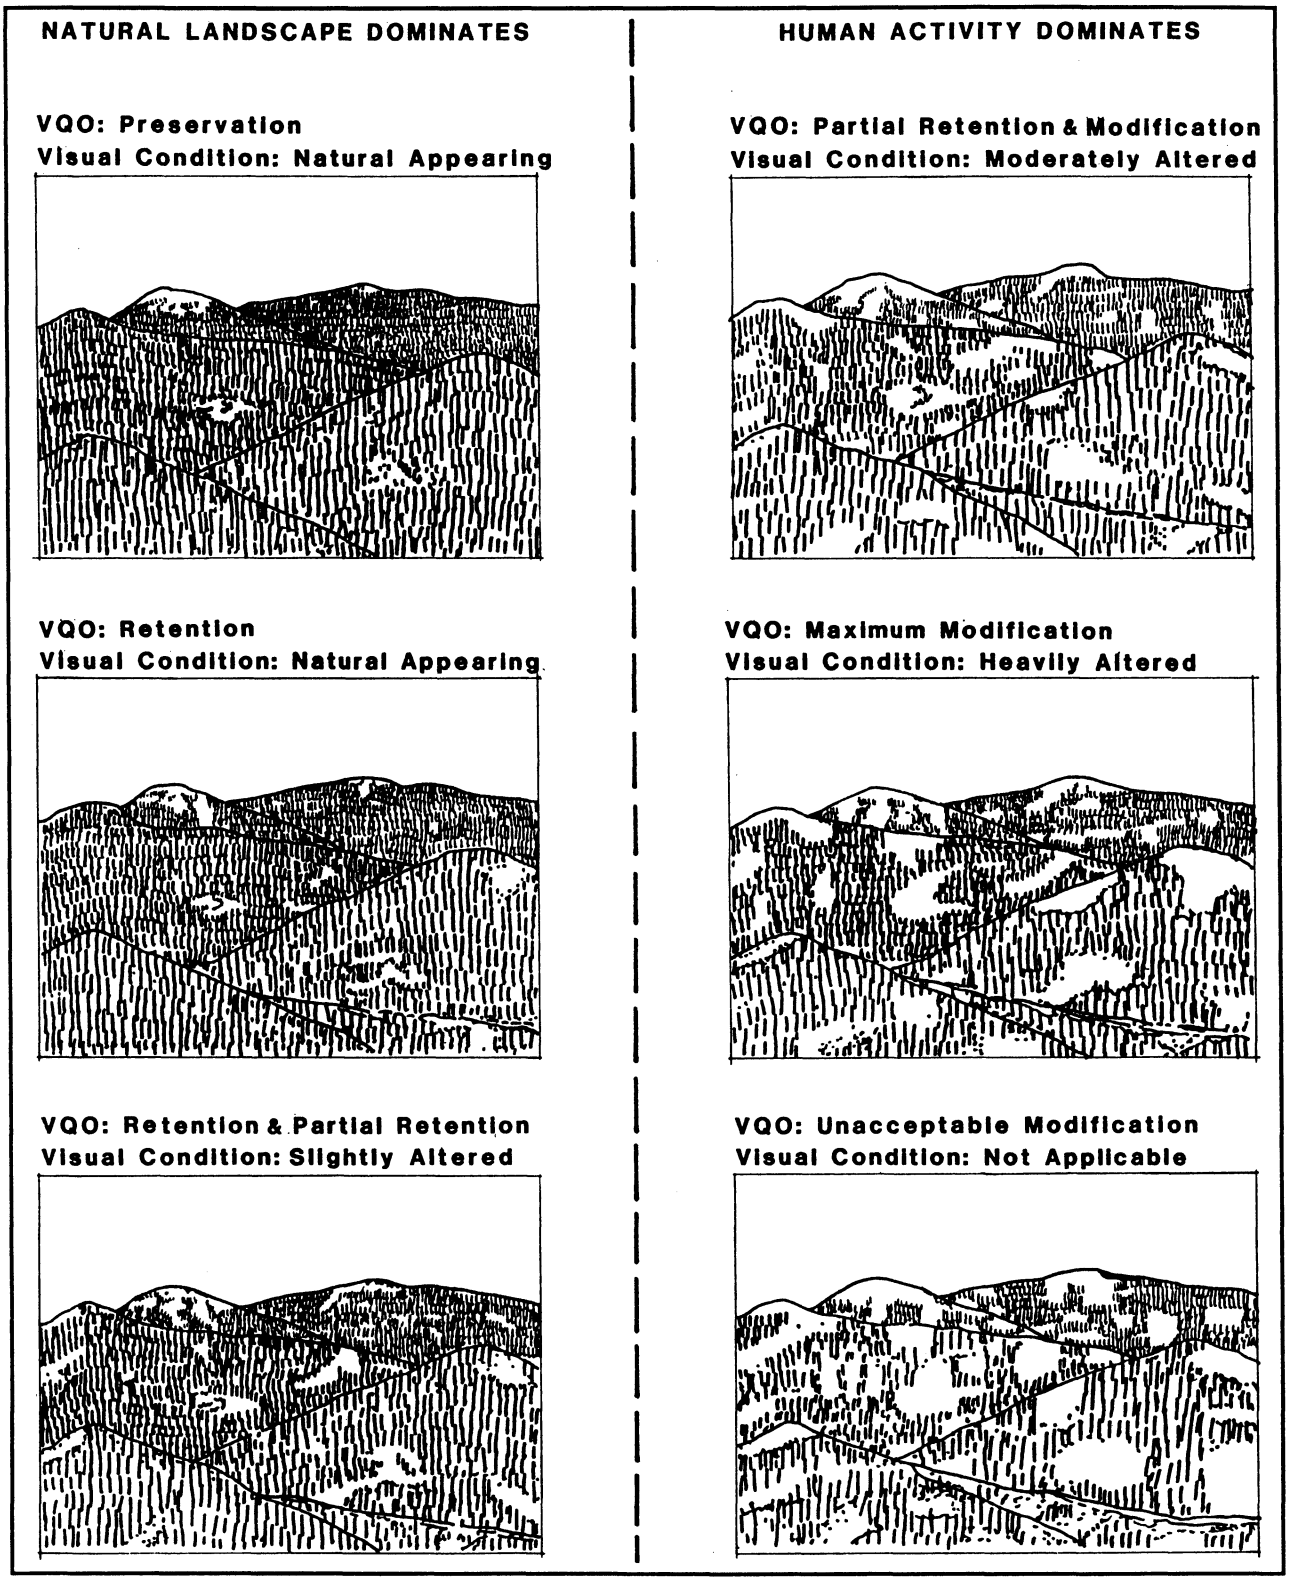
Current Situation

The scenic resources of the Forest are described through the use of four inventories. These inventories display particular aspects of the scenic resource having significance to Forest managers, including the identification of management opportunities, visible areas, existing conditions, and resource limitations. Each of these inventories is described below.

The Forest's potential opportunity to provide scenic resource quality is determined by the Visual Resource Inventory (VRI). The VRI categorizes the Forest landscape into zones of relative scenic importance based upon attractiveness, proximity to travelways and use areas, and the concern Forest users have for scenic quality. Through this process all areas of the Forest are assigned one of five Visual Quality Objectives (VQOs), each representing relative degrees of acceptable alterations of the natural landscape. In addition, through project activities the site specific objectives of enhancement and rehabilitation may be employed to improve existing landscape conditions. A graphic illustration in Figure III-N-1 depicts VQOs on a forest landscape. Definitions and acreages of these VQOs are listed in Figure III-N-2. The spatial distribution of VQOs within the Forest is illustrated by Figure III-N-3.

The distribution of VQOs described in Figure III-N-3 are divided into viewshed and nonviewshed areas within the Forest. The Viewshed Corridor (VSC) includes the visible areas adjacent to important travelways that traverse the Forest. These areas are the most sensitive portions of the Forest in relation to the public's concern for scenic quality. The location and extent of each viewshed corridor is displayed in Figure III-N-4. Figure III-N-5 lists the Forest's most important viewsheds and displays the inventoried visual quality objective acreages fo the Forest.

Figure III-N-1. Visual Quality Objectives and Visual Condition



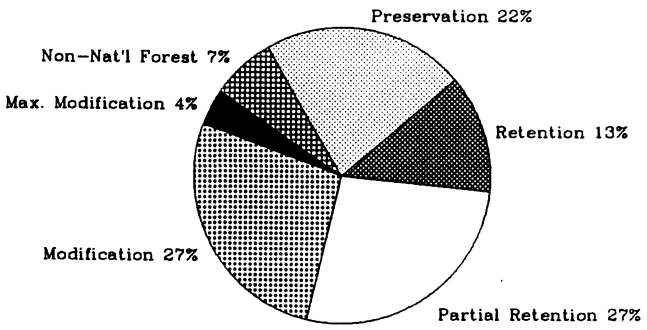


Figure III-N-2. Visual Quality Objectives Descriptions

Category	Description	Acres [1]
Preservation (P):	A VQO that provides for ecological change only.	389,486
Retention (R):	A VQO which, in general, means human activities are not evident to the casual Forest visitor.	232,262
Partial Retention (PR):	A VQO which, in general, means human activities may be evident but must remain subordinate to the characteristic landscape.	488,649
Modification (M):	A VQO meaning human activities may dominate the characteristic landscape but must, at the same time, utilize naturally established form, line, color, and texture, and appear as a natural occurrence when viewed in foreground or middleground.	484,170
Maximum Modification (MM):	A VQO meaning human activity may dominate the characteristic landscape but should appear as a natural occurrence when viewed as background.	80,841
Enchancement (E):	Enhancement is a short-term management practice aimed at increasing positive visual variety where little variety now exists. Enchancement may be achieved through alteration of existing conditions which create additional variety of forms, edges, colors, textures, patterns, or spaces.	--
Rehabilitation (REH):	Landscape rehabilitation is a short-term management practice used to restore landscapes containing undesirable visual impacts to a desired visual quality. It may not be immediately possible to achieve the prescribed visual quality objective with rehabilitation, but it should provide a more visually desirable landscape in the interim.	--
Non-National Forest Land:		123,330

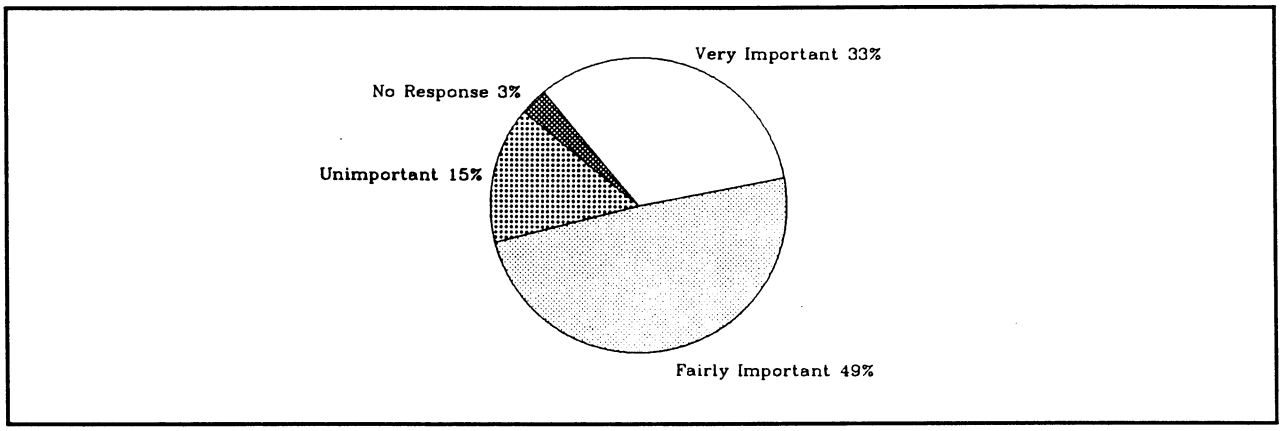
[1]See Figure III-N-2 for Visual Quality Objective descriptions and Figure III-N-1 for a graphic illustration of Existing Visual Condition (EVC) Classes.
[2]Existing Visual Condition (EVC) Classes: NA = Natural Appearing; SA = Slightly Altered; MA = Moderately Altered; and HA = Heavily Altered.
[3]Includes Designated National Scenic By Way route.



A recent evaluation of the Forest landscape was completed to determine to what extent management activities have altered the appearance of the Forest's scenic resources. This evaluation is referred to as the Existing Visual Condition (EVC) assessment and its purpose is to classify Forest lands in relation to the degree they have been altered as compared to the natural appearing landscape. The assessment stratifies the Forest landscape in to as many as four condition classes: Natural Appearing, Slightly Altered, Moderately Altered, and Heavily Altered. A graphic illustration of these EVC classes is provided in Figure III-N-1. The EVC assessment of the Forest reveals that 38% of the Forest landscape remains natural appearing and that 62% has undergone apparent management alteration. The Existing Visual Condition of the Forest's 10 Viewshed Corridors is included in Figure III-N-5. Those portions of the Forest in a natural appearing condition include Wilderness, unroaded areas, the Oregon Cascades Recreation Area, and several of the Forest's major travel corridors. The EVC assessment serves as a benchmark against which to estimate the effects of proposed management alternatives and to measure actual changes in visual conditions at some future time.

The visual resource is vulnerable to management activities and natural phenomena that alter land forms and vegetation patterns. The limitations of the visual resource to absorb these natural and management induced affects is determined through the Visual Absorption Capability (VAC) inventory. The VAC inventory provides an assessment of the relative ease or difficulty with which change may be introduced into the landscape without impairment of its value as a scenic resource. The VAC inventory reveals that 30% of the available Forest land base is rated as having a high visual absorption capacity while 15% is rated as moderate and 33% as low.

Demand for scenic quality is expressed on the basis of visual sensitivity level data and public issue response data. Tabulation of public comment data for the Forest, in 1981, as shown in Figure III-N-6,

documented that 33% of respondents feel that scenic quality is very important, 49% fairly important, and 15% unimportant. Summarization of visual sensitivity data from the VRI reveals that scenic quality is very important to Forest users particularly on lands adjacent to major federal and state highways, the most heavily used Forest roads and trails, and destination type recreation areas and sites. Approximately 48% of these areas is classified as highly sensitive; 25% is moderately sensitive, and 27% has low sensitivity. The publics concern for scenic quality was expressed through more than 4,000 specific comments on the DEIS and Draft Forest Plan. Of these comments, most (85%) favored protection and maintenance of scenic resource quality with a major emphasis on Viewshed Corridors of State Highways and major Forest roads. The remaining 15% of the public comment expressed concerns that too much area is allocated for scenic resource protection and that quality objectives and management standards are too restrictive.

Figure III-N-6. Public Input on Scenery

The Forest coordinates with other agencies (federal, state, and local) to ensure that visual resource quality is maintained along state and federal highways, around reservoirs, in and around utility line clearings and at electronics sites. In areas of the Forest where private land holdings are heaviest (i.e., along portions of State Highway 20, 22, 126, and 58 and along Forest Road 21) the Forest Service has no control over these lands nor the effects that their management may have on scenic quality. However, every opportunity to coordinate management activities with private land owners is persued to maintain or improve the scenic resource quality in these corridors.

The operation and maintenance plans of the Army Corps of Engineers, Eugene Water and Electric Board, Bonneville Power Administration, and the Oregon Department of Fish and Wildlife are reviewed to identify the potential conflict of activities and to ensure coordination with Forest Service Visual Resource Management objectives.

Additionally, the Forest will coordinate with state and county law enforcement agencies for the location, operation, and maintenance of electronic sites; state and county highway departments for the operation and maintenance of roads and roadside zones; Bureau of Land Management (BLM) for their role in managing subsurface minerals; and the Oregon Department of Aeronautics for management of two small air strips within the Forest.

Since release of the DEIS, the Forest Service has sought to draw attention to and encourage use of the nations scenic resources through establishment of the Scenic ByWays Program. National Forest

Scenic ByWays are being established to maintain, enhance, and interpret the extraordinary cultural, geologic, biological and historical features along selected Forest travel routes. Nation-wide Scenic ByWays are being designated for the natural beauty and scenic diversity through which they pass and for their potential to provide enjoyable, memorable experiences for those who drive for pleasure or use the open road for vacation activities.

Two Scenic Byways have been designated on the Forest and more may be nominated for Scenic ByWay status in the future. The Robert Aufderheide Memorial Drive parallels for 70 miles the South Fork of the McKenzie River and the North Fork of the Middle Fork of the Willamette River on Forest Road 19. The McKenzie Pass - Santiam Pass Scenic ByWay loop follows portions of State Highway 20, 242, and 126 for 82 miles through the volcanic landscape of the recent Cascades with spectacular views of mountian peaks and alpine lakes. Scenic ByWay designation of these two travel routes does not preclude other activities such as creating new views or vistas; interpretive programs, wildlife management programs, meadow habitat improvements; or timber harvesting.

Future Trends

The condition of the scenic resource is expected to change as management activities are implemented to fulfill Forest Plan objectives. Human-caused changes in the condition of the scenic resource during the next decade will primarily result from two factors: the rate at which timber harvest and road building occur; and the rate at which harvested and otherwise disturbed areas become revegetated.

Timber resource management activities may change the character of the scenic resource by altering the landscape's vegetative cover through silvicultural treatments. Intensive treatments such as clearcutting present new patterns of openings in the Forest canopy. Depending on how these openings are designed, they have the potential to contrast significantly with the adjacent area. This potential contrast is greatest in areas where the Forest canopy is homogeneous. Planned alterations, in areas with little natural variety, which incorporate those attributes of the characteristic landscape, however subtle, propose to assure the scenic quality of an area. It is anticipated that changes will become more apparent in areas that are at this time natural appearing.

Road construction can also change the scenic resource by creating unnatural appearing cut or fill slopes. This may be especially evident in steep topography where cut and fill slopes appear as strong horizontal lines. This type of change is generally long lasting and apparent even when viewed as background (3-5 miles viewing distance).

Interest in and concern for scenic quality is increasing with the demand for recreational opportunities. As population increases within the Forest's area of influence greater numbers of Forest users will expect attractive and pleasing environments for many of their recreational activities. The quality of view from recreation sites, scenic travelways, and prominent view points will become increasingly important.

Future demand for scenic quality is expected to parallel demand for both developed and dispersed recreational activities for which scenic quality is an integral part. Forest users engaged in recreation pursuits seem to prefer settings that are physically attractive. Many of these users have formed expectations about how the Forest should look and express concern when their observations are different from their expectations.

Recreationists generally are attracted to scenic features and, in turn, tend to generate interest in protection of these features to maintain the integrity of the physical settings for activities in which

they participate. The quality of the experience derived from these settings is becoming increasingly important to the tourism industry as it becomes more dependent on the scenic quality of the forest.

Management to achieve scenic resource objectives may increase the cost of operations due primarily to the techniques employed during project design and actual implementation. Such techniques may include use of unevenaged silvicultural systems, road location, road closures, use of vegetative screens, seeding cut and fill slopes, and use of color applications on rock walls or structures to reduce contrast between management activities or facilities and the surrounding landscape.

WILD AND SCENIC RIVERS

The Wild and Scenic Rivers Act of 1968 (Public Law 90-542 as amended) established a method for providing federal protection for certain of our remaining free-flowing rivers, and preserving them and their immediate environments for the use and enjoyment of present and future generations. Rivers are included in the system so that they may benefit from the protective management and control of development for which the Act provides. Section 4(a) of the Act mandates that all rivers designated as potential additions to the system be studied as to their suitability for inclusion in the system. Rivers can be identified for study for potential inclusion in the System by several means:

1. Federal statute that mandates federal agencies to study a river pursuant to section 5(a) of the Act.

2. Identification for study by the Secretary of Agriculture or the Secretary of the Interior pursuant to section 5(d) of the Act.

3. The Nationwide River Inventory (NRI) developed by the National Park Service.

4. The land management planning process.

In accord with section 4(a) of the Wild and Scenic Rivers Act, the Departments of Agriculture and Interior initiated studies of several rivers which the Act authorized for study as potential additions to the National Wild and Scenic Rivers System. In order to facilitate the study process, it became necessary for the two agencies to agree to a uniform evaluation and management approach. Therefore, the *Guidelines for Evaluating Wild, Scenic and Recreational River Areas Proposed for Inclusion in the National Wild and Scenic Rivers System Under Section 2, Public Law 90-542* was prepared and promulgated in February 1970. The guidelines not only provide guidance for the congressionally mandated studies, but are also useful for evaluations conducted by land management and water resource development agencies under section 5(d) and for States applying for inclusion of State-designated rivers in the national system. In addcord with these guidelines the river planning and assessment process follows a three-step procedure that includes: determination of eligibility; potential classification; and determination of suitability.

Eligibility of a river is determined by applying specific criteria ("free-flowing" conditions and "outstandingly remarkable values") from the Act and from the USDA-USDI Guidelines. For a river to be eligible for designation to the National System it must be "free-flowing" as defined by the Act and posses one or more "outstandingly remarkable values" with in the river area, such as scenic, recreational, geological, fish and wildlife, historical, cultural or other values, including ecological values. Application of these criteria is based on the professional judgement of an interdisciplinary study team and their collective knowledge of individual rivers or river segements.

When a river or river segment is found to be eligible, it is given a potential classification of Wild, Scenic, or Recreation. The classification of a river is based on the conditions of the river and that of adjacent lands. Figure III-O-1 provides a brief description of each river class used in this step of the process.

Table III-O-1. Wild and Scenic River Class Descriptions

Classification	Description
Wild	Free of impoundments Inaccessible except by trail or water surface Watershed or shorelines primitive Waters unpolluted
Scenic	Free of impoundments Shorelines largely primitive Accessible in places by roads Timber harvest may be practiced within the 1/4-mile corridor
Recreation	Readily accessible by road or railroad Some development along shorelines Some impoundment or diversion in the past Segments may be in or near urban areas Timber harvest may be practiced within 1/4-mile corridor

[1]See also Figure III-O-4 for location and extent of designated rivers.

Determination of suitability is the final step in the river assessment process. This step provides the basis for the decision to recommend designation or nondesignation of eligible rivers to the United States Congress . The determination of suitability considers: characteristics which do or do not make an area a worthy addition to the National System; current status of land ownership, including amount and type of private land uses; potential land and water uses that would be enhanced, curtailed or foreclosed; public, State, and local governmental interests; estimated costs of acquiring necessary lands and interests, and for administration if added to the System; and other issues and concerns identified during the river planning process.

In Oregon, rivers can be designated as part of the National Wild and Scenic Rivers System through an Act of Congress or an Act of the Oregon Legislature and subsequent applications by the Governor of Oregon to the Secretary of Interior. In addition, rivers within the Forest may be designated as State Scenic Waterways. The Oregon Scenic Waterways program, established in 1970, is administered under the authority of the Oregon Transportation Commission through the State Parks and Recreation Division (ORS 390.805-ORS 390.925).

Historic Trends

Cultural History

As long ago as 10,000 years, rivers now under jurisdiction of the Forest had been utilized as travel routes and sources of subsistence materials by aboriginal peoples. Prehistoric use of river corridors has been confirmed by archaeological survey along the Blue River, Breitenbush River, South Fork McKenzie River, South Breitenbush River, McKenzie River, Middle Santiam River, Quartzville Creek, North Fork of Middle Fork Willamette River, Middle Fork Willamette River, and the South Santiam River.

In the late 1700s-early 1800s, Euro-American uses of these rivers consisted of trapping, hunting, and fishing. The Middle Fork Willamette country was first explored by Hudson's Bay Company fur traders in the 1820s. Prospecting and mining were important especially along the Little North Santiam River, South Fork McKenzie River, and Quartzville Creek. Later, in the mid-1800s as the Willamette Valley began to be settled by migrants from the east the river corridors were sites of homesteads and livestock

grazing particularly on the South Santiam River, Middle Fork Willamette River, and South Fork McKenzie River. The first recorded passage down the McKenzie and the Middle Fork Willamette Rivers was in 1853. The South Santiam River corridor was explored by early entrepreneurs for location of the Cascade Mountains and Willamette Valley Wagon Road, an east-west passage across the western Cascades. Another historic route, the Oregon Central Military Wagon Road was located along the Middle Fork Willamette River in the 1860s.

By the turn of the century, Euro-American settlers had established lodges and hotels near the hot springs of the Breitenbush River and McKenzie Rivers, and way stations along riverside transportation corridors at Rigdon Meadows (Middle Fork
Willamette River) and Long Ranch (South Santiam River) providing food and shelter for pioneer travellers. Evidence of the 1930s Depression Era can be seen in Civilian Conservation Corps construction of organization camps and trail shelters particularly along the South Santiam, Breitenbush, McKenzie, and North Fork of Middle Fork Willamette Rivers.

Hydroelectric power has been developed within several of the river corridors ranging from small hydroelectric plants on the South Santiam River to Cougar Dam and its much larger power generation facilities along the South Fork McKenzie River. Extensive studies of flood control facility feasibilities were conducted by the Army Corps of Engineers in the 1950s with resultant construction of many of the dams in the 1960s. Dams or reservoirs extant within Forest boundaries are: Blue River, Hills Creek, Lookout Point, Detroit, Trailbridge, Carmen, and Smith.

Planning History

The 1977 Forest Environmental Impact Statement documents that Wild and Scenic River Act criteria were used to evaluate Forest streams in 1970. At that time no streams on the Forest were selected by either the Secretary of Agriculture or the Secretary of Interior for inclusion in the National Wild and Scenic Rivers System. The status of rivers on the Forest changed in the early 1980s when the Little North Fork of the Santiam and the North Fork of the Middle Fork Willamette River, including Waldo Lake were designated by the Oregon State Legislature as State Scenic Waterways in 1983 and 1985 respectively.

The Forest planning process addressed the Wild and Scenic River issue during development of the 1987 DEIS/FP. Planning direction for WSR evaluation at that time required National Forests to focus on rivers identified in the Nationwide Rivers Inventory (NRI). The NRI included segments of the McKenzie River and the Breitenbush River within the Forest. During the process of determining eligibility for both rivers the Breitenbush was determined ineligible for further consideration as a potential WSR. It was subsequently removed from the NRI by the National Park Service (USDI Memo: RES 20-1(PNR-RP) November 16, 1982). The McKenzie River was found to be eligible and met the criteria for classification as a Recreation River. As required by planning regulations, the McKenzie River was recommended for WSR designation in at least one DEIS alternative: Alternative C. Subsequently, the McKenzie River was determined not suitable for inclusion in the National Wild and Scenic River System, but was proposed for management as a Special Interest Area in the Draft Forest Plan.

Following release of the DEIS/FP significant feedback on rivers and river management issues was recieved from several public interest groups. The review comments of these groups focused attention on how rivers were addressed in the planning documents. Review comments included discussions regarding protection of specific rivers, WSR designation, management activities, resource effects, and the planning process itself. The issue of river management intensified during the document review period, and although the subsequent passage of both federal and State river legislation was significatly

influenced by these interest groups, river designation and management of river resources remains a significat issue.

In the Oregon Omnibus Wild and Scenic Rivers Act of 1988 two rivers were designated as included in the National Wild and Scenic Rivers System and two rivers were desinated as Wild and Scenic Study Rivers. Also two additional rivers were added to the State Scenic Waterways System through a State ballot measure on November 8, 1988. Those rivers designated as included within the National Wild and Scenic River System, federally designated as Study Rivers, or designated as State Scenic Waterways are discussed and their designation status summerized below.

In response to public comment and intensified concern regarding the management of Forest rivers, a process was initiated in December of 1988 to determine Wild and Scenic River eligibility of those rivers identified through public comment to the Draft Environmental Impact Statement and Draft Forest Plan. In accord with the laws and regulations described above and through application of the river assessment process described in the Land and Resource Management Planning Handbook (FSH 1909.12 Chapter 8 - Wild and Scenic Rivers Evaluation) and Forest Service Manual 1924, the Forest identified segments of several rivers within the Forest's boundaries as being eligible for inclusion in the National Wild and Scenic Rivers System. The Forest's eligibility assessment of these rivers was completed by an Interdisciplinary Team (IDT) supported by representatives from each Ranger District. The results of the eligibility assessment and determination of potential river classification as either a Wild, Scenic, or Recreation River segment are sumerized later in this section.

Current Situation

Designation Status of Forest Rivers

Through both federal and State legislation in 1988 the Forest gained two federally-designated Wild and Scenic Rivers, two federally-designated Wild and Scenic Study Rivers, and two designated additions to the State Scenic Waterways System.

The Oregon Omnibus Wild and Scenic Rivers Act of 1988 designated the McKenzie River, from Clear Lake to Scott Creek, and the North Fork of the Middle Fork Willamette River, from Waldo Lake to near West Fir, Oregon, as National Wild and Scenic Rivers. The same Act designated Blue River from its headwaters to Blue River Reservoir, and the South Fork McKenzie River from its headwaters to Cougar Reservoir and from Cougar Dam to the McKenzie River as Wild and Scenic Study Rivers.

Additions to Oregon's State Scenic Waterways System through passage of a state ballot measure on November 8, 1988 include: the McKenzie River, from Clear Lake to Paradise Campground; and the South Fork McKenzie River, from its headwaters to Cougar Reservoir and from Cougar Dam to the McKenzie River. In addition the Little North Fork of the Santiam River, from its confluence with Opal Creek and Battle Axe Creek to the Forest boundary, and the North Fork of the Middle Fork of the Willamette River, from its headwaters, including Waldo Lake, to the Middle Fork Willamette River are also included in the State Scenic Waterways System. The current designation status of Forest rivers is summerized in Figure III-O-2. A full description of these rivers is included in Appendix E of the FEIS.

Table III-O-2. Designation Status of Forest Rivers [1]

River Name	National WSR	State Scenic Waterway	National WSR Study River
Little North Santiam		X	
McKenzie	X	X	
Blue River			X
South Fork McKenzie		X	
NF MF Willamette	X	X	

[1]See also Figure III-O-4 for location and extent of designated rivers.

The free-flowing conditions and outstandinly remarkable values of designated Wild and Scenic Rivers are protected and managed in accord with: the USDI-USDA Interagency Guidelines (47 Fed. Reg. 39454); the standards and guidelines for each river class as noted in the Land and Resource Management Planning Handbook (FSH 1909.12 Chapter 8 - Wild and Scenic Rivers Evaluation); and the management direction outlined in the Forest-wide and Management Area Standards and Guidelines in Chapter IV of the Land Management Plan. These management standards and guidelines apply to a designated Wild and Scenic River until a River Management Plan is approved and to a designated Study River until it has been determined not suitable for inclusion into the National System or until action is taken by the U.S. Congress. Wild and Scenic River Management Plans for the McKenzie River and the North Fork of Middle Fork Willamette River are currently being developed and are expected to be completed during 1991.

In general interim management of designated or study river corridors should, to the extent the Forest Service is authorized under the law, provide for: control of stream impoundments and diversions, and maintenance of free-flowing characteristics in an unmodified condition; protection and to the extent practicable enhancement of outstandingly remarkable values of identified rivers; and the maintenance of a rivers eligibility for inclusion in the National System at the highest river classification for which it qualifies.

The Oregon Scenic Waterways Act generally requires notification of proposed changes of land use within 1/4 mile on each side of the designated waterway to be evaluated for their potential to impair the natural scene. The Act also requires the Commission to cooperate with local, state, and federal agencies to ensure their compliance with the requirements of the Act and to study additional rivers for possible inclusion in the State Scenic Waterways System.

Eligible and Ineligible Rivers

As described above, the Forest initiated an assessment process to determine eligibility and classification of those rivers identified through public comment to the DEIS for their potential inclusion in the National Wild and Scenic Rivers System. The results of this process, based on application of specific criteria for "free-flowing" conditions and "outstandingly remarkable values" from the Act and and from the USDA-USDI Guidelines are provided below.

Included in summary form in Figure III-O-3 are the findings of the eligibility and classification assessment process and related information. "Outstandingly remarkable values" that are listed for each river are those that were considered (on a scale of 1-10) to be 7 or higher in the following categories: scenic, recreation, geologic, fish, wildlife, historical/cultural, ecological/biological. In addition river miles and approximate corridor acreages are provided for each river segment. Complete descriptions of each

river evaluated for its elegibility for potential inclusion in the National Wild and Scenic Rivers System are located in Appendix E of the FEIS. The location and extent of each river segment evaluated is displayed in Figure III-O-4.

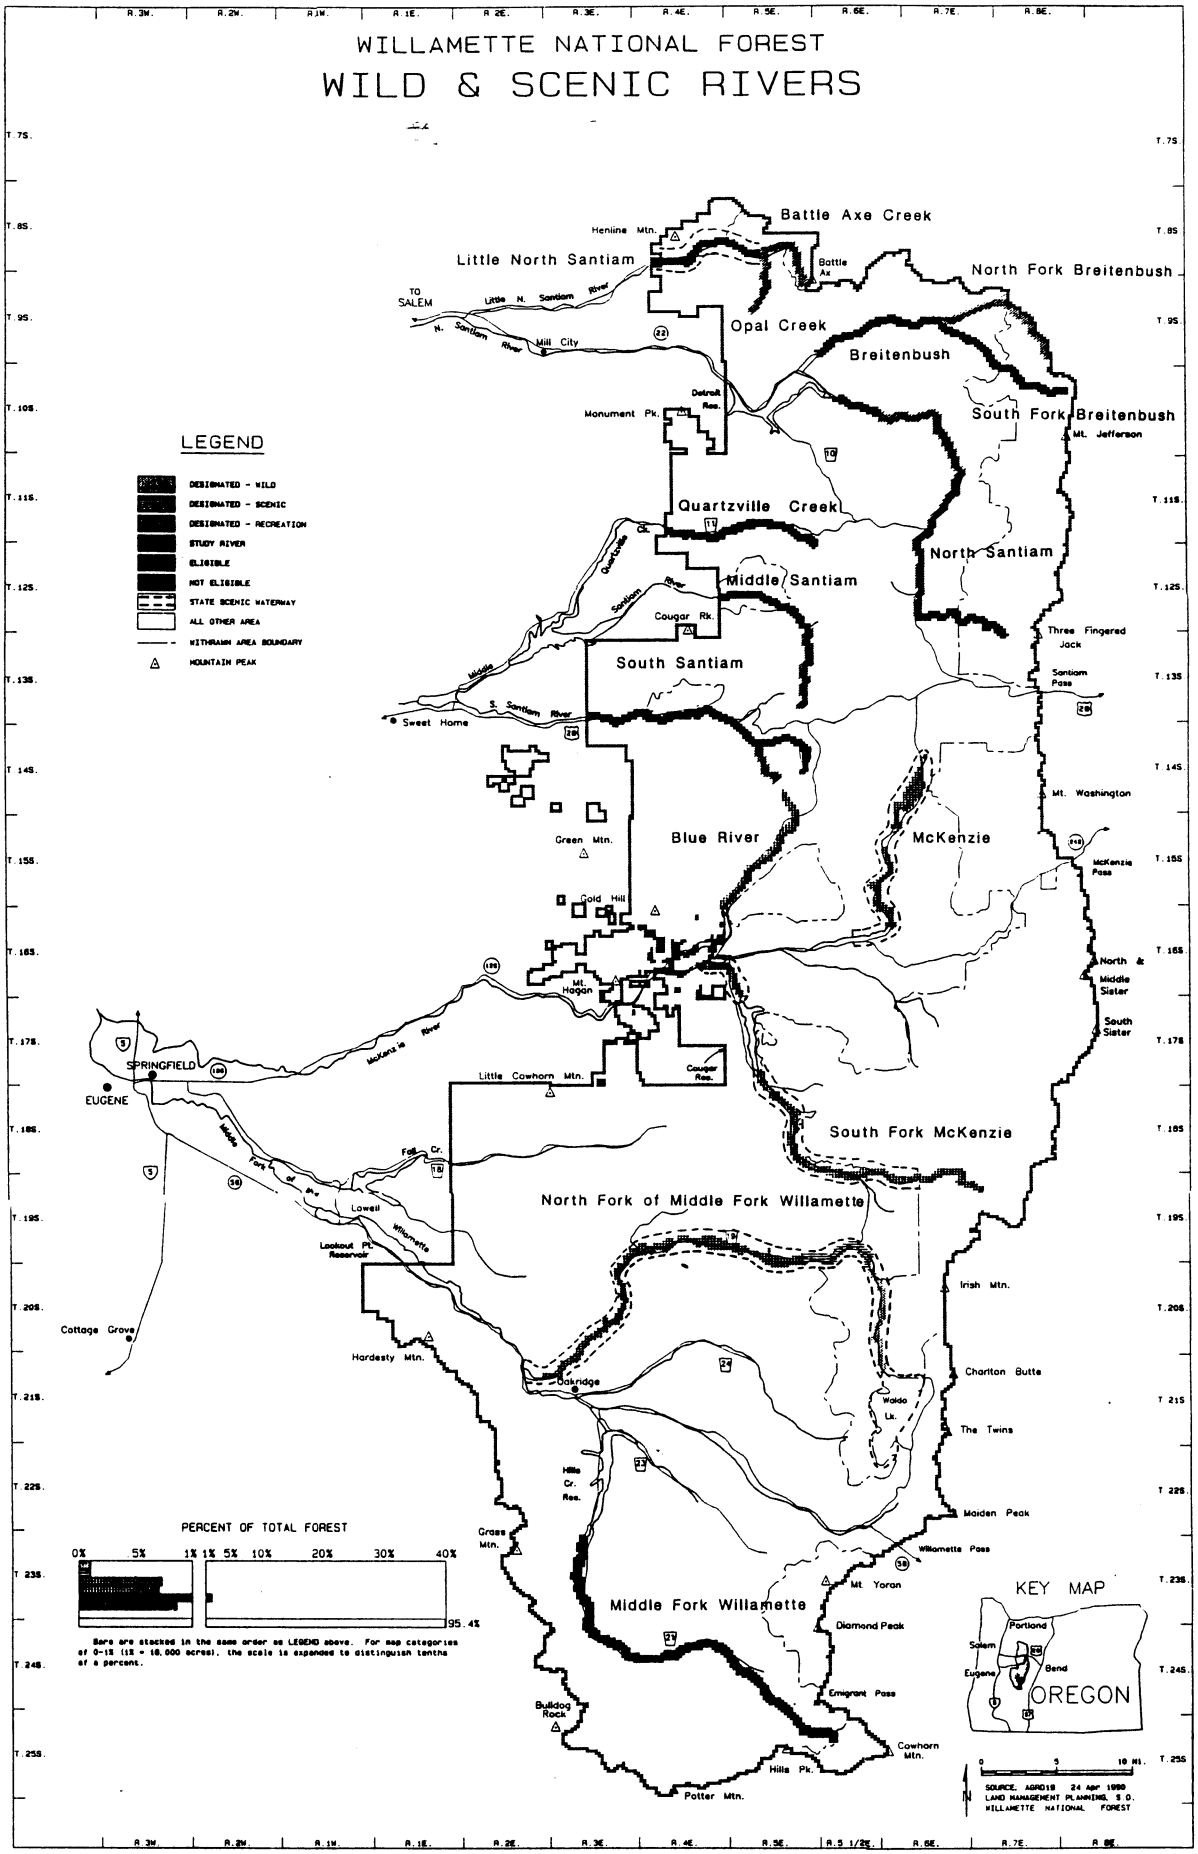
Current planning direction requires protection of free-flowing conditions and "outstandingly remarkable values" of eligible river segments at the highest river classification for wihich they qualify. Protection is extended until a river segment is found not suitable for inclusion in the National System or until action is taken by the U.S. Congress. Land and Resource Management Planning direction also requires that suitability determinations of all eligible rivers be completed with in five years. This process will determine whether a river should or should not be recommended to Congress for inclusion in the National Wild and Scenic River System. River segments determined ineligible for inclusion in the National System will continue to be managed for a wide range of multiple-uses consistent with Current Forest Plan direction.

Generally speaking, the designated and eligible rivers under Forest administration can be described as having outstanding scenery, rich native fisheries and wildlife habitats, unique historic and prehistoric remnants throughout the river corridors, and diverse recreation opportunities ranging from whitewater kayaking to hiking on tranquil riverside trails.

Since the mid-20th century, the river corridors in the Forest have been the focus of tremendous growth in the numbers of recreational users with the majority of visitors utilizing the outstanding recreation potential of those most accessable. Many Forest campgrounds within these river corridors offer developed water-oriented facilities to visitors, and dispersed camping spots are located adjacent to virtually every designated or potential Wild and Scenic River. Recreation outfitters specializing in guiding whitewater or fishing activities depend on seasonal tourism and the continued growth of that industry as do commercial enterprises and service sector businesses.

Figure III-O-3. Eligibility and Classification Status of Forest Rivers

River	Segment Description	River Class	Outstanding Values	Miles	Acres [1]
Little North Santiam River	Battle Axe Creek to Forest boundary	Scenic	Scenic	7.8	2,626
Battle Axe Creek	Headwaters to confluence with Opal Creek	Not eligible	--	5.0	1,727
Opal Creek	Opal Lake to confluence with Battle Axe Creek	Not eligible	--	4.0	1,493
North Fork Breitenbush River	Confluence with NF of NF and SF of NF to SF Breitenbush	Not eligible	--	7.0	1,941
	Headwaters of SF of NF to confluence with NF of NF Breitenbush	Not eligible	--	3.5	597
South Fork Breitenbush River	Russell Lake to Wilderness boundary	Wild	Scenic, Wildlife	4.0	1,749
	Wilderness boundary to Breitenbush River	Scenic	Scenic, Wildlife	6.5	1,834
Breitenbush River	North Fork Breitenbush River to Detroit Reservoir	Recreation	Recreation	9.5	3,040
North Santiam River	Headwaters to Wilderness boundary	Wild	Wildlife	3.8	1,450
	Wilderness boundary to Highway 22	Scenic	Scenic	4.2	1,088
	Highway 22 to Rainbow Creek	Recreation	Ecology	19.5	6,912
	Rainbow Creek to Detroit Reservoir	Not eligible	--	3.5	1,130
Quartzville Creek	Headwaters to unnamed creek west of Bruler Creek	Recreation	Scenic	2.30	875
	Unnamed creek west of Brule Creek to Forest boundary	Recreation	Scenic	10.0	2,944



[1] Acreages are based on a 1/2-mile-wide corridor as represented in the Forest Grid Mapping System database.

Figure III-O-3 Cont. Eligibility and Classification Status of Forest Rivers

River	Segment Description	River Class	Outstanding Values	Miles	Acres [1]
Middle Santiam River	Headwaters to west boundary Section 31	Not eligible		6.0	2,090
	West boundary of Section 36 to Wilderness boundary	Scenic	Scenic	2.0	853
	Wilderness boundary to Forest boundary	Wild	Scenic, Ecological/ biological	6.0	1,493
South Santiam River	Headwaters of Sevenmile Creek to Squaw Creek	Wild	Scenic	4.0	1,706
	Headwaters of Squaw Creek to Sevenmile Creek	Not eligible	--	3.0	1,024
	Sevenmile Creek to Forest boundary	Recreation	Scenic, Wildlife, Historic	10.8	4,287
Middle Fork Willamette River	Lower Timpanogas Lake to Echo Creek	Scenic	Scenic, Historical/ Cultural, Ecological/Biological	16.0	5,674
	Echo Creek to Hills Creek Reservoir	Recreation	Recreation, Wildlife, Historical/ Cultural	14.0	5,247
TOTAL	Rivers Evaluated	--	--	152.0	51,780
	Rivers Eligible	--	--	120.4	41,760

[1] Acreages are based on a 1/2-mile-wide corridor as represented in the Forest Grid Mapping System database.

Figure III-O-4.

Future Trends

Demand for Wild and Scenic River designation is primarily expressed through public comment and response to agency proposals. The degree to which this comment and response favors designation is an indication of demand for a wide range of uses, activities, and resource qualities associated with management of river corridors. One of the primary attractions of designated and potential Wild and Scenic River corridors is the vast opportunities they provide for recreation activities.

Although recreation demand is closely related to present population numbers and projected growth of the local areas, the act of river designation would likely result in increased levels of recreation use in the designated and potential Wild and Scenic River corridors. Principal increases in use, in the event of designation, would probably be in dispersed recreation activities. National designation of the rivers as Wild, Scenic, or Recreation has the potential to increase future tourism development in local areas, enhancing the Forest and the region as a recreation destination as well as providing economic benefits to local communities.

In the event of designation, most Forest management principles will apply only to federal lands within the designated or eligible river area. In the case of both federal and private ownership of river corridor lands, Forest management standards will apply only to the extent required by other laws such as local zoning and air and water pollution regulations.

Management of some river corridors without Wild and Scenic River designation could pose a threat to the quality or conditions of those resource values that permit river segments to be eligible for designation status (i.e., water quality, fisheries, scenic quality, recreation opportunities, and cultural/historic preservation). However, threats to Wild and Scenic River resource values will be relative to the particular Management Areas applied to individual river corridors. Most river corridors identified in Figure III-O-4 are allocated to Management Area prescriptions that in many ways provide conditions equal to those expected within some Wild and Scenic River classes.

Specific activities that could alter river values and thus affect river eligibility or classification include timber harvest, road and bridge construction, geothermal development, expansion of hydroelectric generating facilities, and some forms of development and management of private lands within river corridors. The affects of these activities could result in environmental changes in the river corridors that limit any future consideration of the rivers for inclusion into the National Wild and Scenic River System.

Changes in the natural appearance of the landscape because of timber harvest and or road development could alter the types of recreation experiences people have in these river corridors. Road development can have an effect on the resources of the river corridors as well as the users' sense of loss of remoteness through increased accessibility.

The amount of visible management in the river corridors would vary by the type of Management Area applied. For example, the amount of harvest activity in special categories, such as Recreation River or Scenic Resource areas is moderated by extending the management rotation period from 40 to 120 years longer than that used in Geneeral Forest areas. In addition harvest unit design characteristics are modified and a wide range of silvilcultural systems are employed to minimize affects and protect river values.

Dams and impoundments within river corridors would alter their free-flowing conditions. Altering these conditions would change the eligibility of the river for inclusion in the Wild and Scenic Rivers

System. If a river were to be included in the National Wild and Scenic Rivers System, dam building and development of the river's hydroelectric potential would not be permitted.

WILDERNESS

The Forest Service began administering some of the National Forest System lands to preserve their primitive character as early as 1930. Congress formalized the designation of Wilderness in 1964 with the passage of the Wilderness Act. It contains the following definition:

> A wilderness, in contrast with those areas where man and his own works dominate the landscape, is . . . recognized as an area where the earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain. An area of wilderness is further defined to mean . . . an area of undeveloped federal land retaining its primeval character and influence, without permanent improvements or human habitation, which is protected and managed so as to preserve its natural conditions and which (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least 5,000 acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

The purpose of Wilderness is . . . to assure that an increasing population, accompanied by expanding settlement and growing mechanization, does not occupy and modify all areas . . . leaving no lands designated for preservation in their natural condition . . . (The Wilderness Act; Public Law 88-577 September 3, 1964).

To further this purpose and the intent of Congress, through the Wilderness Act, the National Wilderness Preservation System promotes, perpetuates, and preserves the wilderness character of the lands, protects watersheds and wildlife habitat, preserves scenic and historic resources, and promotes scientific research, primitive recreation, solitude, physical and mental challenge, and inspiration for the benefit of all Americans, to a greater extent than is possible in the absence of Wilderness designation.

The philosophical foundation on which National Forest Wilderness management rests is grounded in values that include aesthetics, water and air quality, wildlife and wildlife habitats, and vegetative diversity, as well as recreation. Wilderness lands within the National Forest have value precisely because they are not required to include a human component; rather, they will be sustained only if human impacts are minimal. This does not preclude public use, but actually enhances the Wilderness experience for those who venture into such an environment.

Wildernesses offer recreationists unique opportunities for physical challenge and solitude in natural settings where evidence of human activities is negligible. In addition to special recreation experiences, Wildernesses provide diverse plant and wildlife habitats as well as summer range for big game such as deer and elk. They often serve as important watersheds, collecting and channeling large quantities of water for downstream uses throughout the year.

Historic Trends

Several trends relating to Wilderness are evident, including establishment of areas, type and amount of use, and management influences.

The preservation of Wilderness has evolved in two ways since the early 1930s. A notable change is the methods of classifying areas to be preserved. Areas were first classified as primitive areas, wild areas,

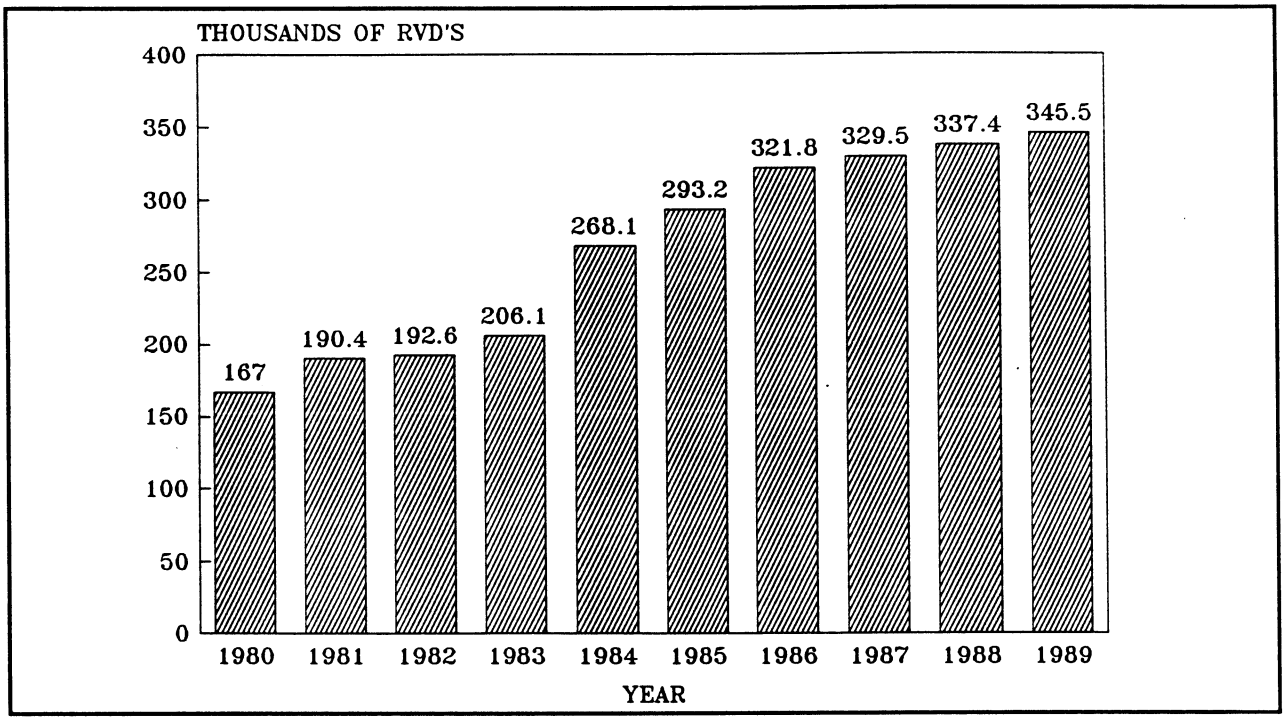
and then Wilderness using agency administrative authorities and, then, after 1964 as Wilderness by Acts of Congress. This latter method is now the only way in which lands are established as Wilderness.

In addition to the change from administrative to congressional designation of areas, the amount of area preserved as Wilderness has increased. Figure III-P-1 illustrates the reclassification trend of areas, and the increases in the amount of land preserved as Wilderness on the Forest since 1930.

Table III-P-1. Wilderness Classification Trends

Classification Type	1930	1933	1937	1938	1956	1957	1964	1968	1978	1984
Primitive Area	32,420	57,520	184,820	240,820	240,820	57,520	57,520			
Wild Area					38,030	54,230				
Wilderness [1]						189,833				
Wilderness [2]							191,063	254,744	301,933	380,805
CUMULATIVE TOTAL	32,420	57,520	184,820	240,820	278,850	301,583	248,583	254,744	301,933	380,805

[1] Administratively designated.
[2] Congressionally designated.



Most of the trails in the Forest Wilderness were originally built for purposes other than recreation. Excluding those trails most recently constructed, most trails were developed for administrative purposes requiring direct access to destinations such as guard stations and fire lookout locations. Little attempt was made, therefore, to design trails with scenic vistas or gentle grades. Since expediency was the rule in the early days of Forest trail construction, some trails may have excessive grades, poor drainage and hazardous stream crossings for packstock and hikers.

Wilderness use, since the mid 1940s, has increased dramatically, and the range of activities that Wilderness users engage in has broadened considerably. Due to significant increases in population, leisure time, and prosperity, National Forest Wilderness visitation since the mid 1940s has increased nearly three times over the use level of the mid 1930s. Recreation activity participation, following World War II, broadened from traditional forms of use such as hunting, fishing, hiking, and camping to include nature study, photography, mountain climbing, snow camping, skiing, and commercially guided pack and saddle trips.

The primary source of visitor use data in wilderness is the Forest's Recreation Information Management (RIM) system. All use and capacity data use here are expressed as Recreation Visitor Days (RVDs). One recreation visitor day equates to twelve hours of use. Figure III-P-2 illustrates Wilderness use in the Forest for the period 1980 to 1989.

Recent trends in total Wilderness use as reported in RIM have shown a steady increase between 1980 and 1989. Some of this increase, particularly since 1984, is a result of the transfer of reported use from dispersed recreation areas, as more Wilderness is designated. The addition of several new Wildernesses in 1984 means that even more use will be attributed to Wilderness than in the past.

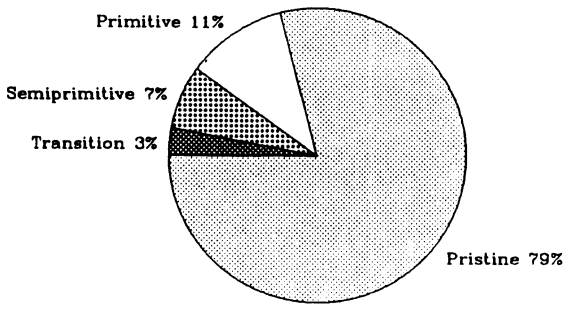
Figure III-P-2. Wilderness Use

During the 1980-89 period, participation in most recreation activities increased at varying rates with some noticeable peaks, valleys, and plateaus in the trend lines. It is evident from the data that recreation use is affected by such variables as weather, travel costs, general economic conditions as well as emerging forms of recreation activities. Total Wilderness use dropped significantly after 1974, following the first "energy crisis" and has only recovered to pre-1974 levels in recent years.

Most recently, the perception of the value of Wilderness lands has expanded from an essentially recreation focus to one that includes consideration for the contributions that Wilderness areas can make to fisheries, water quality, wildlife habitat and healthy wildlife populations, ecosystem research, plant and animal diversity, and commercial use. For example, fisheries experts have recognized that high water quality within Forest Wilderness watersheds is a primary determinant of the viability of downstream fisheries. Most of the lakes within Forest boundaries are in the High Cascades Wildernesses, 74% of which are fish-bearing. Heavy snow pack collects on the permeable lava beds at high elevations supplying critical ground water re-charge. Wilderness lands are also refugia for many plant and animal species, such as arthropods, reptiles, amphibians, and soil organisms, certainly humble but necessary components of the forest ecosystem.

Although the evidence of past fires is not always apparent, especially in the western Cascades, most biological communities have evolved with the presence of fire. Fire suppression efforts during the past 40 to 50 years have generally suppressed fires in Wilderness at a smaller size than free-burning natural fires, modifying the role of fire in Wilderness ecosystems.

The public in its response to the 1987 Draft Environmental Impact Statement was concerned mainly with issues of management planning, development of standards and guidelines, and long term protection; size of Wilderness areas; regulation of user group size and length of stay, including commercial operations;



concern for animals in the Wilderness such as dogs, packstock, and llamas and their effects on the environment and wildlife; consideration for Wilderness values other than recreation; and suppression of natural fires.

Current Condition

The Forest's existing supply of Wilderness opportunities and experiences is derived from eight established areas. Management of five Wildernesses is shared with two other Forests--the Deschutes and Mt. Hood National Forests. The Forest presently contains 380,805 acres of designated Wilderness. This acreage is approximately 21% of the Forest and contains 642 miles of Wilderness trails. Wilderness trails comprise 47% of the Forest's total trail mileage.

The Forest has utilized the Wilderness Resource Spectrum (WRS) inventory process as a method to identify WRS classes within each Wilderness and continues to use this system as a framework for Wilderness management. Figure III-P-3 provides a description of each of the WRS classes.

Figure III-P-3. Wilderness Resource Spectrum Class Descriptions [1]

Classification Type	Descriptions
Pristine	This class is characterized by an extensive unmodified natural environment. Natural processes and conditions have not and will not be measurably affected by the actions of users. The area is managed to be as free as possible from the influences of human activity. People are only brief visitors. Essentially no facilities are required to protect the Wilderness resource. Terrain and vegetation allow extensive and challenging cross-country travel. This class provides the most outstanding opportunity for isolation and solitude, free from evidence of past human activities and with very infrequent encounters with other users. The user has outstanding opportunities to travel cross-country utilizing a maximum degree of primitive skills, often in an environment that offers a high degree of challenge and risk.
Primitive	This class is characterized by essentially an unmodified natural environment. Concentration of users is low and evidence of human use is minimal. This class is managed to be essentially free from evidence of human-induced restrictions and controls. Only essential facilities for resource protection and safety are used and constructed of native or natural materials. No facilities for comfort or convenience of the user are provided. Visitors are encouraged to disperse to desirable existing sites to minimize contacts with other groups. This class provides an high opportunity for exploring and experiencing considerable isolation, solitude, and self-reliance through application of primitive recreation skills in an environment that offers a high degree of challenge and risk.

[1]FSM 2320 R6 Supplement No. 81.

Table III-P-3.Cont. Wilderness Resource Spectrum Class Descriptions [1]

Classification Type	Descriptions
Semiprimitive	This class is characterized by a predominately unmodified natural environment of moderate size. Concentration of users is low, but there is often evidence of other users. This class is managed in such a way that minimum on-site controls and restrictions may be present but are subtle. Facilities are only provided for the protection of Wilderness resource values rather than visitor comfort or convenience. Materials should be natural or natural appearing. In this class moderate opportunities for exploring and experiencing isolation from the sights and sounds of other users; independence; closeness to nature; tranquility and self-reliance through the application of no trace and primitive skills in a natural environment that offers a moderate to high degree of challenge and risk.
Transition	This class includes areas that are characterized predominantly by conditions of relatively concentrated use where encounters with other groups are frequent, opportunities for solitude are limited, and user controls may be highly evident. This zone will provide opportunities for one to pursue satisfaction of one's outdoor recreational needs within a wilderness setting. However this zone will provide experiences in the low to moderate range for isolation, solitude, challenge, and primitive recreation.

[1]FSM 2320 R6 Supplement No. 81.

The WRS management framework establishes classes within the Wilderness based on such criteria as current conditions of use, density of camping sites, and presence of trails. Figure III-P-4 illustrates the current acreage of each WRS class and trail mileage within each Wilderness. Figure III-P-5 shows the capacity of each Wilderness, as currently inventoried, to accommodate human use in RVDs and maximum number of persons at a given time. Figure III-P-6 illustrates the location of each Wilderness in the Forest and the spatial distribution of inventoried WRS classes.

Table III-P-4. Inventoried Wilderness Opportunities by WRS Class[1]

	Pristine		Primitive		Semiprimitive		Transition		Totals	
Wilderness	Acres	Trial Miles	Acres	Trials Miles	Acres	Trail Miles	Acres	Trial Miles	Acres	Trail Miles
Bull of the W	6,314	0.0	1,152	9.5	0	0.0	0	0.0	7,466	9.5

[2]RVD = Recreation Visitor Days and PAOT = Persons-at-one-time.

Forest Service researchers have been working on a process for establishing acceptable levels of Wilderness use called Limits of Acceptable Change (LAC) system. This concept does not propose to eliminate all changes to Wildernesses caused by human use, but recognizes that impacts can be the result of the specific kind of use, user behavior, and the season and distribution of use. The LAC System calls for inventories of existing conditions in each Wilderness and the comparison of existing conditions to the standards and guidelines for each WRS class. The Forest is currently in the process of conducting LAC inventories with an emphasis on areas sustaining heaviest use: Mt.Jefferson, Three Sisters, and Mt.Washington Wildernesses.

Initial findings of LAC inventories in these Wildernesses indicate that specific areas and trail corridors are receiveing use in excess of capacity as determined by WRS class management standards and LAC indicators. These findings further suggest that estimated capacity of some WRS classes in most Wildernesses, as currently inventoried, are overstated when compared with current use levels and physical resource conditions of Wilderness. A listing of specific areas and trails where use capacity is being exceeded and the effects of overuse are present can be found in discussions of each Wilderness later in this section.

Expansion of Wilderness opportunities in the Forest for this cycle of planning include one unroaded area near the community of Blue River. The area is known as the Mt. Hagan roadless area and is 6,292 acres in size. Mt. Hagan is the only area to be addressed as potential Wilderness in the Forest planning process. This area was included as recommended Wilderness in one alternative in the DEIS: Alternative C. The inclusion of the Mt. Hagan area as potential Wilderness is based upon the criteria set forth by Congress in the Oregon Wilderness Act of 1984.

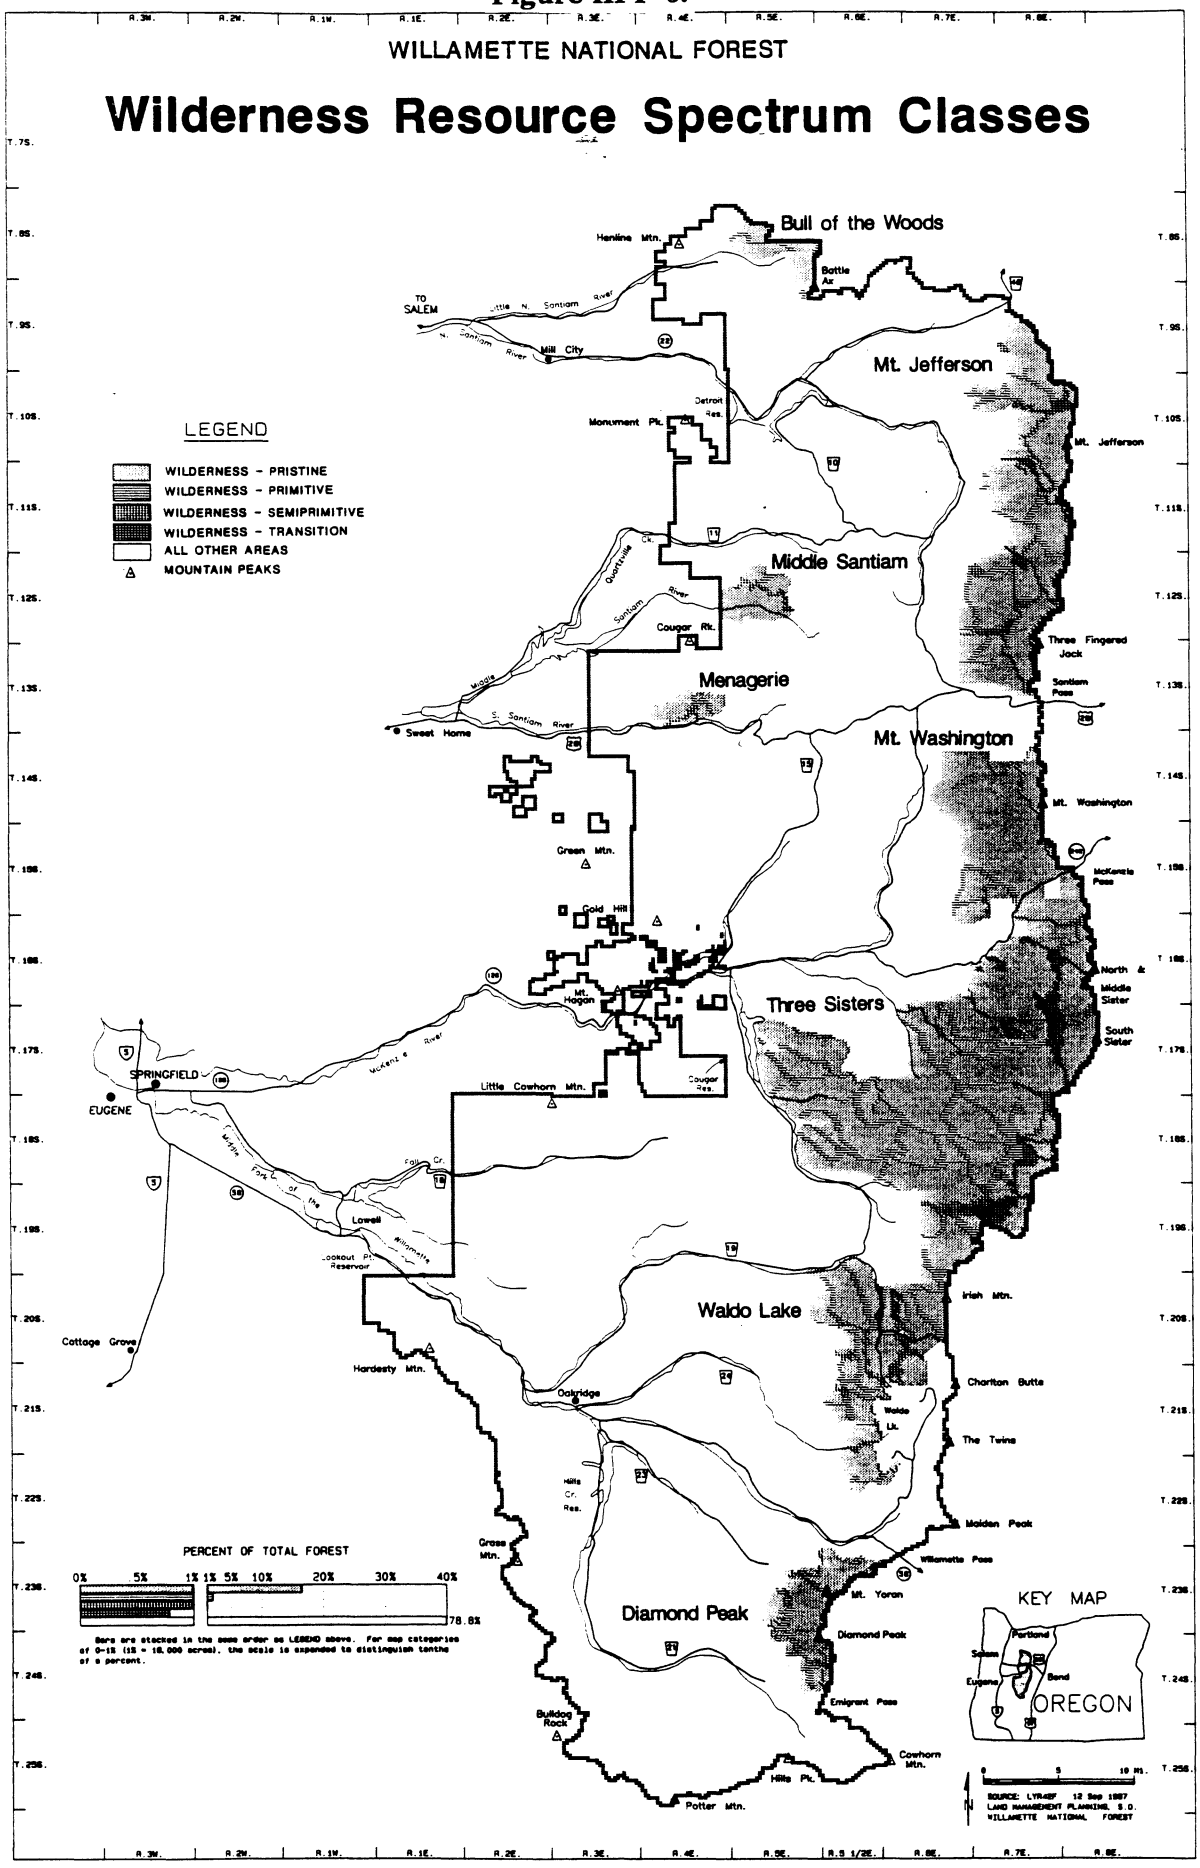
The Oregon Wilderness Act of 1984 directs that for the initial National Forest Management Act (NFMA) land management plans the National Forest lands in Oregon which were reviewed in RARE II or in unit plans and roadless lands which are less than 5,000 acres in size have had adequate consideration of their suitability for inclusion in the National Wilderness Preservation System. The Department of Agriculture will not be required to review the Wilderness option prior to the revision of the plans, but will review the Wilderness options when the plans are revised, ordinarily on a 10-15 year cycle (Section 7(b)(2) Oregon Wilderness Act of 1984). The roadless lands will be managed for multiple use in accordance with the land management plans, and they need not be managed for the purpose of protecting their suitability for Wilderness designation prior to or during revision of the land management plans (Section 7(b)(3) Oregon Wilderness Act of 1984).

The Mt. Hagan area was neither reviewed in RARE II nor evaluated in a Forest Unit Plan and therefore must be considered for the Wilderness option in the current planning process. The WRS inventory indicates the Mt. Hagan area is suitable for providing primitive Wilderness opportunities. See Appendix C for a description of this area.

The unique ecosystemic contributions that Wilderness lands make to the ecology of the Western Cascades and Willamette Valley include significant influences on maintenance of high quality air and water; protection of habitats required by diverse animal species; and conservation of vegetative diversity through protection of representative plant communities. Establishment of several Research Natural Areas within Wilderness boundaries is reflective of the research value of the Forests Wildernesses. A Research Natural Area has been established within the Middle Santiam Wilderness boundaries, and RNAs are proposed for establishment in the Three Sisters Wilderness (McKenzie Pass RNA) and the Waldo Wilderness (Torrey-Charlton RNA).

Specifically, Wilderness lands are critical to continuance of high water quality which has direct bearing on terrestrial and aquatic species dependent on water and riparian habitats, and are primary factors in maintaining floral and faunal diversity. Without Wilderness lands, there would be a significant decline in species richness and abundance. These designated lands are a mixture of all forest types ranging from low to high elevations and encompassing forested and nonforested communities including meadows, sub-alpine, and alpine types. For example, the Menagerie Wilderness, Middle Santiam Wilderness, and the French Pete section of the Three Sisters Wilderness are prime low elevation lands with significant stands of old-growth Douglas-fir. Species preferring this kind of habitat are Northern Spotted Owls, wolverines, peregrine falcons, and bald eagles. Other animals favoring wild lands, especially along the crest of the High Cascades, are martens, fishers, and cougars.

Wilderness lands along the crest of the High Cascades (Three Sisters, Mt. Jefferson, Mt. Washington) are important as high use summer range for herds of deer and elk that winter on both sides of the summit. Because of this shared summer range, interbreeding between mule-deer and black-tailed deer occurs. These designated Wilderness lands serve also as an unbroken corridor for plant migrations and genetic exchange. They are an important transition zone between east and west sides; in addition, the mechanics of wind and water in the river corridors are dispersal agents for seeds and pollen from Wilderness plant communities out into managed lands.



Wilderness lands are intact natural systems and, therefore, reservoirs of natural processes such as nutrient cycling, geologic events, etc. In addtion, they are repositories of natural genetic stock and variability providing the ecosystem with vigor and protection against disease. They are a baseline against which we can compare managed lands not only on a short-term basis, but in the face of such significant trends as global warming, on a larger scale.

Within Wilderness boundaries is scattered evidence of prehistoric and historic cultural behavior. Remnants of cabins, homesteads, old roads and livestock trails frequently can be found especially in Wildernesses, primarily due to the undeveloped status of the land. Evidence of aboriginal use of the land can often be seen in deposits of chipping waste and fragments of stone tools. Many of these cultural resources have been inventoried and are protected by the same legislation that directs cultural resource preservation and management on other parts of the Forest.

Primary issues that currently concern the public regarding Forest Wilderness lands do not diverge much from issues and concerns following publication of the DEIS in 1987. Briefly, the public is concerned with natural processes, social and resource impacts, trails and access, information sharing and public involvement, and regulation of use. Specifically, the Forest has been asked to address issues of recreational impacts from commercial and individual users to Wilderness ecosystems at popular areas and the effects of these impacts on other Wilderness values such as wildlife, plants, ecological processes; trail and sign maintenance and map updates; regulating Wilderness use through permit or registration procedures, thus, reducing impacts; enforcement needs.

The Forest will continue to involve the public in the Wilderness management process through consultation and communication during all levels of decision making.

Figure III-P-6.

Bull of the Woods Wilderness

The Bull of the Woods Wilderness was established by the Oregon Wilderness Act of 1984. This 33,851 acre Wilderness is located in the Willamette (7,466 acres) and Mt. Hood (26,385 acres) National Forests, approximately 68 miles southeast of Portland and 65 miles east of Salem. In the Forest this area is accessible from the west by the Little North Santiam Road, by French Creek Road on the south, and Elk Lake Road on the east.

The area is characterized by steep mountainous terrain dissected by numerous mountain streams. Within the Wilderness are the headwaters of the Collawash, Breitenbush, and Little North Fork of the Santiam Rivers. Elevations range from 1,600 to 5,560 feet. Lower slopes are typically covered by dense stands of Douglas-fir and western hemlock while upper slopes are forested with Douglas-fir, true fir and mountain hemlock. Rocky slopes and outcrops are common on upper slopes and are often associated with a shallow soil layer. There are several small lakes scattered throughout the Wilderness, many supporting an abundance of fish. These lakes are usually isolated from one another by steep, high ridges. Nongame wildlife species are varied and abundant; however, big-game populations are sparse.

Recreational opportunities within the area are hiking, horseback riding, backpacking, mountain climbing, fishing, hunting, rockhounding, and nature study. The Bull of the Woods Lookout is one of the most heavily used areas in the Wilderness as it commands a 360 degree view of the surrounding area. Mine shafts, old pieces of equipment, and other evidence of the area's mining history are found in this Wilderness.

Recreation use of the Bull of the Woods Wilderness consists primarily of hiking, camping, and fishing. The most popular trail in this Wilderness under the administrative jurisdiction of the Forest, meanders from Battle Axe Creek over to Whetstone Mountain to Gold Creek. At this time the trail receives only light recreational traffic.

There are many physically-challenging recreation opportunities in Bull of the Woods Wilderness, particularly during cross-country travel. In the upper elevations above the continuous stands of timber, the variety of terrain, the scenery and excitement of travel provide excellent mountaineering experiences. A sense of spaciousness and solitude can be experienced within most of this Wilderness.

Bull of the Woods Wilderness maintains the flow of high quality water in the Little North Santiam watershed which is the main water supply for the City of Salem in-take. In addition, the Little North Santiam which originates in the Wilderness is one of the few free-flowing streams in the Forest that supports an anadromous fish population.

Mt. Jefferson Wilderness

The Mt. Jefferson Wilderness is jointly administered by the Willamette (72,565 acres), Deschutes (32,734 acres) and the Mt. Hood)(3,793 acres) National Forests. The Wilderness extends approximately 25 miles in a north/south direction along the crest of the Cascades with portions of the area in Jefferson, Linn, and Marion Counties. The area is approximately 60 miles southeast of Salem and 40 miles northwest of Bend, Oregon. U.S Highway 20 parallels the southern boundary and Oregon State Highway 22 parallels the western boundary.

This area was originally established as Mt. Jefferson Primitive Area in 1930; when Congress passed Public Law 90-548 in 1968, it was designated as Mt. Jefferson Wilderness and with passage of the 1984 Wilderness Act, the size of the Wilderness was expanded to 109,029 acres.

Scenic highlights in this region are two steep-sided volcanic cones: Mt. Jefferson (10,497) is located to the north and Three-Fingered Jack (7,841) is located in the south. As is common with rapidly decaying volcanic mountains, the lower slopes of these peaks are covered with talus and deposits of pumice and glacial debris on which dense conifer forest begin to occur. These slopes are dissected by stream valleys that are predominantly U-shaped as a result of previous glacial erosion. At the heads of these U-shaped valleys are the formations of bare glacier-formed piles of rocks known as moraines. Moraines often form natural dams creating small lakes from the glacial run off. Above the timberline where the moraines occur, only alpine plant species are present. These include: subalpine fir, mountain hemlock, and various shrub and ground cover species. The middle elevations between 3,000 and 5,000 feet support subalpine types, consisting primarily of silver and white fir, lodgepole and whitebark pine and mountain hemlock. The lower elevations below 3,000 feet support Douglas-fir, Ponderosa pine, western hemlock, white fir, and juniper.

Mt. Jefferson Wilderness provides favorable habitat for many species of wildlife and fish indigenous to the Oregon Cascades. The Pacific Crest National Scenic Trail provides major access to the area. Fishing quality and hunting attract numerous visitors as the early High Cascade deer hunting season allows visitors to combine hunting and fall fishing.

Due to the area's easy accessibility, it has become very popular for day use and overnight visitors. Ease of access along with the growing demands for high quality outdoor recreation activities have resulted in the Wilderness receiving use in excess of its capacity in some areas. Signs of resource damage such as soil compaction, destruction of vegetation, loss of ground cover, declining water quality, and use of snags for firewood are becoming apparent. These impacts are especially severe in the subalpine areas where the growing season is short and damaged areas recover slowly. Areas that have received the greatest impacts from recreational use are: Jefferson Park, Pamelia Lakes, Hunts Cove, Marion Lake, Mowich Lake, duffy Lake, Santiam Lake, Square Lake, Wasco Lake, Cabot Lake, Ann Lake, Carl Lake, Canyon Creek Meadows, Rockpile Lake, Shirley Lake, Long Lake, Lower Berley Lake, Jorn Lake, Blue Lake, Bowerman Lake, Red Butte, Dixie Lakes, Lake of the Woods, Jenny Lake, Prill Lake, Swallow Lake, Crown Lake, Turpentine Lake, Ruby Lake, the Eight Lakes Basin, and the Pacific Crest National Scenic Trail corridor.

Water quality and purity in the Mt. Jefferson Wilderness affect the heavily-used Breitenbush River recreation area. High water quality, cold temperatures, and excellent clarity enhance this publically-popular downstream zone.

In spite of heavy localized use and the visible effects which can result, the Mount Jefferson Wilderness is an area of outstanding beauty and scenery. It offers backpacking on miles of shady trails, mountaineering on Oregon's second highest peak, horseback riding, fishing, hunting, and many other wilderness-oriented recreational activities.

Middle Santiam Wilderness

The Middle Santiam Wilderness was established by the Oregon Wilderness Act of 1984. This 8,553 acre area is located in Linn County within the Sweet Home Ranger District and is bordered by National Forest lands on its north, south, and east boundaries and by private timber lands to the west. The west portion of this area is accessible by private roads and from other directions by National Forest roads.

Located within the Wilderness boundaries is the Middle Santiam Research Natural Area near Chimney Peak which includes representative old-growth stands of 450+ years Douglas-fir and western hemlock. Research issues being addressed at the RNA are productivity of old-growth forests and their significance

as wildlife habitat; composition and successful development of forest communities; and the role of coarse, woody debris in stream stabilization.

Elevations in this area rise from 1,600 to over 5,000 feet. Topographically, there is an abundance of gentle slopes and benches that rise to form dissected steep slopes, ridges, and high peaks. Vegetation varies from true fir associations at the higher elevations to the Douglas fir/western hemlock associations at the lower elevations. The Middle Santiam River transects the area and has several small tributary streams feeding into it.

Recreational opportunities include hiking, backpacking, berry picking, fishing, hunting, horseback riding, rock hounding, and nature study. Wildlife species are varied and plentiful in the area. Big game populations are moderate with the elk population especially showing an increase. Chimney Peak, Knob Rock, the Middle Santiam River and Donaca Lake are prominent features in the Middle Santiam Wilderness.

Timber harvesting activities on lands around the perimeter of the Wilderness could detract from a visitor's sense of remoteness and feeling of solitude within the Wilderness. Possible overuse is occurring along the Chimney Peak and Gordon Peak Trails which lead to Donaca Lake. Signs of this include soil compaction or increased erosion and loss of vegetation. Increased numbers of people using the trails have also affected opportunities for solitude, and may limit some forms of primitive recreation.

Intense management of private lands in the vicinity of the Wilderness have amplified the importance of the designated lands in maintaining the high water quality required by downstream users. Protection of the watershed and related fisheries through Wilderness designation is critical. In addition to its hydrologic value, the Middle Santiam Wilderness is important as a potential low elevation old-growth habitat for such wildlife species as: Northern Spotted Owls, wolverines, peregrine falcons, and bald eagles.

The Middle Santiam Wilderness area contains approximately 12 miles of trails that provide opportunities that range from nonstrenuous low elevation hiking to middle elevation backpacking, or off-trail mountaineering. Whatever the interests of the individual might be, the area's combination of rivers, streams, forests, peaks, and lakes offer a variety of Wilderness use opportunities.

Menagerie Wilderness

The Menagerie Wilderness was established by the Oregon Wilderness Act of 1984. This area is located in Linn County within the Sweet Home Ranger District. Access is primarily from trails originating at points along U.S. Highway 20, the area's southern boundary.

The Menagerie Wilderness is 4,949 acres in size and is characterized by steep dissected slopes. Smaller areas of more gentle slopes are present. The Rooster Rock area in the Menagerie Wilderness has a series of pinnacles that rise above the surrounding landscape; Rooster Rock is the largest. These basalt spires offer some of the most challenging rockclimbing opportunities in the Western Cascades. Elevations in the Wilderness range from about 1,600 to 3,560 feet.

Vegetation consists predominantly of the Douglas-fir/western hemlock association with few natural openings. Two streams supporting native cutthroat trout populations drain from the area. Black-tailed deer are the most usual big-game species with resident herds of elk depending on the area as winter range.

Included within the designated boundary are 85 acres of privately owned land. Except where private lands adjoin the Wilderness boundary to the north, much of the Menagerie Wilderness is bordered by National Forest lands.

Recreational opportunities include day use activities such as fishing, hunting, hunting, sightseeing, hiking, and nature study. The area has some opportunities for low elevation trail hiking and has approximately seven miles of developed trails. Current use patterns indicate that the trails from Trout Creek and Fernview Campgrounds into the Wilderness receive the heaviest use, primarily for day hiking. These trails show few effects from recreationists, although evidence is beginning to accumulate that the main ridges leading to the rock spires may receive use in excess of capacity.

Although the topography and dense vegetation make the area physically challenging, the experience of solitude and spaciousness is limited because of the area's size and its proximity to the highway and industrial activities.

Mt. Washington Wilderness

The Mt. Washington Wilderness is located in Deschutes County in the Deschutes (13,356 acres) National Forest and Lane and Linn Counties in the Willamette (40,996 acres) National Forest. The summit of the Cascade Range runs north and south through the Mt.Washington Wilderness, forming the east boundary of the Forest.

The Mt. Washington Wilderness was first established as a "Wild Area" in 1957, and as a Wilderness by the Wilderness Act of 1964. The area was recently enlarged to 54,559 acres by the Oregon Wilderness Act of 1984. This Wilderness is accessible on the south from the McKenzie Highway which forms a part of the south boundary. On the north it is easily reached by the Big Lake Rd. and the Old Santiam Wagon Road. On the west side, access is provided by several Forest Service roads and U.S. Highway 126. The main entrance point on the south is at the Pacific Crest National Scenic Trail (PCNST) crossing on McKenzie Pass Highway (State Highway 242). This point accesses immense lava flows originating from Belknap Crater and Little Belknap Crater.

The Mt. Washington Wilderness area offers varied recreational opportunities for the High Cascades traveler. Its diverse terrain ranges from forest, to lava beds, to scree slopes, to the steep vertical walls of Mt. Washington itself.

The principal attraction within the area is Mt. Washington, a spectacular peak, with an elevation of 7,802 feet. Wilderness trails provide hikers with excellent views of Mt. Washington's extensive lava beds and scenic views of other mountains and forested areas. Other popular activities include hunting on the east and west sides of Mt. Washington where deer are plentiful, and fishing at Patjens Lakes.

The gently sloping terrain would be ideal for camping were it not for the scarcity of water. Water supplies are practically nonexistent in the area because of the high permeability of the volcanic rock and soil. Over half of the Mt. Washington Wilderness area is lava flows covered occasionally by grass and low-growing shrubs, although vegetative cover varies with elevation. Lodgepole pine and true fir-mountain hemlock cover types are the most widespread, with Douglas-fir comprising less than 7% of the total area.

The Belknap lava field covers approximately 10,000 acres of the Mt. Washington Wilderness. Most of the lava flow is characterized by jumbled blocks of solidified magma with bristling, jagged surfaces. Visitors should be especially cautious on the lava flows where the unwary risk injury on sharp, rough rocks. Climbing of the mountain itself requires exacting safety precautions with the final ascent through

chimneys and vertical rock faces. Due to the technical difficulty of the climb and friable nature of the rock, the summit of Mt. Washington was not conquered until August of 1923.

Specific locations in the Mt.Washington Wilderness appear to be receiving use in excess of capacity. They are: Benson Lake, Tenas Lake, Hand Lake, George Lake, Patjens Lake, and the Pacific Crest National Scenic Trail corridor. Overuse is indicated by compaction and erosion of soil, destruction of vegetation, reduction of water quality, and the use of dead woody material and snags as fuel for campfires. These impacts are especially severe in subalpine zones where the environment is slow to recover. In these same areas, opportunities for solitude and primitive recreation are declining due to increasing numbers of users.

Three Sisters Wilderness

The Three Sisters Wilderness was first established as a 184,820 acre Primitive Area by the Chief of the Forest Service in 1937. In 1938, it was enlarged to include 56,000 acres of Forest land located between Horse Creek and the South Fork of the McKenzie River. In 1957, the area was reclassified as the Three Sisters Wilderness by the Secretary of Agriculture under Regulation U-1. At this time, 53,000 acres of the 56,000 acres added to the Primitive Area in 1938 were excluded from Wilderness classification. The Three Sisters Wilderness was given Congressional designation with passage of the National Wilderness Preservation Act of 1964. The American Endangered Wilderness Act of 1978 added to the Three Sisters Wilderness 47,200 acres of the 53,000 acres deleted from the Primitive Area upon its classification as Wilderness in 1957. The most recent addition to the Three Sisters Wilderness resulted from passage of the Oregon Wilderness Act of 1984. Through this Act, the total allocation was enlarged to its present size of 283,593 acres. Management of this Wilderness is shared by the Willamette (189,346 acres) and the Deschutes (92,706 acres) National Forests.

The western portion of the proposed McKenzie Pass Research Natural Area is located partially in the Three Sisters Wilderness. Refer to the FEIS, Chapter III for a description of the RNAs on the Forest.

Access to the Three Sisters Wilderness is by trails and Forest roads that originate from State Highway 242 on the north; Cascade Lakes Highway on the east; Waldo and Irish Taylor Roads on the south; East Fork Road and Aufderheide Drive (Forest Road 19) on the west.

Favorite recreational activities include fishing, hunting, nature study, mountain climbing, camping, hiking, and horseback riding. The Wilderness trail system traverses the Wilderness from north to south providing outstanding views of subalpine country, the Three Sisters, and other prominent peaks and cones along the Cascade Crest. Trails pass through fir, hemlock, and lodgepole pine stands on the north and south ends of the Wilderness and have evolved from earlier sheep driveways, firefighters' way trails, packers' routes, and fishing trails. One-day hiking and riding trips are possible in the peripheral areas such as Proxy Falls, Linton Lake, Sunshine Meadows, Sister's Mirror Lake, Horse Lake, and Green Lakes. Backpackers as well as riders with packstrings can spend many days exploring the more remote interior areas.

Fishing is a favorite recreational activity in the Mink Lakes Basin which contains a cluster of about 60 lakes surrounded by fir, mountain hemlock, and lodgepole pine forests of the southern portion of the area. Mink Lake at 360 acres is the largest in the Wilderness. These areas are showing signs indicating use in excess of capacity.

Originally constructed by the Civilian Conservation Corps for the convenience and safety of hikers and riders are five historic trail shelters, located at James Creek, Cliff Lake, Mink Lake, Buck Meadows,

and Muskrat Lake. All but Muskrat Lake are considered eligible for listing on tthe National Register of Historic Places.

A recreational activity that has become very popular over the past few years is mountaineering. The volume of climbing traffic particularly on the Three Sisters peaks has become heavy. On midsummer weekends it is often necessary to wait for preceding parties to pass through certain exposed areas on popular North Sister routes. Due to this overcrowding on the summits, climbing accidents as well as litter have become a problem. Climbing camps that receive considerable day use are located at the Sunshine Meadows-Obsidian area below North and Middle Sister, and the Green Lakes area between South Sister and Broken Top. North Sister at 10,094 feet is most difficult of the Three Sisters to climb while Middle Sister (10,053) and South Sister(10,354) are not technically difficult climbs.

The mosaic of forest, meadows, and openings within the Wilderness is a complex response to the interaction of climatic, soil, and geologic factors, insect and disease outbreaks, and fire. In the lower elevation canyon country on the west side of the summit there are extensive stands of Douglas-fir. On both sides of the crest in higher elevations true fir, mountain hemlock, and lodgepole pine stands prevail while timberline and subalpine areas are characterized by clusters of slow growing subalpine fir, mountain hemlock, and an occasional whitebark pine. Meadows and openings interspersed with the scattered trees in this zone form a scenic setting which is generally favored by recreation users.

The Three Sisters Wilderness is favorable habitat for black-tail deer, mule deer, Roosevelt elk, and black bear. Elk are generally from the herds that winter in the South Fork McKenzie River, and North Fork Willamette River areas, often ranging as far east as Tumalo Creek and Crane Prairie Reservoir.

Linton Meadows is the most popular area for early season deer hunting and winter elk hunting. Mule deer, black-tail deer, and elk inhabit the area in and around the meadows and on Lane Plateau. Hunters often hike or ride in by way of Obsidian Trail, Frog Camp, or from Lava Camp on the Pacific Crest National Scenic Trail. The patient observer can see many other indigenous mammals such as marten, coyote, fox, mink, weasel, bobcat, beaver, and badger. Birds typical of the Wilderness include Clark's nutcracker, gray jay, Stellar's jay, common raven, turkey vulture, hairy woodpecker, winter wren, Oregon junco, red breasted nuthatch, and chestnut-backed chickadee. Hawks, owls, osprey, bald and golden eagles, waterfowl, and shorebirds also prefer the high elevation habitat.

The effects of overuse in the Three Sisters Wilderness can be seen in environmental degradation and increasing resource damage. Locations exhibiting these effects include: Sunshine/Obsidian Falls, Arrowhead Lake, Eileen Lake, Husband Lake, Linton Meadows, Lower Linton Meadows, Linton Lake, Otter Lake, Erma Bell Basin, Proxy Falls, Sisters Mirror Lake, Horse Lake, Golden Lake, Moraine Lake, Chambers Lake, Park Meadow, Buck Meadows Shelter, James Creek Shelter, Cliff Lake Shelter, Rebel Rock Lookout, Muskrat Lake Cabin, Mesa Creek, Blow Lake, Doris Lake, Hinton Springs, Honey Lakes, Nash Lake, Porky Lake, South Sister Climbing Trail, Mink Lake and Mink Lake Shelter, North and South Matthieu Lakes, Soap Creek Crossing, Camp Lake, Green Lakes, Ollalie Guard Station, Olallie Lookout, the Pacific Crest National Scenic Trail corridor, and Lower French Pete Trail. Also past commercial grazing and the presence of nonconforming facilities within the Wilderness have affected the environment and Wilderness experiences

The effects of more than a half century of fire protection are apparent in the succession which is taking place in many of the fire-formed openings. Lodgepole pine and mountain hemlock are filling in these openings which resulted from fire, insect epidemics, or other natural processes. Some of this succession may be influenced by recent climatic events.

Mountain pine beetle and white pine blister rust are found in the western white pine which is a minor element in the Douglas-fir and true fir/mountain hemlock stands. Balsam woolly aphid infestations slightly near the epidemic stage have occurred in some stands of true firs at upper elevations. Other biological disturbances particular to this area include *Phellinus* (root rot) in mountain hemlock stands, and western spruce budworm.

A water power withdrawal covering Horse Creek and Separation Creek is in effect. The U.S. Army Corps of Engineers has made a preliminary proposal for a flood control dam outside the Wilderness. If constructed, the dam would back water into the Wilderness in Horse and Separation creeks.

Waldo Lake Wilderness

The Waldo Lake Wilderness was established by the Oregon Wilderness Act of 1984 and is located entirely within Lane County and the Forest. The area lies 20 miles to the east of Oakridge, directly north of Highway 58 and west of Waldo Lake Road. Primary access points include: Taylor Burn, North Waldo, and Shadow Bay campgrounds; Forest Service roads in Furnish Creek, Salmon Creek, and Black Creek drainages; and trailheads located along the upper end of Road 19 and the Waldo Lake Road. Prior to 1984, the area was managed as the Waldo Lake Recreation Area.

The Waldo Lake Wilderness includes 37,157 acres of Oregon's High Cascades between the volcanic remnants of the Three Sisters and Diamond Peak. Waldo Lake, adjacent to the Wilderness, is a most prominent feature and a popular recreation destination. The lake was named after Judge John B. Waldo, a Pioneer son who died in 1907.

Elevations range from 2,800 feet to over 7,100 with an average elevation of approximately 5,000 feet. Generally, topography can be described as gently rolling foothills, except in the northwest portion where the North Fork Willamette drainage breaks up the area to form steep dissected slopes.

Wilderness lands include more than 200 small lakes, ranging in size from small seasonal ponds to the 100 acre Lower Eddeeleo Lake. Almost all of the larger lakes in the area contain fish, and planting of fish in the more popular lakes by the Oregon Department of Fish and Wildlife commonly occurs. The majority of the lakes have rocky shorelines and are set in small basins surrounded by unbroken stands of timber, providing maximum seclusion for anglers and other visitors. Water clarity and purity in Waldo Lake, Oregon's second largest lake, is dependent on maintenance of high water quality within the Wilderness.

Stands of mountain hemlock, lodgepole pine, true fir, Douglas fir, western hemlock, and some true fir associations are typical of the Wilderness. Natural openings of shrub, grass/forb types are present. Many small streams originate in these openings and flow to the larger tributaries of the North Fork of the Middle Fork of the Willamette River. A variety of birds, animals, and amphibians inhabit the area, while deer and elk summer in the meadows and adjacent forested lands.

Hunting activity is light in the eastern part of the area, and heavier in the west. The upper end of the Black Creek drainage and North Fork of the Middle Fork of the Willamette River are the most popular deer and elk hunting areas with easy access and transport of game occurring by boating across Waldo Lake.

Many other recreation activities are available including: hiking, backpacking, horseback travel, boating, scenic viewing, hunting, fishing, wildlife observation, photography, and nature study. Unusual geologic features and indigenous plants add to the diversity of the area.

Nonconforming facilities in the Wilderness such as Waldo Mountain Lookout, Black Meadows Cabin, and Fuji Mountain Cabin may intrude on the natural landscape. There is some concern that certain locations are receiving recreation use beyond their capacity. Areas that show environmental degradation are: Eastern Brook Lake, Winchester Lake, Gander Lake, Wahanna Lake, Rigdon Lake, Kiwa Lake, Six Lakes, Torrey Lake, Whig Lake, Quinn Lakes, Long Lakes, Swan Lakes, Salmon Lakes, and Eddeeleo Lakes. Increasing numbers of visitors are affecting opportunities for solitude and primitive recreation. Some trails are also beginning to exhibit signs of overuse including: Winchester Trail, Rigdon Lakes Trail, Black Creek Trail, Six Lakes Trail, Wahanna Trail, Whig and Torrey Way Trails, and Salmon Lakes Trail. Evidence seems to suggest that commercial activities may be occurring in the Wilderness without permits. These activities may be adversely affecting the area through its use by excessive numbers of people in one location at the same time, groups too large for a wilderness setting, and increased probability of site damage from concentrated horse use.

Forest Service trails and trail structures, mountaintop land survey control points, and abandoned Forest Service lookout stations are evidence of human activities. In addition, old campsites are evident in meadows and near lakes. Industrial activities and the resulting change in visual quality of adjacent lands are visible from within the area along the northern and western boundaries.
The Torrey-Charlton proposed Research Natural Area, within the Waldo Lake Wilderness boundaries, was proposed in the 1977 Forest Multiple Use Land Management and Timber Management Plan. An establishment plan for the area is close to completion.

Diamond Peak Wilderness

The Diamond Peak Wilderness was first established as a "Wild Area" by the Chief of the Forest Service in 1957. The area was reclassified as Wilderness by the Wilderness Act of September 1964 and was recently enlarged to 52,773 acres by the Oregon Wilderness Act of 1984. Management is shared with the Deschutes (32,964 acres) and the Willamette (19,773 acres) National Forests.

The Cascade Crest runs generally north and south through the area. Diamond Peak (8,744 feet) is the most prominent point and dominates the Wilderness. This is a massive, barren mountain consisting of at least three major peaks with broad ridges extending east and west as well as along the Cascade Crest. Blocky lava, pumice, and red cinders cover the slopes above 7,200 feet in elevation. There are two other significant volcanic peaks within the area: Mt. Yoran, just to the north of Diamond Peak, and Lakeview Mountain near the east boundary.

The west slope of the Cascades is broken by many drainages and drops steeply to several lakes just within the Wilderness boundary. To the north of Mt. Yoran the ground tends to be characterized by benches and gentler ridges. Small meadows and potholes are typical. Near the north boundary the terrain breaks steeply to Salt Creek. The eastern portion, bounded on the north by Trapper Creek and on the east by Lakeview Mountain, is gently rolling terrain sloping gradually toward two ridges which form a basin at the foot of Diamond Peak.

Diamond Peak is an important watershed with drainages radiating in all directions. Trapper and Whitefish Creeks feed Odell and Crescent Lakes respectively. These streams and the ground water from nearly 20,000 acres are the major source for these lakes. Fall Creek and other drainages to the north feed Salt Creek and these with the many streams originating on the west slope, form a network of tributaries to the Willamette River. About 41 small lakes are scattered throughout the area, the largest of which is 27-acre Yoran Lake.

The area is generally snow covered from October to May. Summer days are usually warm and dry with temperatures near freezing at night.

The west slope of the Wilderness is heavily wooded with large stands of fir and hemlock. The remainder of the area is typically upper forest stands of true fir-mountain hemlock. A large band of lodgepole pine traverses the fir-hemlock stands in the eastern half of the area. The true fir-mountain hemlock understory is dense growths of dwarf manzanita or varieties of huckleberry. Little understory or ground cover is found beneath lodgepole pine stands.

Alpine flowers such mimulus, lupine, penstemon, and Indian paintbrush are common along the trails, streams, and lakeshores. Diamond Peak lakes are widely dispersed across the landscape, trails are usually in the timber, and opportunities for open meadow travel are scarce. Large areas of the Wilderness have no access trails; many sections of existing trail are unusually steep. One cannot circle Diamond Peak by trail within the Wilderness and much of the area is rugged so cross-country travel is challenging.

Rainbow and eastern brook trout have been planted in about 30 lakes. The area's streams offer only average fishing for various reasons including frequent water level and temperature fluctuations, lack of feed, and natural barriers. The lakes near the west boundary offer some of the best fishing and are just a short hike from access roads. On the east edge, there are no easily accessible lakes, but Odell and Crescent Lakes are near the Wilderness and many visitors to these areas enter the Wilderness for day hiking.

Black-tailed and mule deer, elk, and black bear inhabit the Wilderness. Deer and elk populations are limited by available forage. Wildlife populations are probably increasing on the western fringe of the Wilderness due to the number of timber harvest units on the Forest. Wildlife populations have remained stable on the eastern slopes. Both hunting and fishing pressure have been gradually increasing. Resident small mammals include marmot, snowshoe rabbit, pine squirrels, pine marten and pika. Birds found here are grouse, raven, Clark's nutcracker, Oregon jay, and water ouzel. In summer, numerous insectivorous birds and seed eaters frequent the area. Bufflehead and goldeneye ducks occasionally nest near the lakes.

Trails, bridges, and signs are the only improvements within the Wilderness. Many of the old trails were fishing or trapping trails which have been maintained by the Forest Service in essentially original locations. Consequently, trail grades are often steep with hazardous stream crossings, although Diamond Peak and Mt. Yoran provide fairly easy climbing routes which are popular with beginners. Wilderness trails often are in locations inappropriate to optimum user enjoyment, have poor drainage, and frequently duplicate routes to destinations.

There are two nonconforming cabin structures within the Wilderness boundaries and Vivian Lake seems to be receiving use in excess of its capacity.

The quality of Wilderness experience is good from the standpoint of solitude. However, noise from the Southern Pacific Railroad is heard in most of the eastern portion, particularly at night.

A light outbreak of balsam wooly aphid in the Wilderness at one time reached epidemic proportions around Odell Lake, but due primarily to change in timber type is not expected to cause major problems.

The Diamond Peak Wilderness is one of Oregon's most rugged and pristine wildernesses. The area's relative inaccessibility and diverse landscape truly can set the stage for a wilderness experience that offers the visitor solitude, challenge, and primitive recreation in many forms.

Future Trends

Future Wilderness use will likely be affected by changes in various socio-economic indicators (e.g., population growth, disposable income, leisure time, etc.), the availability of opportunities, technology, weather conditions and other variables. Due to large uncertainties about the variables affecting future use, projections become more tenuous as they are extended further into the future. However, to assess whether current Wilderness use capacity is adequate to satisfy future demand it is necessary to develop estimates for a 50 year planning horizon.

Participation in most activities has shown steady growth over the past decade and is projected to increase during the planning horizon. For all Wilderness Resource Spectrum classes, except for the Pristine class, the existing supply of opportunities is inadequate to meet current or future demand. Figure III-P-7 compares individual Wilderness and total Wilderness use for 1989 and projected 2040 use with current estimated capacity by WRS Class.

These comparisons on a Wilderness-wide basis indicate that Wilderness use, if permitted to increase, would exceed inventory capacity in the pristine class by 2030; primitive class by 2000; and transition class by 2010. Use in the semiprimitive class exceeds inventory capacity at this time. Supply and demand comparisons change considerably on an individual Wilderness basis. Current use in primitive areas exceeds capacity in three Wildernesses: Mt. Jefferson, Middle Santiam and Menagerie. In all other Wildernesses, except Bull of the Woods, current use also exceeds inventory capacity in the semiprimitive WRS class.

It may be necessary to regulate use and some types of activities in order to retain or restore Wilderness conditions where evidence of overuse is apparent or where such use is an impairment to Wilderness experiences. Mt.Jefferson, Mt.Washington, and Three Sisters Wildernesses have been identified as top priority areas with regard to establishing management strategies which will focus on achieving balance between capacity and use. The reconciliation of use and capacity will be critical in other Wildernesses as well.

Adjustments in the amounts or distribution of WRS classes, elimination of trail segments, or closure of specific areas would all directly affect use capacity of individual Wilderness. In addition the redistribution or changes in inventoried WRS classes would reduce current and future Wilderness use opportunities but would provide for enhanced user experiences and recovery of resource conditions.

Calculation of existing capacity assumes management of WRS classes as inventoried and current access to individual Wildernesses. In addition, as use increases above WRS class capacity levels the intended experience opportunities decrease. A reduced experience opportunity and the resource degradation associated with overuse can cause an area to effectively shift into a less primitive WRS Class. Rigorous application of the Wilderness non-degradation policy, adherence to WRS class management standards, and the "Limits of Acceptable Change" (LAC) principles are intended to prevent such an occurrence.

Overuse in many Wilderness areas is currently a serious problem. User education and regulating or modifying access (e.g., through permit systems, road and trail closures, etc.) are management options that may be employed to prevent further degradation and enhance user experiences.

Table III-P-7. Wilderness Capacity and Use Comparisons[1]

Wilderness Name	WRS[2] CLASS	RVD Capacity	1989 Use[3]	2040 Use[4]
Bull of the Woods	Pristine	26	9	36
	Primitive	300	267	564
	Semiprimitive	--	--	--
	Transition	--	--	--
Mt. Jefferson	Pristine	6,258	2,156	5,529
	Primitive	28,517	32,515	83,160
	Semiprimitive	37,012	39,390	104,114
	Transition	6,406	9,330	25,441
Middle Santiam	Pristine	227	60	144
	Primitive	320	476	1,409
	Semiprimitive	964	1,664	4,393
	Transition	6,258	1,220	3,249
Menagerie	Pristine	107	81	215
	Primitive	152	400	1,128
	Semiprimitive	904	1,701	4,832
	Transition	--	--	--
Mt. Washington	Pristine	2,920	1,574	3,948
	Primitive	5,568	3,301	8,457
	Semiprimitive	11,336	13,654	36,023
	Transition	--	--	--
Three Sisters	Pristine	23,305	9,481	24,412
	Primitive	104,408	66,840	170,268
	Semiprimitive	63,118	81,949	215,696
	Transition	83,326	34,459	93,199
Waldo Lake	Pristine	1,020	355	898
	Primitive	7,947	3,837	9,867
	Semiprimitive	18,374	20,933	55,352
	Transition	8,390	6,346	17,133
Diamond Peak	Pristine	996	284	718
	Primitive	8,419	2,728	7,047
	Semiprimitive	6,642	7,218	18.890
	Transition	3,213	3,245	8,714
TOTALS	Pristine	34,859	14,000	35,900
	Primitive	155,631	110,400	281,900
	Semiprimitive	138,350	166,500	439,300
	Transition	107,593	54,600	147,700

[3]1989 Use estimate.
[4]Proportional distrabution of projected use based on historical use patterns.

Wilderness managers will rely on a wide range of management strategies (such as registration, permits, use limitations) to restore any areas which are not within standards. Implementation and monitoring plans will be developed for each Wilderness on the Forest. Public input is invited throughout the process.

As Wilderness use increases the most desirable campsites and major attractions are affected. These areas are likely to incur impacts to vegetation, soil, and adjacent water features. Some forms of Wilderness use such as pack and saddle activities have a greater effect than average hiking groups. Pack and saddle users generally require larger campsites near water and meadow areas for stock maintenance purposes. In addition, commercial outfitters and guides tend to bring in larger groups with greater potential for impacting the isolation and solitude of smaller groups of users.

Land management activities, such as timber harvest, have the potential to cause localized effects along the boundary of the Forest's Wilderness. Timber harvest and road construction within view from Wilderness use areas may incur higher than normal costs due to attempts to minimize effects. Wilderness use in general can affect the location of new roads, may require road closures to maintain Wilderness character, and may require specific mitigation treatments in order to achieve management objectives of Wilderness.

Forest Wildernesses contain a wide variety of cultural resources, e.g. several shelters and cabins dating to the 1930s-1940s. The Wilderness Act directs that historic structures not be rehabilitated for long term preservation; these buildings will be evaluated, documented and allowed to deteriorate gradually, unless a definite safety or administrative problem develops. Evidence of prehistoric utilization of Wilderness lands can be found throughout the Forest and is of concern to Wilderness managers. As with historic resources, prehistoric resources are of regional importance to understanding land use patterns and human behaviors. Certain protective or data retrieval measures may be necessary in areas of heavy recreational use.

Efforts to suppress both lightning and human-caused wildfires have modified the role of fire in Wilderness ecosystems. Over time continued suppression of natural fires at small sizes will alter natural vegetative successional processes giving rise, in some cases, to a loss of meadows and open spaces through encroachment of surrounding tree species and in some areas a buildup of dead and down fuels. The Forest will continue to provide cost effective fire protection on Wilderness (and nonwilderness lands) by suppressing all fires with the least cost plus net value loss to resources. In the future, prescribed burning may be planned for areas in the Wilderness where natural ecosystem succession would be perpetuated or other resource objectives met without threatening adjacent nonwilderness lands.

Although the evidence of past fires is not always apparent, especially in the Western Cascades, most biological communities have evolved with the presence of fire. Within Wildernesses, the natural role of fire is most evident. Fire management plans for Wilderness lands will include consideration for re-establishing fire in its natural role as a major factor in retaining a variety of plant communities and overall ecosystem processes. During suppression of all naturally occurring fires in Wilderness, preference will be given, whenever possible, to methods that preserve Wilderness values and have the least physical impact on the land.

ROADLESS LANDS

Roadless areas are defined as areas or islands of "undeveloped Federal land within which there are no improved roads maintained for travel by means of motorized vehicles intended for highway use. A roadless island is further defined as an area that is surrounded by permanent waters or that is markedly distinguished from surrounding lands by topographical or ecological factors such as cliffs, canyons, thickets, or swamps" (RARE II inventory criteria, USDA Forest Service).

Areas in an unroaded condition have been inventoried (see roadless area in glossary) on the Forest. Roadless lands are inventoried for the purpose of identifying areas within the Forest that meet minimum requirements for consideration as Wilderness. To achieve this purpose, criteria have been established to guide resource specialists in the inventory process. Specific criteria for size, area manageability, and nonconforming uses are used to determine whether an area qualifies for inclusion in the roadless area inventory.
The identification of roadless areas serves to highlight the environmental condition of specific areas within the Forest landscape, and to emphasize their potential for a wide range of multiple resource uses, including Wilderness. In addition, roadless inventories serve to make known the extent of the roadless resource and to provide a data base managers and legislators can use to formulate land management proposals and planners may use as to assess resource effects and trade-offs. Further such inventories provide the opportunity for thoughtful consideration and evaluation of an areas full potential and highest use through planning analysis and management decision processes.

Historic Trends

The subject of roadless areas gained prominence in the Forest during the early 1950s when Forest management began to intensify and the Chief of the Forest Service deleted a 53,000 acre area, known as French Pete, from the Three Sisters Primitive Area. Public concern intensified about French Pete and other roadless areas within the Forest during the following 30 years. In addition, the issue of preserving roadless areas for their wilderness character and primitive recreation opportunities has expanded to include concerns for providing adequate habitat to sustain viable populations (see the Wildlife section) of wildlife and fish, protecting sensitive soils and unstable lands; and maintaining representative ecosystems of the region and nation. The intensity and depth of public concern about how roadless lands would be managed were factors in the development of the RARE and RARE II processes as well as Wilderness legislation.

Figure III-Q-1 illustrates, for the Forest, changes in the amount of designated Wilderness and land inventoried as roadless during the past 25 years. Figure III-Q-1 also illustrates that roadless land have decreased as more Wilderness has been designated by Congress. However, decreases in roadless land are also due to Forest development activities such as road construction and timber harvest.

Table T033. Trends in Wilderness and Roadless Land Acreages (III-Q-1)

Current Subject	1964	1968	1973	1978	1979	1984	1984	Current Total

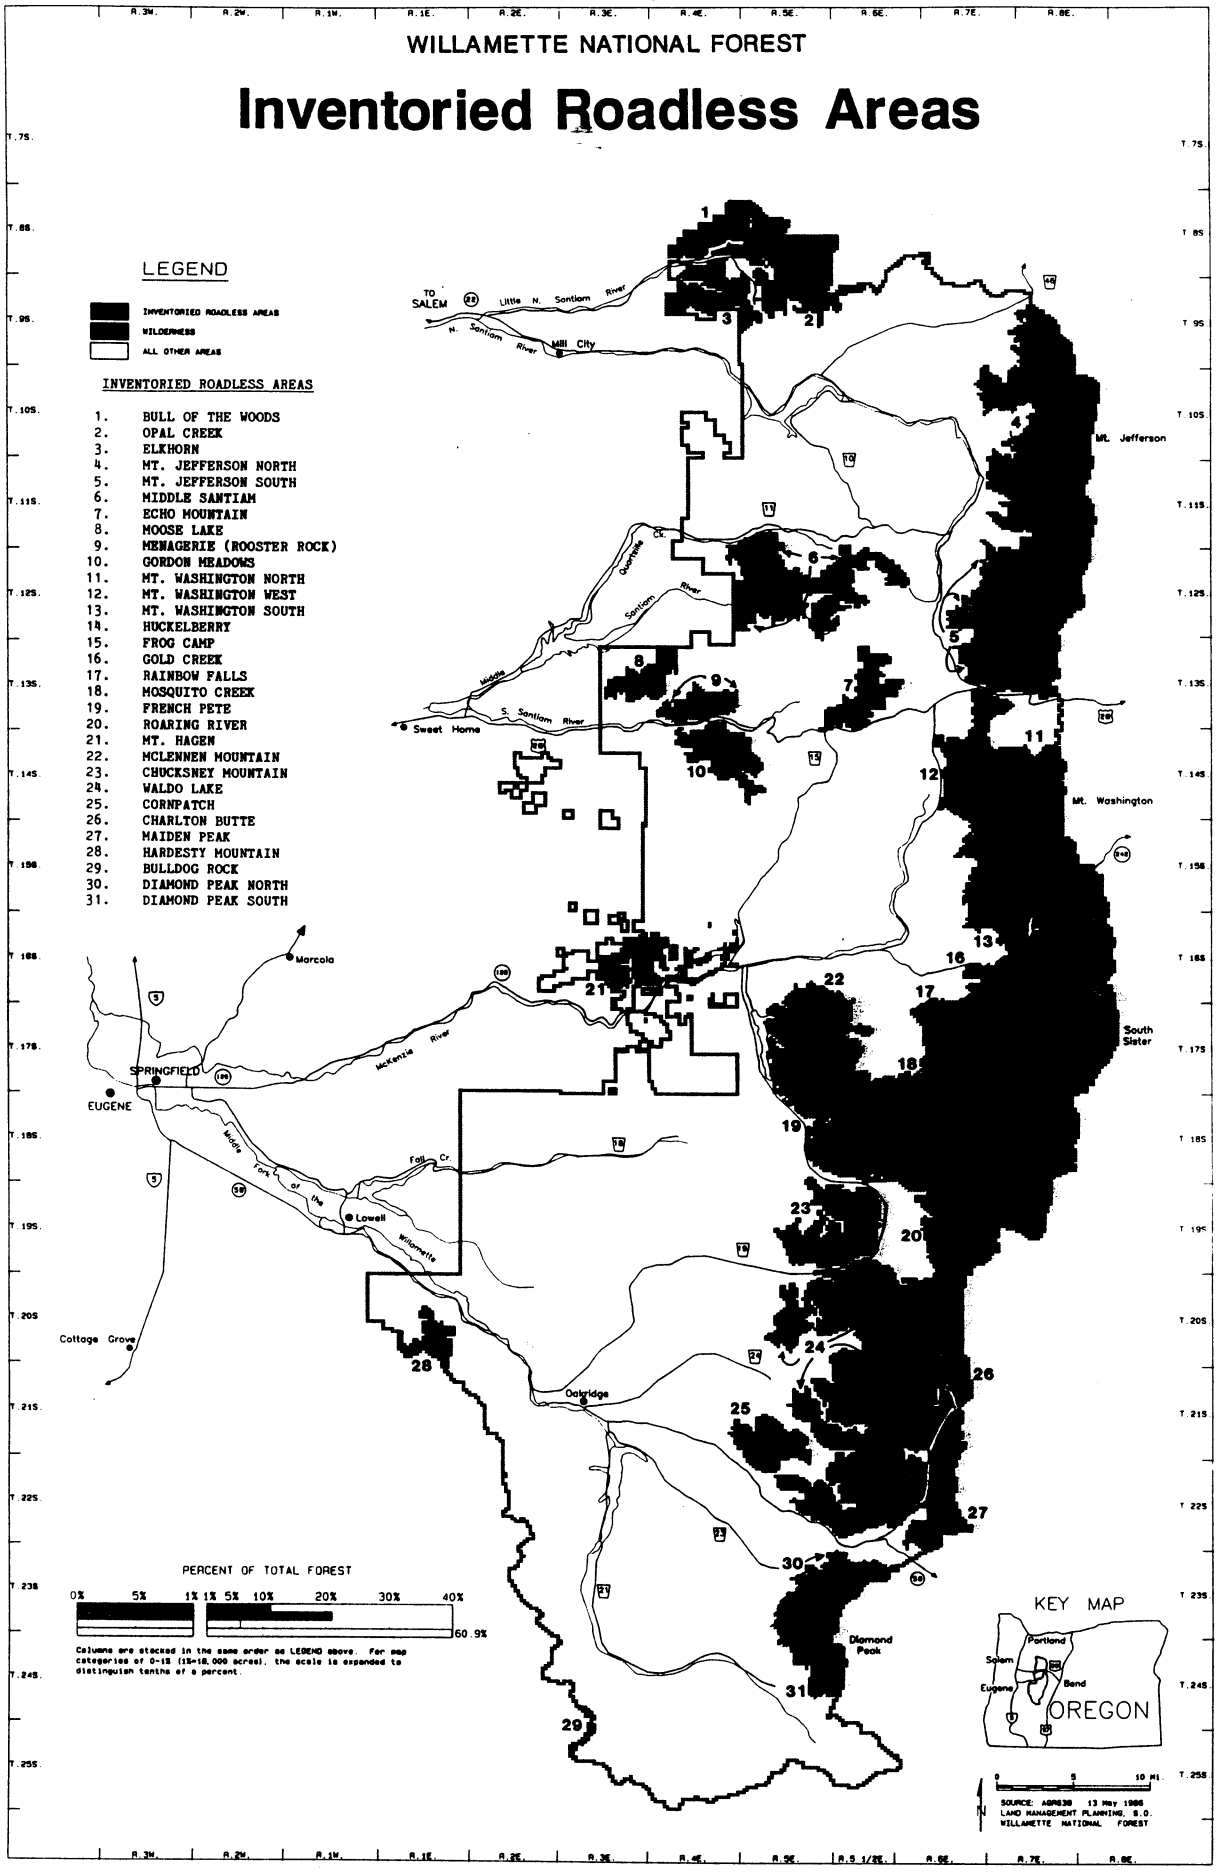
[4]Second-Roadless Area Review and Evaluation (RARE II - 1979).
[5]National Forest Management Act (NFMA) Roadless Area Inventory.

Current Situation

Areas in roadless inventories have typically been evaluated for their suitability, availability and need as wilderness during formalized planning efforts such as Unit Planning, RARE or RARE II. This process has been validated, with some alteration, by the Oregon Wilderness Act of 1984 (P.L. 98-328). The Act designated 78,872 acres of inventoried roadless area on the Forest as new Wilderness and 6,292 acres of roadless land as the Oregon Cascades Recreation Area.

The Oregon Wilderness Act of 1984 directs that, for the initial National Forest Management Act (NFMA) land management plans, the National Forest lands in Oregon which were reviewed in RARE II, or in unit plans, and roadless lands which are less than 5,000 acres in size, have had adequate consideration of their suitability for inclusion in the National Wilderness Preservation System. The Department of Agriculture will not be required to review the Wilderness option prior to the revision of the plans, but will review the Wilderness options when the plans are revised ordinarily on a 10-15 year cycle (Section 7(b)(2) Oregon Wilderness Act of 1984).

The roadless lands will be managed for multiple use in accordance with the land management plans, and they need not be managed for the purpose of protecting their suitability for Wilderness designation prior to or during revision of the land management plans (Section 7(b)(3) Oregon Wilderness Act of 1984).



The Forest prior to release of the DEIS had 31 inventoried roadless areas which following passage of the Oregon Wilderness Act of 1984 totaled 210,207 acres. During the period 1984-1987 and the period following release of the DEIS (1987-1989), management activities were being implemented in many of these areas. A recent assessment of inventoried roadless area conditions indicates that 38,200 acres have been affected by management activities since the 1984 inventory was completed. The roadless area inventory currently includes 31 areas for a total of 172,007 acres. Figure III-Q-2 lists each roadless area by name; amount of area released for multiple-use management in 1984; amount of area affected since 1984; and remaining area in a roadless condition. A complete discussion of each area's attributes and resource potentials is provided in Appendix C. Areas identified in the roadless inventory are widely distributed throughout the Forest. Figure III-Q-3 illustrates the spatial distribution of areas.

Figure III-Q-2 Roadless Area Inventory

Roadless Inventory		Status of Inventoried Roadless Areas 1984-1989			
Areas listed below of less than 5,000 acres are either contiguous to designated Wilderness or roadless areas of adjacent National Forest.		Roadless area designated by Oregon Wilderness Act 1984[1]	Areas released for multiple use management by the Oregon Wilderness Act 1984	Acreages affected by Management Activities 1984-1989	Current size of inventoried roadless areas

[1]Acreages are tentative until area boundaries are approved by Congressional Committee.
[2]This area was evaluated for the Wilderness option as well as other multiple uses; in the DEIS.
[3]This area is divided into several parts for purposes of description in Appendix C.
[4]Included in the Oregon Cascades Recreation Area as designated by the Oregon Wilderness Act of 1984.

Figure III-Q-3.

In addition to the Forest's Inventoried Roadless Areas, the Forest has also identified 24 unroaded land areas that range in size from 1,500 acres to 4,500 acres. These areas, too small for inclusion into the Forest's Roadless Area Inventory but large enough to provide semiprimitive dispersed recreation opportunities, are included in the Forest's Recreation Opportunity Spectrum (ROS) Inventory. The ROS Inventory is displayed in the Recreation section of this Chapter.

Under the provisions of the Oregon Wilderness Act of 1984, only one of the Forest's inventoried roadless areas has been evaluated for its suitability, availability, and need as potential Wilderness: Mt. Hagan. The Mt. Hagan roadless area, 6,292 acres, located near the community of Blue River, was neither reviewed in RARE or RARE II nor evaluated for the Wilderness option in a Forest Unit Planning process. In the DEIS the Mt. Hagan area was included in Alternative C as proposed Wilderness. The remaining roadless areas have been examined for their suitability to provide a full range of other multiple resource uses such as wildlife and fish habitat, scenery, recreation, research, wood products, and water in the DEIS Alternatives and the Alternatives included in this FEIS.

Public comment on the DEIS and Draft Forest Plan was highly polarized between the desire on one hand to maintain inventoried and other unroaded areas in an undeveloped state, and on the other hand a desire to enter and develop these areas in accord with "multiple use" objectives. Reasons stated for maintenance of roadless lands included: consideration for future Wilderness, ecological integrity, unroaded recreation, wildlife habitat, old growth preservation, and providing biological diversity. Respondents favoring development of roadless areas cite the Oregon Wilderness Act of 1984 as having settled the issue. This segment of the public feels that sufficient amounts of the Forest are currently dedicated to roadless area dependent uses.

Future Trends

It is anticipated that during implementation of the Forest Plan some roadless areas will become developed through road construction, mineral exploration, recreation facility construction and timber harvest; and others will remain in a roadless condition. The extent of development or preservation of roadless land is dependent upon the type of use to which areas are allocated in the Forest Plan and applicable management direction. However, if the Forest Plan favors development of roadless areas, the Forest's ability to satisfy future demand for uses dependent upon roadless conditions or evaluate areas for Wilderness in the next cycle of Forest Planning will be diminished. Conversely, if the preservation of roadless areas is favored then it is more likely that demand for uses dependent upon roadless conditions can be met and that more areas will qualify for Wilderness evaluation in the next cycle of Forest Planning (10-15 years).

The allocation of roadless areas to uses that do not permit development activities such as timber harvest, road construction, and mineral exploration have the potential to alter the economic base and social patterns of dependent communities. Allocation of roadless areas to uses that permit development activities on the other hand may result in changes to land form, vegetation, and size of individual areas. These changes typically alter an area's potential to provide isolation, solitude, and primitive recreation experiences, and hence their suitability for future Wilderness evaluation.

The extent of potential change to individual areas and the inventory as a whole is relative to the amount of roadless land either developed or maintained in an undeveloped state. The effect of allocation decisions of each alternative and their associated management activities on roadless areas is discussed in Chapter IV and in Appendix C.

SPECIAL INTEREST AREAS, OLD-GROWTH GROVES, AND NATIONAL NATURAL LANDMARKS

The Forest includes areas that exhibit unique ecological and biological communities, and geological characteristics. These lands are inventoried to identify their recreational and scientific values for the purpose of enjoyment and study. Special Interest Areas (SIAs) are designated to protect and where appropriate foster public use and enjoyment of areas with scenic, historical, geological, botanical, zoological, paleontological, or other special characteristics. Old-Growth Groves (OGGs) within the Forest have been identified for the purpose of protecting a unique component of the forest ecosystem. The principal values considered significant in managing OGGs are aesthetic, recreational, educational, biological diversity, wildlife habitat, and research. National Natural Landmarks (NNLs) are designed to preserve sites illustrating the geological and ecological character of the United States, enhance educational scientific value of preserved sites, and foster a greater concern for the conservation of the Nation's heritage.

Historic Trends

As resource management activities have extended into undeveloped areas, concern for the protection of unique and special Forest environments and features has been increasing. In general, public response to the issues of wildlife, plants and fish, dispersed recreation, developed recreation, visual resources, and cultural resources has focused on the concept of preserving areas of the Forest. Some responses have indicated the need to protect and preserve unique ecological and scenic values. Concern was expressed about the impact that developed recreation may have on sensitive habitats such as meadows, bogs, and lakes. Some responses stressed the need to preserve habitat which is suitable for Threatened and Endangered species and unique cultural resource areas.

This trend of concern for special areas is reflected by requests from the public to set aside specific landscape features as SIAs or OGGs. This trend has been supported by Forest proposals to establish more SIAs and OGGs. The value and importance of preserving unique and special aspects of our natural environment is emphasized by an expanded inventory of potential areas to be considered for designation by Forest managers. Five SIAs existed at the time of the 1977 Land Management Plan. The 1977 Plan proposed establishment of four new areas for a total of nine SIAs. Four of the five established SIAs in the 1977 Plan were reclassified as Wilderness when the French Pete area was added to the Three Sisters Wilderness by the Oregon Endangered Wilderness Act of 1978.

There has been a groundswell of public concern, both organizational and individual, for preserving for the benefit of present and future generations some of the most significant and representative stands of old growth. In 1976 the Forest Supervisor initiated an effort to identify and manage selected Forest OGGs, especially for their aesthetic and recreational values. Accessibility, stand and tree size, natural condition, and volume per acre were some of the criteria used in the selection. The 1977 Forest Land Management Plan listed 34 OGGs, 6 of which were later subsumed by the Wilderness Act of 1984.

Current Situation

The Forest currently contains one administratively established SIAs: the Lamb Butte Scenic Area located within the Blue River and McKenzie Ranger Districts. This area is mainly an open meadow with a variety of plant species; it provides summer range for Roosevelt Elk and black-tailed deer. Surrounding timber types are subalpine fir, true fir, and Douglas-fir. Taylor Castle, Lamb Butte, and English Mountain are three peaks of particular interest within this area of about 390 acres. Topography

is steep and elevation ranges from 4,800 to 5,600 feet. The area is managed to provide opportunities for high quality recreational experiences and to preserve its unique scenic resources.

The Forest also contains 49 potential SIAs. Of these, four areas were recommended for designation and are presently managed as SIAs under the current Forest Plan: Monument Peak Botanical Area, Tamolitch Valley Geological Area, Wolf Rock Geological Area, and Tumblebug Gorge Geological Area. Following release of the 1977 Forest Plan an establishment report was prepared for Monument Peak and the Moon Point area was identified as a potential SIA, however, Forest planning direction at the time reserved the establishment of any new SIAs until completion of new Forest Plans. These areas are included in Figure III-R-1; a complete listing of potential areas, their size, and classification type.

In addition to four proposed SIAs the current Forest Plan maintains 28 areas as designated OGGs. Ten additional OGGs have been identified and added to the inventory sine 1984, bringing the total number of OGGs to 38. Figure III-R-2 is a complete listing of inventoried potential OGGs.

The Forest contains no designated NNLs. There are currently, however, 21 potential NNLs within the Forest that have been identified by the National Park Service. These areas, in many instances, occur within the Forest's existing Wilderness or are coincidental with both established and potential SIAs, OGGs, Research Natural Areas, and the H.J. Andrews Experimental Forest. Figure III-R-3 is a complete listing of potential NNLs, their size and Forest location.

As shown by Figures III-R-1,2, and 3, numerous opportunities are available to establish SIAs and designate OGGs by the Forest Service and recommend establishment of NNLs by the Park Service. However, the choices among the potential SIAs is limited for potential zoological areas. This lack of representation of zoological areas for SIA designation could be compensated for through the establishment of Special Wildlife Habitat Areas. For a listing of potential Special Wildlife Habitat Areas refer to the Wildlife section in this Chapter.

Future Trends

Recreational use of designated SIAs and OGGs is likely to increase in the future. The fact of designating areas and identifying their locations serves to advertise availability and may inspire increased use. Actual use levels will, however, parallel those of general dispersed areas.

Unresolvable conflicts could occur between the various resource values protected within SIAs, OGGs, and NNLs. As an example, needed improvements to big game habitat may be incompatible within a Botanical Interest Area. In areas set aside for wildlife habitat purposes some management activities, such as burning, may conflict with recreational use or other values in specific locales for limited periods of time.

Certain types of developments within some potential NNLs or in SIAs or OGGs could result in disturbances to the specific values to be preserved, studied, or enjoyed.

Natural catastrophic events, such as fire, windthrow, and flooding could destroy the values protected within designated or potential SIAs, OGGs or NNLs . Management activities such as timber harvest and road construction could limit opportunities to maintain unique values if areas are recognized through protective designations. In addition, SIAs, OGGs, and NNLs could face the hazard of overuse by interested publics.

RESEARCH NATURAL AREAS AND H.J. ANDREWS EXPERIMENTAL FOREST

The National Forest Management Act (NFMA) of 1976 called for Forest planning to establish a nationwide system of Research Natural Areas (RNAs). Research Natural Areas are biotic preserves which serve as ecological reference points, or as experimental controls, against which it is possible to measure and assess the results of Forest management activities. They also serve as field laboratories to monitor natural processes and storehouses of genetic diversity.

The role of RNAs is limited to research, study, observations, monitoring, and educational activities that are nondestructive and nonmanipulative, and that maintain unmodified conditions. Research Natural Areas can be used to preserve a wide spectrum of numerous natural situations. These comparatively small sized areas provide the following functions:

- Preserve and maintain genetic diversity.
- Protect against serious environmental disruptions.
- Provide educational and research areas for ecological and environmental studies.
- Monitor environmental and hydrological conditions as baseline information for determining effects of land management practices on terrestrial and aquatic systems.
- Serve as baseline areas or controls for research measuring ecological and hydrological effects of land management manipulation techniques and practices.
- Preserve gene pools for typical and threatened and endangered plants and animals.

The H.J. Andrews Experimental Forest was dedicated for development of better methods for managing forested lands in the Western Cascades and to determine the effects of timber management activities on soils, fish, wildlife, and water quality and quantity. Timber is harvested to meet the specific needs of research on an irregular basis. Harvesting may include a full range of silvicultural practices and harvesting methods.

Historic Trends

Early research on the Forest began around 1910 by Thornton T. Munger. Mungar initiated a series of Region-wide sample plots in second growth Douglas-fir, the first in a 50-year-old stand near Oakridge. Between 1910 and 1914 a number of expiermental plantations were established to test the adaptability of eastern hardwoods in various areas of the Forest. Under the direction of Julius Kummel several areas; 3.25-acre tracts behind the McKenzie Bridge Ranger Station, a tract near West Boundary Ranger Station, and some strips near Dead Mountain were planted. According to research records these "apparently were all failures." A number of large plantations were also set up, mainly in old burns, including the Battle Ax tract on the border of the Mt. Hood and Santiam National Forests in 1913-1915; Breitenbush tract, near the springs in 1915; Dead Mountain, 1915-1917; and Seven Mile Hill in the same period. Trees planted in these tracts with the aid of forestry students from Oregon State University were Douglas-fir, western white pine, and with some tracts of noble fir.

These early research efforts were later followed by the formal designation of Forest lands for research purposes. The establishment of Research Natural Areas (RNAs) and Experimental Forests has been

increasing since the McSweeny-McNary Act of 1928. The H.J. Andrews was established 20 years subsequent to this Act, and between 1965 and 1979, four RNAs were created. The number of research projects undertaken each year in established areas has also increased.

The Experimental Forest is representative of mid- and upper-elevation forests on steep slopes with extensive areas of unstable land. It was established for the study of forest and watershed management problems associated with conversion of old growth Douglas-fir and upper-slope mountain hemlock and noble fir to young managed stands. In the beginning, most studies were about methods of cutting timber and building roads.

Over the years, use of the Experimental Forest has gradually shifted and expanded. In the 1960s, research attention focused on the effects of forest practices on water quality and quantity. Beginning in 1969, basic research on ecological and environmental phenomena was intensified, and use by university scientists increased. From 1969 through 1978, the Experimental Forest served as an intensive study site of the Coniferous Forest Biome Project of the International Biological Program. In 1974, it became part of an international system of Biosphere Reserves designated by the United Nations Education, Cultural, and Scientific Organization. The primary objectives of these reserves was conservation of genetic diversity, environmental research and monitoring, and education.

The H.J. Andrews Experimental Forest increases in value as a research site as data about various processes of ecosystem functioning accumulate from old and new long-term studies. One reason it is uniquely suited to ecosystem studies is that scientists of many disciplines are working side-by-side, sharing data, looking at the same processes and products from different viewpoints, and making use of the many years of record. Some records date almost to 1948 when the Experimental Forest was established. Indirect records (i.e., tree rings) provide information that goes back about 850 years in some areas. Precipitation has been measured since 1951 and temperature and humidity since 1957. Three experimental watersheds were established in 1952 and a plant collection was begun in 1958.

In 1977, the Experimental Forest was selected as the Nation's first Experimental Ecological Reserve supported by the National Science Foundation. In 1980, it became a charter member of the National Science Foundation's Long-Term Ecological Research network of research sites. The network now totals 15 sites and includes many of the major ecosystem research sites and groups in the nation. The list of publications stemming from work done at the *H.J. Andrews Experimental Forest since 1948* contains almost 600 reports, papers, and abstracts that address the the consequences of various management actions related to silviculture, soils, hydrology, wildlife, geology, ecology and fire.

Current Situation

The Forest currently administers one Experimental Forest and four established Research Natural Areas. There are no proposed additional nor anticipated Experimental Forests in the Forest. Five areas have been identified as potential RNAs. In addition the Wildcat Mt. RNA is proposed to be enlarged by 384 acres. Figure III-S-1 displays information about the established Research Natural Areas.

Table T037. Established Research Natural Areas (III-S-1)

Area	Acres	District	Established Date
Gold Lake Bog RNA	463	Oakridge	1965
Olallie Ridge RNA	720	McKenzie	1963
Middle Santiam RNA [1]	1,145	Sweet Home	1979
Wildcat Mountain RNA	1,000	Sweet Home	1968
TOTAL ACRES	3,328	--	--

[1]Within the Middle Santiam Wilderness.

The four Research Natural Areas (RNAs) established in the Forest as representative "cells" (i.e., a basic unit such as an ecosystem, vegetative community, or habitat) are listed by the Pacific Northwest Research Natural Area Committee as component parts of the overall coniferous forest ecosystem of the Northwest. Each of these established areas is briefly described below.

Olallie Ridge RNA: Established in 1963 to represent mountain meadow and true fir-mountain hemlock communities prevalent on high ridges in the Western Cascades of Oregon. The area provides unusual opportunities for studying subalpine meadow-forest mosaics. Many subalpine meadows are becoming increasingly impacted by recreation use. Research on an unimpacted area should help with planning management regarding use problems. The RNA is also an important refugium for disjunct populations of numerous plant species. Research in this area includes studies of distunct flora, distribution and role of fungi on conifer needles, and habitat classification.

Gold Lake Bog RNA: Established in 1965 to preserve some prime subalpine bogs. It provides for the protection of six uncommon species of bog plants. The surrounding forest land creates opportunities for studying the variation in composition, structure, and productivity of forest communities along an environmental gradient from wet, low-lying to dry, upland areas. Research in this area includes studies of the bog communities and their flora.

Wildcat Mountain RNA: Established in 1968 to preserve prime examples of the noble fir stands found on mountain ridges in the Western Cascades of Oregon. This area provides numerous opportunities for studying the various management concerns related to noble fir (i.e., cone production, amount and quality of annual seedfall, soils, growth and yield of stands, and causes of mortality). Other studies on the RNA include distribution of birds and mammals in relation to plant communities, relation of site index to habitat types in the Pacific silver fir zone and ecological monitoring of long-term effects of energy development.

Middle Santiam RNA: Established on May 23, 1979, is now within the boundaries of the Middle Santiam Wilderness Area which was designated by Congress in 1984. The area includes representative stands

of old-growth (450+ years), Douglas-fir/western hemlock forests of the Western Oregon Cascades, and three drainage tributaries to the Middle Santiam River. Studies taking place on the Middle Santiam have included: productivity of old-growth forests; composition and successional development of forest communities as related to environmental factors such as soil, aspect and topographic position; role of coarse woody debris in stream stabilization and sediment routing; and research on old growth as wildlife habitat.

Of the potential RNAs, Hagan Block and Torrey-Charlton were proposed in the Forest's 1977 Multiple Use Land Management and Timber Management Plan. Establishment reports for these areas are generally complete. There is a proposal to add about 425 acres to the Hagan Block area to complete some ecological systems, for a total of 1,280 acres. The Rigdon Point area is a specific cell listed for the knobcone pine species but does not represent the specific plant community (i.e., SAF timber Type 248). The Mckenzie Pass potential RNA is a subalpine lava flow with representative vegetation. This ecosystem is well protected by the surrounding Wilderness. The ecotone between the younger unvegetated lava flows and the older vegetated flows that surround the area should provide good opportunities for successional studies. The Three Creeks area is a stand of old-growth timber including trees exceeding 700 years in age. The proposed expansion of the Wildcat Mt. RNA includes two parcels totaling 384 acres along the northern edge of the area. Figure III-S-2 includes information relating to each of the potential RNAs.

Table T038. Potential Research Natural Areas (III-S-2)

Area Name	District	Acres
Mt. Hagan	Blue River	1,280
Torrey-Charlton [1]	Oakridge	2,154
Rigdon Point	Rigdon	300
McKenzie Pass [2]	McKenzie	1,195
Three Creeks	Sweet Home	661
Wildcat Mt. Addition	Sweet Home	384
TOTAL ACRES		5,987

[1]Partially within the Waldo Wilderness.
[2]Partially within the Three Sisters Wilderness.

The H.J. Andrews Experimental Forest (HJA) was established on the Blue River Ranger District in 1948 as a site for research and education on the ecology and management of coniferous forests and watersheds in the Douglas-fir region by the Pacific Northwest Forest and Range Experiment Station. Through a use agreement, Oregon State University in recent years has used the HJA extensively in teaching programs and for student research projects. Management of the Experimental Forest is a joint effort of the Pacific Northwest Forest and Range Experiment Station and the Forest.

The HJA is a 15,700 acre area that includes the entire Lookout Creek drainage north of the town of Blue River. It has steep, densely forested slopes ranging from 1,500 to 5,000 feet in elevation. Rich forest soils produce high quality/quantity Douglas-fir with minor amounts of Pacific silver fir, noble fir, western hemlock, western redcedar, and a few pine species.

Roads have been constructed to harvest timber and are maintained periodically to protect resources and provide safe travel routes. There are no developed recreational facilities within the HJA but many

forms of dispersed recreation may be enjoyed throughout the drainage, except where restrictions are posted.

Future Trends

With the increasing demand for the various uses of forest land (both public and private) including the utilization of renewable resources, more knowledge is necessary to protect and keep these lands productive. This has been specifically recognized by Congress (see McSweeny-McNary Act, May 22, 1928; and the McIntire-Stennis Act, October 10, 1962). It is evident that the importance of the existing and proposed research and experimental areas will continue to grow locally, nationally and worldwide.

The demand for Experimental Forests and Research Natural Areas is derived from the kinds of management problems that are experienced daily and the kind of habitats that are encountered. Areas of land have been selected and/or proposed which contribute to the maintenance of biodiversity, and are representative of cells (habitats, communities, organisms, etc.) deemed important elements in the Pacific Northwest coniferous biome.

The current demand is established through management needs for managing Forest lands and renewable resources. An additional demand is expressed through the need to protect the cells listed before they have been changed ecologically by Forest management activities.

Climatic, geologic, and biologic systems are dynamic. Thus research involving these systems will be expanding and becoming more intensive as land uses and resource utilization intensify.

Minor changes in conditions are expected, over and above those inherent in the management of RNAs or the HJA. All areas are subject to change resulting from natural events such as wind, fire, insect, and disease. Olallie Ridge and Gold Lake Bog RNAs are popular sites for the "recreation botanist" and other amateur biologists. University students also make use of the areas for study and research. As a group, these uses tend to alter existing conditions of the more unique plant habitats. Extensive timber harvesting on the perimeter of these areas has the potential to reduce the effective size of some of the included habitats (cells). In the case of RNAs, the establishment report sets forth an area objective of maintaining the ecosystems within the boundaries in a natural state of succession. Where necessary, the management of adjacent lands is expected to be modified to protect these values and the integrity of the RNA. The Torrey-Charlton proposed RNA surrounds several fishing lakes. Existing recreation use of this area will be recognized in the establishment report and research plans, however, recreation use is not an objective of Research Natural Areas.

The research and activity interactions within the H.J. Andrews Experimental Forest include those of RNAs, as well as vegetation, landform, wildlife habitat, soil, and water alterations. Conditions resulting from these alterations are due to timber harvest and road building activities and are induced for the purpose of study and research.

RANGE

The heavily forested Forest has limited capacity for grazing of domestic livestock. There has been some use of the suitable areas for grazing cattle and sheep under fee permits and some free-use grazing of recreational stock.

Historic Trends

Permitted livestock grazing presently occurs on several scattered areas in the Forest, although domestic livestock grazing on the Forest has declined significantly over the years. In 1934, there were about 848 Animal Unit Months (AUMs) of permitted grazing by cows and 19,260 AUMs by sheep. An Animal Unit Month is equal to one 1,000-pound animal feeding for 30.5 days. However, by the mid-40s permit use had already started to decline and by 1951 there were no sheep grazing permits and only about 797 AUMs of permitted cow and horse use. (Forest Service file 2230.)

There were 398 AUMs permitted on two cattle allotments under a term permit in 1984, and free-use grazing permits on 15 recreation grazing allotments which reported 190 AUMs. There is also potential for livestock use in the form of transitory range.

The decrease in range use on the Forest can be attributed to several factors. Grazing for some permittees became less economically efficient due to the increased cost in labor and the transportation of livestock without similar increases in livestock values, and the higher cost associated with maintaining permits due to increased needs to protect the soil and water resources. The amount of available range has declined over the years due in part to Wilderness establishment. In new Wilderness, allotments were not available to new permittees. The amount and location of grazing permitted on the Forest has also been limited by other factors including the protection of water quality, sensitive plants, and unique habitats.

Livestock have considerable dietary overlap with elk; they often consume or damage forage that elk would otherwise eat. This competition for forage is especially significant in winter range which big-game need to compensate for a condition of low energy reserves.

In addition to forage competition with big game, livestock host diseases that may be detrimental to native species. Studies conducted on the Forest in the late 1970s suggested that domestic sheep hosted diseases that infected black tail deer. As more sheep were placed on the allotment, there was an increased incidence of several parasites within the overlapping deer population. (Forest Service files 2600.) Where range use between sheep and black tail deer overlap, these diseases can be a greater problem for deer than forage competition.

Predation by bear, coyote, and cougar on permitted livestock was suspected during the 1940s and 1950s. The conflict between native wildlife species and domestic livestock meant, in some instances, that the predators were destroyed. This is an adverse effect on wildlife and makes fewer animals available for viewing by the recreational user.

Current Situation

Livestock grazing has contributed to localized decreases in water quality due to defecation and streambank instability caused by trampling. Livestock have also, in localized areas, contributed to soil compaction which can change the soil structure, affect water absorption and holding capacity resulting in reduced plant growth. Compaction is minimized by ensuring that grazing lands are relatively dry

before grazing occurs. However, naturally moist meadows receive some damage regardless of when they are grazed.

Taking into consideration potential forage produced on harvested acres throughout the Forest (transitory range), the plant forage potential on the Forest is underutilized.

The narrow profit margin for both range cattle and sheep operations have made the use of the grazing opportunities on the Forest less desirable to potential permittees.

Future Trends

Future use of cattle and sheep grazing opportunities is difficult to predict. However, given current market conditions, there will be no significant changes in livestock grazing use on the Forest in the foreseeable future. Expected increases in future recreation use will probably result in more recreation stock utilizing forage on the Forest.

FACILITIES

Facilities on the Forest include Forest Service administrative sites and structures, special use structures, and utility corridors. Administrative sites serve a variety of purposes related to the administration and management of the National Forest. Utility corridors provide the land area needed for transmission facilities for basic utilities, such as electricity, telephone, and water lines. Special use structures are facilities developed and operated under special use permit to serve the specific purpose of the operator. These uses are widely varied; their role is to provide permittees with the opportunity to use Forest land as a base for activities or operations which are compatible with the environment and management of the other resources.

The use of these permits may impact several components of the environment including vegetation, water, soil, scenery, and wildlife. The USDA Forest Service provides for the continued existence and use of the present long-term high capital investment special use permits. However, if a permit is found to be in violation of legal requirements or minimum standards of other resources values, compliance is sought to remedy the violation. The authorized officer may revoke, suspend, terminate, or renegotiate terms of the permit.

Historic Trends

In the past two decades, construction of buildings has not kept up with needs for space, particularly office space. While positions were added to deal with more intensified resource concerns, construction of offices and related service buildings was reduced. Even after recent staff reductions and some new construction, the Forest has some overcrowded working conditions in outdated offices and temporary facilities.

Current Situation

Administrative Sites

The headquarters of the Forest is the Supervisor's Office located in Eugene. The Forest is subdivided into seven Ranger Districts with offices in Oakridge, Westfir, Lowell, Blue River, McKenzie Bridge, Sweet Home, and Detroit. Administrative sites located on National Forest System land include one work center, two seed orchards, and a variety of offices, residence bunkhouses, workhouses, tree coolers, shops, and other project related buildings.

The Forest has 8 buildings that were constructed for office space; 5 were built in the 1950s and 3 were built in the 1960s. There are also 4 leased office buildings, several converted garages and houses, and approximately 16 modular units being used for office space.

Currently 45 residences are available for employee use on the Forest. They are of varying ages, having been constructed in the following decades: 2 in the 1920s, 9 in the 1930s, 28 in the 1950s, 4 in the 1960s, and 1 in the 1970s.

A total of 14 permanent buildings have been constructed to provide warehouse and equipment storage space. They were built as follows: 1 in the 1920s, 5 in the 1930s, 5 in the 1950s, 2 in the 1960s, and 1 in the 1980s. Other buildings of various purposes exist at each site. Generally, their age classification is similar to those described above.

The Forest has one heliport under its jurisdiction at the Detroit Work Center. The Oakridge and McKenzie airports are also used as heliports. These heliports are used for fire and administrative activities.

Others

Various other facilities are found on the Forest including:

- A powerplant for the city of Eugene.
- Access roads and assorted facilities for the Southern Pacific Railroad.
- Electronic sites at 15 locations throughout the Forest.
- Facilities for the Bonneville Power Administration, Portland General Electric, and Eugene Water and Electric Board.
- A camp and picnic area operated by the Oregon State Parks and Recreation Division.
- Winter sports sites at Willamette Pass and Hoodoo Ski Bowl.
- A total of 248 recreation residences situated on 85 acres of the Forest.
- 21 small-scale hydroelectric projects in various stages of development, (only one project, Falls Creek, is on line).

Permits that alter the vegetation include utility corridors, ski areas, transportation corridors, and recreation residences. It is necessary to limit height of vegetation with in the corridors and ski area so the vegetation does not interfere with the use. Forage habitat with long linear edges is available for wildlife. Transportation corridors may add edge effect, but the noise and congestion of traffic also affects travel routes.

Hoodoo Ski Bowl is located one mile south of U.S. Highway 20 on the Santiam Pass. Facilities located on the 644 acre area includes three chair lifts, two rope tows, two day-lodges, and utility buildings and other facilities. The ski runs are essentially located on the east and northeast slopes of Hoodoo Butte.

Willamette Pass Ski Area is located at the crest of the Cascade Mountains on State Highway 58. This 1,100 acre facility will be implementing an expansion plan during this planning period. After expansion is completed the area will include six chair lifts, two day lodges, ski patrol building, parking overpass, utility buildings and other facilities. Environmental documents can be found at the Forest headquarters in Eugene.

Water quality has been affected by recreation residence use. This has been attributed to old systems of sewage disposal and illegal installations. Soils near these residences are generally not conducive to adequately filtering or storing waste.

Potential transmission corridors have been identified throughout the Western United States by the utility industry. These are displayed in the Western Utility Group's "Western Regional Corridor Study" of 1986. The Study identifies potential (and existing) utility transmission corridors across the crest of the Cascade Mountains at Willamette Pass (State Highway 58), at McKenzie Pass (State Highway 242), and down the North Fork of the Breitenbush River.

Future Trends

Monitoring of special uses will continue to avoid or remedy violations of legal requirements or violation of minimum standards of other resource values.

ROADS

Access into and through the Forest is provided by more than 200 miles of county, state, and federal highways. To facilitate protection, management, and use of the Forest, approximately 6,500 miles of permanent Forest roads have been constructed and are being maintained at various use levels. Forest roads originally were built, primarily, to access timber harvest units and for other administration purposes. Today roads also provide the primary access to lakes, trails, picnic and campgrounds, and the trailheads for hiking into the beautiful backcountry of our Wildernesses. They continue to facilitate resource management and wildfire suppression.

Historic Trends

The first roads on the Willamette were pioneer wagon roads. Some of these historic routes are now major roads and highways. The Santiam Wagon Road is one example; it carried the first auto over the Santiam Pass in 1902, and continues to carry auto and truck traffic today. Since the 1940s the majority of road construction and reconstruction has been in support of timber management activities. Recreation use has an increasing effect on the operation, maintenance, and management of the Forest road system. Historically, motor vehicle access by the public was allowed and encouraged throughout the entire system. This level of access resulted in high road costs.

Road management practices became more cost-effective during the early 1980s. Multiple-use opportunities and resource outputs can be provided without constructing and maintaining every road for every use. Many of the minor local roads are now maintained only for high clearance vehicles or allowed to close naturally, maintaining only the drainage system to avoid washouts.

Current Situation

The transportation system objectives are to plan, develop, and operate a network of roads that provide user safety, convenience, and efficiency of operations to accomplish the land and resource management objectives of the Forest.

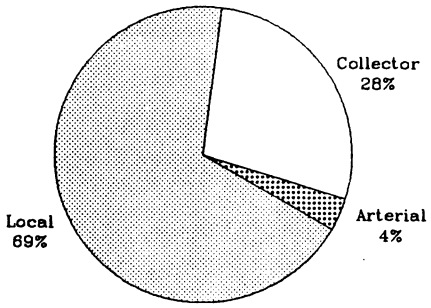
Roads are classified as either arterials, collectors, or local roads. Arterial roads are primary roads, quite often double lane and paved, that provide the main access into and out of the Forest. Local roads serve as terminal roads or "work" roads that access the smaller work areas. Collectors are the roads that connect local and arterial roads. Collectors may be double lane roads but normally are single lane. Some collector roads are paved but most are rock aggregate surfaced. Figure III-V-1 lists the existing road system by functional classification, including roads under contract to be constructed by the end of fiscal year 1986.

The Forest has defined the traffic service level for each road. The traffic service levels describe the traffic and operational characteristics for which the road is managed. Figure III-V-2 shows traffic service levels for existing arterial and collector roads.

The current trend is to reduce costs of development, operation, and maintenance. Roads are now being developed, operated and maintained to serve only objectives identified during project planning. This results in reduced road clearing, road width, surfacing requirements and varied management techniques than required to accommodate the low clearance passenger car. In addition, roads serving small geographic areas, single project activities, or limited in use by weather and design features are being closed to prevent resource damage and reduce costs. Approximately 24% of the existing road system is suitable for use by low clearance vehicles. (See Figure III-V-3.)

Figure III-V-1. Existing Road System

Classification	Miles
Arterial	232
Collector	1,815
Local	4,480
Total Miles	6,527



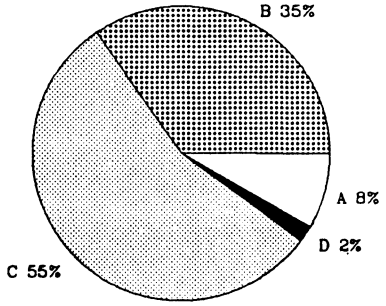


Figure III-V-2. Existing Arterial and Collector System [1]

Level	Miles
A	168
B	710
C	1,132
D	37
Total	6,527

[1] Traffic service levels are defined as:

- A - Free flowing traffic with adequate passing facilities and smooth surface.
- B - Congested during heavy traffic such as peak logging or activities. Surface is stable for the normal use season and smoothness is commensurate with the design speed.
- C - Traffic interrupted by limited passing facilities or slowed by the road condition. Surface may not be stable under all traffic or weather conditions during the normal use season.
- D - Flow is slow or may be blocked by an activity. Two-way is difficult and may require backing to pass. Rough, irregular surface is stable during dry conditions.

Table III-V-3. Existing Road System by Maintenance Level

	Operational Maintenance Level [1]					
Forest	1	2	3	4	5	Total
TOTAL	804	4,188	1,101	149	285	6,527

[1]Those roads in Level 1 (16%) maintenance are managed in a storage category and are closed for resource or safety reasons or are allowed to close naturally--being open for use until that happens. Those in Level 2 (60%) are kept open for high clearance vehicles, (pickups) but they are allowed to "brush in" and become much more natural until the next commercial use. The roads maintained in Level 3 and above (24%) are maintained suitable for use by low clearance vehicles (cars), those in the higher levels providing more comfort.

On the Forest the demand for roads is a function of the demand for recreation and timber. The amount of new construction depends mainly upon the need for access to timber sale areas. Some new road construction will occur for recreation purposes, (i.e., access to new campgrounds), depending upon the need for additional recreation facilities. The mileages of road construction and reconstruction are shown in Figure III-V-4.

The Forest manages traffic and roads for long-term, seasonal, and project purposes to support resource management objectives. Closed roads may exclude a variety of user groups or may provide access to a single user when imposed for one or more of the reasons listed below:

1. Wildlife--Closures may be used to protect and enhance high potential elk management areas, spotted owl habitat, and nest sites of Osprey and Bald Eagles. Road closures are also used to provide quality hunting areas. Some wildlife closures are open to vehicles during seasons of the year when disturbance of the wildlife has a lesser impact. The Forest cooperates with the Oregon Department of Fish and Wildlife in this effort.

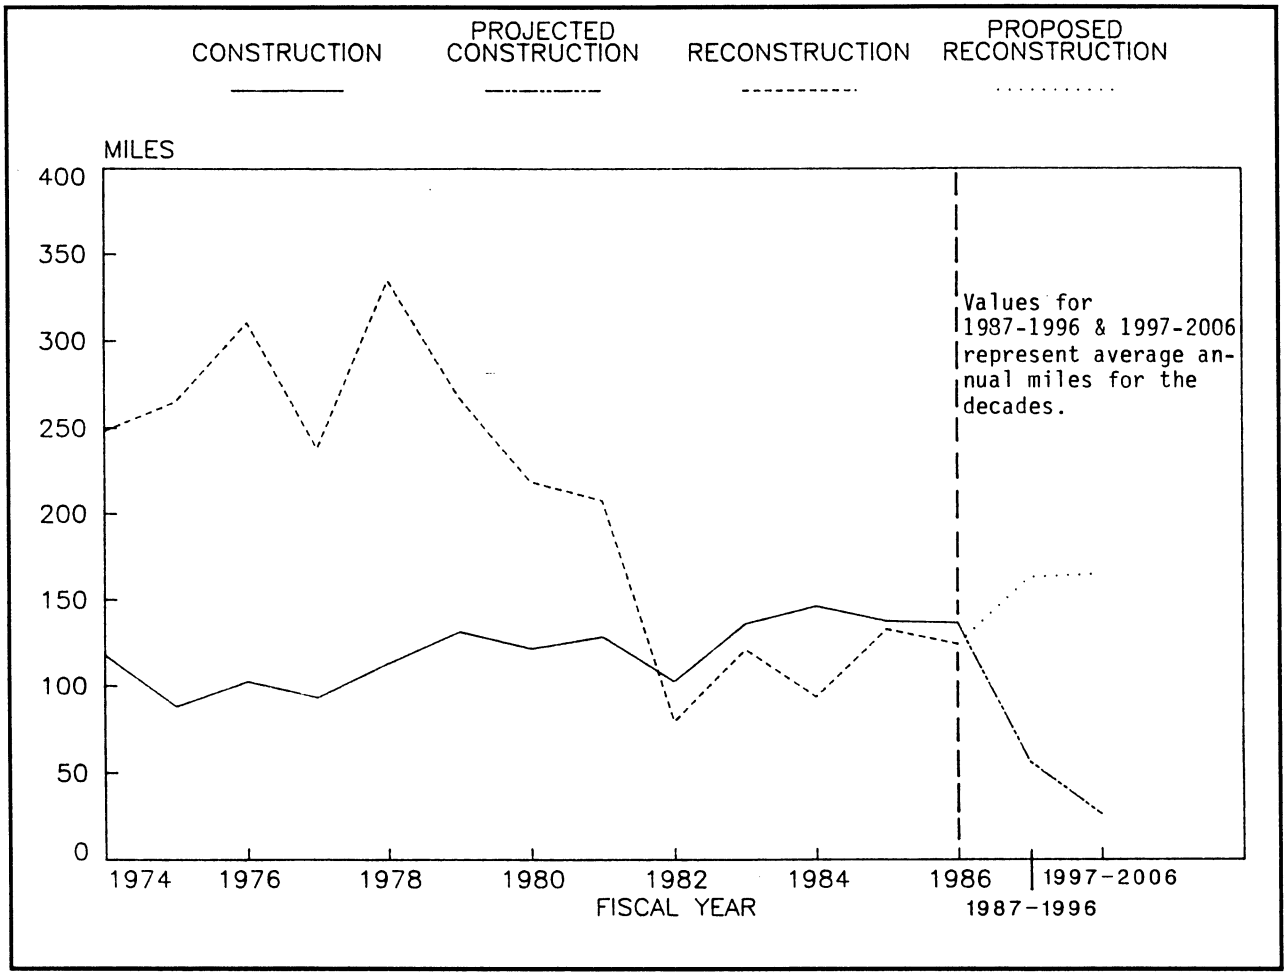
2. Water quality and erosion control--Roads can be closed to prevent rutting and surface disturbance, and to reduce erosion and sediment entry into streams.

3. Public safety--Damaged roads or structures, wildfires, or activities dangerous to visitors require closure to certain users. Closure may also be required during certain activities including search and rescue operations.

4. Conflict of use--In a few cases, usually for user safety, it is necessary to give preference to one user over another. Examples are log hauling on a narrow road with few turnouts, or compliance with share cost agreements.

5. Maintenance cost reduction--The cost of maintaining the road system can be reduced by closure.

6. Legal mandates--Some areas, such as Wilderness, are afforded protection by Federal law from the use of motorized vehicles (36 CFR 261.16, 261.19, and 293.17 USC 551) without proper authority. Closures of this type are signed and enforced.



Future Trends

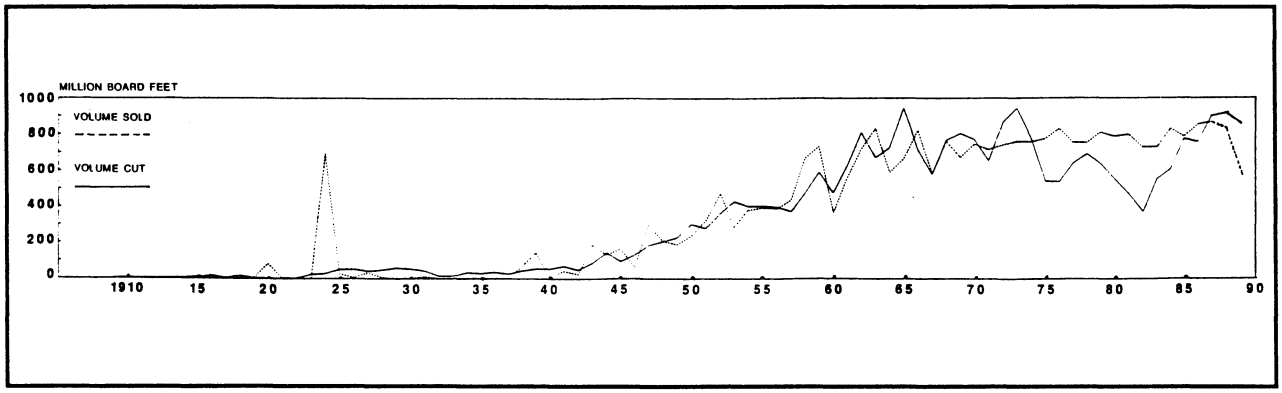
The development, maintenance, and management of the Forest development road system will continue as needed to respond to resource management objectives.

The rate of new road construction will continue to decrease as the road system nears completion. New roads constructed will be low standard (traffic service Level D) and usually will be maintained to Level 2 maintenance. Maintenance and reconstruction will increase in response to water quality needs on some existing roads. Some other existing roads may be closed to motor vehicle traffic and be minimally maintained (maintenance Level 1) for extended periods of time.

Some existing permanent roads will no longer be needed for resource management objectives. These roads will be permanently closed to motor vehicles; and have vegetative cover and natural-like drainage patterns reestablished.

Figure III-V-4. Road Construction and Reconstruction Mileage

TIMBER



Trees utilized for commercial harvest are one component of vegetation. Timber is discussed with separately in Chapter III because of its importance as an economic resource and the effects that harvest has on other components of the environment.

Historic Trends

The earliest record of timber sale activity on the Forest was in 1909, when 100 MBF (gross) was sold for $106.00 ($1.06/MBF). The sale and harvest of timber was a minor activity for the first 3 decades, with the cut averaging about 23 MMBF per year. Management on the Forests during this time emphasized protection of the resources. In 1924, the Forest sold 696.3 MMBF, a large amount even by current standards. Of this amount in one huge sale of 685 MMBF to the Westfir Lumber Company of Oakridge was used to help establish a sawmill. The contract stipulated that not more than 50 MMBF could be harvested per year.

During and after World War II, the demand for wood products rose steadily and the sell and harvest of timber on the Forest kept pace. Management on the Forests began to favor development of the resources and sustained yield of timber. Since about 1962, the annual volume sold has remained about the same, averaging about 750 MMBF. During this time the volume cut has fluctuated from a low of 370 MMBF in 1982, to a high of 945 MMBF in 1973. Two other years have exceeded 900 MMBF, 1965 and 1988, with 943 and 908 MMBF respectively. The annual cut has averaged 708 MMBF per year. Figure III-W-1 shows the pattern of sell and harvest on the Forest from 1909 through 1989.

Figure III-W-1. Historical Perspective of Commercial Timber Sales: 1909-1989

The Forest has completed 3 timber inventories since 1962 which have assisted in the development of Forest Plans. The inventory information displayed in Figure III-W-2 shows the land base as it was inventoried, not as it was described and analyzed in the subsequent Forest plans. Changes in the total landbase are a result of land purchases and exchanges. Inventoried land base changes and trends can be summarized as follows:

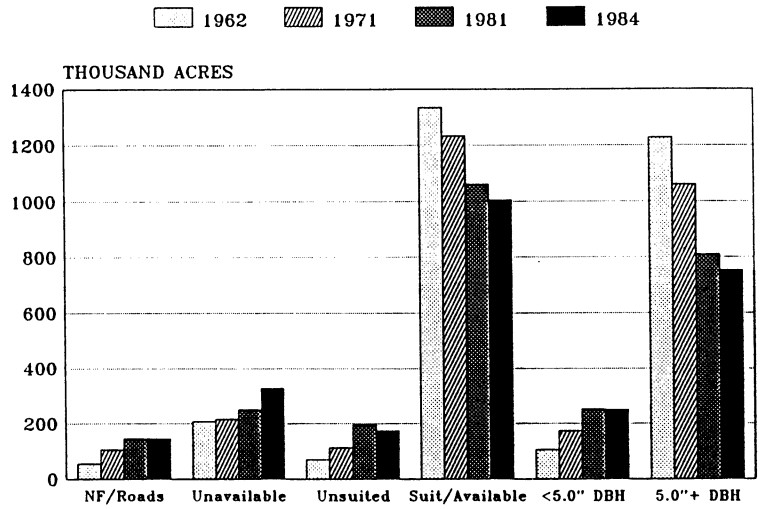
- Nonforest lands have steadily increased as each inventory typed the land to tighter specifications.
- Unavailable lands have increased with additions to existing Wilderness and the addition of new Wilderness.

- Unsuited lands have shown a steady increase as definitions have changed and more information has been gathered concerning reforestation problems and unstable soils.

- As a result of increases in the above categories, the suited available land base has decreased by 25% since 1962.

- The amount of land occupied by timber stands that are less than 5.0" d.b.h. has increased since 1962 but should be close to leveling out. It takes the average stand about 30 years to reach 5.0" d.b.h., so the acres in this category are the harvested acres for the last 3 decades.

- The inventoried stands are those suited, available lands stocked by trees greater than 5.0" d.b.h. These have decreased with each successive inventory as a result of continued harvesting on a shrinking land base. These acres will level off under a given set of land allocations.



- The inventoried volume is the net volume from the stands greater than 5.0" d.b.h. and shows a decrease for the same reasons. This volume will eventually remain constant under a given set of management intensities.

- The average volume per acre has increased as a result of deleting the nonforest and unsuited lands from the inventoried land base.

Since the beginning of the current plan in Fiscal Year 1977, the potential yield has declined with the addition of new wilderness, while the annual volume sold has remained fairly constant, averaging 779 MMBF (gross). The volume harvested has averaged only 86% of the volume sold, or 672 MMBF. (See Figure III-W-3.) This resulted in an increase in the amount of volume under contract, from about 2.6 years in 1977 to 4.8 years worth of volume by the end of 1985. (See Figure III-W-4.) The increase in volume under contract was particularly noticeable in 1981 and 1982, during the worst of the recession, when only 59 and 51% of the volume sold was harvested.

Passage of the Federal Timber Contract Payment Modification Act in 1984, resulted in almost 2 years worth of volume being returned to the Forest (1,219 MMBF). An additional 279 MMBF of volume under contract was defaulted. For the last 3 years the volume cut has exceeded the volume sold, further reducing the volume under contract.

[1] This represents the maximum volume that could be produced, assuming no restrictions of funding or workforce, and solving all technical problems involved in managing marginal lands. Gross volume was estimated (for comparison to cut and sold volumes) by multiplying net volume from TM Plan by 1.25.
[2] Taken from the Forest cut and sold reports.
[3] Based on 234 MMBF (net) sold, plus 233 MMBF sold but not awarded until FY90. Net volume of 467 was multiplied by 1.25 to estimate gross volume.

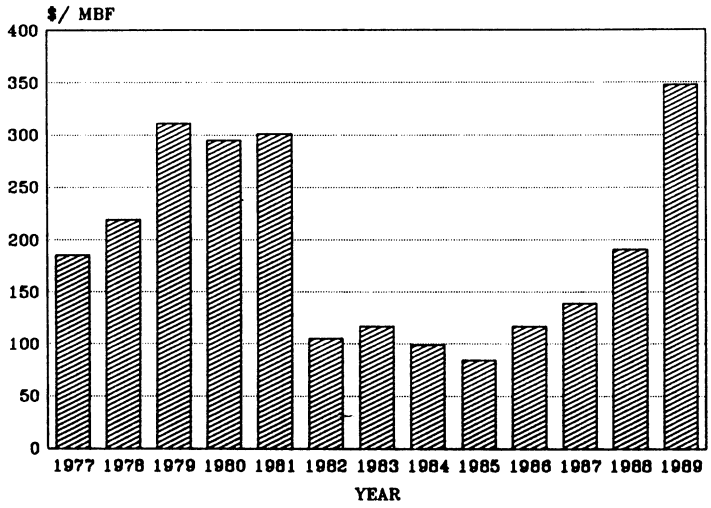

Figure III-W-4. Contract Volume

The average selling price of timber has varied widely since the earliest records beginning in 1909. The lowest average price was $0.16/MBF in 1938 and the highest average was $348.42/MBF in 1989. Figure III-W-5 shows the average selling price since the current plan went into effect.

Twenty-five percent of the total timber sale receipts from Forest lands and 50% of the receipts from converted Oregon and California Railroad grant lands are returned to the counties. The remaining funds go into the U.S. Treasury.

Table III-W-5. Average Selling Price of Timber [1]

Year	Volume Sold (MMBF)	$/MBF	Total Value Million $
1977	756.7	184.67	139.7
1978	755.3	218.82	165.3
1979	811.2	310.85	252.2

1989[2]	583.8	348.42	203.4

[1]From Forest Cut and Sold Reports (does not include Purchaser Road Credits).
[2]Includes sales that were sold in FY89, but not awarded until FY90.

Current Situation

The 1981 timber inventory shows approximately 62% of the Forest is tentatively suited for timber management. (See Figure III-W-6.) This amounts to 1,032,138 acres, which is about 8% of the suited Forest land in Region 6. (See Regional Guide.) This is a falldown of 32,478 acres (3%) from the 1,064,616 regulated commercial Forest acres under the current plan after adjusting for the Oregon Wilderness Act of 1984. The change is due to better identification of unsuited soils and changes in land categories, particularly the dropping of the marginal category. Figure III-W-7 shows the Forest Land Classification under the current plan and can be compared with Figure III-W-6 to see the changes.

The total standing volume on the Forest, available for harvest (5.0" d.b.h. +), is about 33.0 billion board feet on 705,127 acres (from 1981 Timber Inventory Statistics updated through FY 1989). Douglas-fir is by far the predominant species accounting for 70% of the standing volume. Other important species include: western hemlock (14%), Pacific silver fir (4%), noble fir (4%), mountain hemlock (3%), and western redcedar (2.5%). The following species are also found on the Forest in small amounts (less than 1%) and are listed in order by volume: western white pine, grand fir, Engelmann spruce, sugar pine, incense cedar, lodgepole pine, alaska cedar, subalpine fir, and ponderosa pine. Hardwood species make up less than 0.2% of the standing volume with the most common being bigleaf maple, followed by black cottonwood, golden chinkapin, red alder and Pacific madrone. None of the hardwoods are commercially important as yet but they are very popular for firewood use.

In addition to the 33 billion board feet (BBF) of timber on tentatively suited lands, there is approximately 12 BBF on 325,000 withdrawn acres (poles and larger), and about 6 BBF on 130,200 unsuited acres. At the beginning of FY 1990, the total standing volume on the Forest was about 51 BBF on 1,160,000 acres of timber at least 5.0 inches in diameter.

Table III-W-6. Land Suitability for Timber Production

	Acres not Suitable for Timber Production	Total Forest Land Acres
Total National Forest Area		**1,798,737**
Other Ownerships	123,330	
Net National Forest Area		**1,675,407**
Water	23,101	(I-I.A)
Nonforest (not stocked with 10 % tree cover, or lands developed for other than timber production purposes)	123,052	
Roads	24,764	
Forested Lands (stocked with 10 % or more treee cover)		**1,504,490** (II - (II.A + II.B + II.C)D)
Withdrawn from scheduled timber production (219.14(a)(4))		
Wilderness	305,915

TOTAL	1,064,616				

[1] Amendment 2 (7-27-84)

[2] This differs from Figure III-W-5 (1981) due to land exchanges.

The biological potential yield of the Forest, including all forested lands, with no falldowns for other resource considerations, technical problems, or workforce requirements is estimated as shown in Figure III-W-8

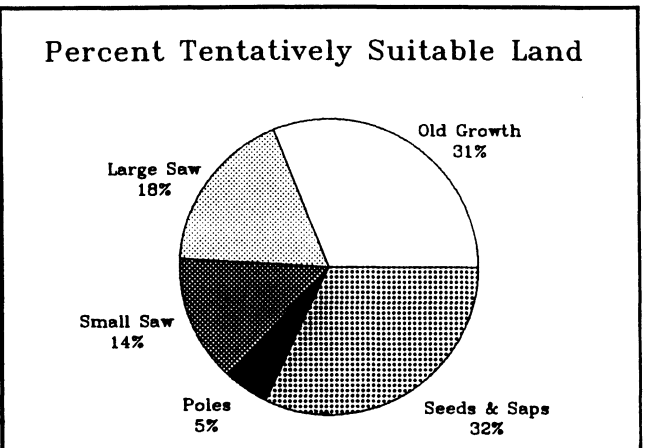
Table III-W-8. Potential Yield

Land Classifications	Acres	Annual Yield MMBF (Net)
Tentatively Suited	1,032,138	763.2
Withdrawn	327,501	192.9
Unsuited	144,851	105.7
TOTAL	1,504,490	1,061.8

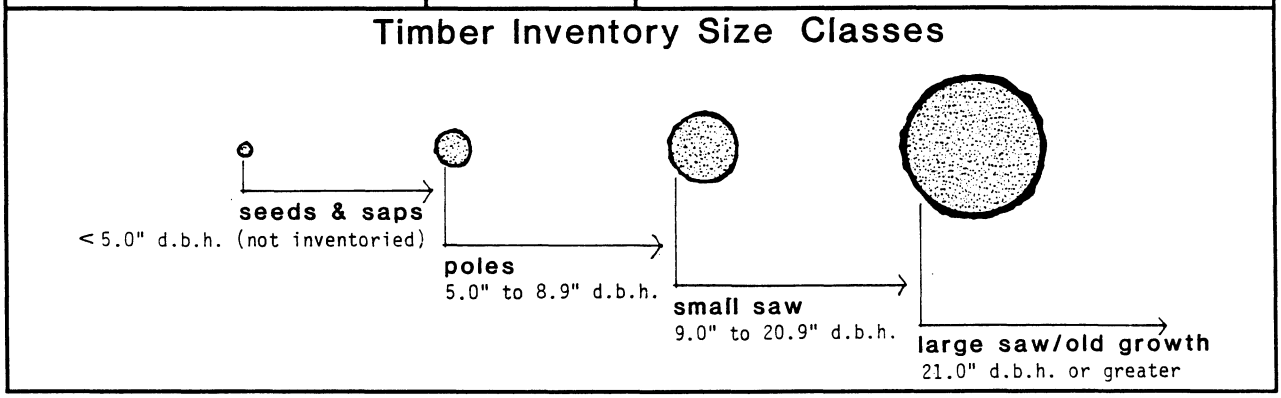
Four working groups represent the site class and vegetative associations of the Forest. These working groups are the basis for development of empirical and managed yield tables. (Appendix B of the FEIS contains more detail on how the working groups are modeled in FORPLAN.) The four working groups stratify the major species as follows:

1. Douglas-fir/Hemlock - This is the major working group on the Forest comprising about 82% of the available and suitable acres. It covers the whole broad spectrum of site and vegetation associations within the Douglas-fir, western hemlock, and grand fir series of forest communities.

2. Douglas-fir/True Fir - This group is made up of the Pacific silver fir and grand fir series, and accounts for about 10% of the suitable acres. Douglas-fir is the dominant species and is featured in management. Noble fir is also an important associate. Western white pine may also be found but is more commonly featured in the true fir or mountain hemlock types. The strata is cooler and generally wetter than the Douglas-fir/hemlock type with snow cover common in the winter. It starts at about 3,000 feet on certain slopes and aspects and reaches maximum area between 3,500 and 4,000 feet.



3. True Fir - This working group occurs in the Pacific silver fir series and occupies the least area on the Forest with about 3% of the suitable acres. It occurs in the same elevation range as the Douglas-fir/true fir strata but on cooler and wetter sites. Most of it lies on the rolling uplands of the New Cascades. Noble fir is the preferred management species with Douglas-fir, silver fir, white pine, and Englemann spruce as minor associates.



4. Mountain Hemlock/Lodgepole Pine - This working group occupies the highest and coldest areas of our commercial Forest land and occurs in the Pacific silver fir and mountain hemlock series. This group totals about 5% of the suitable acres and is located on the rolling land of the High Cascades. Seral species include lodgepole pine, silver fir, white pine, Englemann spruce, and noble fir. Alaska yellow cedar and Douglas-fir are minor associates. The cedar tends to occur in well defined pockets. The lodgepole pine is often a pioneer species on cold, frosty sites; then silver fir and mountain hemlock come in underneath the lodgepole pine, replacing it in 60 to 80 years.

As part of the inventory process, stands are grouped into the four size classes illustrated below. Figure III-W-9 shows the tentatively suited acres by size class (1981 inventory).

Figure III-W-9. Tentatively Suited Acres by Size Class

Size Class	Acres
Seedlings and Saplings	326,985
Poles	57,485
Small Sawtimber	140,930
Large Sawtimber	189,113
Old Growth [1]	317,625
TOTAL	1,032,138

[1] See Chapter III, Section G, Vegetation for information on old-growth.

Under the current plan, the total annual sell program of timber on the Willamette National Forest has averaged about 779 million board feet (gross). This represents about 15% of the timber production from Forests in Region 6 (Oregon and Washington) and about 7% of the production from the entire National Forest System (Regional Guide).

Timber management has been guided by a Timber Management Plan approved in 1977, which programmed an annual net sell volume of 615.6 MMBF. The plan has been amended twice to account for reductions in the land base due to new Wilderness and to take into account the effect of Timber Stand Improvement (TSI) accomplishments. The latest projections indicated the reduction in acreage was offset by increased TSI work and the net sell volume actually increased to about 641 MMBF.

Future Trends

National and Regional Timber Supply

The principal projections used in guiding the development and evaluation of long-range plans and programs for management of the Forests are contained in the latest Forest and Rangeland Renewable Resources Planning Act (RPA) Assessment (i.e., the 1984 Update and the President's Statement of Policy, September 19, 1986). These projections focus on the long-term (50 years) in 10-year increments

and do not recognize short-term local and regional fluctuations. A summary of projected RPA trends for timber supplies follows:

Hardwoods - The current balance between growth of wood and its removal shows that the hardwood forests and eastern softwood forests can support additional timber harvests. This balance will change, however, and future harvests, particularly in the decades beyond the year 2000, could vary over a wide range. Nonetheless, if commercial timberland owners continue to respond to price and inventory changes, timber harvests can be increased substantially in most geographic regions during the next few decades. Hardwood increases are expected to rise from about 3.4 billion cubic feet from 1980 to 9.4 billion in the year 2030 (RPA 1984). The largest increases will be in the South.

Softwoods - Total projected softwood roundwood harvests are expected to increase from 9.6 billion cubic feet in 1980 to 11.9 billion cubic feet in the year 2030. Though the outlook is for increased softwood harvests nationally, there are important differences among the major softwood timber producing regions.

In the Douglas-fir subregion, projected annual harvest from 1980 to 1990 is about 2.3 billion cubic feet. It then declines slightly to about 2 billion cubic feet per year. This level is roughly maintained through the rest of 50-year projection period.

In contrast softwood timber harvests in the South are projected to rise from about 4.1 billion cubic feet in 1980 to 7.3 billion in the year 2030. Much of the expansion in the South is due to greater diversification in its wood products production as compared to other regions of the country.

Local Timber Supply

Potential timber supply levels from the Forest have been calculated for each of the Alternatives presented in Chapter II of this document. To fully assess the potential impacts of these supply levels on the local timber industry, it is necessary to understand the relationship between the demand for and the supply of timber in the local market area of the Forest's affected environment. The significance of the impacts of changes in timber supply from the Willamette will depend upon assumptions about both future demand and the future supply available from other ownerships in the market area.

The major portion of the market area for timber from the Forest consists of Lane, Linn, and Marion counties in West-Central Oregon. Approximately 97% of the total land base of the Forest is located in these three counties. Over 98% of the total harvest from the Forest is processed into wood products in this three-county area. Small amounts are processed in some of the other adjacent counties with the most generally going to Douglas County. Of the amount processed in the three-county area about 66% is processed in Lane County, 27% in Linn County, and 7% in Marion County. The percent harvested by county is similar to the percent processed.

Both the demand for wood products and the supply of timber are important to the health of the timber industry. In the past, demand-related factors have been primarily responsible for the fluctuations which have occurred in the market for timber. The supply of timber has generally been abundant. There is some evidence, however, that this may be changing for some regions of the country including Western Oregon. A number of studies done within the last 10 to 15 years have pointed to the real possibility that harvest levels from private industrial lands will decline during the next 2 or 3 decades. This could occur because of reduced inventories brought on by harvesting in recent decades at levels higher than can be sustained over time. The harvest projections in one of these studies, *Timber for Oregon's Tomorrow: The 1989 Update* will be used here and in Chapter IV to assist in the assessment of the impacts of Forest harvest levels on the total available supply in the market area.

There are three major influences on the potential supply level: the amount of land available for harvest, the intensity of management on those acres, and the harvest flow schedule (nondeclining flow or departure). The available acreage is the most significant influence, since large changes in standing timber volume are directly related to land allocation. Departure from nondeclining flow can increase harvest level temporarily, but entails a decrease sometime in the future. Intensive management practices influence the supply level by affecting the growth rate of trees. The most effective practices for increasing and improving growth are planting of improved stock (genetics), stocking level control (precommercial thinning) and fertilization.

The most recent timber resource inventory of all ownerships in the study area was done by the Forest Service's Pacific Northwest Forest and Range Experiment Station in 1973-1976. The most recent inventory of the Forest was completed in 1981. Figure III-W-10 presents the entire study area by land class. Figure III-W-11 shows the amount of commercial forest land by ownership and the volume of growing stock. Of particular interest is that while the Forests contain less than half of the total acres of commercial forest land in the three-county area, they have (or had) over two-thirds of the existing growing stock. In contrast, forest industry owns over 24% of the commercial timberland, but has only about 13% of the existing growing stock. This indicates that industry has historically been harvesting its own lands at a faster rate than the harvest on the Forests.

A comparison of the Forest and industry inventories further supports this point. About half of the Willamette's suited timberland contains old-growth and large sawtimber while only about 17% of industry's land is in this timber size class. The % of industry's land that is in the smallest size class (i.e., seedlings, saplings, and nonstocked) is also about twice that of the Forests.

Table III-W-10. Study Area [1] by Land Class

Land Class	Thousand Acres	% of Total
Commercial Timberland	3,474	67.9
Reserved Timberland	201	3.9
Other Forest Land	184	3.6
Non-Forest Land	1,259	24.6

[1] Study Area = Lane, Linn, and Marion counties.

An examination of actual harvest levels shows that between 1970 and 1988 the harvest from industry lands nearly equaled that from Forest lands. Figure III-W-12 shows the average annual harvest levels by county and ownership class for the market area.

Harvest on industry and Forest lands accounted for an average of 83% of the total harvest in the market area. Thus, significant changes in the harvest levels from either ownership will impact the total harvest of the area.

As the result of present stand conditions, the supply of timber from forest industry lands is expected to drop significantly for a period of time during the next 10-20 years. Figure III-W-13 displays actual and projected harvest levels from the various ownerships within the study area.

[1] Millions of Board Feet.

Future harvest levels are based on projections developed in the study *Timber for Oregon's Tomorrow* by Beuter, Johnson, and Scheurman (also known as the Beuter Report). This information has been updated to 1989, but was not available to change the data in Figure III-W-13. These projections reflect a specific set of assumptions about the rate of harvest and management intensity for all ownerships. In this study, all ownerships are assumed to maintain their current level of intensified management. The rate of harvest for public ownerships is held constant for the first 3 decades with private ownerships trying to maintain the total harvest level of the area. Figure III-W-13 shows the actual harvest level for Forest lands, not the level which was projected in the study. Harvest for all ownerships is maximized subject to a long-run sustained yield constraint after the 3rd decade.

These projections indicate that if the harvest from public lands remains at current levels or declines, the total supply available to processors in the three-county area would be reduced beginning in the 2nd decade. Opportunities for alleviating this potential falldown by augmenting the supply with timber from adjacent areas are not realistic. The only western Oregon timbershed which could provide additional volume is the North Coast timbershed. Haul distances associated with obtaining timber from this or any other region, however, would create a significant competitive disadvantage for mills in the Willamette's market area.

The supply of timber available for harvest in the market area will not, by itself, dictate the future condition of the local timber industry. Demand for wood products will also affect the amount of timber that is harvested. In general, demand for timber from the Pacific Northwest was quite low during the recession of the early 1980s. High interest rates, the influx of inexpensive timber from Canada, and the expansion of the South's market area contributed to the reduced demand during this period.

In 1985, however, demand for timber rebounded dramatically as the total timber harvest in Oregon was at a record high level. Lower interest rates and a record level of raw log exports contributed to the increased harvest. There was little change in the amount of wood processed, however, and the value of the wood products produced actually declined.

Despite the record harvest in 1985, employment in the woods products industry declined. Increased productivity, automation, and a desire to reduce costs continued the trend that began a couple of decades ago and accelerated during the recession. Substantial reductions in employment occurred during the recession as many of the older mills closed or cut back on production. Some of this employment is returning as smaller companies are reopening mills with smaller but more efficient operations.

One measure of the potential for the timber industry to meet future demand within a market area is the installed capacity of local mills. Area mills will operate at the capacity needed to provide the wood products demanded by society. Figure III-W-14 shows how the number and capacity of mills in the three-county area have changed between 1968 and 1982.

[2]Capacity Measured in the Following Units:

- Sawmills; Thousand Board Feet (MBF) per 8-hour shift;
- Veneer and Plywood; Thousand Square Feet (MF) per 8-hour shift, veneer production only;
- Pulp Mills; Tons per 24 hours.

While estimates of future demand for Forest timber involve a number of assumptions and contain a great deal of uncertainty, they are necessary to assess the overall supply implications of land management planning alternatives. Figure III-W-15 contains estimates of demand for Forest timber.

Table III-W-15. Projected Demand for Willamette National Forest Timber [1]

Peiod	Estimated Total Demand	Non-Willamette NF Harvest	Demand for Willamette
1986-1995	1,533-2,045	1,264	269-781

2026-2035	1,533-2045	1,096	437-949

[1]Million Board Feet per Year

These projections were developed using the process and assumptions discussed as follows.

The actual amount of wood harvested and processed in any given time period provides a measure of demand for wood from a particular area. A range of potential future demand can be estimated from high and low periods of harvest. In the Willamette's market area, a high level of sustained production (an average of 2,045 million board feet per year) was maintained during the 1970 to 1979 period. A very low level of production (1,533 million board feet occurred during the recession of 1980 through 1982. These two extremes provide a realistic range of potential future demand assuming the many variables affecting supply and demand do not exceed the limits of variation experienced during these time periods.

Demand for Forest timber can be estimated by subtracting nonnational forest and other Forest harvest from the range of total estimated demand. "Demand" is defined as the volume of Forest timber that would be purchased (if available) by area mills in response to the combination of demand for final products and supply from other sources. The potential supply provided in the land management planning alternatives will be evaluated relative to this range of potential demand in Chapter IV of this document (see "Cumulative Effects of Alternatives on Timber").

Demand

Over the next 10 years, timber demand from the Pacific Northwest geographic region will grow slowly. Although there is a backlog of unfulfilled housing demand, the future will depend primarily on the continuing strength in personal income and the availability of affordable housing and financing. In addition, projections of exports to the Pacific Rim countries show a continuing slow economic growth. The analysis acknowledges there will be a declining trend in the construction sector. Structure replacement, rather than new construction, will characterize the market. The projections for increases in demand may be described as considerably restrained and cautious (Nomura 1981).

The long-term outlook for the solid wood products industries contains a number of challenges. Evaluation of recent data and information indicates that the demand for timber is changing to a moderate rate of increase as compared to the slowdown that occurred in the early 1980s.

The ability to sustain this increase on a long-run basis is linked to the critical issue of costs. The short-term future of timber and wood products demand is clouded by factors, such as the severity and length of the housing and wood products recession that began in 1980. The long-term trends in housing demand, the growing popularity of construction methods that use less wood, availability of wood substitutes, and a shift in business management strategies and methods, all contribute to a potential shift in future demand (Adams and Haynes 1985).

Wood supply will continue to be an issue in the sense that it will be highly dependent on the ability of producers to lower costs to be competitive with wood substitutes (Schallau 1986).

Although overall current timber supply levels in the Pacific Northwest region may be capable of meeting future demand, there are some problems within the subregional market areas. This needs to be recognized in terms of a shifting of industry within the region and also in the shifting emphasis on the types of wood products produced, as well as the ability of the subregion to supply the various kinds of wood needed.

A broader vision of the future that includes developing a flexible regional basis for stabilizing wood supplies and applies to forward-looking perspective on wood fiber management, will also better allow the Pacific Northwest timber industry to utilize the opportunity to increase exports to international markets. To achieve this, the Forest products industry will need to learn the workings of a different market system and provide more products in the form demanded. (Campbell et al. 1983.) In addition, actions by industry, such as modernizing facilities, adopting state of the art technology, reducing costs, and diversifying into other sectors of production (similar to what the southern region has done) could help to rebuild and stabilize the wood based sectors of the region (Schallau 1985).

Private and Public Land Interrelationships

Currently, part of the timber formerly supplied by the Pacific Northwest Region is now being supplied by the South and Canada. However, the supply situation from these other sources can be expected to change as soon as about 6 years, or at least by the year 2000. The projected change indicates a drop in supply capability of 30 to 50% from the current relatively high levels. By the 2nd decade (2000-2009), shortly after the drop in supply begins in other regions, the growth of wood fiber on private lands in the Pacific Northwest will start increasing. The private lands in the Pacific Northwest could then become a major source of supply for softwoods to meet national and international demand. Further, during the period before the private lands in the region regain their full supply potential, the public forests would be looked upon as a major source for a relatively stable supply of wood fiber (Schaullau 1985).

The land use planning process determines the range of harvest levels that the Forest can meet under a variety of conditions. This information is fed into the Resources Planning Act process which establishes Forest targets over a 5-year period plus long-term targets for a 5-decade period beyond that. These targets are adjusted on an annual basis depending on funding levels and political decisions. There are also targets for acres of reforestation and timber stand improvement.

The RPA target for timber production programs increases from a low of 792 MMBF in 1982 to a high, sustained yield of 870 MMBF in 2001. (See Figure III-W-16) The RPA program has not yet been updated to account for recent changes, like the Spotted Owl Management guidelines.

Table III-W-16. 1980 RPA Targets [1]

	1982	1983	1984	1985	1986-1990	1991-2000	2011-2010	2011-2020	2021-2030
MMBF	792	802	812	823	834	869	870	870	870
MMCF	145	147	149	151	153	159	160	160	160
Refor. (M Ac.)	17.154	16.990	16.800	16.675	15.729	15.200	15.500	16.920	16.920
TSI (M Ac.)	1.070	10.800	10.710	10.620	9.360	9.360	9.720	9.900	10.080

[1] Includes cull volume.

Figure III-W-17 shows the Forest targets contained in the Forestry Program For Oregon (FPFO). The FPFO data also needs to be updated to reflect recent changes affecting the acres available for timber management.

Table III-W-17. Forestry Program for Oregon [1]

Decade	MMCF/YEAR
1980	146.2
1990	149.2
2000	146.4
2010	145.5
2020	143.7
2030	141.0
2040	137.9
2050	136.0
2060	135.8
2070	135.1

[1] Based on 1,005,394 suited acres. Includes cull volume.

The Forest timber production levels play an important role in the Forestry Program for Oregon (FPFO) developed by the Oregon Department of Forestry. The Forestry Department documented the goals and objectives for the FPFO in the *1980 Oregon Timber Supply Assessment* using the computer program TREES (Timber Resource Economic Estimation System) to model harvest levels from all ownerships. The results indicate the longer the industry maintains harvest at the present rate, the greater the eventual decline in timber harvest from these lands. If industry immediately drops its current harvest from about 730 MMCF/year to a sustainable level of about 500 MMCF/year, Oregon's total harvest would decrease by 14% unless the other ownerships picked up the slack. The FPFO contribution from the Forest is estimated to be 149.2 MMCF (gross) per year for the decade beginning in 1990. This is close to the RPA target of 153 MMCF per year. To provide these levels of harvest, the Forest would have to depart from nondeclining yield as authorized by 36 CFR 219.12(d).

The 1990 draft update of the FPFO does not list volume targets for the Forests or other ownerships. Instead, the Board of Forestry has adopted six objectives to "ensure jobs and a quality environment

for all Oregonians, today and for future generations." Regarding timber growth and harvest levels, the objective is to "Promote the maximum level of sustainable timber growth and harvest on all forest lands available for timber production, consistent with applicable laws and regulations and taking into consideration landowner objectives."

Below-Cost Sales

The issue of below-cost timber sales has recently surfaced as a concern of the Forest Service and many members of the public. A below-cost sale is one in which total Forest Service costs exceed revenues. There is currently much discussion on how to analyze available timber sale information so that an assessment of below-cost sales can be made. Areas of particular concern include the type of analysis (i.e., cash flow or cost efficiency), the scope of analysis (i.e., Forest-wide, area-wide, individual projects, per acre, or some combination), the time frame of the analysis (i.e., annual or multi-year), and which benefits (or revenues) and costs should be included.

Many of these questions are interrelated and the cost-efficiency analysis used in the land management planning process represents one approach to the analysis of the issue. In this section, the issue is being addressed using an annual Forest-wide cash flow approach. (See Figure III-W-17.) This is designed to give an overall perspective of the magnitude of the below cost sales problem on this Forest.

Because the values and costs for any given year are for different groups of timber sales, the net receipts are not a direct reflection of the below-cost sale issue. The fact that net receipts averaged 24.8 million dollars over the seven year period is an indication that the Forest does not have a problem with below-cost sales. Only 1 year (1982) had a negative result where total cost exceeded gross receipts. The reason this happened is because 1982 had the lowest volume harvested since 1952, and had the least dollar value per MBF since 1976. This combination provided the lowest gross receipts since 1971. By contrast, the costs for 1982 were due to road construction, brush disposal, and reforestation associated with timber sales over the previous 2-5 years, and represents one of the highest total costs ever at 54.4 million dollars, due to the high level of harvest.

The negative value for 1982 is due to the difference between when the receipts are received and when the costs are incurred for a given sale, and not the result of below cost sales. To this point in time there have been few, if any, timber sales in the Forest that were below-cost.

Some potential exists for certain types of sales to have costs which exceed revenues. As the Forest begins to prescribe harvest of more smaller diameter material either through commercial thinnings or as a result of final harvests under shorter managed rotations, the total value of the timber will tend to decrease given a continuation of current market conditions and price-diameter relationships. Since costs will generally not follow this same trend, some sales may not be economical to harvest.

Another type of sale where total costs could exceed revenues is one that occurs in areas which require special protection for other resource values such as scenery, dispersed recreation, wildlife, and water quality. Numerous constraints on harvesting, including limits on unit sizes, are contained in prescriptions which emphasize multiple-use objectives. These result in higher timber management costs without an increase (and possibly a decrease) in total revenues. The total multiple-use benefits of these types of sales are not reflected in the Forest's cash flow analysis of a timber sale.

To deal with this concern about below-cost timber sales, Congress directed the Forest Service in 1984, to design a new accounting system that would report all costs and benefits of the timber sale program. The Timber Sale Program Information and Reporting System (TSPIRS) was developed and tested, and is now being implemented service-wide. The first official reporting year will be 1989.

The economic effects of the trend towards harvesting smaller diameter material and incurring increased costs for other resource objectives become more important for sales in areas dominated by low value species. On the Willamette, lower values are associated with stands of high elevation species including mountain hemlock, lodgepole pine and the true firs.

Efforts have been made by Forest managers to provide some direction and assurance that future timber sales will be economical from both an efficiency and cash-flow perspective. An example of this is the limitation placed on the minimum average stand diameter available for commercial thinning. A 12-inch diameter provides enough volume to cover the costs of the average sale. Other restrictions based on economic considerations include limiting the number of commercial thinnings for an individual stand and limiting the area that can be commercially thinned based on accessibility.

In addition some areas which are uneconomical to manage for timber production on a cash-flow basis are either dedicated to other uses before the Forest-wide FORPLAN analysis or fall out of solution as uneconomical from a cost-efficiency standpoint. The FORPLAN model will provide the most cost-efficient solution for the specific multiple-use objectives of each Alternative.

Despite efforts to make individual sales return at least as much as they cost, an examination of the total sales program may indicate that receipts did not exceed revenues due to fluctuations which can occur in the demand for timber. While the costs of selling timber may remain relatively constant, revenues for a particular year fluctuate with the amount harvested. This is due to the multi-year nature of timber sales. Figure III-W-18 contains the cost and receipt information for the Willamette.

Table III-W-18. Comparison of Timber Sale Values and Costs

			Values (MM$)			Costs (MM$)				
FY	Volume (MMBF) [1]	$/MBF	Timber Value [2]	Road Value [3]	Gross Receipts [4]	Appro-priated [5]	Allocated [6]	Roads	Total Costs	Net Receipts
1980	554	165	62.0	29.7	91.7	9.2	11.7	29.7	50.6	41.1
1981	471	153	47.7	24.4	72.1	12.1	13.5	24.4	50.0	22.1
1982	370	104	7.7	30.7	38.4	11.7	12.0	30.7	54.4	-16.0
1983	555	108	44.3	15.8	60.1	8.5	8.6	15.8	32.9	27.2
1984	612	107	53.1	12.2	65.3	14.0	11.1	12.2	37.3	28.0
1985	775	100	62.8	15.1	77.9	12.9	13.3	15.1	41.3	36.6
1986	758	95	60.3	12.1	72.4	9.9	15.8	12.1	37.8	34.6
1987	899	123	95.4	15.5	110.9	7.6	12.7	15.5	35.8	75.1
1988	908	155	125.4	14.9	140.3	8.8	14.3	14.9	38.0	102.3
1989	855	196	153.2	14.0	167.2	9.8	23.2	14.0	47.0	120.2
Ave.	676		71.2	18.4	89.7	10.5	13.6	18.4	42.5	47.1

[1]Volume figures include all convertible products harvested.
[2]Value includes all products, Christmas trees, etc. Also includes K-V and BD collections.
[3]Road costs are part of total value and include appropriated road construction, purchaser road construction, engineering, design, and administration.
[4]Gross receipts include timber and road values.
[5]All timber sale costs including program management, sale preparation, administration, stand exams, etc. Does not include road costs.
[6]Includes K-V, brush disposal (BD), salvage sale fund (SSF), and cooperative work (CWFS).

Implementation of the Forest Plan will include monitoring and analysis of the economics of individual timber sales or groups of sales. This will be done to assess the accuracy of planing assumptions and evaluate sale-specific concerns using site-specific economic information. Decisions to harvest and how best to do it will then be made on a sale-by-sale basis considering the differences in important economic and noneconomic factors.

Silvicultural Systems

Silvicultural systems are used to manage forest stands as identified in Agriculture Handbook No. 445. A silvicultural system is a planned sequence of treatments for controlling the species composition and structure of the vegetation during the life of a stand. A stand is a community of trees sufficiently uniform to be distinguishable as a silvicultural or management unit. A stand can be defined as a reasonably homogeneous unit that can be clearly differentiated from surrounding stands by its age, composition, structure, site quality, or geography.

A silvicultural system typically includes cutting trees, growing new trees, and controlling competing plants. Cuttings are classified as regeneration cuttings (those that help to replace stands), and intermediate cuttings (those that maintain or improve the character of existing stands, i.e., thinning harvests). Silvicultural systems are adaptations of natural occurrences. Nature makes "regeneration cuttings" by means of fire, insects, disease, wind, and other phenomena, by removing a single tree, a small group of trees, a stand, or sometimes a whole forest.

Selection of the appropriate silvicultural systems occurs at both the National Forest Land Management Planning level and Ranger District project level by considering the overall planning objectives and ecological characteristics of the Forest. At the Ranger District, project level selection of silvicultural systems is typically made by a certified silviculturist. Choices are based on matching the attributes of the silvicultural systems with specific management objectives and ecological characteristics for specific stands.

The clearcutting, seed-tree, and shelterwood systems are even-aged systems, which means that all of the trees in the stand are approximately the same age. The single-tree and group selection systems are uneven-aged systems because the trees in the stand differ markedly in age, with at least three major age classes present. Uneven-aged stands have no beginning or end points in time.

Even-aged management, with clearcut or shelterwood as the principal regeneration systems, is predominantly implemented on the Forest for the following reasons:

- Even-aged and group selection systems favor plants that can be readily established and which grow well in full sunlight (shade-intolerant plants). Many of our major tree species including Douglas-fir are shade intolerant to various degrees.

- To obtain high timber yields and growth rates, there must be strict control of stocking in regenerated stands. The other option, uneven-aged management, assumes continual replacement of old trees with new. This assumption of prompt regeneration poses a serious difficulty because of sporadic natural regeneration, brush invasion and competition, climatic and economic considerations, and silvicultural characteristics of many common tree species. However, uneven-aged management can be applied where greatly reduced timber yields are acceptable for meeting other important resource objectives (e.g., streamside or visually sensitive areas where maintenance of a forested aspect is important).

- To obtain high timber yields and growth rates, there must be strict control of stocking in regenerated stands. The other option, uneven-aged management, assumes continual replacement of old trees with new. This assumption of prompt regeneration poses a serious difficulty because of sporadic natural regeneration, brush invasion and competition, climatic and economic considerations, and silvicultural characteristics of many common tree species. However, uneven-aged management can be applied where greatly reduced timber yields are acceptable for meeting other important resource objectives (e.g., streamside or visually sensitive areas where maintenance of a forested aspect is important).

- Stand structure is typically poorly balanced in terms of age and size class distribution in our existing stands. The oldest (or largest) trees in any managed forest depend primarily on the management objectives, not on the silvicultural systems. In particular the amounts of large-growth or old-growth to be produced or maintained depend more on cooperatived reductions in yield than on the kinds of silvicultural systems implemented to manage stands.

- The steep topography and rugged terrain found over much of the forest would cause excessive damage to reserve trees during frequent harvest entries. Repeated harvests of the largest trees have often caused undesirable results: understocked residual stands with lower quality, lower value trees.

A full discussion of silvicultural systems and management practices is found in Appendix F.

Tree Improvement

Increasing demand for timber and concern over management costs, indicate a need to produce more volume per acre per year. One method of doing this is to use sound genetic principles to increase growth, improve tree form and wood quality, and increase resistance to disease, insect, and animal pests. The forest is currently planting seedlings from seed collected from superior trees. Seed orchards are being established to further improve the quality of planting stock. Genetic improvement can also be realized through careful selection of trees to be left after precommercial and commercial thinnings as well as overstory trees in areas not clearcut.

Timber Stand Improvement

This refers to cultural treatments that improve the composition, condition or growth of a stand of trees. These treatments include release from brush competition, precommercial thinning and fertilization. Approximately 20% of new plantations require release from brush, 87% require pre-commercial thinning, and fertilizer can be applied to all stands with at least 60% Douglas-fir stocking.

Another form of TSI that has not seen much use in the recent past is pruning limbs to produce high-quality clear wood. However, in the future the Forest Service will be one of the few producers of large trees due to the NFMA requirement that rotation age is at least 95% CMAI (60-120 years). Most other forest landowners are managing on economic rotations of 40-60 years. As the old-growth available for harvest decreases, the demand for clear wood will increase. At the present time, pruning appears to be a neutral investment, but the potential is there for a significant gain in PNV (Mayo 1986). Opportunities will depend on funding and employment considerations.

MINERALS AND ENERGY

The National Forest System by coincidence of geology is a principal storehouse of mineral and energy resources. The search for and production of mineral and energy resources are statutorily authorized uses of the National Forest System, except for those lands formally withdrawn from mineral activities by Act of Congress or by executive authority. The Wilderness Act of 1964 has withdrawn designated Wilderness from all appropriation under the mining laws and minerals leasing acts, subject to valid existing rights.

The Forest encourages, facilitates, and administers the orderly exploration, development, and production of mineral resources to meet present and future needs of the nation integrated with the use, conservation, and protection of other resources.

Mineral activities on the Forest are encouraged in accordance with the national Mining and Mineral Policy Act, and the various applicable Federal and State statutes governing protection of the environment, including air and water quality. The Statutory and regulatory direction separate mineral resources in publicly owned lands of the United States into three categories: locatable, leasable, and salable.

Locatable Minerals

Locatable minerals are those valuable deposits subject to exploration and development under the U.S. General Mining Law of 1872 and its amendments. Commonly, locatables are referred to as "hardrock" minerals, which are naturally-occurring, solid, and usually inorganic compounds. Examples include gold, silver, copper, and zinc.

Citizens, and those who have declared their intent to become citizens, have the statutory right to explore for, claim, and mine mineral deposits on Federal lands including those of the National Forest System subject to 36 CFR 228 and other laws of the United States. Through a Memorandum of Understanding with the Bureau of Land Management (BLM), U.S. Department of the Interior, the Forest Service administers most aspects of U.S. Mining Laws on National Forest System lands. In addition, under the regulations in 36 CFR 228, the Forest Service approves exploration and mining operating plans and administers those operations to ensure protection and reclamation of affected surface resources.

The Forest contains four mining districts: Blue River, Fall Creek, North Santiam, and Quartzville. (See Figure III-X-1 on Mining Districts.) Most of the past and present mining activity is concentrated in the one million to 70 million year old volcanic rocks associated with dioritic and related intrusion. The mineralization occurs in veins which trend northwest and dip steeply. The four districts include the mineralized areas on the Forest which have the highest potential for locatable minerals. Even these areas are small isolated pockets with questionable potential.

Most of the mining activity on the Forest took place from the late 1800s to the early 1900s. During that time, the districts produced over $400,000 in gold, silver, and copper. Recent increases in the price of gold and silver, plus improved mining and metallurgical, techniques have stimulated recreational and commercial interest in the old deposits. An increase in recreational activity has been evident during the summer months and on holiday weekends particularly in the Little North Santiam and Quartzville areas. This may result in more trespasses on areas that have been withdrawn from mineral entry.

Probable future mineral activities include continued prospecting and exploration, and possible development of locatable mineral deposits in the vicinity of the mining districts (drilling, road building, and underground development), and new discoveries outside areas of previous activities. In the more

distant future, the potential exists for development of high grade copper breccia pipes in the North Santiam. The past and estimated future potential for minerals production is shown in Figure III-X-2.

Leasable Minerals And Energy

Leasable minerals include fossil fuels (coal, oil, gas, oil shale, etc.), geothermal resources, potassium, sodium, phosphates, and sulphur. These minerals are subject to exploration and development under leases, permits or licenses granted by the Secretary of the Interior. The controlling statutes currently are the Mineral Lands Leasing Act of 1920 and amendments, the Mineral Leasing Act for Acquired Lands of 1947, and the Geothermal Steam Act of 1970.

The Secretary of the Interior's authority is administered by the Bureau of Land Management (BLM). When National Forest System lands are involved, the BLM requests the Forest Service's recommendation for minerals, other than coal, subject to the 1920 Act, or the Forest Service's consent decisions for minerals subject to the 1947 and 1970 Acts and for all coal deposits. Forest Service recommendations for and consent to the BLM for leasing, permitting or licensing (except for coal) include appropriate stipulations to be included in the issued document for the management of surface resources. The Secretary of the Interior, through the Office of Surface Mining (OSM) for coal, and through the BLM for other minerals, has the authority to administer operations on leased National Forest System lands.

Prior to approval of operating plans, the Forest Service participates with BLM or OSM in the formulation of the site-specific terms and conditions of operating plans, so that the plans provide appropriate mitigation measures to ensure that adverse impact on surface resources will not exceed applicable environmental protection standards. Plans must be designed to minimize the impacts of operations on other uses and surface resources and to provide for prompt reclamation or restoration of affected lands upon abandonment of operations. All such plans and activities shall be an outgrowth of environmental analysis that complies with the National Environmental Policy Act of 1969 (NEPA 1969) procedures.

The Forest is not considered favorable for oil and gas exploration because the Western Cascades are generally composed of nonmarine material of volcanic origin. The High Cascades are characterized by recent volcanic cones, lava flows, and shield volcanoes which would indicate a low potential for oil and gas. In the 1970s there was a surge in lease applications after natural gas was discovered near Mist in the Coast Range. The Forest had about 200,000 acres in lease applications of which most have been terminated due to lack of payment or withdrawn due to cost of exploration and stipulations imposed to protect the resources. These measures reduced chances of recovering investments for the companies.

The Forest contains numerous hot springs and other indicators (such as areas with high heat flow) of geothermal systems at depth. Three hot spring areas, Breitenbush, Belknap-Foley, and McCredie-Kitson are classified as Known Geothermal Resource Areas (KGRAs) by the U.S. Geological Survey.

The Oregon Department of Geology and Mineral Industries identifies additional areas that merit further geothermal exploration the Forest; they include the upper McKenzie River, Horse Creek, and Willamette Pass (Priest and Vogt 1982). The target areas are characterized by high heat flow and are located adjacent to faults where the potential for fracture permeability is high.

There has been considerable interest in geothermal leasing on the Forest. During 1980 and 1981 private companies drilled over 55 exploratory temperature gradient holes and one 9,000-foot test well. Although no discoveries have been made to date, geothermal exploration in the area continues. The location of an energy source may lead to some potential for development on the Forest.

Figure III-X-1.

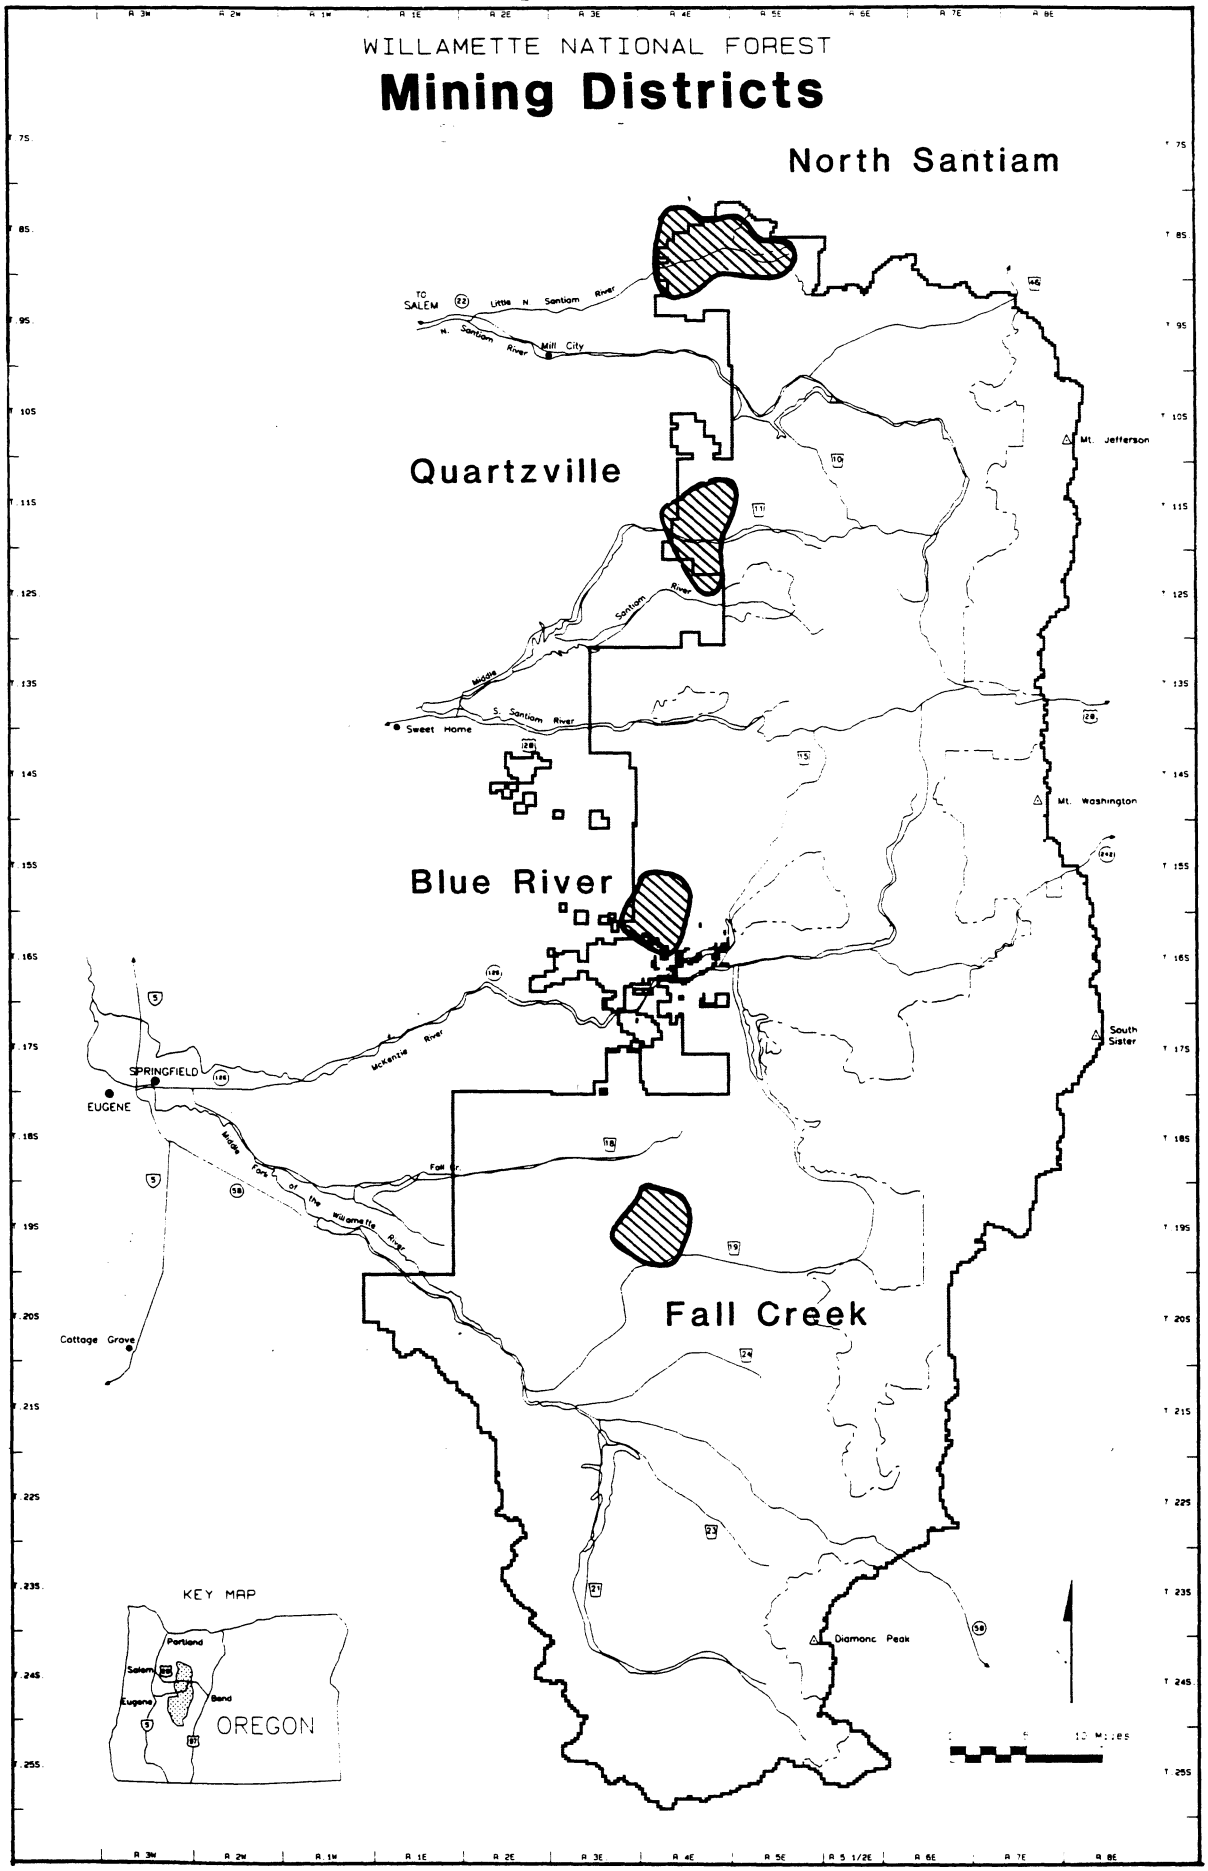

Table III-X-2. Minerals Production

District	Ore Extracted [1]	Minerals	Future Potential
North Santiam	$25,000	Gold, silver, copper, zinc, lead	Active exploration by major company. Medium potentia for gold, copper, gold, and silver.
Quartzville	$181,255	Gold, silver	Minor prospecting, Low potential for copper, gold, and silver.
Fall Creek	Unrecorded	Gold	Limited present activity. Low to medium potential for gold & silver.
Blue River	$200,000	Gold, silver	Limited present activity. Low potential for gold, silver, & copper.

[1] Dollar values at time of production, 1890-1940, from Gold and Silver in Oregon by DOGAMI.

Demand for leasable energy resources has dropped significantly in the years since the initial "energy crisis" of 1973 to 1974. The Northwest Power Planning Council projects an energy surplus for the Pacific Northwest until the 1990s. Thus, in the near term, it seems unlikely that any large-scale energy production or development will occur on the Forest. However, as industry looks to the long term and the development of alternate energy sources, activities associated with identifying potential supplies on the Forest are expected to increase.

Salable Minerals (Common Varieties)

A Federal Mining Statute known as the Act of July 23, 1955, removed common varieties of sand, stone, gravel, pumice, pumicite, cinders, and clay from the category of locatable minerals. The Act placed the common varieties under the Materials Act of 1947. This 1947 Act authorizes disposal of materials, including, but not limited to the above common varieties, on public lands through a sales system.

The use of common variety minerals is mostly for Forest road construction and maintenance in the form of gravel. The High Cascades provide a suitable inventory of good rock sources due to the fairly young nature of the rock. The Western Cascades provide some rock sources but not as many.

Rock sources are located within centralized areas of road development so cost of hauling rock is lowered. There are about 170 active rock sources. Traveling on a road where rock is being hauled can be hazardous where recreation and timber operations may conflict with gravel trucks.

The existing and potential supply of gravel is expected to be adequate to meet anticipated needs until the year 2000. As the inventory is completed, a better estimate will be possible. Demand for small mineral sales (common variety) will continue at about the same or slightly increased rate.

Gemstone sources are quite limited and those known are used by the recreation visitor or "rock hound." Jasper and agate are the principal stones to be found. One source of petrified wood, which is not classed as a gem stone has been located. Several sources of emery stone have been located and prospected to some extent, but have proven uneconomical to work.

Mineral Withdrawals

The Forest's early efforts in withdrawing lands from mineral location involved administrative sites at various locations across the Forest. More recent requests have involved special areas such as roadside zones, the H.J. Andrews Experimental Forest, and some recreation areas. Other withdrawals involved hydroelectric power development and flood control sites. These were quite extensive, covering most of the major streams on the Forest. In the early 1970s these withdrawals represented about 75% of the total area of the Forest where mineral entry on the land was prohibited. Now this has declined to about 40%. Much of this change is the result of reopening Federal Power Commission licensed sites. In accordance with the Wilderness Act, as of December 31, 1983, designated Wilderness became withdrawn from appropriation under the mining and mineral leasing laws, subject to valid existing rights.

As of 1985 there are 447,958 acres where mineral entry is prohibited by specific withdrawal authority. In addition, there are about 90,916 acres covered under special uses, power applications, and power sites where mineral entry is restricted. The USDA Forest Service has authority over 26 withdrawals, which are included in the above acreage figure.

The Forest must review all 26 withdrawals over which it has authority. The review will determine if the withdrawal is to be continued, revoked, or modified. This must be completed by 1990 as required by the Federal Land Policy and Management Act of 1976. The Forest is not responsible for withdrawals that were initiated by other agencies such as the Federal Power Commission or the Army Corps of Engineers.

There will continue to be lands withdrawn in the future. The Forest will make additional requests for withdrawal of lands where natural ecosystems are to be protected or where mining activities are not compatible with land management objectives. However, revocation of withdrawals may be requested where protection is no longer needed.

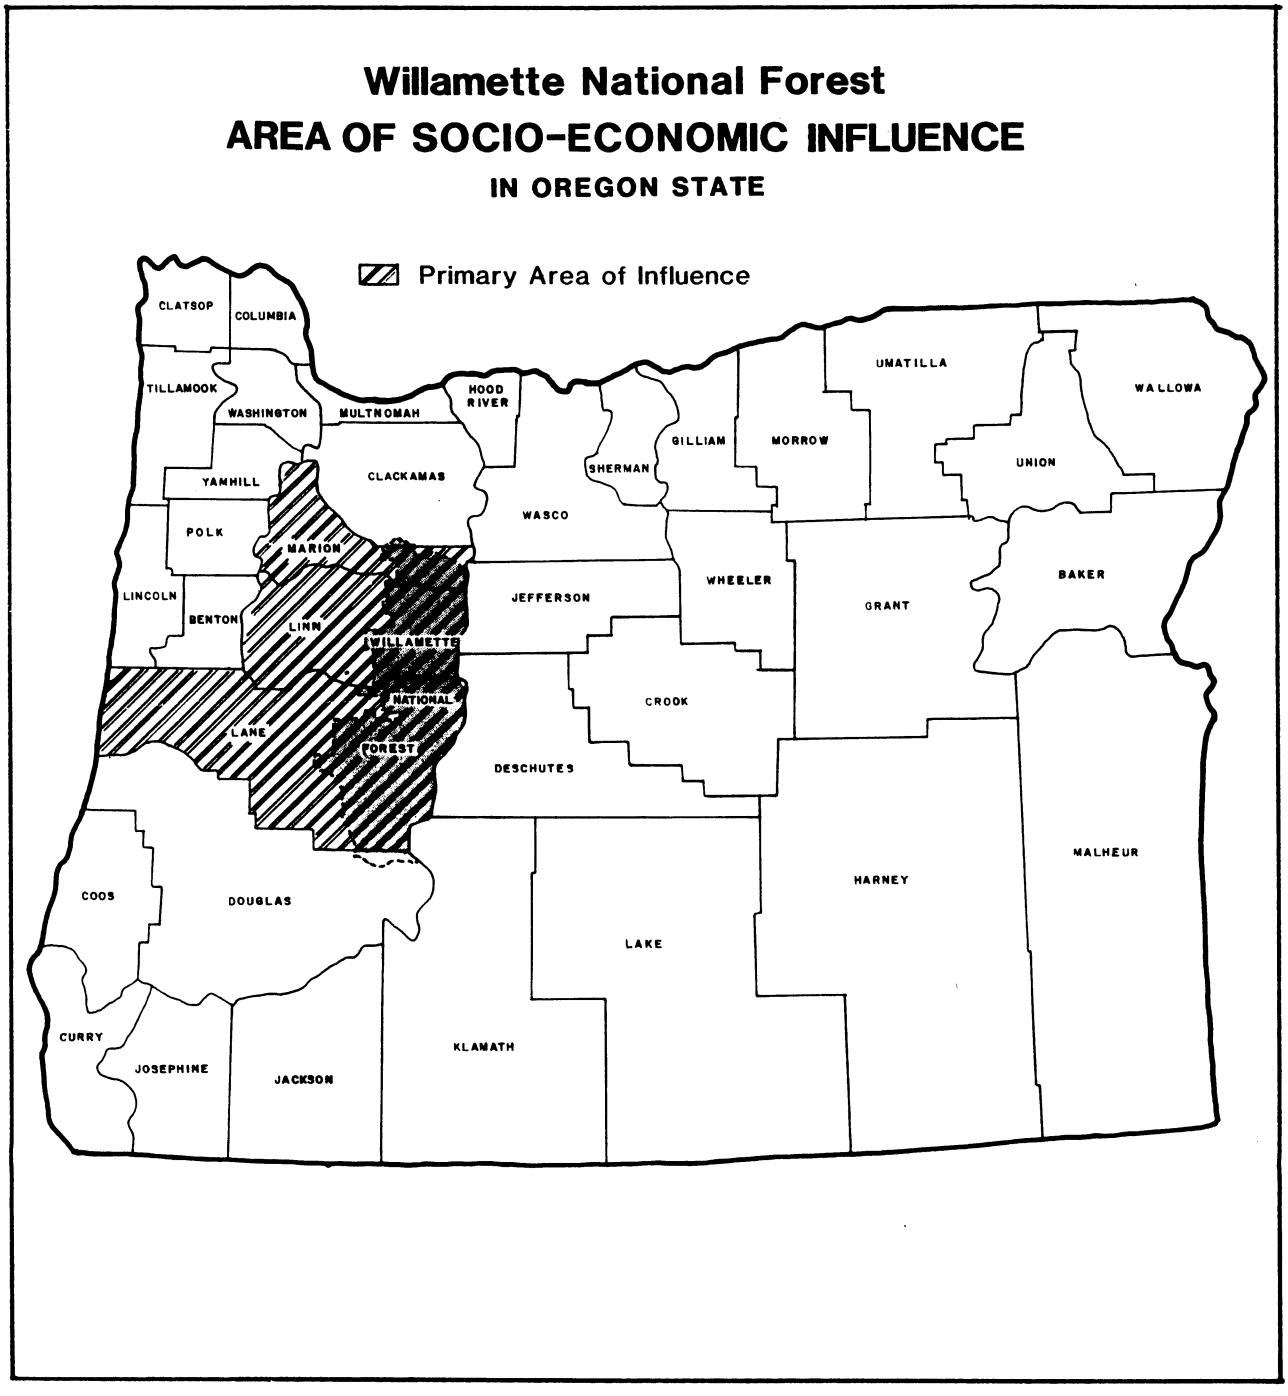
SOCIAL AND ECONOMIC ENVIRONMENT

Introduction

Forest planning focuses on resource-related issues and assesses the environmental, social, and economic impacts of alternative management choices. To make this assessment, the various components of the environment which are affected must be identified. This section of Chapter III describes the social and economic environment which is affected by management of the Forest. Some of the information presented here is a summary of a more comprehensive document on the subject which was prepared for the Forest by Linda Peterson in 1983. That document, *Socio-Economic Overview of the Forest's Area of Influence*, is on file as part of the Forest's planning records.

The Forest is located on the western slopes of Oregon's Cascade Range, within a two-hour drive of Oregon's major population centers in the Willamette Valley. It lies primarily in Lane, Linn, and Marion counties, but also extends south into Douglas County, east into Jefferson County, and north into Clackamas County. (See Figure III-Y-1.)

The Forest's resources play an important social and economic role in these and other Oregon counties as well as in the Pacific Northwest and the Nation. The goods, services, and uses available from or on the Forest represent major components in the lives of many people who live adjacent to or near the Forest.



Many local communities rely on the employment and income generated from the use of Forest resources. A measure of stability is derived from a continuous supply of timber being available for harvest from the Forest, even though supply is not the only determinant of stable markets. Income and employment are also derived from people traveling through communities on their way to use the Forest for recreation and other purposes. An awareness of tourism's importance as a source of future economic and social activity for communities in and adjacent to the Willamette Valley is growing.

In addition to economic activity, the quality of people's lives is greatly enhanced by the physical environment associated with the Forest. A diversity of topography, vegetation, wildlife, and other resources opportunities provide for a variety of quality recreation experiences; and the many scenic and other attractions provide an attractive place to live and work.

All of these goods, services, and uses have value to the people who live in the area. Changes in the quantity or quality of these attributes affect their lives. With a limited resource base and increasing demands from a growing population, conflicts or issues related to the relative values of different goods, services, or uses are bound to arise.

A look at current and expected future conditions in areas influenced by the Forest will be useful to project possible changes in the socio-economic sectors as a result of implementation of any of the Forest Plan alternatives.

Figure III-Y-1. Area of Socioeconomic Influence

Area Of Influence

The area or zone of Forest influence was established by identifying the users of the Forest's resources. The major resources of the Forest include recreation opportunities, fish and wildlife, timber, and water. Each resource is used, processed, or consumed by different, though overlapping, segments of the population located in varying proximity to the Forest. The influence area for this analysis is defined by county boundaries and has been separated into a primary influence area and a secondary influence area.

The primary area of influence includes the counties of Lane, Linn, and Marion in Western Oregon. Each of the three counties contains portions of the Forest. Industries in the primary counties tend to process the bulk of the Willamette National Forest's timber and mineral resources, while also supplying the majority of the recreation users to the Forest. In addition, the counties receive millions of dollars of Federal timber receipts on a yearly basis, depending on the timber harvest volume and bid price for the timber (see the later section on payments to the counties).

A secondary area of influence includes four Western Oregon counties--Benton, Polk, Yamhill, and Douglas and one county in Central Oregon, Deschutes. Douglas and Deschutes counties border the Forest, while the other secondary counties are nearby and border the three primary counties. Although the five secondary counties tend not to share the same resource or recreation uses on or from the Forest, they receive or process some timber and mineral resources and provide some recreation users.

There are other counties and states that are marginally influenced by the management of the Forest. This is apparent in terms of recreation visitors and indirectly through the use of lumber products. The many lakes on the Forest, the migrating Chinook salmon and steelhead that spawn on the Forest streams, as well as the pristine Wildernesses, draw thousands of persons from the western states and other counties. However, the measurable influence that the Forest management alternatives have on these distant persons, counties, states, or nations is almost impossible to calculate.

Social Environment

Historic Trends

Western Oregon has a rich and varied history that was shaped by the people who moved to the area and the natural resources that were readily available. Predominant in the economic development of the Western Oregon region have been agriculture, mining, forestry, and later recreation. Initially, in the 1830s and 1840s agriculture was subsistence oriented. As the settlement base increased, the diversity of agricultural products also increased as cattle, sheep, wheat, corn, and garden vegetables were introduced in the 1850s. Through time, agriculture expanded its base with new varieties of herd animals, wheat and grains, fruits, nuts, and more recently, horticultural specialty crops.

Mining has periodically contributed to the economy of the area. It is one of the least documented activities and probably occurred on a larger scale than has actually been reported. The Blue River, North Santiam, Fall Creek, and Quartzville Mining Districts are located within the Forest boundaries. Today, they remain as some of the most important mining areas in the Western Cascades, although present activities are of a very small scale.

The timber industry has been of paramount importance in the economy of the Willamette's area of influence. On a noncommercial basis, the native trees were utilized by the early trappers, miners, and settlers for shelter and heating. In addition, the settlers removed many of the trees from their homesteads

so that agricultural products could be grown in the fertile soils. By the early 1850s small sawmills were scattered throughout the area and the commercial effort became somewhat profitable. Many townsites were established near the mills and transportation systems. New technology evolved from simple whipsaw operations to more sophisticated steam powered mills. By the early 1900s the lumber industry began to develop a substantial market outside the area, relying on the Southern Pacific railroad system for transportation of lumber products. Today, the timber base is very strong, with centralization, computer technology, and an integrated trucking system assisting the industry.

Transportation systems proved to be important to the development and continued survival of the local communities. The mid-1870s brought the Oregon and California (O&C) Railroad, which boosted the economic potential of the area. The railroad linked the region to new market areas. The Southern Pacific Railroad, which purchased the Oregon and California Railroad, provided some stimulus to help draw emigrants, through the selling of their Federal railroad grant lands. Yet many of the unsold lands were returned to Federal ownership in 1916 as the railroad company did not comply with the terms of the land grant. Administration of these lands became the responsibility of the General Land Office (later called the USDI Bureau of Land Management) and the USDA Forest Service. The O&C land payments which comprise 50% of the gross receipts (constrasted to 25% of standard natural Forest lands), in lieu of taxes, contribute to the economic base for the counties in the Willamette's area of influence.

The highway system in the region developed slowly. Prior to 1920 it relied on numerous local farm roads and a few county funded roads. By the mid-1920s, the State of Oregon began to fund a modern highway system, enabling the construction and paving of the Pacific Highway (U.S. 99), which connects the major population centers of Western Oregon together. In addition, several old wagon roads and toll roads over the Cascade Range were reconstructed in the 1920s and 1930s to an improved standard, with modern widening and paving occurring in the 1950s and 1960s. The latest highway improvement has been the construction of Interstate 5 during the 1960s. The all weather I-5 north-south corridor is the major transportation route, commercial zone, and recreational access for Western Oregon. It also links Oregon to markets and people in California and Washington.

Recreation is another component to the area's economy which has gradually expanded. Initially hot springs, hunting, fishing, and camping were the principle Forest attractions to residents and tourists. By the 1920s remote hot springs and resorts, as well as the high mountain lakes, attracted venturesome tourist expeditions. During the 1930s federal and state actions, often assisted by the Civilian Conservation Corps enrollees, enhanced the recreation potential by establishing numerous campground facilities through Western Oregon, especially along the state roads that cross the Forest. After World War II came the surge of recreation users for hunting, fishing, camping, boating, and many other recreational pursuits. In the last two decades, new recreational interests have expanded into such areas as backpacking, rock climbing, downhill and cross-country skiing, photography, river boating, rafting, and many other outdoor pursuits. As populations grow, so will the need for more recreational opportunities.

The vast timber resources of the Forest were barely tapped until World War II ended, when full scale development of a Forest road system allowed a vastly increased use of the Forest. The highest point of Western Oregon's timber industry was in the 1950s for both production and total employment. Since that time, the production levels have lowered, and the employment has been reduced.

Over 150 years of population growth and natural resource development in Western Oregon have helped to shape the people of the area. The zone of influence is still substantially dependent on natural resource related industries and employment. The three counties (Lane, Linn, and Marion) rely on timber receipts, agriculture, and recreation for a good portion of their income. Much of the recent change in employment

in Western Oregon has been towards secondary or service related jobs and in the future fewer jobs will be directly tied to natural resource production. The ease of transportation and increased leisure time, especially to the metropolitan cities of Western Oregon, has increased the recreation use on the Forest. It is expected that in the future even more persons will take advantage of the living conditions and recreational and job opportunities in the area. The physical attributes which enhance the quality of life for the people living and working near the Forest are also expected to help attract other industries to the area as local economies continue to diversify.

Population

The population in the Forest area of influence is comprised of rapidly growing county seats, smaller communities adjacent to main transportation routes, and rural families and farms. The inhabitants of this zone (see Figure III-Y-2) comprise almost 34% of the state total (1980 census), with most of the concentration around the metropolitan areas of Eugene-Springfield and Salem. There are several small cities within the external National Forest boundary including Oakridge, Westfir, McKenzie Bridge, Detroit, and Idanha.

The prospects for employment and an outstanding natural setting have led to a population growth of over 65% in the Willamette Valley in the last 20 years. This tremendous growth has occurred whether national and state economies have been strong or weak. The population in the State of Oregon has been increasing every decade, with the largest percent increase between 1900 and 1910, when there was a 62.7% rise. The years from 1940 to 1950 showed a rise of 39.6%. The next fastest growth period was from 1970 to 1980 when a spurt of 25.9% was recorded. Urban areas within the state grew at a faster rate during 1970 and 1980 than the rural areas, yet much of the urban growth was in cities with less than 25,000 population. There are no indications that this continued upward trend in the state will reverse despite the small declines in population growth during the early 1980s.

Within the Forest's primary zone of influence, the growth of county populations has taken a similar upward trend. All three counties grew at a rate higher than the state. The lowest change of population from 1970 to 1980 was in Linn County with 24.5% growth, while Lane County grew 27.8%, and Marion County gained 35.3%. The average change for the primary zone was more than 3% above the Oregon average for the same period. During the 1980s population in Lane County dropped in the 1980-1988 period only reaching above the 1980 census during 1988-1989. Linn County dropped below the 1980-census only in 1981 and 1982 and rose above in 1983, a trend which continues. Marion County, on the other hand, never dropped below their 1980 population, gaining almost 20,000 persons in the 9-year period.

In the secondary zone of influence all five counties are above the state growth rate with Deschutes County considerably above. Benton and Polk counties were just above the state average, Yamhill and Douglas counties were higher, with Deschutes County more than four times the state average for growth. The secondary area has about 60% of the population of the three primary counties.

Table III-Y-2. County Populations - Trends and Projections

	PRIMARY ZONE							
	Actual Population [1]			Projected Population [2]				
County	1960	1970	1980	1990	2000	2010	2020	2030
Lane	162,890	215,226	275,226	292,000	334,200	376,500	424,300	478,000
Linn	58,867	71,914	89,495	96,900	109,500	123,400	139,000	156,600
Marion	120,888	151,309	204,692	228,300	267,700	310,600	339,800	382,900

TOTALS	189,724	231,523	324,636	360,400	432,100	486,800	548,500	618,000

[1] Census data from the decade Federal Census for each decade.
[2] The 1990 and 2000 projections are based on the Center for Population and Census estimated population increase for the years 1980-2000 (Center for Population Research and Census, 1984). Projections for beyond the year 2000 were calculated with an average percentage increase of 1.2 percent per year, using the average Bonneville Power Administration population projections for the primary counties (Bonneville Power Administration, 1979).

Current Population

Population in the Forest's primary zone of influence was last estimated in 1989, by the Center for Population Research & Census at Portland State University, to be 594,000 persons or 21% of the State of Oregon total of 2,791,000 persons. Lane County, which has the largest population of the primary counties, has an adjusted estimate of 280,000 persons or 10% of the total in the state. Marion County has about 224,000 persons or 8% of the state. Linn County contributes the smallest proportion with 90,000 persons or 3% of the state population. These official estimates compare favorably with the 1980 census where the three counties comprised 21% of the total state population.

The Forest's secondary zone of influence has about one-half of the population of the primary zone. The five counties of Benton, Deschutes, Douglas, Polk, and Yamhill contribute 345,100 persons or 12.4% of Oregon's population.

Overall, the total Forest zone of influence contains an estimated 939,100 persons or almost 34% of the Oregon population. Two-thirds of these people reside in the primary zone, while the remainder live in the secondary zone. The state of Oregon has about 2.8 million persons, most of whom are concentrated in the large urban areas of the Willamette Valley. Eugene-Springfield and Salem, the

largest cities in the zone of influence, are termed Metropolitan Statistical Areas (MSA), which means that they are eligible for higher funding and special economic programs as defined by the Office of Management and Budget. Salem, in Benton County, is also the state capital.

Population Projections

Based on studies completed in the mid- to late 1970s, (the most recent population projection estimates), the population of Oregon is expected to increase by 250,000 by 1990, 420,000 more by 2000, 418,000 increase by 2010, and 531,000 additional people by 2030. Approximately two-thirds of these new people will find homes and employment in the Willamette Valley. The Forest's primary zone of influence is projected to grow at a slower annual rate than at present (see Figure III-Y-2). Despite the slower rate, Lane County should expect a large increase in population. The secondary zone will experience similar growth patterns, but the total increase will be much smaller. Deschutes County will be the exception, where the population could dramatically increase if the current trends continue.

Overall, the relative population increases in the zone of influence will have a real impact on the Forest. More people means a greater demand for outdoor recreation, forest products, and a higher density of automobiles on the forest road system. As the year 2030 is less than 50 years away, the Forest needs to effectively plan for a steady increase in demand by Forest users. In addition, these people will need employment opportunities, which the Forest will indirectly impact. The larger quantity and greater concentration of people will express more concerns and place more demands on the Forest to provide clean water, air, and recreation, as well as protection of soils and enhancement of visual resource conditions.

Minorities

The last federal census in 1980 (the 1990 census not available until 1991 or 1992) indicated that minority composition within the Forest's primary zone of influence was over 24,000 persons (see Figures III-Y-3 and III-Y-4). This was smaller (4% of total population) than the state percentage (7.9%). Marion County had more minority persons than the other primary counties, with 11,342 members (5.5%), while Lane County had 10,636 persons (3.8%), and Linn County had the least with 2,199 minority persons (2.4%). Lane County had more Black Americans (1,618) followed by Marion County (1,258), and Linn County (135). All three counties had different proportions of Native Americans, averaging about 1%. Both Lane and Marion counties had relatively the same proportions (1%) of people claiming Asian descent, while Linn only had one-half as many as either county. Marion County had a higher percentage (4.7%) of persons of Hispanic origin, who can be of any minority group, with Lane about 2.0% and Linn with about 1.8%.

The secondary zone of influence also had relatively low numbers of minority persons (3.6%) which was almost 2% lower than the state averate. Benton County had the largest proportion of minority people with 5.1%, followed by Polk County with 4.5%, Yamhill at 4.1%, Douglas with 2.5%, and Deschutes County at 1.8%. The minority category with the greatest number of persons was Other, which does not include Hispanic origin or white (4,433), followed by Asian (3,054), American Indian (2,854), and Black (909). The percentage of people claiming Hispanic origin in the secondary counties averages 2.4%, just under the state average of 2.5%. Polk and Yamhill counties contained the highest percentage of Hispanic origin people (around 3.4%), while the other three counties averaged 1.8%.

Native Americans

Lane County had the largest number of Native Americans (2,382), with Marion County following closely with 1,923 persons claiming American Indian descent (see Figure III-Y-4). Linn County had about one-half that amount, while the other secondary counties, except Douglas, had even less. Douglas

County, with 1,093 American Indians, has two Native American tribes; the Cow Creek Band of Umpqua Indians, recognized in 1982; and the newly recognized Confederated Tribes of Coos, Lower Umpqua, and Siuslaw Indians, recognized in 1984. Deschutes County contains portions of the Confederated Tribes of the Warm Springs Indian Reservation.

Over 55% of American Indians in Lane County resided in the urbanized areas of Eugene-Springfield, with another 7% reported living the cities of Cottage Grove, Junction City, and Oakridge. The remaining live in smaller communities and in rural areas. In Marion County, only about 3% live in the Silverton, Stayton, and Woodburn areas, but many more live in the suburban areas around Salem. For the American Indians in Linn County, about 60% live in the Albany, Lebanon, and Sweet Home areas.

The Warm Springs Confederated Tribe is the only federally recognized Native American group that have traditional ties in the Forest. The Confederated Tribe resides on the Warm Springs Indian Reservation in Central Oregon. The western boundary of the reservation is, in part, the eastern boundary of the Forest along the crest of the Cascade Range. The tribe has traditionally used the high alpine areas on the Forest for centuries.

ECONOMIC ENVIRONMENT

Oregon Economy

Gross Product Value - Oregon has historically been dependent on its manufacturing sector as an economic base. Although the State's economy is gradually becoming more diversified industries based on production still dominate with a gross product value of 10.92 billion. Despite the 1981-1982 recession, the lumber and wood products industry is still the largest component of the manufacturing sector with a 1986 gross product value of 2.49 billion. Gross product value (or gross state product) is the value of the final output of all goods and services produced. Other major groupings and their 1986 gross product values are: producer services - 9.54 billion; distributive - 9.17 billion; government - 5.04 billion; social services - 2.85 billion; personal services - 2.08 billion; and extractive - 1.69 billion.

Oregon has traditionally depended on its natural resources as a major source of employment, income, and wealth; however, this industry has declined and is likely to continue to decline over the next decade. The gross product value of the lumber and wood products industry peaked at 2.98 billion in 1979. The national recession caused three years of decline to a low of 1.77 billion in 1982. The gross product value began rising again when the recovery started in 1983 but has not continued a steady growth.

Producer and social service sectors are the fastest growing in the state. Social services has more than doubled from 1.16 billion in 1977 to 2.85 billion in 1986. Producer services replaced at a similar rate of increase from 3.92 billion in 1977 to 9.54 billion in 1986. The transformative category including manufacturing, construction and utilities had the slowest growth of only 49% in the last decade. These figures point towards an economy shifting from a manufacturing base to a service-oriented economy.

The gross product value of the distributive category steadily increased during the last decade experiencing only a small decline during the recession. Overall this category experienced a 90% growth and is now the third largest industry in the state.

The extractive classification which is predominately agriculture is the smallest industry in terms of gross cash receipts. The total value of agricultural production has increased steadily during the 1980s. Values for 1982 through 1983 were lower than the $1.47 billion of 1980 because of lower commodity prices for many crops.

Much of the income associated with agriculture goes to purchases in other industrial sectors (e.g., farm machinery) rather than to labor. Employment in agriculture has been declining due to mechanization and the switch to less labor-intensive crops.

While agriculture is very important to the economy of the sparsely populated east side of the State, the most economically significant area in the State is the agriculturally diversified Willamette Valley. It produced about 40% of Oregon's agricultural product cash income in 1982. In 1984, Marion, Linn, and Lane counties ranked first, seventh, and tenth, respectively, in gross farm sales for Oregon counties. These three counties had $350 million in sales or about 20% of the state total.

The recession of the early 1980s either slowed or reversed established growth trends for many of the state's major industries. The sustained recovery that the nation has been experiencing since 1983 is reversing this decline. Figure III-Y-5 displays recent trends in gross product value for major industries of the state.

Table III-Y-5. Oregon Gross Product Value [1]

Year	Lumber and Wood Products [2]	Tourism and Travel [3]	Farming and Food Processing	Transportation	Construction	High Technology [4]
1983	2.88	1.56	1.97	1.33	1.08	1.39
1982	2.30	1.41	1.87	1.22	1.07	1.42
1981	2.54	1.27	1.89	1.24	1.31	1.39
1980	2.90	0.84	1.93	1.21	1.59	1.27
1979	3.22	0.79	1.61	1.12	1.65	1.07
1978	2.97	0.73	1.38	1.01	1.41	0.88
1977	2.57	0.51	1.09	0.89	1.15	0.70
1976	2.20	0.44	1.15	0.78	0.93	0.55
1975	1.71	0.50	1.14	0.67	0.80	0.48
1970	1.15	0.27	0.64	0.45	0.46	0.28
1965	0.86	0.18	0.48	0.36	0.40	0.16
1960	0.63	0.15	0.45	0.26	0.26	0.09

Oregon: A Statistical Profile, Oregon Economic Development Department, April, 1985.

[1]Billions of Current Dollars
[2]Includes paper and allied products.
[3]Includes out-of-state vacationers only. Other travelers not included.
[4]Includes Machinery, Electrical equipment and instruments. Not all machinery is in the high technology industries but is included here.

Employment - The gradual diversification of Oregon's economy is the result of two major shifts which are best seen through trends in the state's employment. The first is a change within the manufacturing sector. The lumber and wood products industry no longer dominates manufacturing employment to the extent it once did.

Despite high harvest levels in 1985, employment in the wood products industry declined. Increased productivity, automation, and a desire to reduce costs is in part an explanation to a trend that began two decades ago and accelerated during the recession.

Technological advances towards automation have significantly reduced the amount of labor required to process given amounts of timber. In sawmills and planing mills, it took about eight employees to

process a million board feet of timber in 1950. By 1979, only 4.5 employees were needed to process the same amount and in 1984 this was down to 3.4 employees.

In addition to technological advances substantial reductions in employment occurred during the recession as many older and less cost efficient mills closed. From 1980 to 1985 approximately 60 mills have closed in Oregon and have not reopened.

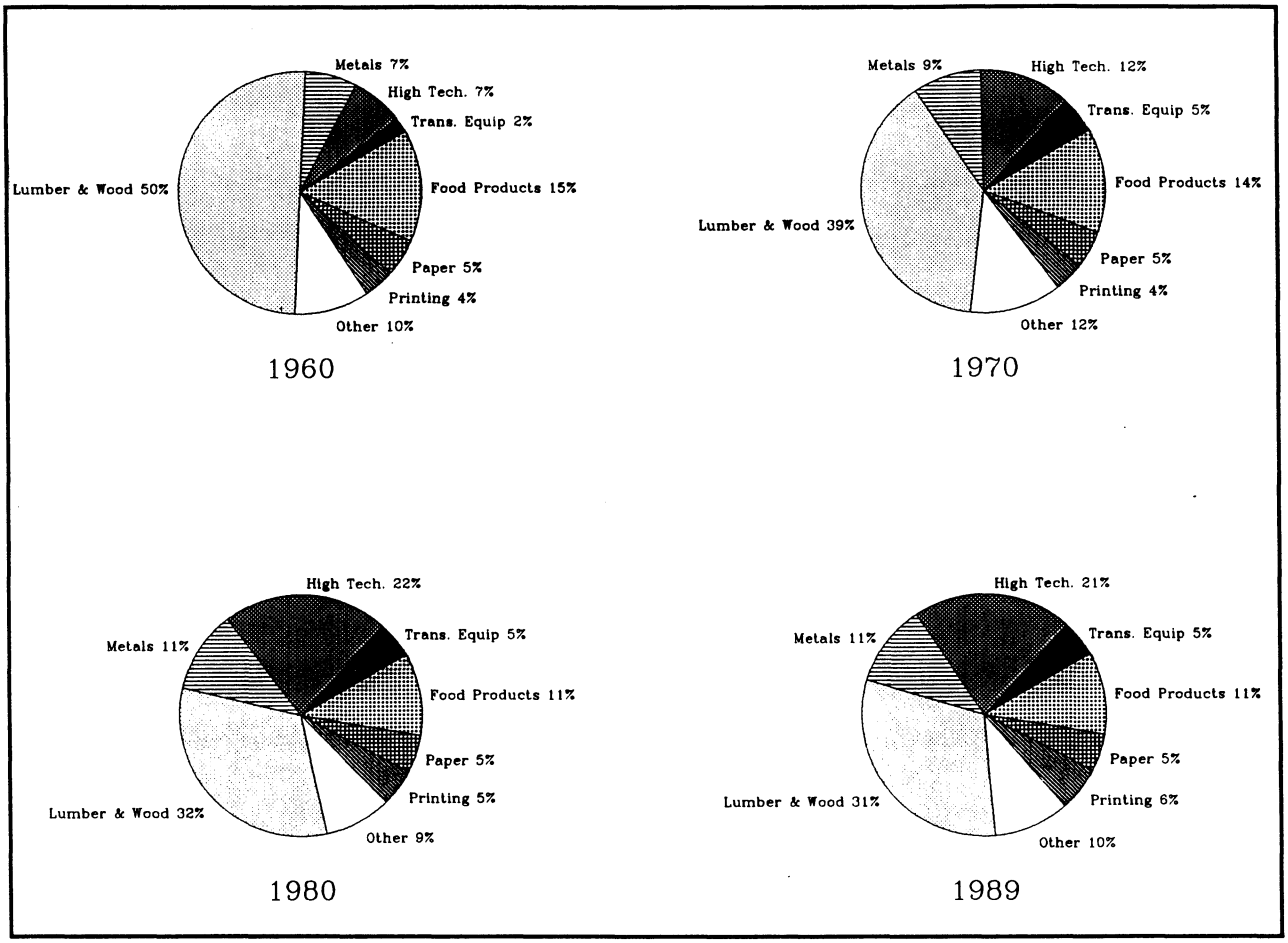
Over 16,000 timber industry jobs have been lost as a result of these changes. Despite having fewer mills with fewer workers, almost as much wood was processed in Oregon in 1985 as in the peak year of 1979. This indicates that most, if not all, of these jobs will never be recovered.

Other manufacturing industries have increased in importance as the timber industry has declined. Employment in high technology and metals increased dramatically in the 1960s and 1970s. The combined employment of these industries exceeded that of the lumber and wood products industry in 1989.

The growth and diversification in the manufacturing sector has not been uniform across the state. Much of it has been occurring in the Portland metropolitan counties. The rest of the state remains heavily dependent on wood products for its manufacturing employment. Figure III-Y-6 shows the percent distribution of state employment for major manufacturing sectors.

The second major change occurring in the Oregon economy is the shift from a manufacturing based economy to a nonmanufacturing or service-oriented economy. The nonmanufacturing component of nonagricultural employment has risen rapidly and been affected less by recessions than manufacturing employment. Between 1970 and 1980 manufacturing employment increased by about 25% compared to 60% for nonmanufacturing. This trend continued from 1980 to 1989 with manufacturing employment increasing by only 1% as compared to a 24% increase in nonmanufacturing. Figure III-Y-7 shows employment and percent of total for major sectors of the state's economy since 1960.

Figure III-Y-6. Oregon Manufacturing Employment



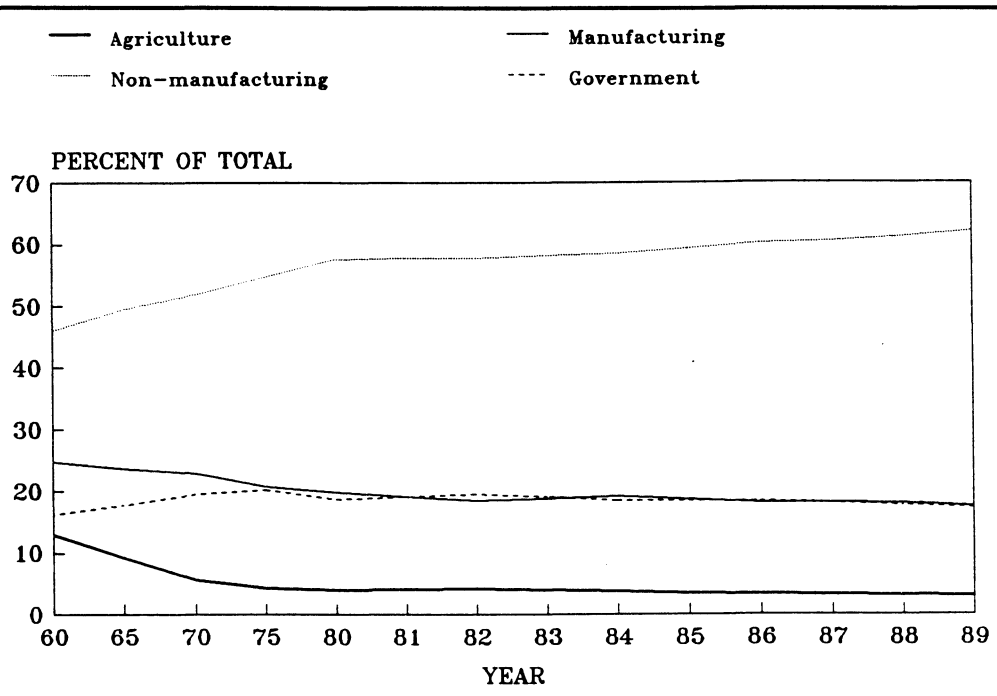


Table III-Y-7. Oregon Employment by Major Sector [1]

Economy of the Primary Area of Influence

Overview - The industries which are important to the State of Oregon are also important to the three counties which represent the Forest's primary area of influence. The impact the Forest has on the health and stability of these industries, however, varies considerably.

All three counties have a significant part of their manufacturing-based labor force in the lumber and wood products industry. Lane, Linn, and Marion county mills processed about 826 million board feet of timber from the national forest land or about 27% of the state's total in 1985. Over 75% of this was harvested from the Forest; consequently, changes in the amount of timber offered for sale by the Forest can affect a large number of people.

The direct effects are felt primarily in communities with lumber and wood products companies. Indirect effects are felt in other sectors over a much wider area. Employment and income in the service, trade, transportation, and other sectors throughout Western Oregon are linked to the lumber and wood products industry. Moderate-to-large changes in timber sale levels by the Willamette will affect these industries.

Other major industries are indirectly affected by changes in Forest management. The agriculture and food processing industries are very important to Lane, Linn, and Marion counties. Management of the Forest, however, has little effect on these industries. Demand for domestic livestock forage from the Forest is expected to remain virtually nonexistent, even though the Forest has some good grazing potential. Commercial fisheries are affected somewhat by changes to fish habitat on the Forest, but these effects occur in the counties along the Lower Columbia River and not in the primary area of influence. Thus, despite being very important to the overall economy in the three-county area, employment and income in the agriculture and food processing industries is not directly affected by changes in Forest management.

Tourism is another major industry in the primary area of influence. Recreation-related trade and services are important to the smaller towns within or adjacent to Forest boundaries as well as to the larger cities in the southern and central Willamette Valley. The Forest provides many of the recreation opportunities that support the industry in this area.

Tourism is an "industry" in the sense that it is a reason for economic activity to occur. The employment and income associated with or dependent on tourism and recreation is rather difficult to estimate. Unlike individual economic sectors such as lumber and wood products, tourism is composed of a broad spectrum of other industries. These include durable (e.g., recreation equipment) and nondurable (e.g., food products) manufacturing, wholesale and retail trade, transportation, and services. Historical information related to the many pieces of sectoral economic activity associated with tourism is generally not available. Thus, the discussion and data on employment and income in the three-county area will not deal directly with tourism as a separate or unique industry.

Employment - *Lane County* - Lane County is the largest county in the primary area of influence in terms of population and employment. It is the leading producer of lumber and wood products in Oregon. In 1985, its mills processed over 527 million board feet from the national forest land or 16% of the State's total. About 421 million board feet or 81% of this was harvested on the Willamette.

The structural changes occurring in the State's economy are also occurring in the economy of Lane County. A changing manufacturing base and a shift towards a more service-oriented economy are resulting in a gradual diversification in a county long dependent on the lumber and wood products industry.

Lumber and wood products employment in Lane County represented about 10% of the total nonagricultural wage and salary employment and about 53% of manufacturing employment in 1989. In 1972 these figures were about 20 and 74%, respectively.

This decline began before the 1981-1982 recession and reflects increased productivity per worker due to improvements in technology. Between 1972 and 1979 about 900 timber industry jobs were lost. The recession accelerated this job loss with about 3,800 jobs being lost between 1979 and 1982. As the economy improved over the next two years about 1,200 jobs were regained; however, pre-recession employment levels in this industry are not expected to return.

The most significant employment increases between 1980 and 1989 were in the service and trade sectors. Employment in services increased by 7,600 from 19,700 in 1980 to 27,300 in 1989. Trade employment experienced an increase of 3,400 jobs from 25,700 to 29,100 during this same period.

In the manufacturing sector employment in the nonlumber component increased by about 56% or about 1,900 jobs from 1980 to 1989. This reflects the slow diversification of the manufacturing sector. Figure III-Y-8 displays actual employment data by sector for a number of years between 1970 and 1989.

The Eugene/Springfield area is somewhat more diversified than the county as a whole. The area serves as a trade and service center for much of Western Oregon. The University of Oregon and Lane Community College in Eugene are also major employers which help put government employment in Lane County above the state average. In 1989 Lane County's government employment sector comprised 20% of the total nonagricultural wage and salary employment compared to 18% for the state.

Many of the outlying smaller communities are more dependent on wood products than the Eugene/Springfield urban area. While mills in some communities rely on wood from other suppliers, others get a substantial amount of their timber from the Forest.

Other communities, like those up Highway 126 along the McKenzie River, are dependent on recreation-related trade and services. The Forest supplies many of the opportunities which attract recreationists who spend money and support the businesses in these communities.

Linn County - Linn County has the smallest population and is the most rural of the three counties in the primary area of influence. Its manufacturing sector has historically accounted for a higher proportion of its total employment than Lane County, but also has been less dominated by the lumber and wood products industry. In 1989 manufacturing employment accounted for almost 33% of total nonagricultural wage and salary employment. Employment in lumber and wood products industries accounted for about 41% of total manufacturing compared to 53% for Lane County in that same year.

Jobs provided in lumber and wood products declined overall by 19% from 5,200 in 1980 to 4,370 in 1989. The services and trade sectors again showed the largest employment increase. Employment and trade services increase 24% from 5,670 in 1980 to 7,010 in 1989. Employment in services increased 56% from 3,800 to 5,550 during the same period. Though, a shifting from manufacturing to a service oriented economy is taking place, lumber and wood sectors are still important to many of the communities in Linn county. Figure III-Y-9 displays actual employment data by sector for a number of years between 1970 and 1985.

Linn County mills processed over 113 million board feet of timber from national forest land in 1985 which was less than one quarter the amount processed in Lane County. About 80% of this came from the Forest. Some of the smaller communities closer to the Forest boundary are somewhat more dependent on the timber industry than the county overall. Both Lebanon and Sweet Home have a number of mills which employ a high percentage of the people in those communities.

Marion County - Marion and Polk counties make up the Salem Metropolitan Statistical Area (MSA). Marion County residents account for approximately 82% of the MSA population. Employment in the MSA is dominated by the government sector which employed over 27,800 people in 1989. More than half of these government workers are employed by the State and work in Salem, the State capital.

Manufacturing employment in the MSA is very small. It accounts for about 15% of total nonagricultural wage and salary employment. Employment in the lumber and wood products industry increased steadily from 1984 to 1988 providing an additional 800 jobs. Slightly less than 192 million board feet of timber was processed in Marion and Polk County mills in 1985. About 56% of this came from the Forest.

Along Highway 22 in the North Santiam Canyon lie the small incorporated cities of Stayton, Mill City, Gates, Detroit, and Idanha. These communities are much more dependent on the lumber and wood products industry than the Salem metropolitan area. Several mills are located in these communities.

Recreation-related trade and services are also important to the North Santiam communities. Many retirees are moving to the area and Highway 22 is a major travel route between Salem and central Oregon.

Figure III-Y-10 displays actual employment data by sector for Salem MSA for a number of years between 1970 and 1989.

Personal Income - Income and wage data are other indicators of the relative health of an economy. Several types of income-related data can be used to compare areas or changes over time. These include total personal income, median family income, per capita income, covered payroll, average hourly earnings, poverty rates, and common wage rates. This discussion will focus on total personal and per capita income. Total personal income is a measure which will be used to compare land management planning alternatives. Most of the other indicators are discussed in the Forest's Socio-Economic Overview.

Total personal income is the income of local residents from all sources before taxes and Social Security are withheld. Per capita income is total personal income divided by the total population of the area.

Total and per capita personal income in Oregon and the three-county area have risen steadily since the recession of 1981-1982. Total personal income in both Oregon and in the primary area of influence increased 35% between 1980 and 1989. All components of total personal income, however, have not increased at the same rate.

Personal income for the three-county area lags behind that of the state and the nation when measured on a per capita basis. Per capita income exceeded the national average in the late 1970's but was hit so hard during the recession that it still lanquishes 8% below the national average. Explanation of the lag in per capita income when compared to the state and the nation can be explained in part by the effects on unemployment of the 1981-1982 recession on the local economies which are structured somewhat differently than the state and national economies. Many of the jobs lost in Lane and Linn counties were in the construction and lumber and wood products industries which are generally

higher-paying jobs. Marion County was not affected as much because it has a lower proportion of its workforce in the industries hardest hit by the recession. It also has a large number of moderate to high-paying jobs in the government sector.

The rate of increase between the counties and the U.S. have remained fairly consistent. Between 1982 and 1989, per capita income increased by 37, 30, and 31% in Lane, Linn, and Marion counties, respectively, 32% in Oregon, and approximately 33% in the nation.

A review of earned personal income (i.e., total income less dividends, interest, rent, and transfer payments) by sector gives an indication of the industries which contribute the most to the personal income of an economy. In Lane County durable goods manufacturing, services, and government each accounted for about 18, 24, 18% of total earned personal income in 1987, respectively. Most of the durable goods manufacturing comes from the lumber and wood products industry. Retail trade was the only other sector accounting for more than 12%.

The pattern is somewhat different in Linn and Marion counties, however. Durable goods manufacturing accounted for 31% of Linn County's earned personal income in 1987. This came primarily from the lumber and wood products industry and primary metals manufacturing. The service and government sector were the only other sectors accounting for more than 12% of the total.

The two sectors which provided over half of Marion County's earned income in 1983 are government with 30% and services with 21%. Marion County has a relatively small durable goods manufacturing base accounting for only 7% of the total personal income.

The distribution of earned personal income for Lane County most closely approximates that of the state. Over 54% of Oregon's personal income is derived from the durable goods manufacturing (16.1%), services (22.3%), and government (16.3%) sectors. Figure III-Y-11 compares the 1983 earnings by industry for Lane, Linn, and Marion counties and the State of Oregon.

An examination of earned personal income by industry over time also gives an indication of how county economies are changing. The 1981-1982 recession had somewhat similar effects on Lane and Linn counties. In both cases the percentage of total income in durable goods manufacturing declined between 1982 and 1987 while the proportion in services increased. Some of this change could be due to the gradual trend towards economic diversification occurring in these counties.

The proportion of income derived from major sectors did not change significantly in Marion County during this time period. A minor shift away from nondurable goods manufacturing and government towards services did occur. Shifts within major sectors such as durable goods manufacturing may also have occurred.

Table III-Y-11. Total Earnings by Sector, 1987 [1]

	Lane County		Linn County		Marion County		Oregon	
Economic Sector	MM$	% of Total	MM$	% of Total	MM$	% of Total	MM$	% of Total

Finally, a comparison of the percentage of income derived from an industry and the percentage of employment associated with it gives an indication of wage levels and the relative employment and income impacts which might be expected from the analysis of Forest plan alternatives. An examination of Lane, Linn, and Marion county data shows that the percentage of total employment in manufacturing, construction, and transportation, communications, and utilities is lower than the percentage of total income. This indicates that these industries tend to have higher paying jobs.

The opposite is for the trade sector. The percent of employment in this sector tends to be higher than the percentage of total income generated. This is a reflection of the generally lower average pay associated with jobs in this sector.

Payments to Counties - Counties having National Forest land within their boundaries receive a portion of the revenues taken in by the Forest from the use of the land or sale of its resources. The distribution of payments to counties occurs in one of two ways. National Forest System lands money that is returned to the federal treasury 25% is distributed to counties based on the amount of National Forest land within their boundaries. These funds are earmarked for schools (25%) and roads (75%).

On Oregon and California (O&C) Railroad grant lands, 50% of the money paid to the Federal Treasury is returned to the Bureau of Land Management for distribution to the counties having these lands.

Revenues from the Forest are derived primarily from the harvest of timber. Over 99% of the Forest's revenues came from this source. Other revenues came from recreation user fees and permits for special uses, grazing, minerals, power, and other land uses.

The "25% funds" from National Forest system lands on the Willamette are divided among six counties: Clackamas, Douglas, Jefferson, Lane, Linn, and Marion. Almost 97% of the money returned goes to the three counties which make up the Forest's primary area of influence: Lane, 60%; Linn 29%; and, Marion 8%. About 3% goes to Douglas County and less than 1% to the other two counties combined.

Revenue from O&C Lands administered by the Forest averaged less than 5% of total timber revenues between 1979 and 1985. The Forest contains over 51,000 acres of O&C Lands or about 3% of its total landbase. Most (99%) of these are in Lane County.

Revenues returned to counties from National Forest land play an important part in county and school district budgets. A 1979 study found that revenues from all the National Forests accounted for an average of 17.4% of all the Oregon counties revenues in fiscal year 1977-1978. This represented a 50% increase over 1968-1969.

Dependency on revenues from any one source can be a problem if that source is subject to unpredictable short-term changes. This has been the case with Forest revenues that are predominantly dependent on the market for timber.

Forest revenues peaked in 1979 when both the volume harvested and the price of timber were high. Prices and volume harvested fell significantly during the 1981-1982 recession, but have recently regained strength with prices approaching the 1980 highs and the third harvest level in 1988 bringing 1/3 higher receipts than the highest previous harvest in 1979.

Receipts rose slowly in 1983 and 1984 and took a relatively large jump in 1985 and again in 1987 as the economic recovery finally reached the wood products industry in Oregon. Most of these increases were due to increases in the amount harvested, not increases in prices. Only recently have prices begun to increase above recessionary levels. From 1987 to 1988 there was a 23% increase in revenues with a corresponding increase in prices and a in volume harvested.

Figure III-Y-12 displays Forest revenues for 1979 through 1989 and their distribution to counties.

As long as payments to counties are linked to volume harvested they will be subject to periodic fluctuations. The relationship between timber prices and harvest levels is an important one affecting both total revenues and payments to counties. While it would appear to be in the interest of local counties to have high prices for National Forest timber, high prices can discourage harvest activity and result in less revenue. Low timber prices encourage harvest activity and may increase payments to counties more than rising prices would.

Timber prices are affected by a variety of factors at the local, regional, and national levels. The Forest's sale quantity, the supply from other producers, and national demand will all affect total revenues and payments to counties.

Table III-Y-12. Forest Revenues [1]

	Fiscal Year						
National Forest Fund (NFF)	**1979**	**1981**	**1983**	**1985**	**1987**	**1988**	**1989**
Timber (Net Stumpage)	93,971.6	65,368.7	39,567.1	63,903.9	94,917.5	117,493.2	122,542.0

[1]Revenues in thousands of dollars.
[2]Knutson-Vandenberg.
[3]25 percent of these funds are returned to counties.
[4]50 percent of these funds are returned to counties by the Bureau of Land Management.
[5]Distribution of National Forest Fund (NFF) funds is based on the percent of total Forest acreage in each county.
[6]Fiscal year 1987 timber receipts incluse $965,211.35 in timber buyout receipts.

Other Influenced Areas

Some counties outside the Forest's primary area of influence are affected, though to an lesser extent, by management of the resources on the Forest. A brief discussion of the relationship of the Forest to some of these counties follows.

Clatsop and Columbia counties, located at the mouth of the Columbia River in northwest Oregon, are affected by the management of fish habitat on the Forest. Their economies are impacted by production levels of spring chinook salmon on the Forest. Up to 75% of the fish taken during the short spring chinook gillnetting season may have originated in the rivers and streams of the Forest.

These counties are lightly populated, although Columbia County is becoming more attractive to Portland commuters. The economies of both counties depend on agriculture, wood products, and paper. Fishing, seafood processing, and tourism are also important to Clatsop County. Although tourism continues to do well, wood products, seafood processing, and fishing have been declining.

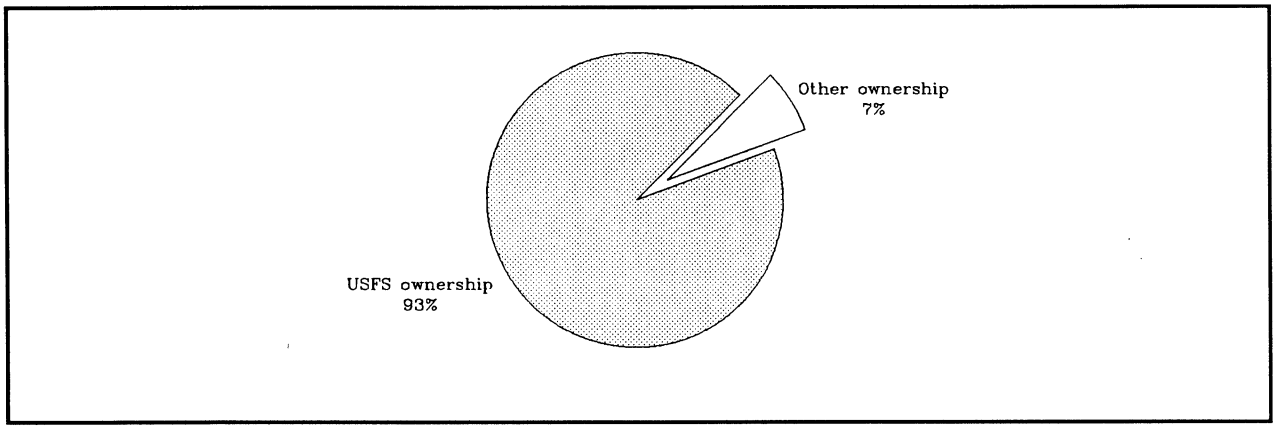
Benton County is lightly populated, but growing. It has one of the more stable economies in Western Oregon. While wood products are important, the biggest employers are not wood products firms, but rather Oregon State University and Hewlett-Packard. Agriculture is also important.

People of Benton County have been strongly represented among the Forest's recreation users, especially in Wilderness use. Unlike Portland area people who can easily visit the Mt. Hood National Forest, Benton County backpackers find that the closest high altitude country is on the Willamette.

Douglas County mills have bought a small portion of Forest timber. The county has been rapidly growing, but still remains lightly populated. Over one-third of its people live in and around the Roseburg urban area. Douglas County is one of the most (if not *the* most) timber-dependent counties in Oregon; over four-fifths of its manufacturing sector employment is in lumber and wood products. In addition, its nonmanufacturing sector is relatively small. During the recession of the past few years, it has had one of the highest unemployment rates in Oregon.

NONNATIONAL FOREST LAND

This section discusses the relationships between National Forest land and lands of other ownerships. This includes parcels of nonnational forest land surrounded by National Forest, and parcels of National Forest lands surrounded by land of other ownerships.



Current And Historic Conditions

Land Ownership Status

There is a variety of land ownership patterns within the proclamation boundary of the Forest. These patterns include unbroken federal ownership, attributable to early Forest Reserve set-asides; checker-board patterns, resulting from land grants made for the construction of railroads and wagon roads; and a mixed mosaic of ownerships, resulting from homestead and mining claim patents; other public land laws which made public domain lands available to the public for acquisition; and blocks of private land resulting from land exchanges.

Most of the Forest is in unbroken federal ownership. Although there are areas where management complexity is increased due to the ownership pattern, the overall impact of the ownership pattern on Forest management is low when compared to other units in the National Forest System. Figure III-Z-1 displays land ownership distribution within the Forest.

Figure III-Z-1. Land Ownership on the Forest

The Corps of Engineers, Bureau of Land Management, and the State of Oregon administer or own land within or adjacent to the Forest. The incorporated communities of Idanha, Detroit, Oakridge, and Westfir are within the exterior boundaries of the Forest. In addition, there are several smaller settlements which are unincorporated.

There are eight major owners of private lands within the Forest boundary: Willamette Industries Incorporated, Weyerhauser Company, Champion International Corporation, Pope and Talbot, Giustina Brothers Lumber and Plywood Company; Young and Morgan, Timber Services Incorporated,and Hill Family Interest.

The management of included or adjacent private land is occasionally encumbered by the need for access across National Forest land. Other landowners may be affected by management activities on the Forest, such as timber harvest and road construction.

Adjacent private ownerships may impact the National Forest through various types of trespass and increased risk of wildfires. Management activities require a coordinated approach to maintain resource values.

Ownership Adjustments

Past adjustments have been made by donations, purchases, interchanges and exchanges. The Oregon and California (O&C) Lands Exchange Act (53 Stat. 1144), July 31, 1939, and Public Law 426 (68 Stat. 170), June 24, 1954 blocked up some Forest ownership by adding over 51,000 acres. Through Fiscal Year 1982, the Forest obtained approximately 60,000 more acres through the other various acquisition methods.

The primary objective of land ownership adjustments on the Forest is to simplify management problems and help improve multiple use management of all lands within the Forest (USDA 1969). High priority is placed on improving efficiency in administering the Forest; protecting and enhancing environmental quality, and maintaining and improving land and resource productivity.

The current land adjustment action plan provides for the consolidation of ownerships, through the acquisition of small parcels of interior private lands and disposal of small isolated parcel of National Forest System lands. In addition, it provides for acquiring lands and rights-of-way needed for administrative improvements and lands with high recreation potential.

Rights-of-way Acquisition and Grants

Existing ownership patterns often require reciprocal granting of rights-of-way for access roads, tail holds, landings, and flyways for timber harvest activities. Special use permits and leases for numerous public utilities, businesses, and community uses of National Forest lands are complicated by these intermingled ownerships. Maintaining visual, fish, wildlife, and water quality management objectives is complicated by mixed ownership of habitats, watersheds, and viewsheds.

There are seven areas on the Forest where the major landowners have agreed to share the cost of construction, maintenance, and operation of a single road system across both private and National Forest lands for the mutual benefit of the landowners. In 1984, there were 136 supplements covering approximately 507 constructed road miles and 77 road miles to be constructed with cooperators in share-cost agreements.

Landowners not participating in share-cost agreement areas generally cooperate with the Forest Service in granting access to federal timber. There are approximately 388 existing rights-of-way acquired from nonshare-cost agreement landowners.

Access across National Forest lands is granted to cooperators and roading authorities by permanent and temporary easements, or special use permits, and is granted to others only through the special use permit process. There are approximately 120 easements existing on the Forest.

Future Trends

The future workload in land adjustments on the Forest could become increased somewhat over that at present. As the commercial timber is harvested from private lands within the Forest boundary, some of these lands could become proposed for exchange by the owners. The extent to which this situation might occur would be affected, in part, by the economic situation related to the lumber industry in the Northwest.

There are other considerations that could affect the rate of activity in land adjustments on the Forest. These include the interchange proposal between the Forest Service and the Bureau of Land Management and the recent Congressionally designated Columbia River Gorge National Scenic Area. The extent of the effects on land adjustment, if any, from these proposals is not clear at this time.

As the Forest development road system becomes completed, it is expected that the number of rights-of-way acquired will be less.

CHAPTER IV

ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

INTRODUCTION

This chapter provides the scientific and analytic basis for the comparison of alternatives presented in Chapter II. The narrative discusses reasons for and causes of environmental effects of the alternatives, and it presents the important interrelationships between resources, land uses, and environmental conditions.

Environmental consequences are discussed in the short- and long-term, and often by decade. Although a Forest Plan for any alternative would guide management for 10 to 15 years, effects beyond the first decade are also considered. This information helps to reveal long-term implications, and explores the potential for implementation of an alternative over time.

Like Chapter III, this chapter is organized by environmental component. The environmental consequences for each component affected by the alternatives are described in terms of direct effects, indirect effects, cumulative effects, relationships with other agencies policies or plans, and mitigation measures. Analysis of each environmental component involves some incomplete or unavailable information. A description of this information and how it was dealt with is provided.

NOTE TO READER

The following note applies to Figures which have an "NA" entry listed for Alternative NC, the No Change Altenative:

NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Forest FORPLAN model. Section D4b, of Chapter II in the Draft EIS describes these differences.

INCOMPLETE OR UNAVAILABLE INFORMATION

Some of the information used to predict environmental effects in this chapter is incomplete, while other information is unavailable at this time. Incomplete or unavailable information is noted later in this chapter for each major resource. The Forest has used the most current information available and state-of-the-art analytical tools to evaluate activities and to estimate effects.

The Council on Environmental Quality's NEPA regulations relating to incomplete or unavailable information have been amended (40 CFR 1502.22), amended at 51 Fed. Reg 15618 (April 25, 1986)). The following discussion complies with the amended regulations.

In the FEIS and Forest Plan:

- The discussions of the managment of the resources on the Forest have involved an evaluation of reasonably forseeable significant adverse effects on the human environment.

- The evaluation of those effects sometimes has been based upon information that is incomplete or only partially available.

- The incomplete or unavailable information cannot be obtained because the overall time and money costs to obtain the information would be exorbitant, and in many cases the means to obtain the information are not known.

Consequently, pursuant to 40 CFR 150.22(b), as amended, the following discussions of management impacts soil, water, air, vegetation, climate, fish, wildlife, artifacts and sites, recreation, scenery, Wild and Scenic rivers, Wilderness, Roadless lands, special interest areas and national natural landmarks, research natural areas and H.J. Andrews Experimental Forest, transportation system, minerals and energy, and social and economic setting include a description of the incomplete or unavailable information which is relavent to the evaluation of reasonably foreseeable significant adverse impacts associated with the alternatives.

CHANGES BETWEEN DRAFT AND FINAL

Changes were made to Chapter IV between the DEIS and this EIS in response to concerns expressed during the public comment period and as a result of newer information becoming available. The major changes are.

- The format of Chapter IV was revised to reflect major resource areas rather than programs or outputs. Specifically, discussions of effects on vegetation include timber, old growth, plant diversity, riparian, and range. Fire is discussed as it effects resouces not as a resource area.

- The discussion of old growth resources has been expanded, and the effects on existing old growth acres has been updated based on new information obtained from the Mature and Over Mature vegetation survey.

- The discussion on diversity has been expanded and is addressed in Vegetation (plant diversity) and in Wildlife (vertebrate diversity).

- Incorporated into the analysis of effects, the Regional FEIS for Managing Competing and Unwanted Vegetation.

- Updated the discussion on effects to spotted owls and spotted owl habitat to reflect the July, 1988 Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide.

- The analysis of current condition and effects of the alternatives on mature and old growth forest Management Indicator Species (MIS) has been updated to reflect the impacts of forest fragmentation on habitat capability.

- The habitat requirements for primary cavity excavators have been revised based on Chapter 7, *Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington* (Brown 1985), and they are been included in the analysis of effects to potential populations.

- The habitat capability model used to predict deer and elk numbers and habitat conditions has been revised. *A Model to Evaluate Elk Habitat in Western Oregon* (Wisdom et al. 1986) was used in this FEIS. Indexes used to estimate potential populations are based habitat effectiveness values were developed in cooperation with the Oregon Department of Fish and Wildlife.

- Included information on newly designated Wild and Scenic rivers, and on eligibility studies on potential wild and scenic rivers.

- Extensive changes were made to the analysis of the risk of cumulative effects between the DEIS and FEIS, in response to substantative public comments. The FEIS considered three watershed characteristics in assigning Watershed Risk, erosion levels, hydrological recovery, and riparian condition; the DEIS considered only the first two components. The terminology used to describe the risk of watershed effects was changed to "High", "Medium" and "Low" from "Probable", "Possible", and "Unlikely", as part of the revised analysis method.

- The FORPLAN model used for the FEIS included watersheds (averaging 54,000 acres) as building blocks, which permitted analysis of the timber harvest levels prescribed by FORPLAN to be analyzed, rather than assuming that harvest was distributed evenly across all watersheds as was done in the DEIS. In FORPLAN, the relative sensitivity of watersheds to increases in peak flows was identified, and FORPLAN was programmed to distribute the harvest according to watershed sensitivity in all alternatives, to minimize the risk from increase peak flows.

- In Alternative W (PA), the sensitivity of smaller subdrainage areas (average 3900 acres) was described, and the level of harvest which would be compatible with maintaining stream channel stability in each subdrainage was estimated. This information was included in FORPLAN modelling.

- The analysis of potential sediment was changed to focus more on the potential sediment from mass movement, specifically debris slides in the FEIS. The potential sediment yields and discussion of effects in the DEIS included calculations of surface erosion. Studies have shown that a very small portion of surface erosion reach streams, lakes, or wetlands.

- Changes were made in the design of each alternative, so that all alternatives considered the possiblity of achieving fish passage around reservoirs on the South Santiam and McKenzie Rivers, and increased success in passage around Fall Creek.

- Changes in the estimates of smolt habitat capability were made in response to direction in the 1970 Memo, dated May 1, 1987 on Anadromous Fish Planning Coefficients.

- A discussion on sensitive fish species was added.

- Changes were made in the acres of land suited for timber production. Four soil types were added for an increase of about 29,000 acres.

- The empirical yield tables were updated to reflect growth through 1994, and adjusted for defect and breakage by species and size class.

- The Forest Inventory was adjusted to account for harvest through FY 1989.

- A new managed yield table was included in the DF/H and DF/TF working groups to allow one heavy commercial thinning.

- The Regional Fertilization Policy was changed to allow fertilizer to be added to stands with at least 60% Douglas fir.

- New Forestry concepts were applied to long-rotation management areas to provide habitat for old growth dependent species at an earlier age.

- A section was added to discuss the effects of the alternatives on Climate.

ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

The environmental consequences for all alternatives, except the No Change (NC) Alternative, fall within certain limits because of Forest-wide management requirements imposed to ensure long-term productivity of the land. While the frequency of occurrence of an output or effect may vary between alternatives, the environmental consequences may not be significantly different between the alternatives due to the common application of standards and guidelines (S&Gs) across all alternatives (except the NC Alternative) or due to the low sensitivity of the resources involved. These S&Gs apply to all management area prescriptions and are designed to protect Forest resources and mitigate adverse impacts.

The estimated effects of the alternatives result from the application of various combinations of management prescriptions. This mix of prescriptions generates different levels of resource outputs, goods and services. For each alternative, the interaction between the level of outputs and the source of production generates distinct environmental consequences. A familiarity with both quantifiable and qualitative outputs and effects is crucial for understanding the analysis and evaluation of environmental consequences. Quantitative outputs as well as nonpriced benefits and environmental qualities all contribute to the environmental consequences of the alternatives.

Environmental Consequences Of The Alternatives On Soil

Introduction

Long-term soil productivity is the natural capability of the soil to sustain the growth of plants and plant communities over time. It also includes the maintenance of soil conditions so that quality ground-water is supplied to lakes, wetlands and streams. Since most Forest uses ultimately depend on a productive soil resource, maintenance and enhancement of long-term soil productivity is widely recognized as a basic requirement of Forest management.

Effects of the Alternatives on Soil

Both external and internal factors affect soil productivity. External factors, such as climate and geology, are not influenced by Forest activities. Internal factors which can be modified by Forest activities are soil nutrients, and soil structure.

The effects of the alternatives on soil productivity will be described in terms of: (1) changes in nutrient levels and cycling; including application of fertilizer, and the role of surface soil organic layers; and (2) changes in soil structure, such as soil compaction and erosion. Forest management activities, such as timber management and road construction have the potential to affect soil productivity. The Forest and Regional Standards and Guidelines (S&Gs) define what kinds and levels of soil disturbances are acceptable, and what levels are considered detrimental to long-term soil productivity.

Table IV-1 displays the amount of the principle activities affecting soil that are scheduled for each alternative. This information provides the basis for the following discussion of effects.

Table IV-1. Primary Activities Affecting Soils

Activity	Units	NC [1]	K	A	J	W	D	L
Fertilization M Acres [1]	Decade 1	NA	102	88	118	96	102	56
	Decade 2	NA	92	99	74	79	74	24

	Decade 5	NA	118	116	82	81	85	23

[1]Total of acres scheduled for fertilization each decade.
[2]All harvests include clearcuts, shelterwoods, and thinnings.
[3]Final harvests include clearcuts and shelterwoods only.
[4]FORPLAN was not used with this Alternative. NA means the information is not available.

Nutrients - The cycling of nutrients through forest soils is essential for the productivity of plant communities, because the largest pool of nutrients exists in the soils. Other major sources of nutrients for the soil is the weathering of bedrock, and inputs from atmospheric sources (Waring and Schlesinger, 1985). Various soil animals are important in the process of decomposition of organic matter, such as needles and leaves, and bark. The majority of the chemical transformations are performed by bacteria and fungi in the upper soil layers.

Nutrient Addition - Nutrients added to the site by management practices such as fertilization would be designed to increase the availability of nitrogen to tree species resulting in additional vegetative growth. Nitrogen, usually in urea form can be applied directly to these soils.

The Forest has been participating in fertilization research for over 10 years, resulting in considerable information about timber growth response on various soil types (Legard 1980). Fertilizer trials have been made on approximately 30% of the Douglas-fir/hemlock zone, primarily on gentle slopes (less than 30%) at low elevations. Based on these trials, all alternatives propose to apply fertilizer to timber stands on suited lands composed of greater than 60% Douglas-fir.

Differences between alternatives in the number of acres fertilized during the first decade range from 56,000 to 118,000 acres, with 96,000 acres in Alternative W (PA). Use of fertilizer in the fifth decade ranges from between 26,000 acres to 107,000 acres, with 73,000 acres for Alternative W.

Nutrient Removal - Soil nutrients would be removed from the site through several processes; volatilization by fire, removal of vegetative material, and leaching.

Removal of the surface soil organic layer and large woody debris (downed logs, and limbs) results in direct loss of soil organic matter, certain plant nutrients, and a supply of energy to soil microorganisms.

Soil microorganism activity has been directly linked to soil productivity (Harvey et al. 1979). Organic matter in the surface layer has been found to be a primary source of nitrogen for young tree growth (Little and Ohman 1985). Large woody debris has been found to be an important link in the life cycle of symbiotic fungi which greatly enhance the ability of the roots of young conifers to take up water and nutrients (Maser et al. 1985). Because of this interdependence between above ground organic material supplies and below ground productivity processes, management of the long-term supply of large woody debris and surface soil layer can strongly influence soil productivity. As a result, the Forest has included S&Gs for the maintenance of large wood and organic matter on soils.

Fires of a high intensity, and moderate intensity fires of long duration, can cause severe impacts to soils. These impacts include the volatilization of up to 85% of the nitrogen content of leaves and twigs (Waring and Schlesinger); the loss of beneficial microorganisms; and the loss of organic matter for the nutrient holding capacity of the soil. However, it appears that prescribed burning of Forest residues at cooler temperatures has minimal effects on the long-term nitrogen content of surface soils. (Kraemer and Herman 1979). High intensity fires can also result in extensive mineral soil exposure and/or the creation of hydrophobic or "nonwettable conditions" which then accelerate topsoil erosion (Boyer and Dell 1980).

Research has not yet been able to quantify potential impacts to timber stand growth from surface organic matter disturbance. Thus, with the apparent long-term stability of nitrogen (the nutrient most subject to change), site productivity does not appear to be affected by prescribed burning when low to moderate fire intensities are utilized to protect a sufficient portion of the duff layer. Experience gained on the Forest over the last 10-15 years has led to guidelines ensuring that low to moderate fire intensities are used to protect surface layer organic matter.

Removal of forest products represents a loss of the nutrients from the forest ecosystem. In most instances the removal of woody biomass results in only a small percentage loss of the total nutrient elements in forest ecosystems, because the largest pools are in the soil, and because the foliage and branches that are left behind contain a large portion of the nutrient pool in the vegetation. However removal of whole trees for pulpwood or biomass energy would result in substantially greater nutrient removals. These may be replaced by natural processes, nitrogen fixing species or fertilizers (Waring and Schlesinger 1985).

Removal of nutrients by leaching into water runoff varies by season, and vegetation type. The highest rates of leaching have been observed following decomposition of organic matter four years after clearcutting (Adams et al. 1989). This is also discussed in the section on Water.

Soil Structure - Soil structure develops over long periods of time and influences the availability of water and nutrients to plants. Some management activities have the potential to alter soil structure. Two major changes which have the potential to occur are compaction and erosion of soil profiles.

Compaction - Soil compaction occurs when soil pore space is reduced in size because of physical pressure exerted on the soil surface. Compaction results in soil conditions that have reduced infiltration, permeability, and gaseous and nutrient exchange rates. Physical resistance to root growth can also occur in soils of high density. Soil compaction can occur on almost all soils with repeated passage of heavy equipment. At least 60 percent of the increase in bulk density in a well used skidtrail occurs after the first three to 5 passes (McNabb and Froehlich 1984). The area in compacted skidtrails can often range from 18 to 40% of the harvest area (Sidle 1980, Froehlich 1974, Dyrness 1972) from a single harvest entry with tractor skidding. Repeated entries for thinnings tend to increase the area in skidtrails, further impacting soil productivity (Chambers 1977). Mechanical slash piling also significantly increases the area disturbed and compacted.

Timber stand growth losses from compaction caused by tractor logging and tractor piling have been found to be significant and persistent. Stand growth loss estimates range from 5 to 13% (Wert and Thomas 1981, McNabb and Froehlich 1984). Growth losses are greatest for young stands, and lesser for older stands due to different portions of the root systems within affected soil layers. Natural recovery rates are generally slow in this region because the mild climate causes limited freezing and thawing of the soil. As a consequence, it is expected that compacted soils will remain compacted over the rotation of managed stands (McNabb and Froehlich 1984, Froehlich et al. 1983). Soil compaction also reduces water infiltration, and may result in increased overland flow. These conditions contribute to increased erosion and higher peak flows. Compaction can be minimized by avoiding or carefully managing tractor logging and slash piling.

Erosion - Surface erosion occurs from the forces of raindrop impacts, gravity (as with dry raveling), and wind in areas where soils lack protective ground cover. Erosion can be greatly increased by freeze-thaw action on some steep slopes. The extent to which this effects soil productivity has not been thoroughly researched. See the Soils and Geology sections in Chapter III for further discussion on erosion.

When soil is eroded by mass movement it often becomes less productive as soil layers are mixed. Removal of tree and shrub cover from steep slopes can accelerate mass movement on soils which are prone to landslides due to the loss of root strength. Groundwater regimes, which affect stability of slump-earth flow complexes, may also be affected by infiltration rate changes associated with timber harvest and road location.

[1]Values represent estimates for the average annual amount of erosion in thousands of cubic yards.
[2]NA = Data Not Available. Alternative NC is estimated to be similar to Alternative K.
[3]Amounts include erosion from decade indicated and a smaller amount carried over from previous decade.

Erosion, both surface and mass movement, would increase above natural levels, based on the acres harvested, acres of unstable soil types harvested and miles of road constructed in each alternative. Erosion index values shown as a basis to compare alternatives are displayed in Table IV-2 and Figure IV-1 above. Estimated erosion volumes do not indicate amount that would be delivered to streams or project downstream effects. The potential effects of erosion on water quality are discussed in the Water Section of this chapter.

The rate of road construction and consequently erosion from newly constructed roads declines after the first decade in all alternatives since most of the transportation system would be in place by the end of the first decade. Of the erosion over natural levels that is generated in the first decade, approximately 13 to 28% would come from new roads with the remainder coming from harvested areas.

Soil disturbance is an unavoidable consequence of Forest management activities such as timber harvest, road construction, and to a much lesser degree, intense recreational use such as repeated use of campsites and trails.

For each harvest entry, the extent of soil disturbance depends upon a number of factors. Soil type and condition, terrain, the volume and size of timber removed, the size of units, the weather, contract compliance, and the skills of individual equipment operators all contribute to the intensity of impact. The area impacted by final timber harvest, the harvest method employed, and the method of site preparation directly affect the degree of disturbance to the soil surface. Differences in acres harvested between alternatives are the most direct indicator of relative risk to soil productivity through compaction.

Differences Between Alternatives - Harvest options vary widely in their impact on the soil according to the yarding system used. Cable and aerial yarding systems affect a much smaller area than does tractor-based logging. High-lead systems may disturb only from 15 to 20% of the harvested area (Dyrness 1967, Sidle 1980). Impacts tend to be higher if downhill yarding is used. Skyline systems generally disrupt less than 10% of the area (Dyrness 1967), and aerial systems affect less than 5% of the ground. In all of the alternatives, the majority of the Forest (60 to 70%) will be harvested by skyline systems. The remainder of the harvested areas will use ground based systems (20% to 30%) or aerial systems (10% to 20%).

Alternative NC would impact the most acres with final harvest during the first decade, with the amount of final harvest gradually declining as commercial thinning increases to the point of providing over half the harvest volume by decade five. Final harvests in Alternatives K, A and J would impact almost as many acres in each of the first two decades, and then decline to lower levels in decades three, four, and five. Final harvests in alternatives W (PA), D, and L would impact progressively fewer acres each decade.

Alternative K would produce the highest amount of erosion in the first decade (153.9 thousand cubic yards annually), representing an increase of 48% over the natural rate and nearly equal to current erosion levels (154.8 thousand cubic yards annually).

Alternative A would produce approximately 144.6 thousand cubic yards annually in the first decade. This represents an increase of 45% above the natural levels and a decrease of about 7% from current erosion levels. In the first decade, Alternatives J and D generate slightly lower amounts annually (122.1 and 117.4 thousand cubic yards respectively). Alternatives J and D would result in erosion levels decreasing approximate 21% and 24% respectively from current erosion levels.

Alternatives W (PA) and L produce the least annual erosion (71.5 and 33.5 thousand cubic yards respectively in the first decade). For Alternative W (PA), this corresponds to an increase of 22% above natural levels and a decrease of approximately 54% from current erosion levels. For Alternative L, this represents an estimated increase of 10% above natural erosion levels and a decrease of approximately 78% from current erosion levels.

In the fifth decade as the area of final timber harvest decrease, and road construction decreases in all alternatives, erosion would also decline. Alternatives K and A would generate the highest annual amounts of erosion at 122.8 and 123.0 thousand cubic yards respectively. Alternatives J and D would produce similar amounts annually of approximately 88.7 thousand cubic yards. Alternative W (PA) would produce a lower volume estimated to be 45.9 thousand cubic yards annually. Alternative L would generate the least amount of erosion of approximately 12.3 thousand cubic yards annually. Alternative NC is estimated to fall in the same range as K and A because the majority of the harvest volume by the fifth decade comes from commercial thinning. The effects of commercial thinning on erosion are estimated to be negligible. This is due to the low degree of disturbance to the soil duff layer where stands are thinned by cable logging systems and rarely treated with fire.

Cumulative Effects on Soil

The cumulative effects of management activities over an area are considered in the S&Gs which require that no more than 20% of an area is cumulatively displaced, puddled, or compacted, and specifies the amount of soil cover and large woody debris to be maintained on the ground. At this time no satisfactory means of testing, or unit measure of long-term soil productivity, has yet been devised. The survival and growth of planted seedlings give an indication of changes in site productivity, but little is known of how indicative short-term performance is of long-term productivity.

Mitigation Measures for Soil

In most situations, preventing soil impacts is the most effective and feasible way of ensuring long-term soil productivity. Determining the suitability of specific soils for timber harvest activities is an important first step in preventing soil related impacts. In responding to NFMA regulations, 144,851 acres of available, forested lands are currently classified as unsuited for timber management. No timber harvest activities are scheduled on those lands because of the potential for irreversible soil damage and/or the inability to ensure regeneration of forested stands within 5 years. Lands that exceed 30% slope gradients, or soils that have high clay or silt content, are not planned for tractor yarding or slash piling because of equipment limitations that lead to excessive soil displacement and compaction.

One-end suspension or full suspension cable yarding systems are used to avoid a high degree of soil disturbance on soils that are highly susceptible to displacement, surface erosion, mass movement, or compaction. Both duff and fuel moistures are used to determine when slash can be burned with minimum impact to surface organic material. Planned slash treatments are either low intensity broadcast burns, burning via small handpiles, or yarding of slash without burning on these more sensitive soils.

Ground skidding equipment is primarily restricted to designated skid trails or not allowed. Reducing the effective weight of the tractors and reducing the number of trips over a piece of ground are other means to reduce the risk of soil compaction and displacement (Froehlich and McNabb, 1983). Yarding over frozen ground, or over a deep, solid snow pack reduces soil disturbances and can protect advanced regeneration. In many situations, cable systems are used for yarding in place of tractors to reduce soil disturbance. Tractor piling will generally not be considered an option unless justified on a unit by unit basis. Additional measures to reduce soil compaction and displacement resulting from tractor piling include cable piling, handpiling, and low to moderate intensity broadcast burning. Rehabilitation with

equipment capable of reaching subsoil depths (generally 10 inches or greater) will be used to loosen and break up compacted soil when appropriate.

On slopes exceeding 30%, cable yarding systems are used. Uphill yarding is preferred over downhill yarding to reduce log gouging of the soil. Cable systems that partially or fully suspend logs do not compact or deeply disturb as much ground as no suspension systems (Dyrness 1972). Long-span cable yarding systems will reduce the road densities needed for ground skidding and shorter span systems. This practice avoids soil and water quality impacts that may result from additional road construction.

Management prescriptions, standards, and guidelines require special management considerations whenever activities have a potential of triggering mass movement events. Avoidance of problem sites is the alternative most preferred. Other than avoiding timber harvest on problem sites, ways to reduce the chances of mass movement include: retaining more trees, shrubs, and ground cover than normally done during timber harvest; using cable yarding systems that one-end or fully suspend logs; allowing felling and yarding only during dry soil conditions; draining wet, unstable areas; and avoiding broadcast burning. Ways to reduce the chance of mass wasting associated with road construction include: avoiding problem sites; not overloading or undercutting unstable ground; special spacing, sizing, and location of culverts; stabilizing cut and fill slopes, (e.g., rock buttresses, retaining walls, and planting); inspecting and cleaning of ditches and culverts; building full-bench roads where slopes exceed 55%, and eliminating side-cast waste; and monitoring of road conditions after construction.

To maintain long-term productivity, compacted areas such as skid trails, landings, temporary roads, stock loading areas or campsites can be tilled or subsoiled. Easily eroded sites can be mulched, fertilized, and seeded or planted. Cross ditches can be installed at appropriate intervals to direct water flowing over compacted surfaces such as trails and roads. Roads can be made more erosion resistant by surfacing. On the older Forest roads side-cast pullback will be implemented to reduce the debris avalanche potential.

These mitigation measures would be used in all the alternatives. The particular measures used would vary depending upon the site specific conditions. Project analysis undertaken prior to project implementation, ongoing project administration, and project monitoring would determine the specific needs and measures used. The degree or amount of specific mitigation measures likely to be used used in each alternative is relative to the amount of acres harvested (Figure IV-1) or miles of road constructed.

Relationships With Other Agency Plans or Policies for Soil

There are no known conflicts between the effects of the alternatives on soil and the plans or policies of other State, Federal, or local agencies.

Information Needs

The Forest recognizes gaps in existing data and research needs that would be desirable to fill prior to the preparation of the next Forest Land and Resource Management Plan. In the area of maintaining long term site productivity, more information is needed on the following:

- The effects of different harvest practices and removal of biomass.
- A further assessment of the effects of burning and compaction.
- The effect of management practices on the incidence and severity of pathogens and insects as they effect long-term productivity.

Environmental Consequences of the Alternatives on Water

Introduction

This section describes the potential adverse direct, indirect, and cumulative effects of the proposed alternatives on water quantity and quality in streams, lakes, and wetlands; on stream channel conditions. Water quality refers to the quality of the water within streams, lakes and wetlands, while stream channel condition refers to the physical structure of the stream substrate and stream bank stability. Stream channel condition is a strong indicator of the quality of habitat for all aquatic species for which anadromous and resident salmonids are Management Indicator Species.

This section discusses both water quality and stream condition because many of the same processes affect both. The influence of water quality and stream condition on beneficial uses is considered here and in the Fish section because fish populations are considered an important beneficial use throughout the Forest.

Direct, indirect and cumulative effects are evaluated against the requirements established in NFMA regulations and the Clean Water Act. Other laws are mentioned where applicable. Management Requirements described in NFMA include the following:

- Minimize serious or long-lasting hazards from flood and erosion unless they are specifically accepted.
- Protect streams, streambanks, shorelines, lakes, wetlands and other bodies of water.
- Special consideration shall be given to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes, and other bodies of water. No management practices causing detrimental changes in water temperature or chemical composition, blockages of water courses or deposits of sediment shall be permitted within these areas which seriously and adversely affect water conditions or fish habitat.

The Clean Water Act declares a policy to "restore and maintain" clean water (Sec.101) and directs states to adopt antidegredation policies. The state antidegradation policy and implementation methods must safeguard existing water uses. No degradation is permitted in "Outstanding National Resource Waters" which includes designated Wild and Scenic Rivers.

Other beneficial uses to be protected are those identified by the State of Oregon (OAR 340.41) and discussed in Chapter III. These include anadromous and resident fish spawning and rearing, private and public domestic water supplies, hatchery intakes, use by wildlife, boating, aesthetic recreation, hydropower, and several others. Stream Classes are defined according to the beneficial uses which occur. Class I streams are those with anadromous fish, significant sports fish, and domestic water intakes. Class II streams are used by resident fish, and Class III stream are other perennial streams. Class IV streams are intermittent. The water quality and stream conditions in Class I and II streams is of primary concern however the influence of Class III and IV streams is equally important in determining the effects in downstream reaches.

Quantitative measures of water quality needed to provide for many of these beneficial uses has not been determined. Where the State of Oregon has established numerical standards designed to protect beneficial uses (ie. for turbidity and temperature), application of Best Management Practices is the primary means of achieving these standards. In the absence of models which can predict under what circumstances these numerical standards would be met, the differences between the alternatives is

described in terms of *risk* of not protecting these beneficial uses. This risk is described in the section on Cumulative Effects.

Direct and Indirect Effects

All alternatives propose activities which have the potential to affect water quality or stream condition to varying degrees. Activities with potential to cause adverse effects are timber harvest, road management, recreation use, and wildlife management. The potential direct and indirect effects from proposed alternatives fall into 5 main categories; changes to riparian conditions, increases in levels of sediments in streams, changes in runoff patterns, changes to chemical characteristics, and changes to water yield. Effects to these 5 watershed processes are described below.

Changes in Riparian Condition - Riparian areas, floodplains and wetlands are the physical link between the upslope terrestrial ecosystem and the stream, lake, or wetland ecosystems. Riparian areas provide shade, large woody material (LWM), and small organic material to aquatic habitat. Riparian areas are also a particularly diverse part of the terrestial ecosystem, providing critical plant and wildlife habitat diversity and 80% of dispersed recreation (Clark et al. 1984). Riparian areas commonly have highly productive timber sites and frequently are the most economic road locations. A full description of the effects of harvest in riparian areas is found in the Vegetation-Riparian section of the Chapter IV. Discussion here is limited to the effects of riparian management on water quality and stream condition.

Practices in riparian areas which have the potential to effect water quality and stream conditions are those which change a) shade, b) streambank stability, c) the rate of input of LWM, d) floodplain characteristics, e) wetland characteristics. These are described in more detail below.

Shade - Increased solar radiation has the potential to increase water temperatures following removal of vegetation.

The direct effect of removal of shading vegetation from streams is to allow more solar radiation to reach the water. The indirect effect is that during summer months water temperatures increase. The Forest is required by the State Water Quality Standards to maintain stream temperatures below specific levels. In cases where summer streamflow is not influenced by snowmelt and where past practices have removed riparian cover, temperatures standards are sometimes exceeded during summer days.

The beneficial use most effected by increases in temperature are fish, particularly Bull Trout in the McKenzie River sub-basin, and fish in hatcheries fed by Salmon Creek.

The degree to which these potential effects occur is determined by the amount of timber harvest and road building in riparian areas and on the methods used. A prescription was developed to determine the maximum level of harvest that would be compatible with meeting Management Requirements specifically related to meeting State water quality standards for temperature. It was determined that timber harvested at rotations lengths of 200 years for Class I and II streams, and 140 years for Class III streams would provide enough shade to maintain stream temperatures based on average widths of streams as determined in the field. (Stewart & Skeesick. 1981) This prescription was modeled as harvest of no more than 5% per decade along Class I and II streams and 7% per decade along Class III streams.

This management requirement prescription was selected for riparian areas in Alternatives A, K, and J. The prescription selected for Alternative D was designed to provide higher quality stream conditions, and would schedule harvest at 5% per decade only on Class III streams on an average. No programmed harvest was scheduled from Class I and II riparian areas. Riparian prescriptions for Alternatives W

and L were designed to provide a high level of assurance that all riparian dependent resources would be protected including riparian dependent plant and animal species; and to maximize the overlap of resource use in these areas. In these two alternatives riparian areas are intended to provide distribution of interior wildlife species, provide optimal thermal cover for big game, and provide quality recreation, in addition to meeting requirements for water quality and stream conditions. No programmed harvest is scheduled for riparian areas in these alternatives. The cumulative reduction of LWM is closely correlated with the cumulative acres of riparian areas harvested which is shown in the section on Riparian vegetation in this Chapter.

Riparian harvest under Alternative NC is taken from the current Land Management Plan, where it was termed timber yield from Streamside Management Units, part of the Special Harvest Component. Riparian areas associated with Class I, II, and III streams were grouped together with a projected timber yield of 72%, which approximates a 140-200 year rotation.

Streambank stability - Direct changes to channel condition have the potential to occur where streambanks are disturbed. Direct distubances can occur during timber harvest, construction of road crossings and trail crossings, and by heavy recreational or livestock use on streambanks.

As used here, channel condition describes the stability of stream banks and the composition of stream substrate. The importance of these characteristics to aquatic habitat is described in the section on Fish. Disturbance of vegetation and soil on streambanks can result in increases in sediment to the stream, and reduction in stable, vegetated overhanging stream banks.

Stable stream banks provide fish shelter, and minimize the risk of increases in turbidity. Substrate which consists of well sorted gravel, with less that 25% fines is considered the best quality spawning substrate.

Disturbance of vegetation and soil has the potential to occur when logs are not fully suspended over streambanks during yarding from or through riparian areas. Streambank disturbance also has the potential to occur during and following construction of road crossings. Road construction which creates large cut or fill slopes adjacent to the stream have the highest potential for adverse effects. Increases in streambank erosion have the potential to occur when culverts are incorrectly placed so the stream current is directed into erodible streambanks. Because of the proximity to the streams, a relatively small disturbance from any of these activities can have an immediate adverse effect to beneficial uses in the immediate area.

On some landtypes root strength is required to maintain streambank stability. Field inventory for the 1977 plan determined that 21.5% of Class I, II and III riparian areas would need to be fully protected from timber harvest in order to maintain streambank stability, because the areas were too steep and unstable to be acceptably managed.

Localized damage to streambanks has the potential to occur in areas of heavy use by livestock. The application of BMP's include measures to control livestock distribution. Only the existing allotment is proposed to continue under the alternatives.

All alternatives propose the use of BMPs for operations in the riparian area. Alternatives with programmed harvest in these areas have a higher risk of direct changes to the streambank occurring.

Large Woody Material - Future management of vegetation in riparian areas has the potential to change the long-term input of Large Woody Material to streams, wetlands and lakes, with subsequent changes to stream channel condition, and streambank stability.

Trees in riparian stands provide input of Large Woody Material (LWM) to the water. As trees in riparian stands are blown over, or the tops broken out, the wood is gradually recruited into stream channels, and functions as an integral part of the stream channel. Research indicates that 90% of large wood is recruited from within 100 feet of the channel on all stream classes.(McDade)

LWM influences the stability of stream channels by armoring streambanks, and dissipating the velocity of water. The role of LWM in a stream differs between stream channel types. A large reduction in the levels of LWM in streams has been shown to correlate with stream widening on low gradient streams.(Grant et. al 1989) Stream widening would result in loss of productive land area, and shallower, more exposed aquatic habitat. Low gradient streams are generally Class I and II streams. On steeper gradient streams, generally Class III and IV streams, instream wood controls the flow of sediment through the system by storing silts, gravels, and cobbles behind them. (Megahan, 1982) Changes in the levels of LWM in Class III and IV effects levels of sediment transported to Class I and II streams, and is discussed more thoroughly in the section on sediment.

Levels of LWM strongly influence the creation and stability of aquatic habitat conditions such as pools, side channels, and well-sorted gravels.

Over the next 50 years, decreases in the number and size of trees falling into the streams would increase the risk that current levels of stream channel stability and the complexity of aquatic habitat would not be maintained over the long-term. Monitoring during the next decade would begin to provide important information on the correlation between existing condition of riparian areas, complexity of aquatic habitat, and stability of stream channels.

As of 1981, 39% or 1,313 miles of Class I, II, and III streams were in or adjacent to harvest units or roads (Stewart and Skeesick, 1982). The amount of protection afforded these streams was variable, but in general, during the 1960s and early 1970s LWM was removed from streams where accessible. Stream habitat features which are created by the presence of large woody debris were reduced, and will not recover until adjacent riparian stands have timber of sufficient size and condition to provide trees which are stable in the stream environment. This potentially occurs beginning 60 to 80 years after harvest in areas where conifers are established. It may take several hundred years for conifers to develop where deciduous stands are currently dominant.

Alternatives A, K,and J would result in forest-wide reductions of input of LWM of more than 4% in the first decade, 7% in the second decade, and 18% by the 5th decade. Alternative D would result in a 0% reduction for the first decade, 2% by the second decade, and 6% by the 5th decade. Alternatives W and L would program no additional harvest over the next 50 years, thus allowing recovery of riparian areas harvested in the past.

Floodplains - Future management of timber within the 100 year floodplains of streams, wetlands and lakes have the potential to alter the functioning and value of floodplains.

Floodplains function to temporarily store floodwaters thereby reducing the risk of downstream flooding. These areas also provide safer, slackwater habitats for fish during high flows. Characteristics of floodplains which reduce stream velocity are standing and downed trees and other vegetation which creates roughness of the floodplain surface.

Executives Order No. 11988 requires that the agency take action to reduce the risk of flood loss, to minimize the impact of floods on human safety, health and welfare, and to restore and preserve the natural and beneficial values served by floodplains. In all the alternatives management activities within the 100 year floodplain would comply with requirements of Executive Order 11988. Alternatives with

programmed harvest from Class I and II streams have a higher risk that these values would not be protected.

Lakes and wetlands - Future management of vegetation in riparian zones on lakes and small wetlands has the potential to adversely effect the water quality and aquatic habitat of these areas.

The requirement to provide protection for the water quality in wetlands and lakes is established in the Clean Water Act. Direction to provide for other beneficial values of wetlands is established in the Wetland Protection Executive Order 11990. This direction has been included in the S&Gs for all alternatives. Alternatives NC, A, K, and J accept higher risk of adverse effects to these resources by scheduling timber harvest from lakeside areas. Alternatives W, D and L do not schedule harvest from lakeside areas.

Small wetlands, such as bogs, ponds, and overflow channels would be evaluated for beneficial values and potentials under all alternatives. These areas are too small to be evaluated for programming harvest.

Riparian Summary - In Alternatives W and L on Class I, II, and III streams, an area of varying width immediately adjacent to the channel would be withdrawn from programmed timber harvest. As a result these alternatives have a high probability of success in protecting beneficial uses that are dependent of cool water temperatures, protecting streambanks, wetlands and lakes, and minimizing serious and long-lasting hazards from floods. The recovery of adjacent, previously harvested riparian stands, as well as stream channels would be promoted. The other alternatives carry a higher risk of not meeting these objectives.

The riparian acre base under Alternative NC is incomplete, and proposed management includes harvest on lands on which current technology cannot assure that irreversible resource damage would not occur. As a consequence, Alternative NC poses the greatest risk to water and fisheries resources.

Changes in Sediment - Water quality in Class I and II streams is often characterized by turbidity levels of the streams. Turbidity usually increases as the amounts of sediment particularly the clay and silt sized particles which reach the stream. Stream conditions and habitat are influenced by the amounts of sediment which is deposited in the stream channel. Water quality of lakes, wetlands and reservoirs is effected by the amount of sediments which travel through Class I, II and III streams, or the amount of sediment which remains suspended in reservoirs, lakes and small wetlands.

Although some sediment is necessary in stream ecosystems, optimum or threshold amounts and sizes have not been identified. The adverse effects of smaller sized material has been shown to reduce the survival of salmonid fry as they emerge from spawning gravel. Increases in sediment can also alter channel width, depth and gradient, with other indirect effects as the channel adjusts to additional bedload. (Bradley, Williams, Klingeman, 1989)

The risk of increasing sediment delivery to the streams increases with the acres of ground disturbing activities and varies according to the source of the eroded material. Table IV-2 in Soils summarizes the estimated relative erosion under each alternative. The primary sources of sediment is from mass movements, particularly debris torrents, and from surface erosion. The risk that these processes would result in increased stream sediment is described below.

Mass Movement - Sediment generated from mass movement, particularly debris slides, has the highest potential to impact water quality, channel stability and aquatic habitat. (Sediment generated from surface erosion is discussed in the following section.) Water quality is effected by debris slides when they reach water. No quantitative link has been made between the volume of soil moved in debris

slides and increases in water turbidity because of the extreme variation in the landtypes being considered. The conclusion can be made however that the **risk** of adverse turbidity levels increases as the incidence of debris torrents increases.
Debris slides which mix with water and continue through a stream channel are termed debris torrents. Debris slides and torrents occur as part of the natural weathering process, and most of the steep headwater channels have been subject to debris torrents at some time. Under natural conditions debris torrents would occur most frequently during major storm events when soil is saturated, and following major wildfires, when root strength is reduced. Under managed conditions, soil saturation and root strength still influence the rate at which debris torrents occur.

The distance debris torrents travel in a stream channel is largely dependent of the sinuosity and gradient of the channel. Torrents move farther in straighter, steep channels, (Swanson and Roach, 1987) and depending on the amount of LWM in the channel available to reduce the velocity of the debris torrent. (Ketcheson and Froelich 1978). Debris torrents often increase in size as they travel downstream, particularly where they fill a culvert, resulting in saturation of the road fill and complete failure of the fill material.

The force of a debris torrent travelling through Class III and IV streams often moves existing LWM and stored sediments out of these steep, headwater streams into the low-gradient streams causing increases in turbidity and bedload. The downstream channel adjusts in width and depth in response to increases in bedload. Where LWM is deposited in bedrock channels it sometimes increases aquatic habitat complexity but in some cases can make the stream temporarily impassible. After a debris torrent removes LWM in Class III and IV streams water velocities may increase and silts and gravels may be scoured from the streambanks and channel bottoms resulting in increased turbidity downstream. Streambanks are susceptible to additional erosion following removal of LWM where composed of deep soils, and where extremes in peak flow runoffs occur during rain on snow events.

Debris torrents have the potential to influence wetlands, lakes and reservoirs also. The effects to small wetlands and small lakes may be to substantially reduce the storage capacity of wetlands, and to reduce the water quality. In larger lakes and reservoirs, debris torrents would also increase turbidity. In some cases, such as Hills Creek Reservoir the material which enters the reservoir, may be very fine, clay-sized material which has the potential to stay in suspension for long periods of time. These sediments may settle out eventually, but are usually resuspended when the reservoir level is drawn down, and the exposed draw-down zone is subjected to rain-erosion. Increases in turbidity have the potential to decrease the recreational quality of the reservoir.

Debris slides occur as part of the natural, unmanaged hillslope process, and in areas managed for timber production. Studies have shown that management practices during the period of 1950 to 1980

The following sections describe the three major influence on changes to the size and frequency of debris slides.

Unstable and Potentially Unstable Landtypes - The inherent stability of the landtypes influences the changes size and frequency of debris slides.

Landtypes with the highest risk of mass movement are those which are currently "unstable". These are areas which have moved recently enough to leave observable signs on the soil profile. These have been mapped as "unsuited for timber production due to irreversible damage", and have been excluded from timber scheduling in all alternatives.

Table IV-3 Percent Suited Lands on Potentially Unstable Soils by Watershed

[1]Not included in this assessment

The next highest risk is from the group of landtypes which are "potentially highly unstable". These are generally steep tuffs and breccias, or shallow soils. Management practices on these soils require extra mitigation measures. The effects of the alternatives would closely follow the number of suited acres on potentially highly unstable landtypes and the types of mitigation measures included. Mitigation measures which would reduce rates of mass movement below levels experienced in the past 40 years are described and referenced at the end of this Water section and in Chapter II, Alternatives Considered in Detail.

The amounts of potentially highly unstable land available to harvest varies by alternative. Only a small proportion of these acres would actually be harvested in the first decade but the total amount available to harvest reflects some of the associated risk for each alternative.

Alternative NC schedules harvest on approximately 128,000 acres of potentially highly unstable land, Alternatives K, and A include approximately 115,000 acres, Alternative J includes 113,000 acres, Alternative W includes 106,000 acres, Alternative D includes 102,000 and Alternative L includes 72,000 acres. The percent of unstable land varies by watershed as shown in Table IV-3.

Timber harvest - Timber harvest has the potential to increase the rate and frequency of debris slides by reducing root strength on steep slopes.

A direct result of the harvest of trees is the loss of root strength which follows. The subsequent indirect effect under some circumstances is an increase in debris slides. Root strength is one important factor in maintaining slope stability on slopes over 60%, particularly in areas where soils naturally have low cohesion characteristics, and in areas where soils become saturated. (Hammond et al.) Slides may occur midslope on potentially highly unstable areas, on steep streambanks, and in headwall areas which are usually adjacent to Class IV streams.

Alternatives vary in treatment of these potentially highly unstable landtypes. All alternatives prescribe BMPS which are intended to maintain slope stability in order to maintain water quality. Alternatives W and L are designed to ensure a that these BMPS are very effective by including S&Gs with specific direction to maintain trees where needed for root strength, and where needed to replace LWM in steep streams with the intent of maintaining the natural rate of debris torrents movement through the stream system. In alternatives NC, K, A, J and D, no specific direction or modelling addressed this effect, consequently the risk of debris torrent occurrence would be higher in these alternatives.

Commercial thinning is expected to maintain enough root strength in these areas so that the risk on debris torrents is not substantially increased following removal of the trees.

Roads - Existing and future roads have the potential to result in increased size and frequency (rates) of debris slides where pore water pressure and/or soil shear strength is altered.

Several studies have identified roads constructed between 1950 and 1980 as primary source of debris slides, and debris torrents. (Swanson and Grant,1982) Road construction often alters the soil shear strength and pore water pressure, two important factors in the size and frequency of debris slides. As these two factors are changed debris torrents have the potential to occur more frequently. They are particularly likely to occur as soil moisture increases particularly when road fills become saturated. Road fills have the potential to become saturated when a culvert is plugged by a debris torrent or when a drainage ditch becomes blocked and runoff is rerouted from the ditch to the road surface and fill. The ditch may become blocked by failures of the cutbank material.

Some existing roads have created conditions where a high potential for debris torrents still exists. At some sites on these roads, uncompacted fills were constructed, or material excess to the construction of the road, was "sidecast" over the edge of the road, also uncompacted. Where this material is uncompacted, it becomes saturated and fails more readily than roads constructed with compacted fills. These sites have the potential to continue failing through the following decade as the root strength continues to decline. Projects to stabilize these sites are proposed in all alternatives. The amount of sidecast material with the potential to fail is estimated to be in addition to that shown in Table I-1-3. This is because during the study period, the root strength in these sidecast areas had not decreased to its current low condition.

Roads constructed in the future, in all alternatives, would use practices which are currently recognized as "Best Management Practices", such as prohibiting construction of uncompacted fills and sidecast material. These practices are described in more detail in the section on Mitigation Measures.

Road closures, as proposed in all alternatives to meet wildlife and recreation objectives, can have an adverse effect on water quality and stream condition, depending on the methods used to close the roads. Where permanent roads include culverts and cross-drains, the ability to reach these drainage structures for periodic maintenence, would be a major factor in the frequency and size of potential road failures from plugged culverts. Road closures can also result in less sediment as fewer roads are available for use during wet weather.

The relative increase in amounts of material moved by debris slides during the first decade is displayed in Table IV-4 for each watershed by alternative. Also shown in the table is the natural rate for each watershed, expressed as cubic yards per acre. Under natural conditions there is a wide variation in the size and frequency of debris slides, associated with the inherent stability of the geology. (Numbers used in this and other tables expressing erosion are index numbers for relative comparisons between locations and alternatives.) The natural level, and the increases from management activities are used as an index of the potential sediment yield and consequently an indicator of decreasing water quality and stream condition. Alternatives with low soil erosion and consequently lower sediment yield should be considered to provide the best water quality. Alternative L has the lowest risk because of the low number of acres harvested, and few miles of road constructed. Alternative W is the next lowest, followed by Alternative D. The major differences between W and D is the reduction in risk of sedimentation by protecting Class IV and headwall stream areas in Alternative W. Alternatives J, A, and K have the highest risk. More information about how the estimates were made is given in Appendix B.

[2]Average annual volumes
[3]Data not available
[4]Management activities in Lookout Creek are not included in this assessment

Surface erosion - Management activities have the potential to increase surface soil erosion, and the associated risk of this soil being delivered to streams. Surface soils are eroded from hillslopes and roads, each process having a different risk of being delivered to streams.

Hillslope erosion - Practices which increase surface erosion from hillslopes have the potential to cause adverse effects to water quality and stream conditions where eroded material reaches waterbodies.

Projects which result in removing soil cover on slopes are timber harvest, fuel treatment activities, and forage improvement projects. Reduction of the vegetation and duff from soils has the potential to result in increased erosion of surface soils. Where the eroding soils are adjacent to streams, wetlands, lakes and reservoirs, some of the material may reach the water, effecting the water quality and stream condition. Research has shown that the main factors influencing the rate of surface erosion from harvest units are the percent of the soil cover which is removed, and steepness of the slope. (Swanson and Grant, 1982) The main factors influencing transport of material to streams is the distance and the roughness of the ground between the eroding site and the stream. (WRENS, 1981)

Surface erosion is transported downhill in several ways. Research in the Coast Range (Bennett 1982) shows that the dominant process in areas of less than 60% slope is raindrop splash and freeze/thaw action. Overland flow is was not observed in unburned areas. On areas over 60% slope and on areas that had been burned the dominant transport mechanism was dry ravel. Most of the material moved downslope was coarser fragments, and 65% of the material moved within 24 hours of the burning. The mean distance this material traveled during the 20 month study was as follows: on slopes less than 60%, 1.1 meters; and in areas over 60%, 5.4 meters. This would imply that transport of surface erosion can be mitigated to an insignificant amount by maintaining soil cover characteristics similar to undisturbed ground in areas up to 5.4 meters or approximately 18 feet adjacent to streams.

The number of acres harvested would influence the risk of surface material reaching streams, and the effectiveness of applied BMPs. All alternatives require application of BMPS to control movement of surface erosion to streams, and these types of BMPS are usually very effective. It is estimated that the amount of material reaching the streams from surface erosion would be negligible.

Commercial thinning is not expected to substantially increase surface erosion, as the duff layer is normally retained except on designated skid roads which are treated with erosion control measures.

Roads surfaces - Road use and construction during winter months have the potential to increase movement of road surface materials to streams.

On the Forest many of the roads used as major haul routes during the winter months are adjacent to reservoirs and Class I and II streams. Erosion of road surface material during these times, and delivery of this material to water can be a major source of sediment and turbidity. In many cases the fine-grained material erodes from road gravels and subsurface. The streams most likely to be effected are those in lower elevation watersheds where the geology of the old Cascades has created fine-grained soils, and where roads are used for log haul and recreation during the winter months.

The limited study of road surface erosion indicates that the amounts eroded are highly variable with the type of road surfacing material, the length of time the road is used, and the precipitation patterns during use (Reid 1981). This variability makes quantification of the amounts of m

delivered to streams very rough estimates. All alternatives would apply the same road surfacing measures, therefore, the amount of sediment generated from road surfaces for each alternative would follow the amount of volume harvested. Alternatives K, and A are highest, and Alternatives W, D, and L are lowest.

Sediment Summary - Alternative L has the lowest risk of debris slides because of the low number of acres harvested, and few miles of road constructed. Alternative W is the next lowest, followed by Alternative D. The major differences between W and D is the reduction in risk of sedimentation by protecting Class IV and headwall stream areas in Alternative W. Alternatives J, A, and K have a highest risk. Surface erosion delivery to streams is estimated to be minimal with the application of very effective BMPs. If measures are not effectively implemented and enforced, the amount of sediment from road surfaces could be very high.

Estimates of the total amounts of erosion from roads is included in Table IV-2. These estimates are of erosion, not delivered sediments.

Evaluation of Runoff Patterns

Runoff patterns refers to the quantity of runoff which occurs during different periods of time. Different parts of the runoff pattern are the "peak flows", "low flows", and "base flows". The causes and effects of peak flows are evaluated in the first section below.

For any period, the runoff pattern would be influenced by the intensity and duration of the precipitation, and the capacity of the watershed area to store the runoff. Factors which influence runoff patterns, but which are not appreciably altered by management practices are precipitation patterns, slope of area, and depth of soils. Management activities can change the capacity of the watershed to temporarily store the runoff by changing snowpack temperatures, snowpack water content, condition of vegetation, and miles of streams or ditches carrying runoff. These processes are described in detail below.

Changes in runoff patterns are most pronounced when warm wind and rain-storms occur on saturated snowpacks. These storm events occur commonly in the transient snow zone between October and March. The transient snow zone is generally between 1500 and 4000 feet elevation on the Forest. Under some climatic conditions more snow accumulates and more rain and wind reach the snowpacks in created openings than in adjacent forested areas. The variation in windspeeds between clearcuts and forested areas was confirmed by studies on the Oakridge District (Christner, 1984). As a result of these changed conditions, more rapid snowmelt can occur during rain-on snow events which are commonly accompanied by warm winds from the southwest. Research on rain on snow conditions recorded 21% more "water outflow" from plots in clearcuts than from equivalent forested areas measured at the same time. (Berris and Harr, 1983). This increased snowmelt can translate to changes in peak flows in streams, and subsurface waters.

The potential effects of created openings on runoff patterns is quantified by estimating the ability of the timber stands to intercept snow, rain, and wind. This functioning is termed the "hydrological condition" of the area, and is quantified with the Aggregate Recovery Percent (ARP) method. On this Forest a timber stand is judged to by hydrologically recovered at 25 to 35 years old.

Stream runoff - Timber harvest has the potential to increase peak flows in subdrainage streams, which may result in an increase in erosion of stream banks and substrate. Increases in peak flows sometimes occur where created openings have increased snow accumulation, snow pack water content, and snow pack temperature.

This effect is sometimes considered a cumulative effect, because the peakflows are a product of the cumulative total of the area clear-cut within a sub-drainage. Peak flows is dealt with as a direct and indirect effect here, because it is one component of the cumulative effects discussed below, the other two components being the effects of riparian management, and increases in sediment.

Changes in snow accumulation and melt in subdrainages (median size 2500 acres), may increased the size of peak flows during rain on snow events. Research in the H.J. Andrews Experimental Forest made comparisons between two small subdrainages, one harvested, and one forested, (Watersheds 9 and 10). When air temperatures reached 4 degrees C. and above, the peak flows from the harvested subdrainage were 50% larger than in the forested subdrainage (Harr 1986) While this analysis does not show conclusively that this is attributed to the clearcutting, it indicates that there is a high likelihood that this effect is occurring at this scale.

The relationship between timber harvest and increases in peak flows in larger watershed areas (15,000 to 100,000 acres) has been studied (Christner and Harr, 1982.) The conclusion that there appeared to be peak flows related to the amount of timber harvest is not unanimously supported in the scientific community.

Effects of increased peak flows on stream conditions - Stream conditions and turbidity are influenced by the amount and timing of water flowing through the channels. Increases in peak flows have the potential to adversely affect stream conditions and water quality by increasing the rate of movement of sediments and bedload already in the streams, and by eroding stream channels. For example, currents with velocities above 0.5 ft/sec are capable of moving silt; while flows of more than 1 ft/sec are required to move sand, and currents above 2.5 ft/second can move gravels. (Yates, 1988).

The potential effect of increased peak flows on stream channels is varied, depending on channel characteristics. Several different effects may occur within any area. For example, in low-gradient reaches, where gravels are normally deposited, increased peak flows may cause gravel-size material to move more frequently, resulting in damage to fish eggs deposited in the gravels. Vegetation may take longer to become established on the higher gravel bars, resulting in increased temperatures, and more exposed habitat. Increased movement of bedload material can influence the width and depth of the stream channel under some circumstances.

The potential effects of increased peakflows on steeper gradient streams is the increased scouring of streambeds and banks, resulting in streambank instabilities, and increased turbidity. Debris torrents may be triggered where steep channels have high amounts of gravels. The effects of debris torrents was described in the previous section.

In landtypes with deep seated mass movement adjacent to the stream channels, increases in peak flows have the potential to undercut the toe of the mass movement. In some cases the rate of movement of the unstable area may be substantially influenced by the amount of the toe material which is eroded by the stream. This process has the potential to increase turbidity and downstream bedload. This type of occurrence is limited to a few critical sites on the Forest. The potential for increases in peak flows to result in adverse effects to stream channels and water quality is related to inherent characteristics, and the beneficial use. Sensitivity of the Forests 454 subdrainages were described based on their average slope, the percent in the transient snow zone, and the local beneficial use. Average slope was selected as an indicator of the velocity of runoff, and the distance debris torrents might travel. The existing stream channel condition is important information which should be considered in assessment of the effects of peak flows on stream channels, but which was not available.

It was estimated that hydrological recovery of between 60% and 85% would maintain channel stability, depending on the subdrainage sensitivity. Each subdrainage was assigned a Midpoint ARP as a reference point for assessment purposes. During project implementation a Recommended ARP would be determined based on site specific characteristics, including existing channel conditions. The Recommended ARP can be considered a BMP to distribute timber harvest in order to minimize adverse cumulative effects. The Midpoint ARP is intended to represent an average of Recommended ARPs, used for modelling purposes.

Table IV-5 shows the theoretical hydrological recovery of subdrainages under different alternatives, with all harvest constraints applied. Many of the subdrainages would be maintained above the Midpoint ARP level because of harvest constraints from scenic and wildlife resources. In approximately one-third of the subdrainages, ARP would be the most limiting constraint. These are primarily very sensitive subdrainages where the Midpoint ARP is 75% to 85%.

Table IV-5. Subdrainage Hydrologic Recovery

	Alternatives [1]						
% Recovery	NC [2]	K	A	J	W	D	L
95-100%	NA	36	38	42	43	51	62
90-94%	NA	25	32	29	39	35	98
85-90%	NA	53	41	64	69	76	109
80-85%	NA	97	92	90	112	83	99
75-79%	NA	96	96	108	103	106	47
70-74%	NA	85	93	66	51	53	10
65-69%	NA	33	33	26	10	21	4
60-64%	NA	3	3	3	1	3	0

[1]Values presented are the number of subdrainages which fall in each category throughout the 1st decade, considering Forest and Non-National Forest land, and all land allocations
[2]No data is available. Alternative NC would be expected to cause the greatest number of subdrainages to fall into the lower 3 hydrologic recovery groupings.

At the watershed scale, the potential for adverse effects from peak flows was assessed based on an aggregation of the subdrainage Midpoint ARP levels. A comparison was made of the number of acres theoretically available for harvest in each subdrainage while meeting Midpoint ARP, with the number of acres scheduled for harvest by FORPLAN in each watershed. Table IV-6 indicates which watersheds would have the Midpoint ARP levels exceeded in all subdrainages, if the acres scheduled by FORPLAN were harvested. The Midpoint ARP levels would be exceeded by 1 to 12%. Where the Midpoint ARP levels are exceeded, there is a higher risk that stream channels and beneficial uses would not be protected.

FORPLAN results showed that harvest could be distributed to the less sensitive watersheds. The DEIS assumed that harvest would be distributed equally across watersheds, resulting in more of the sensitive watersheds being assessed as higher risk. In the FEIS analysis, FORPLAN may have been able to distribute the same amount of acres across watersheds to result in even less risk than is indicated here, however due to limitations on model size this was not feasible at this time.

Alternative K has 3 watersheds totalling 7% of the Forest in an increased risk of peak flows. Alternatives A, J, and D have approximately the same number of watersheds, but which cover less area of the Forest. Alternative L has one watershed at which does not meet Midpoint ARPs, and this is less than 1% of the Forest. All the watersheds in Alternative W meet the Midpoint ARP levels because this was one of the objectives of the Alternative.

[1]"X" indicates that the watershed has a high risk of experiencing increased peak streamflows as a result of activity planned under the alternative.

[2]No information is available. Alternative NC would be expected to cause a greater number of watersheds to experience a high risk of increased peak streamflow and landslide incidence then Alternative B-Departure, due to having a greater amount of timber harvest and road construction.

Subsurface runoff - Timber harvest has the potential to alter the amount and timing of water entering the soil, with subsequent indirect effect on several watershed processes.

Mass movement - Snowmelt in created openings has the potential to result in increased mass movements due to increased subsurface soil moisture during rain-on-snow events.

Research on mass movements confirms that soil moisture is one factor influencing the rate at which mass movements occur. The influence of these factors such as root strength, soil shear strength, and slope, is also important. Theoretically increases in the subsurface water during the periods of rapid snowmelt and runoff could result in increases in mass movements on potentially highly unstable slopes. The risk of this occurring has been described with the ARP method by some hydrologists. The scientific community is not unanimous in their agreement that hydrological recovery of a watershed is the appropriate tool for describing the risk of mass movements, or that control of hydrological recovery will effectively control the frequency and size of mass movements.

Where mass movements occur in clearcuts, it is difficult to ascertain whether the movement is in response to increased soil moisture, or to decreased root strength. Where root strength is a factor, mitigation measures to maintain root strength on specific site can be prescribed. Very little research is available on the proportion of mass movements which are initiated by increases in subsurface water alone, without the influence of decreased root strength.

In this analysis the risk of increased mass movement is evaluated based on the landtypes where the activity occurs, as described in the section above on Sediment.

Aquifer recharge - Timber harvest has the potential to reduce summer low flows, and aquifer recharge during summer months.

Research studies indicate timber harvesting generally increases annual water yields. This is due primarily to reduced evapotranspiration. Harr (1983) developed a regression equation for use in estimating potential increases in annual water yield, which can be expected from clearcutting in western Oregon and Washington based on research results in experimental watersheds. Initial on-site increases of up to 20 inches are predicted, though they completely disappear in about 27 years. The equation predicts a smaller annual water yield increase when annual precipitation is less. Harr estimated that sustained increases in annual water yield from most large watersheds in western Oregon and Washington subject to sustained yield forest management are, at best, three to six percent more than flows from an undisturbed forest. Kattelmann, et al. (1983), estimated similar maximum potential increases in Sierra Nevada watersheds if minimum standards for all applicable laws were followed. However, they concluded that the typical increase in a large watershed drops to approximately one percent when constraints are imposed to meet other resource demands. A similar scenario is expected in Region Six National Forests due to multiple use considerations. Other factors which further minimize potentials to effect changes in streamflow are high natural variability, flow measurement accuracy is within five percent at best (so potential changes are less than what is measurable in large watersheds), and most of the flow increases occur when it is needed the least or is unusable (during spring runoff on the eastside and during fall storms on the westside.)

Research generally shows increases in summer flow result on-site immediately after harvest in western Oregon. However, studies in the Rocky Mountains (Troendle, 1983) showed no change in late summer streamflow following timber harvest, despite annual increases. (These increases occurred during spring snowmelt.) In large watersheds subject to sustained yield harvesting, summer flow increases are temporary and not expected to be measurable at downstream locations.

Effects of harvesting timber on groundwater recharge and aquifers are similar to effects on streamflow, except for timing differences; eg., aquifer responses are typically slower and fluctuate less than streamflow.

The above-mentioned research findings indicate timber harvesting on a sustained yield basis, as is presently practiced and would be practiced under any selected forest plan alternative, is expected to have a negligible, unmeasurable effect on downstream aquifers. There is no realistic potential to modify timber harvesting to measurably increase downstream water supplies. This assumes management practices are conducted in a manner which reasonably maintains water infiltration characteristics, as is typical of current practices on National Forest System lands. BMPs would ensure adequate infiltration characteristics are maintained. Only if extensive, contiguous areas were compacted would infiltration be expected to be reduced so as to adversely effect downstream aquifers.

Road interception - Road construction has the potential to increase the rate at which subsurface water reaches stream channels.

Road construction has the potential to alter natural drainage patterns, causing an increase in the interception of subsurface flows and acceleration of the delivery of subsurface runoff to the small stream channels. (Megahan) These effects most frequently occur in areas with high intensity precipitation and dissected topography.

As subsurface flows are delivered to stream channels, they may increase the flow within channels, having the same effect as described for increases in peak flows due to rapid snow melt. These effects can be compounded during rain-on-snow events in the transient snow zone, when rapid melt of snow accumulated in the road opening may reach the stream channel.

The extent to which this occurs would increase with the miles of roads constructed and timber harvested in the transient snow zone being highest in Alternative K, and A, and lowest in Alternative L and W. BMPs for road design can be effective in providing "relief" culverts, which drain water from ditches before it reaches the streams. These relief culverts, or cross-drains, direct the flow onto the slope below the road, where it infiltrates into the soil.

Runoff Summary - Timber harvesting and road building can have potential effects on patterns of snowmelt, stream runoff, and subsurface water levels, with indirect effects on stream channels. Alternatives which harvest the most acres generally have a higher risk of adverse effects from changes in runoff patterns. Alternative K results in 7% of the Forest area being at a hydrological recovery level with a risk of damaging stream channels.

Water composition

Water on the Forest contains very low concentrations of most chemicals, nutrients, bacteria, and other micro-organisms. Waters of the McKenzie River, Little North Santiam River and of Waldo Lake are widely known for their clarity and purity. Future Forest activities have the potential to change this water quality. To protect beneficial uses numerical water quality standards have been established for Dissolved Oxygen, Ph, and fecal coliform. In additions the State water quality standards prohibit bacterial pollution, fungi, tastes and odors which are deleterious to beneficial users. Numerical standards for some chemicals have been established by EPA for drinking water.

Timber Management - Changes in the chemical concentrations of water have the potential to occur where timber harvest occurs, where fertilizers are applied, and where chemicals are used for vegetation or pest control.

Research has shown that removal of forest trees sometimes results in changes to the chemical composition of water flowing from the area. Studies on the Umpqua N.F., just south of this Forest, found that clearcutting resulted in increases in total dissolved nitrogen (N) from a watershed that had been 77% clearcut, but that at no time did the increased chemical levels degrade water quality, even under the relatively strict drinking water criteria of EPA. (Adams and Stack, Draft, 1989).

Other increases from the clear-cut watershed were observed in ortho-phosphate, total dissolved phosphorus, calcium and potassium concentrations. No effect of beneficial uses has been observed from these increases.

All alternatives propose to fertilize Douglas-fir stands with urea fertilizer annually, when the stands are approximately 30 years old. The potential for fertilizer application to adversely affect water quality has been monitored during the past 10 years on a number of projects. When applied with BMPs, including avoidance of applying it to streams with beneficial uses, the increases in nitrogen would have no known effect on beneficial users.

Other timber management projects which may include use of chemicals is the management of competing and unwanted vegetation. Current direction states that the preferred methods of treatment of competing vegetation is prevention and non-herbicide tools; and that herbicides will be used only when other methods are ineffective or will increase project cost unreasonably. (FEIS Unwanted and Competing Vegetation, and Mediated Agreement.)

Chemicals such as fertilizers, pesticides, and petroleum products can reach streams through accidental spills, particularly along the railroad and major highways which bisect the Forest. Contaminants may also reach streams due to application to areas which contribute surface runoff to streams. Mitigation practices on the Forest include a Willamette N.F. Spill Plan, and existing laws and regulations. Herbicides, in particular, are not applied in the riparian areas adjacent to perennial streams. The chemical composition of water is not expected to vary by alternative.

Recreational Use - Intensive recreation use may increase levels of bacteria and nutrients, and chemicals in waters. In many cases one type of beneficial use may create risks of damage to other types of beneficial users. Recreation programs will be managed with BMPs.

Many recreation activities are located on or near streams, lakes, and reservoirs of the Forest. These activities include no-trace dispersed camping, use of livestock for pack animals, use of developed campgrounds, fishing, stream and lake swimming, use of motorized boats on lakes, and ORV use in reservoir draw-down zones. Designation of Wild and Scenic Rivers usually increases national attention and recreation use. Increased demand for water related activities is expected in all alternatives.

Uses such as dispersed camping, river running and camping, and swimming increase the risk of water being contaminated by human and animal wastes, bacteria, viruses and parasites which people carry. Gastrointestinal illness and skin diseases have the potential to increase from drinking and swimming in contaminated water. The magnitude of contamination and effect on users is not known, but experience on other heavily used recreation rivers suggest that crowding of recreationists would be noticed before water contamination is recognized as a problem. Effects would be greatest in late summer when water is relatively warmer and recreation users increase. Use of chemicals, such as detergents, increases the risk of contaminating lakes where water is not highly aerated and is infrequently replaced.

Concentration of wildlife, livestock, and saddle or packstock can have local effects on the sanitary quality of water. All of the Alternatives have similar chances of concentrating animals near streams or lakes.

Developed campgrounds are designed with measures to control water contamination, and water quality of water supplies for these campground are checked frequently in compliance with the Safe Drinking Water Act. The risk of water contamination increases where developed campgrounds do not have water supplies, and users are more likely to use local streams and lakes for their water needs.

Motorized boats are currently allowed on Waldo Lake, Big Lake, and reservoirs. The potential exists for accidental contamination, such as fuel spills on these waters. The decision to allow or prohibit this type of use is made at the District level, based on public input and environmental assessment

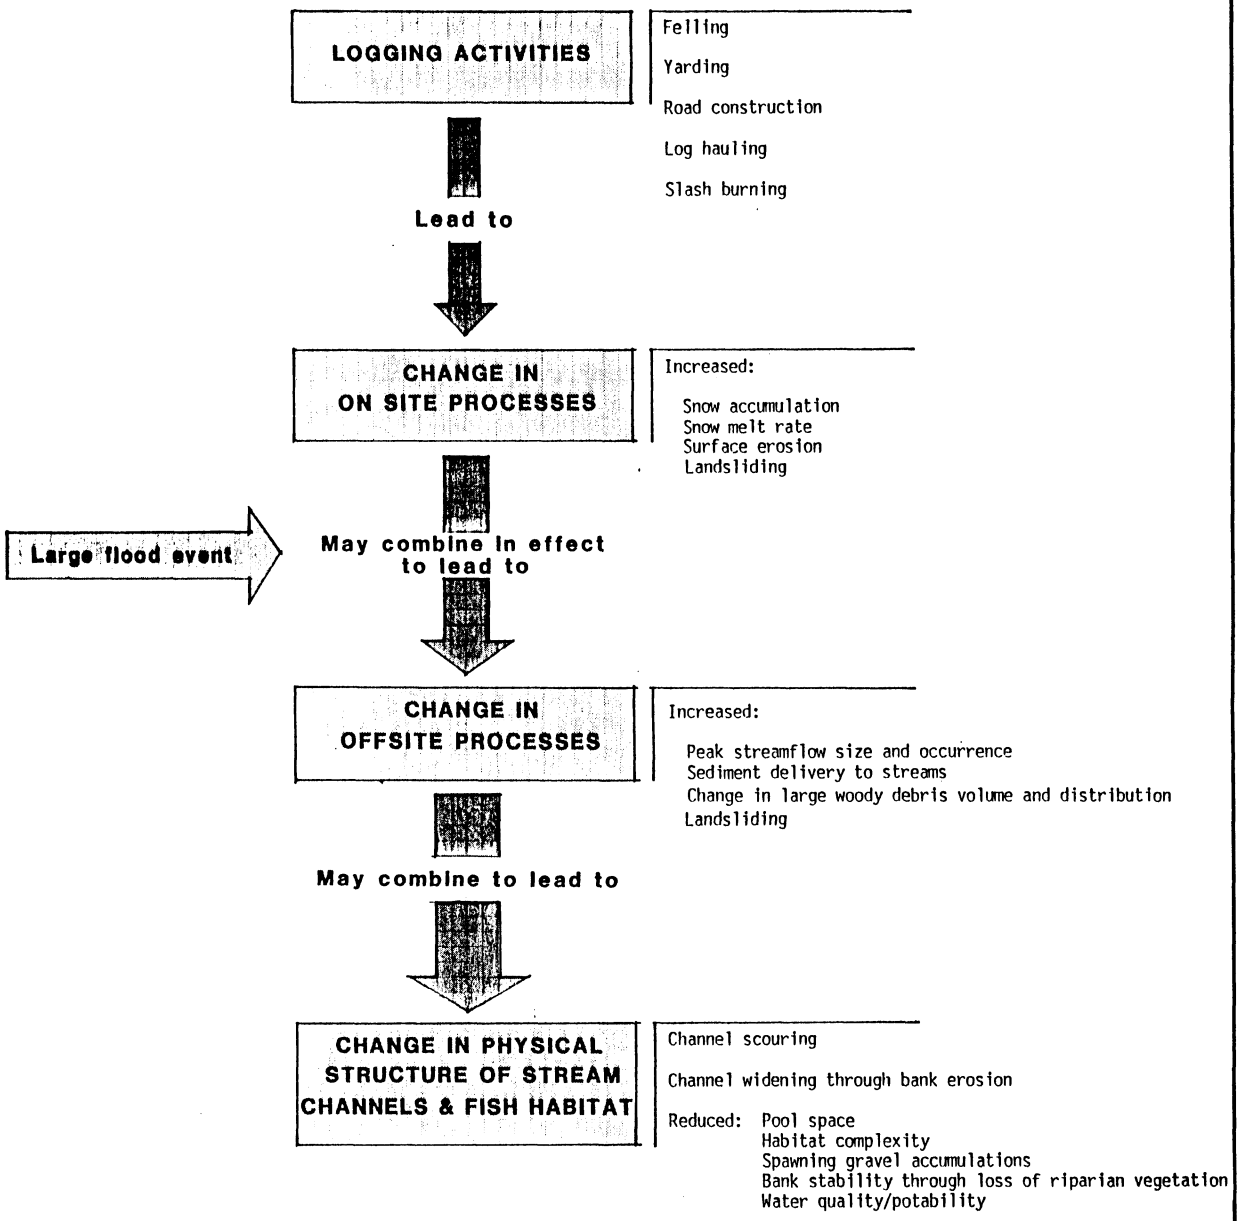
Reservoirs are heavily used for recreation throughout the year, for both fishing, and in some locations, for Off-Road Vechicles (ORV) use in the draw-down zone. ORV use has the potential to decreased the recovery of vegetation on the shallow parts of the draw-down zone (less than 30 feet below high water line.)

Water Yield - Quantity

Forest management practices have the potential to change the quantity of water flowing from the forest.

Watershed research consistently shows temporary increases (5-20 years) in total annual water yield and summer flow from completely deforested land (Harr 1976, 1982). Removal of trees reduces transpiration (the use of soil water by plants) and more water is available for streamflow. Increased water yield is considered a benefit when water supply is limited. Harvest areas, however, combine with undisturbed and reforested areas in large (40 square miles and greater) watersheds to mask streamflow increases. Harr, Fredriksen, and Rothacher (1979) maintain that water yield increases from sustained timber harvest would be smaller than the 5% accuracy of streamflow measurement. Harr (1976) used data from previous research to show that this would be true even when 20% of large watersheds were harvested continuously each decade. Timing of increases further reduce their benefits. None of the alternatives exceed 20% harvest per decade in drainages larger than 40 square miles, and no significant increases in water yield are expected. Chapter III, Water includes a discussion of water supply.

Potential Cumulative Effects



Concepts - The National Environmental Policy Act (NEPA) requires that the Forest avoid "unintended consequences" as a result of land management activities and to be appropriately conservative where knowledge is imperfect. Our knowledge in terms of assessing cumulative effects is limited. There is no consensus within the research community that cumulative effects on water occur or can be demonstrated (Grant 1986). The "state of the art" in assessing the risk or reality of cumulative effects on water is in an infant stage. Techniques for assessing cumulative effects are currently being developed by the scientific community.

The cumulative effects concept is based on the idea that individually minor actions may have additive impacts when viewed on a watershed scale. In this case, changes in riparian conditions, rates of sediment input, and peak flows may not by themselves result in adverse effects, but the changes when considered together, would influence the risk of adverse cumulative effects.

The cumulative effects concept is also based on the assumption that some impacts associated with management activities can be imperceptible for many years and then become of consequence when a large precipitation and flood event act on the altered watershed condition (Grant 1984, Lyons and Beschta 1983). Projecting effects into the future assumes a similar sequence and magnitude of flood events as has occurred in the past. An important assumption is that current channel condition, erosion levels, and hydrologic recovery can be used to predict the continuation of existing effects, or the likelihood of a watershed to experience effects in the future.

Figure IV-2 displays a theoretical linkage of management activities to cumulative, downstream effects on water quality, physical stream characteristics and functions and the fish populations which depend on aquatic resources.

Figure IV-2. Thoretical Linkages to Cumulative Effects

1/ Adapted from Grant 1984 and Grant 1986, "The Management Induced Disturbance System."

Types of Cumulative Effects - Cumulative effects occur over time, across geographical areas, and between several physical processes. In this analysis the potential cumulative effects of past, present, and reasonably foreseeable practices on all land ownerships within the forest boundaries are considered. The cumulative effects of changes in riparian condition, sediment inputs, and runoff patterns are considered on two different scales, the subdrainage scale, and the watershed scale.

There is a low risk of cumulative effects to water composition that are not related to sediment. Effects to water composition which do occur are likely to be direct or indirect effects.

Because of the complex interaction of the physical processes, the potential cumulative effects may become manifest in a number of different ways.

Alternatives which heighten the risk of peak streamflows and landsliding, with lowered inputs of LWM to provide energy dissipation and stream channel stability, may to varying degrees, aggravate existing bank instability and sediment deposition.

Low-gradient streams such as Salmon Creek, parts of the Breitenbush River, the Middle Santiam, and the Middle Fork Willamette may begin to meander or braid more due to changes in the amounts of gravel they transport, changes in flow patterns, and changes in the amounts of LWM. Channel changes, may have subsequent effects on the loss of productive riparian areas, and the quality of aquatic habitat.

Some streams like Fall, Winberry, and Hills Creek have bedrock dominated channels. Increased peak flows and landsliding would likely produce higher suspended sediment and turbidity loads, and reduce the stability of large woody debris. There may be an increase in channels scouring down to bedrock, resulting in a loss of fish habitat.

In watersheds with a high risk of cumulative effects Fish hatcheries and potable water users downstream may be required to increase the amount of water treatment, or limit their use to fewer nonturbid periods. Increases in turbidity may occur from the cumulative increases of debris torrents and channel scour.

Risk Categories - The assessment of the risk of cumulative effects for all watersheds shown in Table IV-8 is based on the combined direct and indirect effects of changes to inputs of LWM, inputs of sediment, and increases in peak flows. Within the harvest constraints and allocations proposed by each alternative, the effects have been minimized by assuming that timber harvest would be distributed according to the sensitivity of the watersheds.

Each watershed is assigned a risk rating of "High", "Moderate" or "Low", to indicate the relative risk of adverse effects. The assignment of risk is applied in Appendix B. A watershed with a High rating would still be expected to support existing beneficial uses, but the amount and relative long term stability of those uses would be lessened. A substantial number of subdrainages within the watershed would be expected to experience a management-induced decline in beneficial use levels if a 10 to 20 year (or larger) rain-on-snow flood event occurs. A watershed receives a Moderate rating if it is anticipated that a management induced reduction in beneficial uses would occur in a small number of subdrainages as result of a 10-20 year (or larger) rain-on-snow flood event. An Low rating is assigned where planned activities represent a low risk to water resources.

Table IV-7. Cumulative Effects Assessment [1]

[1]First decade, National Forest and private land . Risk of adverse watershed impact: H = High; M = Moderate; L = Low.

[2]NA = Data Not Available; could not be reasonably estimated since the NC Alternative (No Change) is based on a significantly different set of assumptions than the other alternatives and could not be modeled with the current Willamette National Forest FORPLAN model. The effects under this alternative would be expected to be greater than Alternative K.

Effects of Non-National Forest Lands - Harvest plans for the next decade for non-National Forest landowners within the Forest boundary have been estimated for calculation of the current and future hydrologic recovery of these lands. No attempt was made to project hydrologic recovery beyond the first decade or to estimate erosion yields from other ownerships.

The effects of private land outside the Forest Boundary was considered, but not quantified. Several alternatives propose activities which constitute a low risk within the Forest. These alternatives would not add to the risk off-forest appreciably. In most watersheds the rate of off-Forest timber harvest in the next few decades would be less than historic levels. Consequently, hydrologic recovery would increase while the rate of road construction and landsliding should decline, resulting in a diminishing sediment yield in major rivers off Forest over time.

Distribution of harvest areas and road construction within major drainages is not subject to Standards and Guidelines on non-Federal lands, and management practices can vary between Federal agencies. Forest project plans would consider activities of others within major watersheds and subdrainages during cumulative effects analyses, and mitigate the effects of increased peak flow and sediment mainly by dispersion of activity. Mitigation would be more difficult where activities on non-National Forest lands vary the most from the assumptions used in this chapter. In those cases, peak flows and sediment yields may increase, with the same effects described earlier. There is little opportunity to reduce water temperature, or improve water yield or chemical composition of water of National Forest streams in order to offset changes which might occur on adjacent lands. For example, providing more than existing effective shade on National Forest streams would not reduce water temperature.

Dispersed harvest on Forest land with intermingled non-National Forest ownerships is expected to help reduce the environmental effects of all alternatives on peak flows, sediment, and fish habitat.

Cumulative Effects Summary - In summary, Alternatives NC, followed by A and K represents the greatest short term risk of cumulative effects to watershed resources, with 29% of the Forest in High Risk category due to the greatest harvest of potentially unstable soils, riparian management at minimum levels, and low emphasis on stream Class IV protection. Alternative J results in less risk, followed by Alternative D. Alternatives L and W represent the lowest risk of cumulative effects to watershed resources. The percent of the Forest in each category is shown in Table IV-8.

The degree of uncertainty which exists in predicting cumulative effects in the short-term, is amplified greatly when projecting to the fifth decade. By the fifth decade, erosion levels in most Alternatives is approximately equal to or less than that for Alternative D in the first decade. In addition, by the fifth decade, the proportion of timber volume coming from clearcut harvest in the transient snow zone would be reduced. Consequently, hydrologic recovery levels would increase.

Table IV-8. Cumulative Effects Summary

	Alternatives						
Risk Category [2]	**NC [3]**	**K**	**A**	**J**	**W**	**D**	**L**
High %	NA	29	29	18	0	12	0
Moderate %	NA	27	25	17	0	10	0
Low %	NA	44	47	65	100	78	100

[1]National Forest and private land.
[2]Values presented are the percent of the Forest in in each category in the 1st decade.
[3]Data is not available. Alternative NC would be expected to produce greater effects than Alternative B-Departure.

Mitigation Measures for Water

Mitigation of the potential effects are summarized in the following sections. Mitigation measures would be used to avoid or repair direct, indirect, and cumulative effects already discussed.

Mitigations used to meet water quality objectives usually fall into the category of Best Management Practices (BMPs). An agreement between the Forest Service and Oregon Department of Environmental Quality establishes the use of (BMPs) by National Forests as the means to control nonpoint sources of pollution from silvicultural activities. The agreement is authorized under the Federal Clean Water Act (Public Law 92-500 as amended). Best Management Practices would be selected and tailored for site-specific conditions to arrive at project level BMP's for the protection of water quality. See BMP Appendix H for a discussion of specific BMPs, and the implementation process.

Some of the mitigations below are discussed in terms of "Effectiveness". Evaluation of BMP effectiveness is part of the format described for BMPs in Appendix H. This appendix includes criteria used to describing the effectiveness of the BMPs as High, Moderate, or Low.

Mitigation in Riparian Areas - Measures to mitigate potential increases in stream temperatures include implementation of timber harvest prescriptions which would not remove excessive amounts of shade; and to revegetate riparian areas with rapidly growing hardwood species to provide additional shade in a minimum amount of time. On larger streams, it is important that taller conifer species are also established in order to shade streams from mid-day sun.

Measures to minimize direct disturbances to stream channels would require use of yarding equipment which is capable of providing adequate suspension of logs over the streambanks. Measures to minimize streambank disturbance during road construction are to select stream crossing sites which require only small cut and fill slopes, to design road crossings perpendicular to the stream, and require equipment which is capable of moving around the site without excessive disturbance. The potential for streambank erosion following culvert placement would be mitigated by ensuring site characteristics are considered, and by using material to stabilize streambanks where needed.

All alternatives also propose to replace LWM in order to rehabilitate stream condition and aquatic habitat degraded by past practices, and where operation of heavy equipment is feasible. The rehabilitation practice of placing LWM is most successful in streams with low gradients, and watershed areas of less than 50,000 acres. This mitigation would be implemented in approximately 15% of Class I and II streams, and could not be accomplished in less than a decade. This is a relatively new practice. Its long term effectiveness is still being evaluated.

Actions in floodplains and wetlands are required to minimize impacts to those areas, under Executive Orders 11988 and 11990. Where adverse effects are anticipated, they must be formally declared with notification to the public.

Executives Order No. 11988 requires that the agency take action "to reduce the risk of flood loss, to minimize the impact of floods on human safety, health and welfare, and to restore and preserve the natural and beneficial values served by floodplains.

Executive Order No. 11990 requires that the agency take action "to minimize the destruction, loss or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands."

In addition to the legal direction concerning floodplains and wetlands, riparian areas and fish habitat are protected through reduced harvest entry, directional falling for protection of streams, and maintenance of the current amount and future supply of stable large woody debris in streams. These practices have been found to be necessary and effective in the maintenance of stream functions, fish habitat, and the productivity of the aquatic ecosystem (Keller and Talley 1979; Brown 1972; Harmon et al. 1986; Martin et al. 1981). When catastrophic events occur, or when preventative measures have failed, riparian areas adjacent to fishery (Class I and II) and nonfishery streams would be rehabilitated. Common measures are the planting of grass and tree species with rapid growth characteristics to regain bank stability, shade and reduce erosion. Streams are rehabilitated or improved by introducing boulders, gabions, or large woody debris to increase long-term channel stability and fish habitat. Accumulations of woody debris limiting access to upstream areas for fish, threatening improvements, or excessively degrading water quality, would be removed.

Mitigation of Sediment - The potential to increase the occurrence of debris torrents can be mitigated by retaining the root strength of live trees in areas of potentially highly unstable sites as identified during project planning in the field. The area and number of trees to be retained would be based on a prescription which considers the interaction of root strength with soil type, geologic characteristics, the role of groundwater and other influencing factors. These prescriptions should be more conservative when potentially unstable areas are in close proximity to a stream, wetland, lake, or reservoir. Alternatives which propose specific measures which would be highly effective are Alternatives W, and L. The other alternatives propose measures that provide a lower probability of effectiveness.

Mitigation measures used to minimize the rate at which debris slides occur from harvest units and from roads range from measures that have a high probability of effectiveness to those that have a low probability of effectiveness. Measures to mitigate the potential for increases in the rate at which debris torrents travel through Class III and IV streams to Class I and II streams also have a range of effectiveness.

The frequency of debris torrents moving down steep, headwater stream channels, can be mitigated by requiring retention of LWM in headwater channels. This includes maintaining existing instream wood along Class III and IV streams, and provisions to ensure the future recruitment of LWM along potentially highly unstable, and moderately stable Class IV streams. Maintaining the near background levels of LWM in these streams would maintains the current rate at which debris torrents reach Class I and II streams. This measure is required and modelled in alternatives W, and L.

The potential for increases in debris slides and torrents from new roads would be mitigated with measures commonly recognized as Best Management Practices. These practices include selection of stabile of road locations; design of appropriate road widths and compaction standards; installation of special drainage structures where needed; ensuring ditches, stream crossing culverts, and "cross-drain" culverts are maintained. It is estimated that these practices can improve the stability of the roads by 80%

when compared to roads constructed between the early 1960's and the mid-1970's with most of the increase due to increased compaction requirements for fills, and by ending sidecasting practices. Improvements in road construction BMPs are required in all alternatives.

The potential debris torrents from existing roads would be mitigated by stabilizing road fills, either through pulling back the uncompacted material, improving drainage around the fills, and providing additional surface stabilization where appropriate. These projects are costly, but effective, and are required in all alternatives.

Mitigation of surface erosion from slopes is accomplished by measures which retain or replace soil cover. During timber harvest the type of yarding systems, and the fuel reduction practices used can make large differences in the amount of soil cover removed. The potential for surface soils to be transported to streams can be mitigated to negligible levels by ensuring that streamside ground vegetation and woody material is maintained.

Numerous methods to provide stable road surfaces are available, and more are being developed. Practices such as asphalt paving are very effective. Less expensive materials are also available to provide stable surfacing during the months when the road is being used for haul. The use of low-pressure tires on trucks can provide substantial reductions in the amount of sediment generated from road surfaces. The use of contract clauses to restrict the season of haul is also an option for any project, where road conditions and proximity to streams would create turbidity in excess of State Water Quality standards.

Introduction of sediment from the road system is an important effect to mitigate. Roads are made more erosion resistant by addition of surfacing rock. Erosive sites are mulched, fertilized, and seeded with grass species. Ways to reduce the amount of surface erosion and risk of landsliding associated with road construction include: spacing, sizing, and location of drainage culverts; stabilizing cut and fill slopes; inspecting and cleaning ditches and culverts; building full bench roads and eliminating side cast waste where slopes exceed 55%.

Mitigation of changes in runoff patterns - There are few measures to mitigate the increases in rates of snow accumulation and melt in clear-cuts, and its subsequent effects. The most direct method is to control the rate at which clearcuts are created within an area influencing a stream channel. This has been done in the past, and would continue to be done, using the analysis method of Aggregate Recovery Percent (ARP). ARP is a tool to assess the hydrological recovery of an area. Hydrological recovery refers to the recovery of the vegetation's ability to intercept warm winds and rains during warm rain-on-snow events. This mitigation measure is discussed in additional detail under the section on Evaluation of Runoff Patterns, in the Direct and Indirect Effects Section. This practice is considered a BMP to respond to the potential for adverse cumulative effects.

Measures to mitigate the potential for increased stream flows to increase stream scouring and down-cutting stream channels is to maintain historic amounts of large wood within the channel. Up to 80% of the stream energy is dissipated while passing over log steps. (Keller and Swanson, 1979). This level of mitigation does not reduce the risk of increases in stream channel scour during increased peak flows when compared with natural conditions, but would not add additional risk of channel erosion. Where past practices have removed wood from streams, the increased peak flows have potential to decrease stream channel stability.

Many design techniques are available to mitigate potential adverse effects of road runnoff. These designs are commonly implemented BMPs, and include the use of frequent cross drains between stream crossings to disperse runoff which has collected in the ditch before it reaches the stream.

Professional knowledge of current conditions, subdrainage sensitivity, and hydrologic recovery would be used to minimize the risk of negative consequences by dispersing harvest activities to the subdrainages in the best condition. In some instances, subdrainages would be scheduled for some harvest entry, for the express reason of collecting Knutson-Vandenberg funds (generated from timber sale receipts) for the purpose of rehabilitating and improving problem areas.

Planning at the project level is the most appropriate for a focused cumulative effects analysis and site-specific design of mitigation measures and Best Management Practices. The attributes and relative sensitivity of areas within the subdrainage would be analyzed for cumulative or direct effects from past management and projected to options for future management based on the most current knowledge, management direction and desired condition of aquatic resources. Through the use of an interdisciplinary process, trade-offs between management options and relative risk of effects would be assessed. As a result, a site-specific reasoned decision which best meets multiple-use goals and mitigates or avoids direct or cumulative effects would be implemented.

Mitigation of changes to water composition - Potential changes to water chemistry which have adverse effects on beneficial uses are limited primarily to accidental spills of material. The Forest maintains a Spill Incident Response Plan, to deal with these situations. Efforts would be taken during projects such as application of fertilizer to minimize the risk of adverse spills of this material.

Measures identified in the FEIS for "Unwanted and Competing Vegetation" and the Mediated Agreement would be applied during projects of this type.

Mitigation of Cumulative Effects - Mitigation of direct effects is the primary method of ensuring that cumulative effects do not have significant impacts. The practice of dispersing harvest activities over time and throughout the landscape (Christner 1982; Rice 1980) is one means of mitigating some of the direct, indirect, and cumulative effects. According to Rice (1980) any other approach "cannot be supported by current knowledge concerning the propagation of flow or sediment in steep, rough, natural channels."

Monitoring of Mitigations - Monitoring would be the principal means by which the Forest would assess whether the Standards and Guidelines are being implemented as prescribed, as well as if the results of that implementation are producing the desired and predicted effects. The implementation of the S&Gs would be monitored through activity reviews and water quality monitoring of unusual or innovative projects. Water temperature would be monitored through long-term trend stations.
A major focus of the monitoring effort for water resources would center on testing the accuracy of the assumptions driving the cumulative effects assessment. A major assumption was that current channel condition, erosion levels, and hydrologic recovery could be used to predict the continuation of existing effects, or the likelihood of a watershed to experience effects in the future. By testing the assumptions, more effective and efficient mitigation measures can be used.

Relationships With Other Agency Plans or Policies for Water

Implementation of the State Water Quality Management Plan on lands administered by the U.S. Department of Agriculture--Forest Service (USDA Forest Service) is described in a Memorandum of Understanding (MOU) between the Oregon Department of Environmental Quality (DEQ) and USDA Forest Service (2/79)), and "Attachment A" referred to in the MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest 1978). This MOU and plan provide the basis for the interagency agreement, whereby the Governor of the State designates the Forest Service as the implementing agency for nonpoint source pollution control on lands under its jurisdiction.

This agreement has been updated with a Memorandum of Agreement (MOA) 1990, between the DEQ and USDA Forest Service, pursuant to Section 319 of the Clean Water Act.

The 1979 agreement provides for annual meetings between Region 6 and the DEQ to evaluate the program and progress being made and provides the basis for recertification by the Governor. Available monitoring information is reviewed, revisions, or additions to the best management practices are addressed, progress on problem identification and treatment is provided, and reports are written and submitted by the State to the Environmental Protection Agency (EPA).

In compliance with Section 319 of the Clean Water Act DEQ has issued the "Oregon Clean Water Strategy" to provide a strategic management plan for the prevention and correction of non-point source water quality problems. The Forest would work with DEQ to resolve the water quality status of waters on the Forest.

The Alternative development has been coordinated with the Basin Plans of the Oregon Water Resources Commission for the use and control of the water. The commission has restricted use of the water in most of the major streams and all of the tributaries, and most of the natural lakes on the Forest, to recreation, instream and low consumption uses. In addition the Commission has established minimum perennial streamflows in proximity to the Forest Boundary on many of the rivers flowing off the Forest. Streams within nearly all of the Forest contributes to the flows at these points, although many of the flows are controlled by reservoir dams.

Incomplete or Unavailable Information

Assess the relationships between rain on snow events, the hydrological recovery concept, peak flows, and channel stability.

Determine the amount, sizes and characteristics of timber in riparian areas needed to provide for in-stream large woody debris recruitement.

Improve knowledge of interaction of riparian conditions, peak flows and increases in sediment on water quality and channel stability.

Improve understanding of baseline stream and lake water quality and channel conditions in areas with differing geology and use patterns.

Determine cumulative effects of forest fertilization on water quality in reservoirs and lakes.

Improve information on effectiveness of road stabilization measures.

Improve understanding of effectiveness of protection of Class IV and headwall areas.

Improve understanding of influence of rain-on snow events on mass movements.

Environmental Consequences Of The Alternatives On Air

Clean air is a renewable resource, and the management of the airshed is a responsibility of all Federal natural resource managers. The Clean Air Act, as amended in 1977, directs Federal agencies to comply with State and local regulations directed at preventing and controlling air pollution.

Visibility is the air quality parameter most sensitive to management activities on the Forest. Studies are currently being conducted regarding visibility impairment and air quality impacts, Region-wide. Data from one study indicates that the suspended particulates in smoke from forest slash burning and agricultural field burning cause the greatest impacts during visibility impairment periods (DEQ 1985).

While smoke and haze detract from a Forest user's visual and recreational experience as it pertains to vistas, panoramic views and the expectation of fresh air, no emissions from forestry burning have yet been identified by the Environmental Protection Agency (EPA) as hazardous to human health, and no threshold limit has been set for compounds in Forest smoke (Sandburg et al. 1979). However, in residential areas smoke from wood stoves is becoming a health concern as more people are using wood for home heating. This smoke combines with other urban pollution sources and contributes to periods of air quality degradation in the Willamette Valley. Forest smoke can have a cumulative impact on air quality in urban areas when it occurs in conjunction with periods of cold weather that result in high use levels of firewood. In addition, firewood use is an air quality concern for the Forest because the Forest is one of the major sources of firewood for adjacent communities.

Although the "scrubbing effect" of the westerly winds improves air quality in the Willamette Valley and along the western edge of the Forest, smoke and haze is then directed toward other sensitive areas. Mt. Jefferson, Three Sisters, Diamond Peak, and Mt. Washington Wildernesses are mandatory Class I Federal areas protected from air quality degradation by law. Other sensitive areas adjacent to the Forest include Salem, Springfield, Eugene and other cities in the Willamette Valley. Communities within the Forest and east of the Cascade Crest, such as Bend, where recreation and tourism are important, have also expressed increasing concern about air quality. (See Chapter III, Air, for an airshed map.)

Direct and Indirect Effects of the Alternatives on Air

Pollution sources that affect the airshed of the Forest come from a number of causes. Forest management activities that affect the airshed include slash burning, dust and vehicular emissions from travel on Forest roads, and the use of chemicals for the control of insects, diseases and vegetation. Off forest emissions sources include pollutants from vehicles and factories; smoke from slash burning by private landowners and other land management agencies; smoke from agricultural burning; herbicide and pesticide use; and airborne dust from unvegetated areas and farm lands.

Wildfires also have a high potential to impact air quality. Unlike prescribed fire, frequency of wildfire, the amount of emissions, direction and dispersal of smoke, and duration of smoke inundation cannot be predicted or controlled. Increased use of the Forest for recreation and project activities increases the potential for human caused wildfires, thus the frequency of adverse effects to air quality from wildfire could increase.

The increased use of wood for home heating and industrial hog fuel also contributes to air pollution. During the winter months and periods of air inversions this is becoming increasingly evident in communities within and adjacent to the Forest.

Forest management activities such as road construction, road maintenance, and commercial traffic on the roads results in localized reduction in air quality due to increased particulates in the air, primarily in the form of dust.

Prescribed burning and Potential for Wildfire - Of the Forest management activities, prescribed burning has the greatest impact on the air quality. Historically, air quality impacts have been directly proportional to the amount of timber harvest. As timber harvest activities increased, so did burning. Primary consideration was the elimination of fuels on the units and reduction of residual vegetation which competes with conifer seedlings. Alternative NC has the highest harvest rate, and air quality is a greater concern, with harvest and air quality problems decreasing in K, A, J, W (PA), D and L, respectively.

The effects on air quality from wood smoke are measured in particulate matter less than 10 microns (PM-10). Emission rates for the Forest are based on projections of the amount of final harvest acres to be treated by prescribed burning, research on slash consumption and the amount of PM-10 in the resulting smoke. PM-10 emissions vary with the wood source being burned. Douglas fir generates 23.12 pounds of PM-10/tom of wood consumed. Mixed conifer has 20.53 lb. PM-10/ton of wood burned. Depending on both site specific conditions and efforts to reduce smoke emissions, not all final harvest acres will necessarily be treated by prescribed burning.

Alternatives NC, K, and A would produce the highest levels of PM-10 emissions annually as a result of high harvest levels and emphasis on maximum harvest of old-growth and mature Douglas fir which would require high treatment levels. Annual emission levels are lowest in Alternatives D, W (PA), and L. Emissions would be reduced in Alternative W (PA), even on lands intensively managed for timber production because of increased concern for ecosystem function and vegetation diversity.

Based on timber harvest levels, Figure IV-5-1 displays the average number of acres that could be treated annually by prescribed burning. Depending on site specific fuel loadings, efforts to reduce smoke emissions, and resource objectives all of acres may not be treated.

Implementation of Alternatives NC, A, J, and W (PA) would result in a higher potential for wildfire occurrence. Activities associated with these alternatives would cause approximately 22 to 53 general Forest and recreation use fires and 8 to 10 fires related to timber harvest or industrial operations. In addition, 10 to 14 wildfires resulting from escaped prescribed burns would be expected to occur annually. These fires would result in an estimated annual burned acreage from 437 to 609 acres.

Firewood Availability and Use - Management of forest residue by the Forest to provide firewood for public consumption indirectly results in reduction in air quality in local communities and major urban areas. Reducing the amount of firewood coming from Forest land, may not improve overall air quality due to increased use of alternative fuel sources, increased efficiency of wood stoves, and availability of firewood from lands in other ownerships.

Availability of firewood is directly related to the timber harvest levels on the Forest. Alternative NC will have the greatest availability of firewood, with Alternative L having the least. Demand for firewood is not expected to exceed availability through on and off Forest sources under any of the alternatives, but access to the available gathering areas may not be as convenient in the alternative with the lower harvest levels.

Smoke from wood stoves creates air quality impacts in the more populated areas off Forest. Wood stove emissions are becoming an increasing health concern and, as of July 1, 1986, state law requires stringent emission controls on all wood burning stoves sold within the state of Oregon. It is estimated

that the use of firewood for home heating produces about 72 pounds of PM-10 emissions per cord burned (Lane Regional Air Pollution Authority 1986). While it is difficult to predict both local demand for and consumption of firewood, every 10,000 cords of firewood supplied to the public would generate approximately 360 tons of PM-10 emissions when burned.

Commercial use of wood products to fuel industrial plants results in increased utilization of forest residues. The direct effect of the Forest's emphasis on increasing utilization would indirectly affect air quality in industrialized areas off the Forest. Wood chips used as hog fuel would be expected to produce similar amounts of PM-10 emissions per unit of measure as firewood, though industrial emission control devices will filter out much of this matter.

Cumulative Effects on Air

The Council on Environmental Quality (CEQ) regulations require that all Federal agencies consider cumulative impacts in environmental analysis. Analysis includes impacts associated with actions "regardless of what agency (Federal or non-Federal) or person undertakes such actions" (40 CFR 1508.7). To assess the influence of cumulative effects it is necessary to model the "cause-effect" relationship between emissions and atmospheric response. This is accomplished by monitoring burning activity, transport winds, and the resultant impacts. While several methods of modeling and monitoring impacts on the airshed exist, few, if any, have provided quantitative evaluation of the actual impacts on the environment.

In all proposed alternatives, harvest levels and public concern indicate that future use of prescribed burning on the Forest would be lower than current levels.

Wildfires are not generally thought to be a major contributing source of cumulative effects associated with particulate emissions. Although site specific cause and effect relationships have not been well defined in the past, visibility and atmospheric conditions are currently being monitored by the State of Oregon Department of Environmental Quality (DEQ). This study may establish baseline data useful for future evaluation of environmental impacts.

A decrease in available firewood from the Forest is not expected to result in a major decrease in firewood use, as demand would shift to alternative sources. Although the demand for firewood may remain high, the availability of firewood from both private and Federal lands could decrease in the future. It is doubtful that the timber harvest levels predicted in the alternatives would cause the demand for firewood to exceed the potential supply. Increasing availability of firewood by reducing slash burning could compensate for losses associated with decreased timber harvest in some areas. Even with the implementation of Oregon's 1986 woodstove law, it is expected that woodstoves will still produce more air pollution than other home heating sources, although the use of more efficient clean-burning woodstoves and the burning of dry, cured firewood are expected to significantly reduce particulate emissions and subsequent impacts on air quality (Lane Regional Air Pollution Authority 1986).

Monitoring of past activity by the U.S. Forest Service, the National Park Service, the State of Oregon Department of Environmental Quality (DEQ) and local citizens groups has shown that elevation, timing and spacing of prescribed burns both on and off forest are all important factors in the management and dispersion of smoke through the airshed. Many uniform haze episodes have been a result of the cumulative effect of dispersed field and forest slash burning activity. Due to weather restrictions and other constraints, potential prescribed burning periods are extremely seasonal and concentrated, with various State, Federal and private agencies utilizing the same periods for prescribed burning. This temporarily results in a cumulative concentration of air quality problems.

The cumulative effects of Forest management activities on air quality are poorly understood. To date, no specific adverse effects of particulate emissions caused by Forest management activities have been identified by the Environmental Protection Agency (EPA) as a human health hazard.

There is growing global concern for the increasing effects of carbon dioxide and carbon monoxide emissions on the quality of the human environment. Past, present, and future burning of forest residues by industry or managers of private, State, and Federal forest lands may cause significant adverse cumulative effects to climate, including global warming. These effects cannot be addressed at a Forest level. Only the contribution of Forest management activities to the problem can be disclosed. Refer to the discussion on Climate for further information.

Mitigation Measures for Air

All of the proposed alternatives would implement the best available technology for prescribed burning to meet the following objectives:

- Manage the smoke in accordance with the Oregon Smoke Management Plan;
- Implement burning plans that are site specific to fuel conditions and are designed to achieve acceptable emission rates;
- Schedule burns to disperse smoke and minimize the impacts to the airshed.
- Utilize a number of operational measures,as specified in the standards and guidelines to minimize the potential impacts of smoke in the Forest airshed.

To manage smoke concentrations and prevent smoke intrusions into Designated and Manditory Class I areas, the Forest complies with smoke management instructions that are issued daily by the State Forester's Office in Salem. These instructions specify where and when burning is allowed and coordinate all prescribed burning activities on Federal, State and private land in western Oregon.

A reduction in the total emissions produced by the Forest will be achieved by a combination of methods including:

- Increasing the utilization of forest residues including firewood, posts, poles, chips, and hog fuel for industrial plants;
- Burning when fuel moistures are higher to reduce the amount of material consumed;
- Leaving increased amounts of standing dead and defective trees and large woody debris;
- Reducing prescribed burning as a post harvest treatment of forest residues.

When burning is prescribed to meet resource objectives, burn plans will specify optimum burning conditions. Early, aggressive, mop-up will also be used to reduce particulate emissions from the smoldering phase of a burn.

Additional fire precaution measures for industrial operations, which limit operations during periods of higher fire danger and requiring firefighting equipment at operations with the potential for fire starts, will continue as a part of the overall fire prevention program. Contract provisions specify preventative

measures and the availability of additional personnel and equipment required for the prevention, early detection, and suppression of fires within the project area.

Intensified fire prevention patrols and contacts will be used to increase public awareness.

Relationships With Other Agency Plans or Policies for Air

All prescribed burning operations in western Oregon, and on the Forest will continue to be conducted in accordance with the Oregon State Smoke Management Plan (Oregon State Forestry Directive 1-1-3-410), under the direction of the State Forester's Office in Salem. On days when only limited burning is allowed, an area of potential conflict exists between the Forest, adjoining National Forests, State and other Federal land management agencies. The conflict centers around burning priorities, and who is allowed to burn. While the State Forester's Office coordinates all burning activities in the State of Oregon, resolution of scheduling conflicts is made between the local agencies involved.

The long term effects of emissions generated by burning wood products on global warming.

Health hazards associated with forest workers subject to high doses of suspended particulates while working on wildfires or prescribed fires.

Environmental Consequences Of The Alternatives On Climate

The climate of the Willamette Valley and western Cascade Mountains is referred to as Pacific Maritime, and has a strong influence on the vegetative patterns of the Forest. The relatively dry, cool summers and mild wet winters are particularly favorable to forests of evergreen conifers (Waring and Franklin, 1979).

Site specific microclimate conditions also play an important role in determining vegetation types, and are directly affected by land management activities.

On a global scale, forests account for about 75-80% of the carbon stored in plant biomass on the land surface, (Ajtay, et al. 1979) and play an important role in regulating the levels of carbon dioxide in the atmosphere. Whether or not global warming is occuring, and what effect it will have if it does, is cause for ongoing debate and controversy. The Forest/Atmosphere Interaction Priority Research Program (FAI-PRP) was initiated by the USDA Forest Service in FY 1990 to build upon existing research efforts and to use a complete ecosystem perspective when examining the interactions between forests and the atmosphere (USDA Forest Service, 1990)

Direct and Indirect Effects of the Alternatives on Climate

Microclimate - Timber harvest, particularly under even-aged systems, creates openings in the forest canopy that result in lower humidity, increased solar radiation, and changes in wind patterns. On a small scale, these openings become areas of climatic extremes, unbuffered by the canopy. Indirect effects of climatic extremes may lead to temporary loss or dislocation of plants or animals from the affected area.

Global Climate - Deforestation has been a source of increasing carbon dioxide in the atmosphere in the last century (Harmon, et. al., 1990). Alternatives that harvest the most timber, generally construct the most miles of road, decreasing the amount of forested land. The decrease in the first decade ranges from about 400 acres in Alternative NC to 40 acres in L. Alternatives K, A, J, W, and D will result in decreases of 275, 250, 225, 200, and 150 acres of forested land respectively. The existing road system accounts for about 24,750 acres. Most of the remaining road system will be constructed in the first decade for each of the alternatives.

The harvest of old growth releases carbon stored in plant materials and the forest floor into the atmosphere as carbon dioxide. Fast growing, intensively managed stands absorb carbon dioxide rapidly but generally lack long-term storage in dead materials and deep forest floors. Converting from an old-growth stand to a stand managed on short rotations would result in a net loss of about 150 tons/acre of stored carbon (Ibid.).

Cumulative Effects of the Alternatives on Climate

Microclimate - Alternatives that harvest more acres will maintain a proportionally larger percent of the Forest acreage in created openings at any point in time. The increased solar radiation and lower humidity will increase the risk of fire as vegetation and fuels become drier. Increased wind movement near the ground may cause higher transpiration rates, reducing soil moisture.

Global Climate - Conversion of old-growth stands to intensively managed second growth results in a net loss of stored carbon, even when considering multiple rotations (Ibid.). The magnitude of loss is estimated to be about 150 tons per acre of old growth harvested. Data is not available on the amount

of old growth harvested in Alternative NC. Alternatives K and A would result in reductions of stored carbon by 8.2 and 8.1 million tons respectively, in the first decade. Alternatives J, W, and D will reduce stored carbon by 6.1, 6.6, and 6.3 million tons, with Alternative L having the least reduction at 0.5 million tons.

The total amount of carbon stored in old growth on the Forest is about 164 million tons. The first decade harvest represents a decline in stored carbon of about 5% for alternatives K and A, down to about 0.3% for Alternative L. Alternatives J, W, and D show a decline of about 3.7, 4.0, and 3.9% respectively in the amount of stored carbon. In the western Cascades of Oregon and Washington there are an estimated 4.9 million acres of old growth, with about 1.35 billion tons of stored carbon (Ibid.). The old growth harvest in alternatives K and A represent a stored carbon decline of about 0.6%. Alternatives J, W, and D represent a decline of about 0.5%, and Alternative L a decline of 0.04%.

The effects of the alternatives are not significant when compared against regional or global levels of carbon storage or acres of deforestation. However, long-term monitoring and research is needed to evaluate the effects of management activities on climate, particularly in light of the increasing concerns about global warming.

Mitigation Measures for Climate

Microclimate - Harvest systems that maintain a portion of the overstory can be used to avoid creating a harsh environment that may not be able to be regenerated within 5 years. Artificial shading, shelterwood harvest, or uneven-aged management can be used in place of clearcutting. Careful sale design and layout can also avoid potential microclimate problems.

Global Climate - On a global scale, mitigation includes increasing the amount of forested land, and reducing fossil fuel use. At the Forest level, mitigation will result from the application of some of the "New Forestry" practices. Harvest units with overstory trees left to provide attributes of old-growth habitat at an earlier age, and leaving large woody debris on the ground, will keep a greater amount of carbon in storage. Managing for a diversity of plant and animal species will allow ecosystems and plant distributions to shift as climate changes. High levels of genetic diversity will also allow species to adapt to climatic changes through natural selection.

Incomplete or Unavailable Information

As a result of increasing concerns over global warming, there is an international effort underway to determine the causes and impacts. Specific research designs and long-term monitoring are needed to detect and evaluate the effects of a changing chemical and physical environment.

Environmental Consequences Of The Alternatives On Vegetation

Vegetation on the Forest is dominated by dense stands of Douglas fir and other conifer species covering about 90% of the Forest land base. Woody shrubs and lush herbaceous plants are found in the understory of these timber stands. Interspersed within the major Forest plant communities are meadows, rock cliffs, and extensive alpine and subalpine parklands. Hardwoods such as alder, big-leaf maple, and willow generally dominate riparian areas adjacent to rivers and lakes, and wetland areas contain grasses, forbs, and sedges.

There are 21 sensitive plant species on the Forest; no plants are currently listed as threatened or endangered. These species are usually associated with plant habitats that include bogs and wet areas; rocky ridge tops and slopes; and open slopes, fields, or meadows above timberline. Any proposed activity that affects the population or distribution of sensitive plant species will be evaluated on a case by case basis to determine the extent of potential impact and level of necessary mitigation.

Plant communities and vegetative conditions change naturally. Silvicultural activities such as harvest, reforestation, release, thinning, fertilization and salvage will also affect vegetative conditions, usually at a faster pace than natural changes.

Successional stages, plant diversity, old-growth forests, timber, riparian zones and range are discussed in this section. The consequences of the alternatives on wildlife habitat, scenery, H.J. Andrews Experimental Forest, and Research Natural Areas (RNAs) are described in detail in their respective Chapter IV sections.

Direct and Indirect Effects of the Alternatives on Vegetation

Because of the Standards and Guidelines (S&Gs) that govern all Forest management activities there is little difference in the types of direct effects on vegetation among the proposed alternatives. Differences among the alternatives are generally the result of the amount, scheduling, and location of the proposed activities that remove or alter vegetation. The differences range from Alternative NC, which includes short-rotation timber management activities on about two-thirds of the Forest, to Alternative L, with a mix of long and short rotations on only one-third of the Forest.

Successional Stages

Disturbance to vegetation, whether natural or human caused, affects species composition, size, age, density, and the overall pattern of vegetative cover. Natural successional patterns are maintained in a number of areas on the Forest, which promotes vegetative diversity. Natural plant succession is most apparent in designated Wilderness, and vegetative conditions remain generally undisturbed in old-growth groves, subalpine and alpine plant communities, nonforest lands such as meadows, wetlands, and rocky cliffs, and in areas managed for semiprimitive recreation with timber harvest constraints. On these lands, disturbance to vegetation is usually the result of events such as fire, floods, or windstorms, or impacts from wildlife or recreation use. Vegetation may be altered in developed recreation sites for the safety and convenience of Forest users.

Changes in vegetation are most apparent in areas of the Forest managed intensively for timber production. During timber harvest and reforestation activities, the successional stage of a stand of trees is abruptly changed from large trees, to brush, grasses, and seedlings. (See Chapter III, Vegetation, Figure "Successional Pattern of Stand Conditions.") Trees are removed, and falling and yarding operations uproot and crush many of the understory shrubs and forbs. Harvest units may be burned to reduce

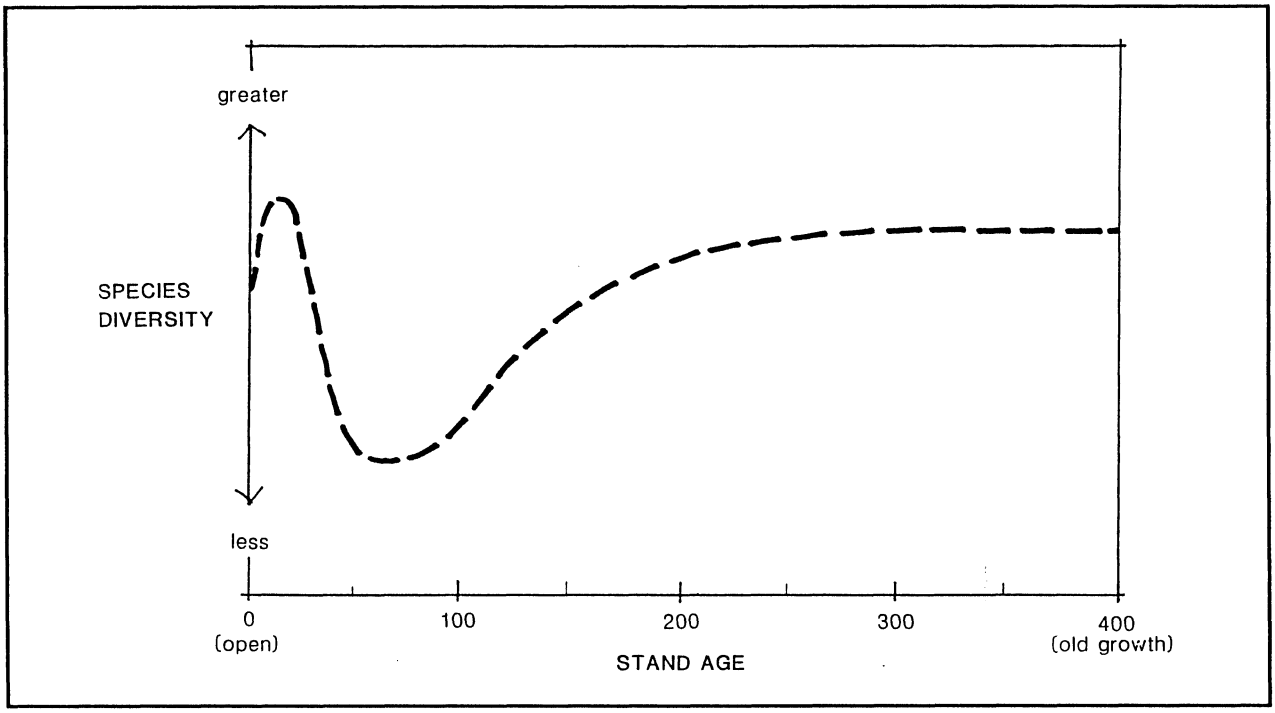
logging slash and prepare sites for reforestation. While some understory vegetation is destroyed, other plants respond to these disturbances with vigorous new growth. As a result of both increased sunlight and reforestation efforts, species composition generally changes from shade tolerant to shade intolerant species.

The survival, growth, and vigor of desirable tree seedlings are enhanced by timber stand improvement activities. These activities include reducing brush competition, precommercial thinning, and fertilization. The scheduling of silvicultural treatments manipulates species composition, density, successional stage, and age of the stand. Methods include mechanical, manual, and biological techniques, and the use of prescribed fire and chemicals. See Appendix F for a full discussion of silvicultural practices and techniques.

The harvest level associated with each alternative will determine the amount of the Forest which will undergo abrupt changes in successional stage each decade. This will determine, not only the ultimate condition of the Forest, but the rate at which the Forest moves toward that condition. Alternative L will result in a forest that is generally older, with a greater representation and wider distribution of the later successional stages of large, older trees and accompanying understory vegetation. Alternatives J, W (PA) and D are similar to each other, but will have fewer acres in later successional stages than Alternative L. Alternatives NC, K, and A have the fastest harvest rates, and will result in a forest that is younger, overall, with less representation of the later successional stages, than the other alternatives. The faster rates of harvest will result in more fragmented distribution and declining effectiveness of habitat in the older stages.

Plant Diversity

Diversity can be discussed in terms of richness (i.e., the variety of species) and evenness (i.e., the relative population levels of each species). In forested plant communities, the early successional stages (grass/forbs) and old growth stages have the greatest diversity of plant species. (See Figure IV-3) Special and unique habitats associated with cliffs, talus, meadows, marshes, bogs, and riparian areas contribute significantly to the overall plant diversity of the Forest.



Most management activities directly affect vegetation resulting in changes to seral stage, species composition, and plant diversity. While timber harvest activities, which influence the greatest amount of area, may not affect overall species richness, they do significantly change species evenness. Alternatives NC, A, and K provide little or no protection of special and unique habitats other than T&E plants. This would cause significant disturbance and result in a high risk of losing many plant species. In addition, these alternatives propose to harvest most old growth stands, converting them to intensively managed forests which may not maintain well distributed populations of plant species endemic to the Forest. Alternatives J, W (PA), D, and L, respectively provide increasing protection for special and unique habitats and maintain old growth stands distributed throughout the Forest. Alternative L maintains most of the Forest vegetation in an unmanaged condition.

Silvicultural and vegetation management practices directly affect vegetation diversity by favoring commercial tree species like Douglas fir over hardwood trees and minor conifer species. Vegetation management activities involving the use of herbicides significantly reduce the diversity of broad-leaved forbs, shrubs, and trees in early seral forests. Prescribed fire directly affects plant diversity by consuming existing vegetation and could eliminate fire-sensitive species. Aggressive non-native plants commonly invade burned areas.

Recreation use can adversely impact plant species growing in sensitive environments. Areas receiving heavy use by hikers and campers could be damaged resulting in a loss of plant diversity from trampling, soil compaction, or development of campsites.

Habitat enhancement activities involving the establishment of preferred forage plants could directly affect the establishment and seral development of native plants.

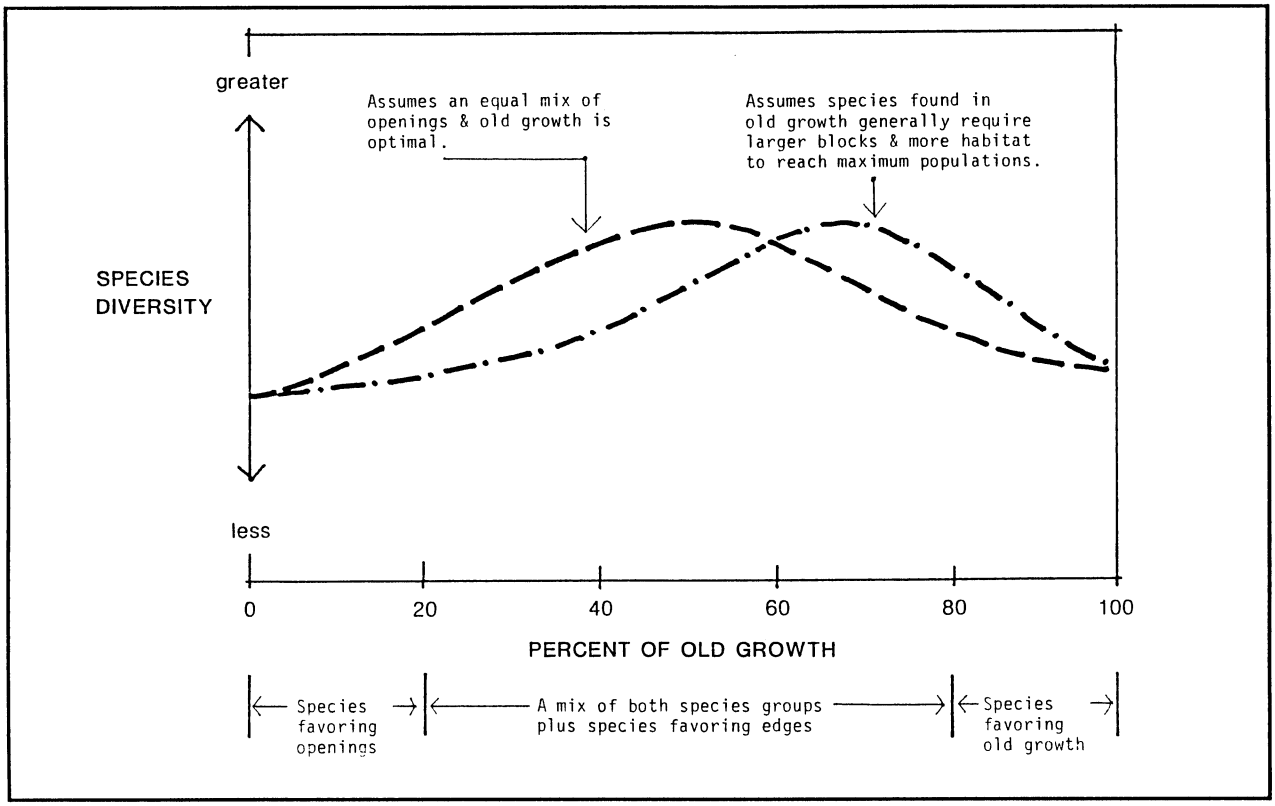


Figure IV-3. Diversity by Stand Age

From a Forest-wide standpoint, the greatest diversity would occur with a mix of old growth and forest openings. This would provide habitat for species adapted to old growth as well as those adapted to openings, second growth, and edge habitat. Figure IV-4 shows two assumptions regarding the optimal mix of old growth and openings. One line shows the relationship of species diversity and the amount of old growth with the assumption that the greatest diversity occurs when their is an equal mix of old growth and openings. The other line assumes that species adapted to old-growth conditions require larger blocks and more habitat to reach maximum populations and that the ideal amount of old growth would be more than 50%. In either case, substantially reducing the amount of old growth could reduce overall species diversity, particularly evenness.

The current condition of the Forest has about 40% of the forested lands in the old growth successional stage. At the end of the first decade, there is little difference between the alternatives (NC at 33% to L at 38%) as to the amount of forested lands remaining in old growth. After five decades the differences are more apparent. Alternative L provides the best balance between successional stages, maintaining about 35% of the forested lands in old growth. Alternatives D and W (PA) maintain 24%, and Alternatives J, A, and K are at 23, 22, and 20% respectively. Alternative NC will provide the least balance between successional stages, maintaining about 17% of the forested lands in old growth.

Figure IV-4. Forest-wide Diversity

Old-Growth Forests

One stage of natural vegetative succession that is not duplicated in stands managed intensively for timber production is old growth. Old growth is characterized by multi-layered canopies, large old trees, standing snags, and large logs in streams and on the Forest floor. The values associated with old-growth timber relate to its importance for wildlife habitat, scenic qualities, clean water, awe-inspiring recreational and spiritual qualities, maintaining diversity of the gene pool for future stands, supplying timber of exceptional quality and value, and providing a living connection with the past.

There are currently about 594,800 acres of old-growth trees on the Forest that meet the Pacific Northwest Region definition of old growth (see Regional Guide). Of the total old-growth forest, 78% is low elevation Douglas fir/hemlock. The higher elevation types are found in the following proportions: Douglas fir/true fir and true fir combined is 16%; and mountain hemlock/lodgepole pine is 6%.

The major effect on old growth will be through the sale and harvest of timber, which causes a sudden change from old growth to the grass/forb successional stage. Most of the area harvested will be managed with a rotation length shorter than the time necessary to reach a similar old-growth stage. The size, shape, and arrangement of old-growth stands affect their integrity as habitat for plants and animals. Harvest activities will reduce the size, increase the amount of edge, and fragment the old-growth stands allocated to timber yield. Effective old-growth habitat in these areas will be substantially less than the actual acres of old growth (Hemstrom 1986). Figure IV-5 shows the relationship of effective old-growth habitat and stand size. As the size of old-growth stands are reduced through timber harvest,

the effectiveness of the habitat begins to decline at a much faster rate than the decline of actual old-growth acres.

Figure IV-5. Effective Old-Growth Habitat

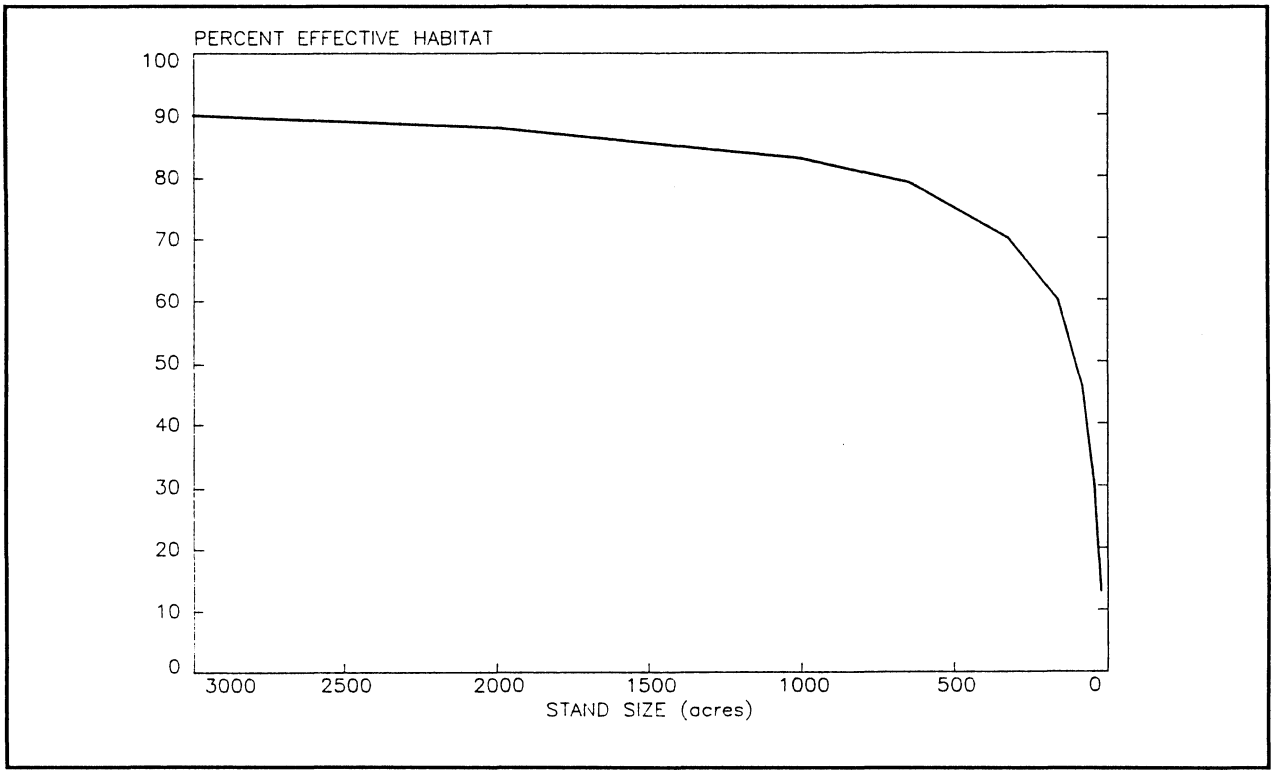

Figure IV-6 shows the distribution of old growth on the Forest at the present time, by no-harvest allocations and land unsuited for timber production. Also shown are the acres of old growth available for some level of timber harvest.

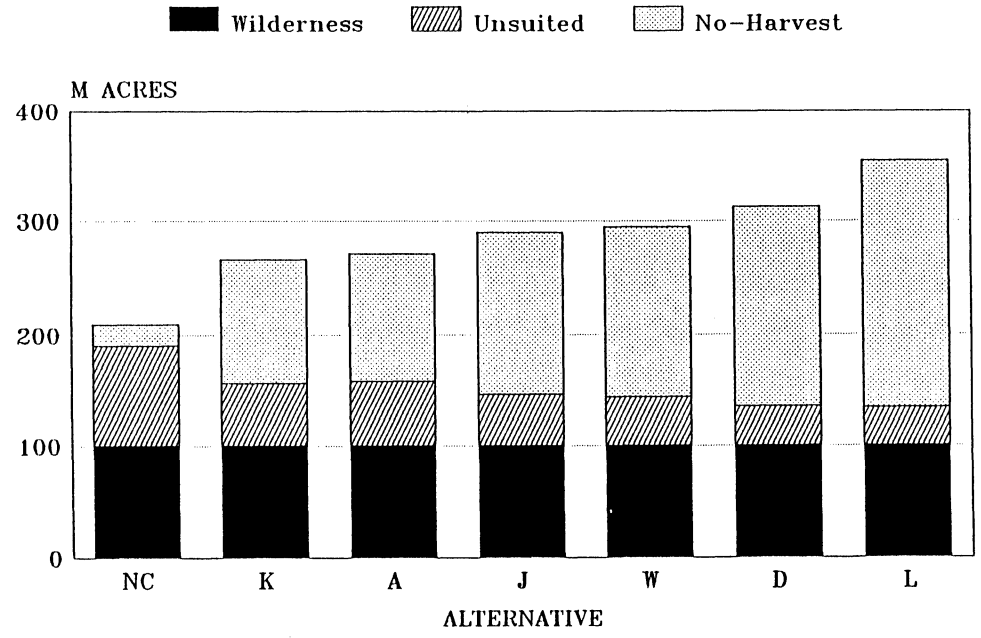

Alternative L, which sets aside 419,500 acres of old growth, retains 71% of the current total. Alternatives D, W (PA), and J retain 53, 50, and 49% respectively, followed by A and K at 46 and 45%. Alternative NC has the least amount set aside, with 35% of the current 594,800 acres of old growth.

Table IV-8 shows the acres of old growth at the end of decades 1, 2, and 5. Also shown is the total of forested acres that will not be harvested for each alternative. In the absence of natural disturbances, these figures represent the potential amount of old growth as the smaller size classes gradually move through the successional stages over time.

Alternative L maintains the greatest amount of old growth at the end of five decades (523,100 acres). With fewer acres harvested per year, there will also be a slower decline in the effectiveness of the old-growth habitat. Alternatives D and W (PA) maintain about 30% fewer acres. However, Alternative D will result in greater fragmentation and fewer acres of effective old-growth habitat than W (PA), because it harvests old growth at the same rate as W (PA), but on a smaller land base. Alternatives J, A, K, and NC drop to 35, 36, 42 and 50% less than the acres in L. From Alternative L to NC, (with

the exception of Alternative W (PA)) there is a corresponding increase in the annual harvest of old growth and a proportional increase in the rate of decline in effective old-growth habitat. The gap between acres of old growth and acres of effective old-growth habitat widens from Alternative L through Alternative NC.

Figure IV-6. Old growth by Allocation

		Alternatives						
Allocation	**Unit of Measure**	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Wilderness	M Acres	100.8	100.8	100.8	100.8	100.8	100.8	165.4
Unsuited	M Acres	89.9	56.5	58.2	45.9	43.5	35.1	33.8
No-Harvest[1]	M Acres	19.3	109.2	112.4	143.6	150.6	177.1	220.3
TOTAL [2]	M Acres	210.0	266.5	271.4	290.3	294.9	313.0	419.5
Timber Harvest	M Acres	384.8	328.3	323.4	304.5	299.9	281.8	175.3
Current TOTAL	M Acres	594.8	594.8	594.8	594.8	594.8	594.8	594.8

[1]No-harvest allocations can include semiprimitive nonmotorized, riparian, special wildlife habitat, Special Interest Areas, and MRs.

[2]This figure displays the minimum amount of old growth that could be maintained over the planning horizon (150 years) by alternative. None of the alternatives actually reach this minimum level due to in-growth.

Table IV-9 Old-Growth Acres Over Time

	Alternatives [1]						
	NC [2]	K	A	J	W	D	L
Decade 1 (M Ac.)	494.0	522.4	528.4	534.9	533.4	537.2	578.3
Decade 2 (M Ac.)	NA	449.7	460.9	473.6	479.1	478.4	558.1
Decade 5 (M Ac.)	259.8	305.1	337.0	341.4	365.2	367.8	523.1
Decade 15+ (M Ac)	440.1	571.7	630.2	651.1	729.9	785.1	951.4

[1]Acres of old-growth timber, in all allocations, remaining at the end of each decade. Decade 15+ values show potential old growth on forested no-harvest allocations, assuming no catastrophic events.

[2]NA = Data Not Available; could not be reasonably estimated, or compared to other alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other alternatives, and could not be modeled with the current Forest FORPLAN model. Appendix B of the FEIS describes these differences.

Timber

With the reduction of uncontrolled wildfire, timber management activities have become the major cause of ecosystem disturbance on the Forest. Silvicultural activities are aimed at establishing and tending timber stands and at harvesting wood products from the Forest. These include site preparation, reforestation, timber stand improvement, commercial thinning, and final harvest. Most silvicultural practices on the Forest are implemented with the intent to perpetuate the growth and development of even-aged stands of timber.

A specific amount of timber harvest is proposed in all alternatives. The magnitude of the effects of the alternatives on the timber resource depend on three basic factors. The most important of these is the number of acres suited for timber production. The other factors are the intensity of management and rate of harvest. These factors determine the amount of volume to be offered for sale during the plan and the level of harvest that can be sustained in the long-term.

Effects on Suited Acres - Figure IV-10 shows the comparison of lands suited for timber production by alternative and percent of full yield. For all alternatives except NC, there are 1,032,138 acres on the Forest that are tentatively suitable for timber management. (See Chapter III, Timber.) Removal of 85,513 acres for management requirements (MRs) leaves a potential land base for timber management of about 946,625 acres. Alternative NC with different suitability standards and no consideration of MRs, exceeds this potential by 12% (1,064,616 acres). Alternatives K, A, and J schedule harvest on 99, 92 and 90% of this potential respectively. Alternatives W (PA) and D are in the medium range with 82 and 76%, and Alternative L schedules harvest on 58% of the potential land base for timber management.

Table IV-10. Comparison of Suited Timberlands

					Timber Yield Acres with Yield Reductions to Meet Other Resource Objectives					
Alternative	**Acres with Timber Yield**	**% of Tent. Suited -MRs[1]**	**No Yield**	**% of Tent. Suited - MRs**	**Acres of Full Yield [2]**	**%**	**75-94% Full Yield**	**%**	**50%-74% Full Yield**	**%**

Rotation Age					60-110 years		140 years		200 years	

[1] Suited acres minus MRs = Total Forest acres (1,675,407) - nonforest acres (146,153) - withdrawn acres (327,501) - roads and unsuited acres (169,615) = 1,032,138 acres tentatively suited - acres required for resource management objectives (36 CFR 219.14 (c)) which preclude timber production (85,513) = 946,625 acres.

[2] Full yield is that developed in a yield simulator, less operational falldown, without further reductions for other resource considerations, and available for harvest at CMAI (or 95% CMAI).

[3] Alternative NC has the same land allocations as Alternative A (No Action) but is based on different land suitability standards and does not include MRs. It also assumes the necessary budget, workforce and technology will be available to produce full timber yields from 125,000 acres of "marginal" land.

[4] This table includes 74,941 acres that are managed on rotations of 330 to 660 years, with timber outputs that are less than 50% of full yield.

The timber volumes produced are a direct result of, and follow the same trend as, the number of acres managed. Table IV-11 shows volume by harvest method for the alternatives. The alternatives that produce the most timber volume are NC, K, and A which harvest 146, 117, and 110 MMCF per year in the first decade, respectively. Alternatives J, W (PA), and D provide moderate levels of timber at 95, 87, and 86 MMCF per year, with Alternative L producing the least amount of timber at 27 MMCF per year in the first decade.

Historically, firewood has come from a portion of the cull material associated with timber harvest and is part of the timber sale program quantity (TSPQ). The amount available for firewood use varies depending on the market for chips and cull peelers, and contract specifications for size of cull material to be removed from the harvest unit.

Because of their proposed high levels of timber harvest, Alternatives NC, K, and A would provide the most firewood, with 72, 57, and 54 thousand cords per year in the first decade. Alternatives J, W (PA) and D would provide moderate levels of firewood at 46 to 42 thousand cords and Alternative L would provide the least firewood at about 14 thousand cords per year in the first decade. Availability of firewood in all alternatives decreases over time as the harvest of older existing stands is replaced, to a great extent, by the harvest of managed stands and commercial thinning. By the fifth decade, firewood supplies are expected to decline to about 50% of the first decade levels.

Commercial thinning volume is nearly equal in the first decade for all alternatives except L, because the size classes available for thinning are mostly on lands that are suited for harvest under all alternatives (Table IV-11). By the fifth decade the commercial thinning volume shows more variation, reflecting the differences in harvest levels and management intensities. Exact figures for Alternative NC are not available, but commercial thinning in the fifth decade will account for about 50% of the total volume.

The long-term sustained yield capacity (LTSYC) for each alternative is a prediction of the maximum timber volume that can be sustained annually from the tentatively suitable timber lands on the Forest consistent with the multiple use objectives of the alternative. The difference in long-term sustained yield capacities between alternatives reflects the number of acres suitable for timber management, and the intensity of timber management and rate of harvest assigned to those acres.

The long-term sustained yield capacities of the alternatives are influenced most by the number of acres suited for timber management. Alternative NC has the highest capacity at 146 MMCF because it has the most acres suited for timber management. The LTSYC of the other alternatives decrease as the amount of land considered unsuited, or allocated to non-timber or more restrictive timber uses increases. (See Tables IV-10 and IV-11.)

For all alternatives, except NC, LTSYC is greater than beginning harvest levels (See Table IV-10). This occurs because the managed stands of the future will produce or grow more volume than the existing stands of mature timber are currently growing. In the sixth to eighth decades there will be a shortage of mature timber available for harvest because the bulk of the second growth will not have reached 95% of culmination of mean annual increment (CMAI). Application of the nondeclining yield constraint means that harvests in the earlier decades must be held below LTSYC to avoid a drop in volume in decades six to eight. Alternative NC avoids this situation by relying heavily on commercial thinning volume to offset the shortage of mature timber available for harvest in the sixth to eighth decades. As many as six thinnings, spaced ten years apart are prescribed for some stands, with the total yield from commercial thinning accounting for half or more of the volume in some decades.

Effects on Intensity of Management - Intensity of management refers to the mix of silvicultural treatments applied to the acres which are suited for timber management. The silvicultural treatments

used in the alternatives include reforestation, release, precommercial thinning, fertilization, commercial thinning, and regeneration harvest. The difference between alternatives is the number of acres to which these treatments are applied. These are displayed in Figure IV-4-8. The individual treatments and their effects are described in Chapter III, Timber.

Alternative NC, K, and A harvest the most area with an average of 14,400, 12,600 and 12,100 acres per year in the first decade. Alternatives J, W (PA), and D are in the moderate range with 10,200 to 9,100 acres. Alternative L harvests the fewest number of acres at 3,300.

The other silvicultural treatments are a function of the acres harvested, accessibility, and response to fertilizer (except Alternative NC which did not include the use of fertilizer).

Historically, treatments to release seedlings from competing vegetation have been necessary on about 20% of the acres reforested. The Forest Plan incorporates the Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation. In implementing the Forest Plan through project activities, the Forest will comply with the Record of Decision issued by the Regional Forester dated December 8, 1988, and the Mediated Agreement of May, 1989. Use of all vegetation management techniques is allowed only when other methods are ineffective or will unreasonably increase project costs. Emphasis must be on prevention and early treatment of unwanted vegetation and full public involvement in all aspects of project planning and implementation.

[1] Data not available.

Effects on Rate of Harvest - Constraints on rate of harvest are used to disperse harvest units spatially so that large openings are not created at any one point in time. The size and shape of created openings varies with resource management objectives. Harvest rate constraints are also used to distribute harvest units over a period of time (temporal) to limit the cumulative effects of timber harvest. In areas where both spatial and temporal constraints apply, the one with the most limiting rate of harvest was modeled.

Constraints on rate of harvest affect the rotation length of a timber stand. Rotation length is the number of years from the regeneration of a new stand to the time of its harvest. Generally shorter rotations (less than 110 years) are designed to increase timber production or achieve economic objectives while longer rotations (more than 140 years) are used to harvest timber while focusing on wildlife, recreation, riparian, and scenic objectives. Table IV-13 shows the range of rotation ages by species, management intensity, and constrained rates of harvest as applied to all alternatives except NC. The percent culmination of mean annual increment (CMAI) volume is also shown, to compare yield potential. Alternative NC was not analyzed with the FORPLAN model and had no constraints which applied directly to the rate of harvest. Areas like streamside zones and scenic corridors had reduced yields to simulate a longer rotation. Comparing the NC alternative to the others is difficult because the yield tables are based on a different grouping of species and site indexes.

All alternatives except NC tend to harvest the unconstrained acres at 95% CMAI to maximize present net value (PNV) and minimize the shortage of stands at rotation age in the 6th to 8th decades. Alternative NC rotation ages are at full CMAI on unconstrained acres. Table IV-10 shows the acres by yield category which can be translated into rotation ages. In this figure harvest rates of 10 and 12% are included in the full yield column while the acres with 7% and 5% harvest rates are in the 75-94% full yield and

50-74% full yield categories respectively. Percent of full yield for Alternative NC is taken directly from the current TM Plan.

Although the actual acres managed on long rotations vary substantially by alternative, they result in a fairly consistent percentage of the total timber yield acres for each alternative except L. The range is from 11% for Alternatives W (PA) and D, 14% for NC, 15% for K and A, and 16% for J. Alternative L manages 43% of the suited lands on long rotations of up to 660 years.

[1] Rotation age and percent culmination of mean annual increment (CMAI) volume are displayed by management intensity, species, and harvest rate per decade.

CMAI = Culmination of mean annual increment.
Fert. = Fertilization.
PCT = Precommercial thinning.
FSLC = Full stocking level control.
Hvy CT = FSLC with one heavy commercial thin.

Riparian Areas

Although riparian vegetation occupies only a small part of the overall acreage of the Forest, these areas provide critical diversity and stability in the forest ecosystem. In riparian corridors along streams, rivers and lakes, the presence of multiple vegetative layers provides a variety of nesting sites, cover areas and food sources for wildlife. The roots of riparian vegetation help to stabilize streambanks and adjacent slopes. Vegetative screening maintains low water temperatures by shading streams from solar radiation, and woody material provides spawning and rearing habitat for anadromous and resident fish. Riparian areas have different microclimates from the surrounding coniferous forests due to increased humidity, a higher rate of transpiration, shade and greater air movement. These conditions are preferred by some wildlife species, as well as by people participating in a variety of water oriented recreation activities during the summer months. Within riparian areas disturbance to vegetation and soils is minimized and harvest rates are reduced or eliminated in all of the proposed alternatives.

Alternatives A, J, and K prescriptions are at the MR levels designed to protect water quality and streambank stability. Alternative D allows no programmed harvest along Class I and II streams, and 5% per decade along Class III streams. Alternatives W (PA) and L have no programmed harvest along Class I, II, and III streams. The effects of these practices on water and fish resources are discussed in their respective sections elsewhere in this Chapter. Alternatives with higher rates of harvest in riparian areas will have the following effects: 1) reduced soil and channel stability, 2) reduced water quality, 3) greater fluctuation of stream flow and ground water, 4) less input of large woody material in future years, 5) greater modification of vegetative diversity, 6) reduced opportunity for quality dispersed recreation, and 7) less habitat for wildlife species, such as primary cavity excavators, optimal thermal cover for big game, and dispersal corridors for species that require interior habitat.

Table IV-14 displays riparian acres by stream class which are scheduled for timber harvest per decade. Also shown is the estimated cumulative percent of riparian harvest by alternative. The actual amount of harvest which occurs will be based on localized watershed and stream conditions. The expected pattern will be a mosaic of partial and no-cut areas from which timber yields are expected to approximate the modelled rate. This table also shows the cumulative percent harvested over five decades. The percents shown reflect the overlap of riparian areas with management areas that do not allow harvest.

Table IV-14 Riparian Harvest Acres and Cumulative Percent Harvested Rate by Stream Class [1]

	Alternatives

Decade 5	NA	18%	18%	17%	0	6%	0

[1]Stream class definitions are in Chapter III, Water.
[2]Riparian 1 refers to the zone adjacent to Class I streams, Riparian 2 along Class II streams, and so forth
[3]Percent harvested of Riparian areas of all stream classes, in all land allocations.
[4]No data is available. In the current Land Management Plan, Class I, II, and III streams were grouped together, and assigned a timber yield of 72 percent of full yield, which approximates a 5 to 7% rate per decade.

Range

The heavily forested land base has limited capacity for grazing of domestic livestock, although there has been some use of the suitable areas for grazing cattle and sheep under fee permits and some free-use grazing of recreational stock. Grazing use on National Forest land by domestic livestock has been a traditional use which has declined significantly over the past five decades. Although many of the older allotments have areas of suitable range, the reduction in the use of Forest land for range can be attributed largely to increasing labor and transportation costs without like increases in livestock returns. Examples include costs of hauling to the allotment and live stock control to keep stock on the allotment. In addition, the establishment of Wilderness has made some areas with historic grazing use unavailable to new applicants.

The effects of the alternatives on the range resource are minimal since permitted livestock use historically has been low and the large amount of forage in range allotments and transitory range is expected to far exceed anticipated demand. Although the quality of transitory range varies by habitat type and terrain, generally the alternatives that harvest more timber provide more transitory range.

Cumulative Effects of the Alternatives on Vegetation

There are approximately 123,000 acres of non-National Forest land within the forest boundary. The management of these lands will contribute to the cumulative effects on vegetation. Harvest on these lands are generally based on economic return rather than non-declining even-flow. Most of these lands have been cutover and are being managed intensively for maximum economic return. For the first two decades of the plan, these stands will be in a young, fast-growing stage of development, providing good watershed recovery, and cover for big-game, offsetting some of the impacts of harvest on National Forest lands. By about the third decade they will be ready for harvest and cutting will likely take place at a rapid pace, impacting watershed conditions and maximizing forage at the expense of thermal cover. In all but a few watersheds, the amount of non-National Forest land is a small percentage and

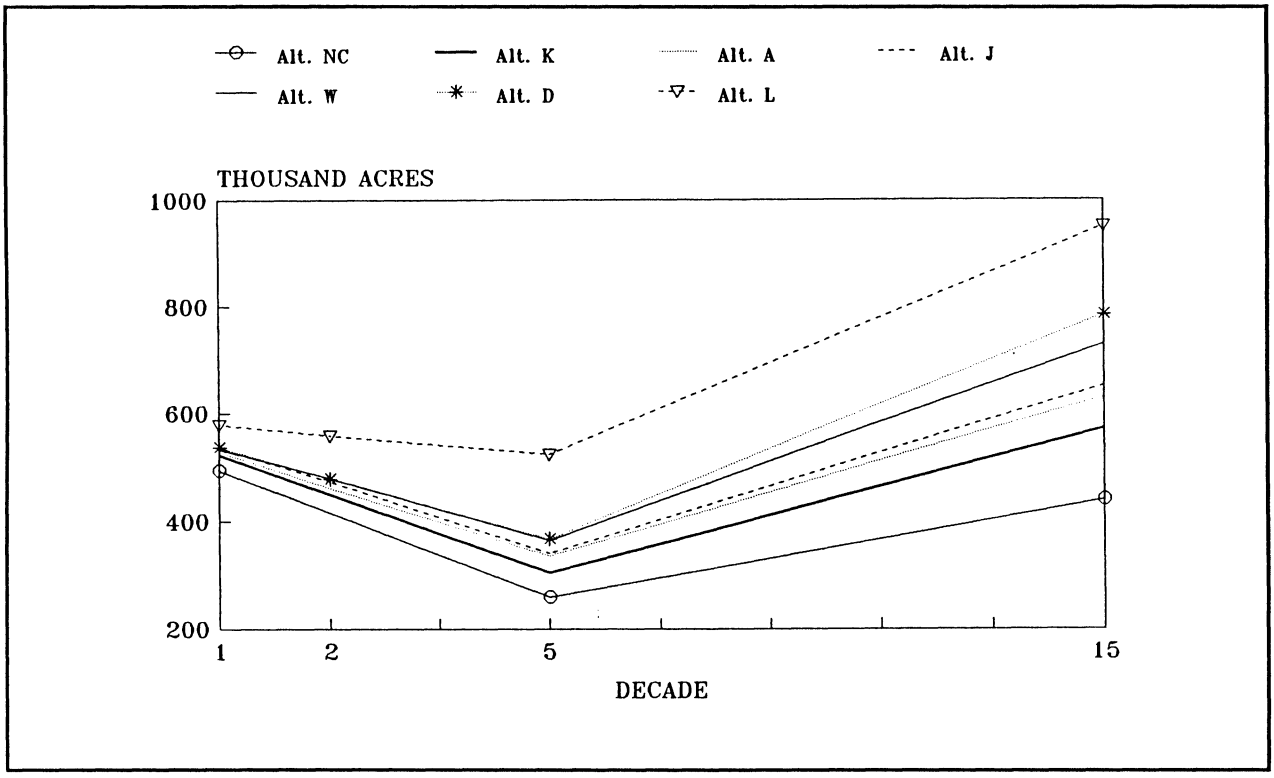
the effects can be balanced with the management of National Forest land. In some areas, Forest management activities will be influenced by vegetative conditions on private lands.

Cumulative Effects on Succession - All alternatives must meet the S&Gs concerning percent cutover, size and dispersion of units, reforestation, and rotation age. Regeneration harvest under even-aged management will determine patterns of successional stages as timber sale plans are implemented. A greater variety of age classes will be present with stands having greater populations of shade intolerant species. Differences between alternatives are measured by how much of the Forest is affected and the rate at which the effects occur. Alternatives which allocate more acres to timber harvest will gradually result in a balanced array of successional stages between grass/forb and large mature trees on a larger part of the Forest, and a smaller share maintained in old growth. Figure IV-14 shows the difference in alternatives as to acres managed for timber yields. For a typical 100 year rotation, a balanced array of successional stages would result in the following Forest condition on the managed acres: about 5% would be grass/forb, 10% shrub, 15% open sapling/pole, 50% closed sapling/pole/ small sawtimber, and 20% large sawtimber.

The portion of the Forest in no-harvest allocations would remain in, or gradually grow into, the old-growth successional stage (barring natural disturbances such as fire, insects, disease, and windthrow). Non-National Forest lands will generally not be managed beyond the small sawtimber stage.

Cumulative Effects on Diversity - Figure IV-4 shows the relationship between the amount of old growth and the variety of species (plant and animal). At the present time, about 40% of the forested land is covered with old growth. The alternatives differ as to the ultimate balance of successional stages and the time it takes to get there. At the end of the fifth decade, the alternatives are generally at the point where Forest-wide diversity is lowest and when the amount of old growth will begin increasing as the younger age classes begin to move into the old-growth successional stage. After five decades Alternative L has the highest amount of old growth Forest-wide at about 35% of the forested land. Alternatives D and W (PA) are at 24%, followed in order by J, A, and K at 23%, 22%, and 20% respectively. Alternative NC has the lowest amount of old growth after five decades, at 17% of the forested land.

After this point in time, Forest-wide old growth amounts will begin increasing. The highest level would occur after the fifteenth decade. Alternative L has the highest potential with 63% of the forested land capable of old growth. Alternatives D and W (PA) could be at 52 and 49%, followed by J, A, and K at 43, 42 and 38%, and NC at 29%.



The decline in Forest-wide diversity will occur at a faster rate with alternatives that harvest more acres per decade. The old-growth habitat becomes less effective as it is broken up into small areas by harvest units, and more edges are created. The amount of effective old-growth habitat in harvest allocations will decline more rapidly than the actual acres of old-growth trees. Application of a "minimum fragmentation" strategy can delay or reduce this effect, and is an option with all alternatives where appropriate. Table IV-12 shows the difference in acres harvested for decades 1, 2, and 5.

Cumulative Effects on Old Growth - Figure IV-7 shows the amount of old growth remaining by decade for each alternative. By the end of the fifth decade most of the old growth on lands allocated to full timber yield will be gone. Management areas in retention middle ground and foreground will be maintained in a late mature or old growth stage of development, but are not specifically preserved like wilderness or Old-Growth Groves. As the harvest of old growth proceeds, the effectiveness of remaining old-growth habitat will diminish because the larger blocks of old growth will be gradually broken up by harvest units. The old growth that is set aside in each alternative is in large enough blocks to provide effective habitat on a continuous basis and will generally be connected by riparian corridors. The end of the fifth decade generally marks the low point of old growth acres for each alternative. Alternative L maintains the most old growth with about 523,100 acres. Alternative D is next with 367,800 acres, followed in order by W (PA) (365,200), J (341,400), A (337,000), K (305,100), and NC with the lowest cumulative total after five decades of 259,800 acres.

After five decades, the amount of old growth will begin rising as harvest occurs increasingly in regenerated second growth stands, and the younger age classes in no-harvest allocations gradually become old growth. The actual amount of old growth in no-harvest allocations will depend on the occurance of fire or other disturbances. After 15+ decades, Alternative L has the potential to exceed current levels of old growth with about 951,400 acres. Alternative D has a potential of 785,100 acres, followed by W (PA) (729,900 acres), J (651,100 acres), A (630,200 acres), K (571,700 acres), and NC with the least potential at 440,100 acres.

The 123,000 acres of non-National Forest lands will have little or no cumulative effect on old growth. There are less than 3,000 acres (2.5%) of old growth remaining at the present time. Most of the remaining acres that are manageable will soon be harvested. These non-National Forest lands will generally be managed on relatively short economic rotations and will not provide old growth in the future.

Figure IV-7. Old-Growth Acres

Cumulative Effects on Timber - The magnitude of the following cumulative effects will depend on the total acres managed for timber production. Table IV-9 shows the total acres with timber yields for each alternative.

In general, alternatives which harvest more acres will gradually result in younger age classes, fewer stands of old-growth, and a younger average age of timber stands in the Forest. Along with the younger ages will come smaller average tree sizes. There will be less defect and breakage as diseases found in mature and overmature trees have less chance to develop in the younger stands. The amount of acreage in age classes from 100 to 200 years will decline in the future as the majority of the managed stands will be on rotations of 60 to 100 years, and the unmanaged stands continue to age. Laminated and blackstain root rots may show some increase with intensive management, but losses can be minimized by planting and favoring resistant species and timing precommercial thinning to minimize spread of disease by insects seeking out the fresh cut stumps.

For all alternatives, the total volume of standing trees (5"+ dbh) on land allocated to timber management will be less at the end of the planning period than at the beginning. Standing volume will decline over a period of decades until a point of equilibrium is reached where growth equals harvest (decade 2-5). Per acre growth rates will be greater at the end of the planning period than at the beginning, on timber management acres, because regenerated managed stands grow at a faster rate than existing unmanaged stands.

The per acre yield of commercial products from the Forest will increase as stands are managed to maintain fast growth rates by controlling competition. Growth will also be enhanced through fertilization

and genetic selection. Cross-breeding for desirable genetic traits will provide greater increases in successive generations. Care must be taken to avoid reducing genetic diversity which could make the Forest increasingly susceptible to insects and disease. All alternatives meet or exceed the requirement that the growth rate by the year 2030 be 90% of LTSYC. Concerns about maintaining long-term productivity are addressed by the S&Gs that minimize soil compaction and erosion, and maintain large woody debris within harvest units.

Future firewood supply will be dependent on the health and age of forest stands being harvested, and prescriptions for removal and piling of unmerchantable material to provide planting spots and/or reduce fuel accumulations. The availability of firewood will decrease over time with the implementation of any of the alternatives, as harvest shifts to regenerated, managed stands with less cull material.

Cumulative Effects on Riparian Areas - In the overall forest setting, riparian areas are relatively high in diversity of plant and animal species. Harvesting adjacent to these areas will change the species composition by allowing more light to reach the ground favoring the more shade-intolerant species. As harvest progresses in and adjacent to these corridors, the risk of blowdown will increase. Construction of roads associated with harvest will reduce vegetation, particularly along Class III streams where there is more area that still requires road access in order to conduct management activities.

Figure IV-9 shows the differences between alternatives as to the number of riparian acres that will eventually be harvested. The data for Alternative NC is not available. Alternatives K, A, and J are all very close with 17 to 18%, Alternative D will harvest 6% in Class 3 only, and Alternatives W (PA) and L harvest no riparian acres at all along Class I, II and III streams.

For all alternatives that harvest riparian areas along Class I and II streams, the rotation age is 200 years, which will result in large mature tree to old growth successional stages. For alternatives that harvest riparian areas along Class III streams, the rotation age is 140 years which will provide trees in the large mature successional stage.

Cumulative Effects on Range - Livestock grazing can cause surface compaction around salt blocks or watering areas, fences, loading ramp facilities, and trails. Over time, compaction alters plant composition and may even eliminate plants almost all together. In some areas, frost action tends to break up surface compaction and some of the polygonium species will establish on areas that are not severely compacted. However, if the situation occurs over too long a period or if the areas are continually overused, vegetative density and composition can change. On domestic range allotments where meadow habitat types are grazed, naturally moist meadows and other areas may receive damage if not managed to maintain desired plant species composition.

Relationships with Other Agency Plans or Policies for Vegetation

The S&Gs associated with vegetation management activities in this Plan will meet or exceed those found in the plans of other agencies.

The Forest Plan incorporates the Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation. In implementing the Forest Plan through project activities, the Forest will comply with the Record of Decision issued by the Regional Forester dated December 8, 1988, and the Mediated Agreement of May, 1989.

Mitigation Measures for Vegetation

A wide range of mitigation measures can be used to avoid, minimize, rectify, reduce, or compensate for undesirable environmental impacts to vegetation. These types of mitigation will not vary by alternative, although the degree to which they will be applied will be relative to the amount and location of activities which disturb or remove vegetation. Mitigation measures include the protection of the basic soils resource to maintain productivity, and protection from damage as a result of fire, insects, or disease.

Openings will not be created adjacent to any natural openings such as meadows, cliffs, caves, and talus areas, unless adequate vegetation along the edge can be developed or retained in sufficient density to protect wildlife values and visual management objectives. To minimize disturbance to natural openings, management activities will be planned in a manner sensitive to site productivity, microclimate, and special wildlife or plant habitat needs. Where practicable harvest systems, schedules, and patterns will maintain late seral stage timber in at least 30-50% of the edges of these areas, also dead and defective tree habitat is maintained when safety conditions permit.

Forest openings created by even-aged silviculture will not exceed 60 acres unless otherwise justified (36 CFR 219.27(d)). The Regional guide allows exceptions for catastrophic events (fire, insects, wind); use of logging systems to reduce damage to soil, water, and other resources; to reduce the spread of diseases (mistletoe, root rot) from adjacent stands; and to improve scenic quality by shaping and blending units to fit the land-form. The S&Gs further restrict unit sizes within some Management Areas. Sizes range from one acre maximum in the retention foreground areas to thirty acres in modification background areas. Harvest rates for these areas vary from 10% to a more limited 5% per decade.

There are a number of methods that are used to minimize impacts on vegetative diversity. These include protecting non-forested areas; planting a mix of commercial timber species to simulate natural conditions; managing noncommercial vegetation to maintain a variety of ecoclasses and successional stages; and maintaining old growth in no-harvest allocations. If Federally listed threatened or endangered plant species are identified, recovery plans will be initiated and the USDI Fish and Wildlife Service will be consulted. Timber management or other activities will be modified or eliminated to meet the requirements of the Endangered Species Act of 1973. Species classified by the State of Oregon, as being threatened or endangered, will also receive the protection necessary to insure viable populations.

A number of logging techniques are used to protect residual regeneration, forage, seed trees, or wildlife trees which could be damaged by timber harvest activities. These techniques include scheduling of activities when vegetation is less susceptible to damage; suspension of logs during skidding; skidding logs over a designated depth of snow; and designating buffer corridors. Riparian areas have different logging requirements to minimize disturbance to vegetation. In Alternative W (PA) and L, timber would not be harvested in riparian zones; the other alternatives would allow harvesting at different rates (see Table IV-9).

Riparian areas will be maintained as habitat for riparian-dependent resources. Measures include project design that maintains vegetation both vertically and horizontally, resulting in greater plant and wildlife diversity; wildlife migration routes and travel corridors; and dead and decaying tree habitat. In addition, along perennial streams the existing cover directly above the channel and within 20 vertical feet of the stream surface will be maintained at 60% or greater of the existing natural level.

Damage to vegetation as a consequence of recreation use is minimized by a number of practices. Healthy native vegetation will be maintained around campsites and the loss of trees as a result of human activity

will be avoided. Vegetation at these sites will be monitored for adverse losses. The size of groups and groups with trail stock will be limited in dispersed camps. Dispersed camping areas are to be located more than 100 feet from lakes, streams, trails, and key interest features in some of the Management Areas.

Experience in mitigating potential adverse impacts on vegetation has been gained on the Forest in places such as Jefferson Park in the Mt. Jefferson Wilderness. Here in the late 1970s the vegetation was suffering from intensive use by campers. By 1980 it became the practice for Wilderness rangers to instruct campers about the need to preserve the vegetation and disperse camps away from the lakes. By dispersing camps with a 200 foot set back, vegetation began recovering. String fences were used to delineate and protect areas that were rehabilitating. Seed from native vegetation was gathered and used to rehabilitate areas damaged by concentrated use.

To regulate and monitor collection activity, and avoid potential harmful impacts a permit is required for collection of vegetative material including ferns, seedlings, bear grass, tree boughs, Christmas trees, and cascara bark. Rehabilitation projects, trail and area closures, and visitor contact can be implemented when necessary.

A wide range of activities can be used to avoid, minimize, or compensate for impacts to timber quantity and quality. The types of these measures will not vary by alternative, but the degree to which they are applied will depend on the amount and location of timber harvest. Alternative NC does not include the use of fertilizer.

Decreases in allowable harvest levels can be mitigated in two ways, by increasing the number of acres available and suited for timber management and by increasing yields from each acre. Research is ongoing to find cost-efficient methods of reforesting unsuited soils within five years of harvest. Research is aimed at providing safer and more effective ways to release trees from competition and protect them from insects, disease, and animal damage. These efforts result in earlier establishment and faster growth. Forest soil types are being tested to determine if the increased tree growth off-sets the cost of fertilizer. The genetic improvement program is moving into the next stage with the establishment of seed orchards. The present yield table uses a 10% increase in yield for using seed from superior trees in reforestation. Additional gains may be possible by further testing and cross-breeding these superior trees in seed orchards.

Higher yields may also result from new technology allowing commercial thinning over longer distances with less damage to residual trees. About two-thirds of the suited land base is accessible for thinning. New technology and more widespread use of existing techniques like directional felling can increase yields by reducing breakage and increasing utilization of wood that is presently left on site or burned to prepare the site for planting.

A range of controls is available to prevent damage to seedlings in plantations. These are found in Appendix D, General Management Standards, Vegetation Control and Integrated Pest Management. These control damaging agents such as wildlife, plant competition, disease, and insects. An example of reducing animal damage to seedlings is the use of vexar tubing placed over the tree to prevent browsing or clipping by wildlife. Burning of logging slash removes cover for hares, mountain beavers, woodrats, porcupines, and other small mammals. Burning also slows growth of vegetation for several years and lessens competition for light and moisture (Black and Hooven 1978).

The timing of these measures can be critical to their success and to minimizing their impacts. For example, slash burning must be accomplished when fuel moisture levels are dry enough to reduce slash to desired levels, but duff is wet enough to prevent the burn from becoming too hot and damaging

the soil. Another example is timing precommercial thins to avoid the spread of blackstain root disease by beetles attracted to the fresh cut stumps.

Detailed silvicultural prescriptions will address environmental conditions that pose a limitation to a species that is not exclusively adapted to the conditions that are present. An example is planting a mix of species. The silvicultural prescription will also be guided by the S&Gs that will limit size of openings, harvest rates, and disturbance according to Management Area. (See Chapter IV, Vegetation.) All the various forms of even-aged regeneration cutting will be available for use including clearcutting, shelterwood, and seed tree. Where appropriate, uneven-aged management will be accomplished by group selection in some Management Area Prescriptions.

Pruning is another measure that may be used in the future to mitigate impacts on wood quality due to younger age classes and smaller tree sizes. The removal of lower branches can encourage high quality, high value clear wood not otherwise found, except in old-growth trees.

Careful design, layout, and administration of the harvest operation can increase yields by protecting site quality, reducing breakage and logging damage to residual trees, and minimizing the risk of windthrow and escaped slash fires.

Decreasing supplies of firewood in the future can be mitigated to some extent by considering non-traditional sources such as precommercial thinning and commercial thinning slash, and through small sale or salvage sale programs.

On lands that are suitable and available for domestic livestock grazing, permits and the Range Allotment Plans will distribute and limit the number of animals on each area. Range Allotment Plans are revised and updated on an annual basis. This interaction promotes the resolution of environmental issues and the anticipation of potential conflicts.

The control of noxious weeds that are toxic to livestock is achieved on the Forest without the use of chemicals. Biological forms of control are administered by the State of Oregon. Allotment Plans promote grazing rotation to reduce the amount of thistle and other pasture weeds. Mechanical pulling of undesirable vegetation may be implemented if necessary.

A number of mitigation measures can be utilized to reduce or minimize undesirable impacts to range and grazing resources. For example, salt block and watering locations are periodically moved to promote optimum grazing patterns and minimize long term animal concentrations and soil compaction. Range improvements and maintenance projects can also be utilized to prevent resource damage and to sustain the productivity of existing permits.

Environmental Consequences Of The Alternatives On Fish

Introduction

Thirty species of native and naturalized fish live in aquatic habitat within the waters found on the Forest. Although historically fish populations on the Forest have declined slightly, commercial and recreation industries are still supported in part by Forest fish resources. The management and enhancement of fish habitat by the Forest Service and the Oregon Department of Fish and Wildlife (ODFW) has had a positive correlation with recreational use and values. Fishery related businesses include those of guide services, motels, restaurants, processing plants, and of boat and equipment dealers.

Direct and Indirect Effects of Alternatives on Fish

Although all fish species are considered important, only the anadromous salmon and resident trout species are considered as management indicator species (MIS) on the Forest. These species were selected because of their value as sport and commercial fish species and because they have special habitat requirements that may be significantly influenced by management practices.

Both fish production and habitat capability are important measures of fish habitat conditions on the Forest. While many relationships between fish and their habitat are complex and not every detail is completely known or thoroughly understood, biologists do know that the ability of a species to inhabit a given environment successfully is dependent on a number of factors which ensure the basic survival and reproductive requirements of the species. These factors are water temperature within minimum and maximum tolerances, spawning gravel within size limits used by each species, adequate food supplies, and living space for protection against excessive predation and severe hydraulic events.

Anadromous Fish - The effects of proposed activities on anadromous salmonids is described with a smolt habitat capability index (SHC). This index was based on the best available information and coordination with Oregon Department of Wildlife. The Index can be adjusted as new and better information becomes available. (See Monitoring, Chapter V of the Plan.) Three major factors influence the effects of an alternative on SHC; elimination of major barriers to fish passage by other agencies; the level of enhancement projects provided by each alternative, and the level of timber harvest in and adjacent to riparian areas.

The existing SHC is estimated at approximately 169,000 smolt, from 139 miles of existing anadromous fish habitat. These numbers reflect a low number of returning chinook, to the McKenzie River, and low returns of winter steelhead to Fall Creek and the Santiam River. The potential SHC of this habitat is estimated at approximately 437,000 smolt assuming adequate adult escapement to fully seed existing freshwater habitat.

All alternatives propose to provide rehabilitation and enhancement of approximately 60 miles of the existing habitat. The full effectiveness of these projects may not be seen until the second decade when the SHC would be at over 500,000 smolt.

The elimination of major barriers to passage for spring chinook in the South Santiam, and McKenzie watersheds would add an additional 106 miles of habitat, and would improve smolt production and potential adult anadromous fish escapement in all alternatives. These projects are primarily under the jurisdiction of the Army Corps of Engineers, Oregon Department of Fish and Wildlife, and Eugene Water and Electric Board; agencies with which the Forest will work with cooperatively to increase the

miles of available habitat. The completion of these projects is expected to increase smolt habitat capability by an additional 500,000 smolt the first decade. Habitat rehabilitation and enhancement projects on 30 miles of the potential habitat would increase the smolt habitat capability by almost 800,000 over existing habitat levels during the second decade. These projections also assume harvest regulations that allow sufficient adult escapement to fully stock the habitat.

In addition to instream improvements, several types of on-Forest enhancement projects would increase anadromous fish populations. These projects focus on expanding the utilization of anadromous fish habitat to presently unoccupied sites by hauling adult fish around small, on-Forest barriers such as waterfalls; and by increasing smolt production through the use of egg incubator boxes along streams.

Timber harvest within the riparian area and adjacent to the riparian areas has direct impacts to the fishery habitat. The processes which create the changes to aquatic habitat are described in more detail in the Water section of this chapter. These processes focus on changes in riparian conditions, levels of sediment, and changes in runoff patterns. The assessment of the influence of timber harvest on smolt habitat capability is based on the same three parameters.

Tree removal within the riparian areas reduces a number of important fish habitat components. When riparian trees are removed, so is the source of fine organic material which is used as food or cover for aquatic food organisms, is no longer available. The large woody material (LWM) such as limbs, boles, and root wads that interact with hydraulic forces to cause gravel sorting, scour, and ponding are no longer providing that function. Reduction of habitat diversity and productivity is reflected in the reduced fish availability.

At least one side of at least 39% of Class I, II, and III streams had already lost the stream-side vegetation, the effect will be long-lasting. Recovery of hardwood vegetation to 75% canopy closure takes approximately 25 years. Recovery of full-sized conifers may take up to two hundred years to produce future large woody debris where hardwood species have become dominant in riparian areas.

When trees in the riparian areas are harvested, there are other indirect effects to the fish habitat. Riparian areas along streams and lakes act as filter strips that trap sediment and sideslope debris from adjacent roads and harvested areas. Riparian areas become less efficient filter strips as trees are removed allowing the sediment and debris to reach adjacent streams. Excessive sediment has the potential to deposit in slow moving areas, reducing the dissolved oxygen to salmonid eggs and alevins. (Chapman and McLeod, 1987) Debris torrents and rocks can destroy fish habitat by washing out in-stream cover filling, in rearing pools, and reducing the habitat diversity within a stream. Removal of trees within the riparian areas also causes reduction in root strength and increases the risk of erosion through streambank and streambed scouring.

In the alternatives, the maximum rates of harvest per decade in riparian areas vary. Alternatives K, A, and J emphasize commodity production with low to moderate emphasis on amenity resources such as fish. The fish resource is not considered a high commodity resource and these alternatives would allow the greatest amounts of harvest in the riparian areas associated with Class I, II, and III streams. In these alternatives, a 5% harvest rate per decade is allowed in the riparian areas associated with Class I and III Streams, and a 7% rate of harvest in riparian areas associated with Class III Streams. These alternatives would allow a 10% harvest rate in lakeside riparian areas. In Alternatives K, A and J, there would be a reduction of food supply and large woody debris in the stream compared to the other alternatives.

Alternatives W (PA), D, and L have a higher emphasis on fish resources. Alternatives would allow no harvest in riparian areas associated with Class I and II areas, and 5% harvest in riparian areas associated

Class III stream areas. Alternatives W (PA) and L would allow no programmed harvest from Riparian areas adjacent to Class I, II, and III streams. These alternatives would allow no harvest in riparian areas adjacent to lakes. Food and nutrient supply levels as well as large woody debris recruitment should be higher in these three alternatives than in Alternatives K, A, J.

Table IV-15. Smolt Habitat Capability Index

	Alternatives						
	NC [1]	K	A	J	W	D	L
Smolt Produced [2]							
FIRST DECADE							
Existing Habitat	NA	392	397	410	437	432	437
Potential Habitat	NA	439	443	458	488	433	488
TOTAL		831	840	868	925	865	925
SECOND DECADE							
Existing Habitat	NA	616	621	641	681	674	681
Potential Habitat	NA	686	692	716	763	676	763
TOTAL		1302	1313	1357	1444	1350	1444

[1]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model.
[2]Thousands of smolts

Harvest levels would be less in Alternatives W (PA), D, and L than in the others which result in fewer acres being disturbed due to road building or harvesting of units. The mass wasting levels are expected to decline significantly under Alternatives W (PA) and L, which provide additional direction for protection of Class IV streams and potentially highly unstable landtypes. The risk of adverse effects from mass movement during major storm events, is discussed in the Water section. Mass movement, at rates increased above natural levels, has the potential for damage to fish, as debris fills pools, and increases levels of fine sediments in spawning substrate. First decade erosion levels are below levels in previous years based on the occurrence of normal storm events.

Alternatives W (PA), D, and L would produce the highest levels of smolt (over 560,000 smolt) from existing habitat during the first decade, while Alternatives A, K, and D would produce between 500 and 550 thousand smolt. Per decade harvest rates and smolt populations were not determined for Alternative NC. However, due to increased instream sediment loads, smolt populations are expected to be lower than population estimates in Alternative K.

Erosion in the stream would be higher in Alternatives K, A, and J, compared to the other alternatives due to increased road building at the higher elevations and head wall areas to meet the objective of higher harvest levels. A larger proportion of the road building and harvest activities would occur adjacent to Class III, and IV streams where much of the available timber still remains.

Resident Trout - The habitat capability for resident trout populations would be influenced by streamside cover, woody debris and erosion as with anadromous fish, but to a lesser degree Forest-wide. The majority of trout production sites are located in reservoirs and in Wilderness lakes, and in the McKenzie River system. The lakes are less affected by timber harvest activities than are streams and rivers. In-stream production is a small portion of trout production on the Forest and much of the in-stream production is also supplemented with hatchery stock.

All alternatives would complete 1335 acres of reservoir improvement, presuming adequate funding and technological developments. Alternatives W (PA), D, and L would accomplish an additional 118 acres of streamside improvement for resident trout. As a result, there is only a 3% difference in trout populations based on habitat capability between Alternative L and Alternative K; Alternative L would produce 2,505,900 legal size trout and Alternative K would produce 2,426,800 fish in the first decade. All of the alternatives, except Alternative NC, manage for over 97% of the biological potential for resident trout. Population outputs for trout were not determined for the No Change Alternative.

Sensitive Species - Two fish species currently listed as Sensitive in the Region are bull trout *Salvelinus confluentus*, and the Willamette Oregon chub *Oregonicthys crameri* exist on the Forest.

Bull Trout populations are currently found in the McKenzie sub-basin, including the South Fork McKenzie. Historically the populations were also found in the Middle Fork Willamette and North Fork Middle Fork Willamette, and the North Santiam. Currently an multi-agency group including U.S. Forest Service, Oregon State University, Oregon Department of Wildlife, and National Park Service, are cooperating to evaluate the status of the populations.

Many of the factors which limit these populations are not yet understood, however it is known that water temperature is important for initiation of breeding, for embryonic development, rearing, and for adult habitat. They are seldom found in tributaries with summer temperatures exceeding 18 degrees C, and are often found near cold perennial springs. (USDA Forest Service, 1989)

Alternatives W (PA) and L provide the best protection of this species, because no harvest is programmed from riparian areas in these alternatives, and risk of increases in stream temperature is low. It is possible that future management of this species may require reestablishing it in its historical species. This would be made more difficult under alternatives with programmed harvest in riparian areas due to a greater probability of increases in water temperature.

The Willamette Oregon chub was historically widespread throughout the Willamette drainages, and is now restricted to scattered populations along 15 miles of the Middle Fork Willamette. This species inhabits areas with primarily slow velocities, such as those created in overflow channels of flooding rivers. The containment of the Willamette River for flood control purposes has reduced the historical habitat of this species. Population declines may also be due to competition from introduced species. (Pearsons 1989)

The Fish and Wildlife Service was petitioned in the spring of 1989 to list this species as Threatened. The agency will follow the established procedure in making the determination of status. Management of habitat for this species will be based on recommendations developed in cooperation with ODFW. These would be followed under all alternatives.

Cumulative Effects on Fish - Many of the Forest's fish are anadromous fish, and as a result, utilize both on Forest and off Forest habitat. The construction of reservoirs by the Army Corps of Engineers has interfered with access to and from the potential habitat on the Forest and has totally blocked access to 66% of it. Continued interference with emigration and immigration due to management of interspersed private land may prevent the Forest habitat rehabilitation efforts from becoming fully effective and populations from reaching levels where the available habitat would be fully utilized.

Both habitat capability and fishery populations are expected to increase in the future due to rehabilitation projects. In the short-term, bedrock-control type streams would be rehabilitated more rapidly due to advances in current technology. Glacial out-wash type streams would be harder to rehabilitate because hydraulic responses are less predictable and the base of current knowledge for anchoring large structures within streams is still on-going. Over time, habitat projects that improve fish passage around reservoirs will provide access to additional habitat.

Mitigation Measures for Fish

The management activities that take place in the Forest's watersheds are governed by standards and guidelines that specify ways to protect features of quality fishery habitat for water temperature and turbidity. On a site specific basis, additional mitigation measures can include a wide range of actions that avoid, minimize, rectify, reduce or compensate for undesirable environmental impacts on the fishery resource.

The degree to which they will be applied will be relative to the amount and location of the activities proposed by the alternatives and site specific impacts. For example, Knutson-Vandenberg Act funding opportunities for fish habitat improvement projects would be higher in alternatives with high levels of timber harvest to mitigate for adverse conditions caused by timber sales and road construction.

Habitat improvement projects can be specifically designed to establish desirable habitat conditions and also to correct past adverse impacts on fish resources. Proposed projects should be evaluated for need as well as cost-effectiveness. Special projects can include cleaning spawning and rearing beds, rehabilitating riparian areas, improving fish passages, and modifying stream structure with gabion construction or logs to create more diverse habitats and improved pool/riffle ratios.

In Alternative W (PA), protection of the vegetation in the areas within 100 feet of perennial streams, wetlands, flood plains, lakes and other large water bodies will reduce impacts on fish habitat. The existing vegetation will be utilized to shade the stream channel and to reduce erosion. Large woody debris will be maintained in perennial streams and lakes at a minimum of 90% of the existing level. In certain site specific upland areas adjacent to these riparian corridors, soil and vegetative disturbance will be minimized by requiring suspension of logs during logging. Disturbance during yarding operations can also be minimized by directional felling of trees.

Protection of water supplies for hatcheries can be accomplished by many of the same site specific measures previously discussed, and those discussed in the Water section.

Road construction, reconstruction, or maintenance projects adjacent to or within streams can increase deposition of sediment and cause temporary impacts on water quality. Potential adverse effects to fish can be minimized by scheduling work outside of spawning or migration periods, and during slack fishing periods. Scheduling work during normal dry seasons will allow newly disturbed areas sufficient time to be rehabilitated prior to the rainy season. Deposition of sediments can be reduced by designing roads and access routes to minimize road cut and fill erosion, and by reseeding and replanting exposed areas (Reeves 1982).

Debris jams that impede fish migration, or remove suitable spawning areas from production, may be removed as long as removal does not adversely affect stream gradient and configuration. The debris may be removed in phases, and conditions can be monitored periodically. When a culvert hinders or blocks upstream access, replacement may be the best approach, and new culverts can be positioned to protect fish habitat. Culverts can be placed to allow sediments to accumulate, creating dart and rest areas for small fish. Road reinforcement structures such as pilings or walls can also be placed to form slow moving pools within a stream (Reeves and Roelofs 1982).

Fishing is a form of dispersed recreation that directly affects fish populations. To a large degree, ODFW regulates the level of fishing by setting catch limits and seasons. Developed sites tend to concentrate fishing pressure which often decreases fishing success, although increased fishing pressure may be beneficial to some brook trout populations where fish size is stunted due to overpopulation. Trampling of riparian vegetation near streams and lakes can also impact fish habitat. Damaged sites can be rehabilitated and restrictions can be placed on dispersed campsite locations and conditions. Access sites for fish liberation trucks can be spaced to allow a better distribution of fish and provide dispersion of anglers.

Relationships with the Other Agency Plans or Policies for Fish

There are a number of plans and policies formulated by other parties with regard to the management of the aquatic habitat. Most of these plans and policies have elements that deal specifically with fish habitats. In general, they address two basic elements of fish habitat: (1) the maintenance of existing habitat; (2) the restoration, rehabilitation, and/or enhancement of fish habitat.

Four pertinent plans or programs:

- *The Columbia River Basin Fish and Wildlife Program, 1984*, (Northwest Power Planning Council). This plan was prompted by passage of the Pacific Northwest Electric Power Planning and Conservation Act of 1980 (P.L. 95-501). This plan emphasizes the restoration of Columbia River anadromous fish runs diminished by basin-wide hydroelectric development and operation. Restoration provisions include protecting fish survival, encouraging their reproduction, and rehabilitating and enhancing their habitats in the Columbia River and its tributaries.

- Sub-basin plans for the Santiam, Calapooia, McKenzie, Middle Fork Willamette and Willamette mainstem are currently being reviewed for consistency with this plan. Upon adoption by Northwest Power Planning Council and Bonneville Power Administration, they will have a profound effect upon all agencies responsible fish and fish habitat. These sub-basin plans will establish specific goals and prioritize habitat investments.

- *Comprehensive Plan for Production and Management of Oregon's Anadromous Salmon and Trout, 1982* (Oregon Department of Fish and Wildlife). This statewide plan deals with all major anadromous species. Habitat management considerations focus on the maintenance and improvement of anadromous fish habitat.

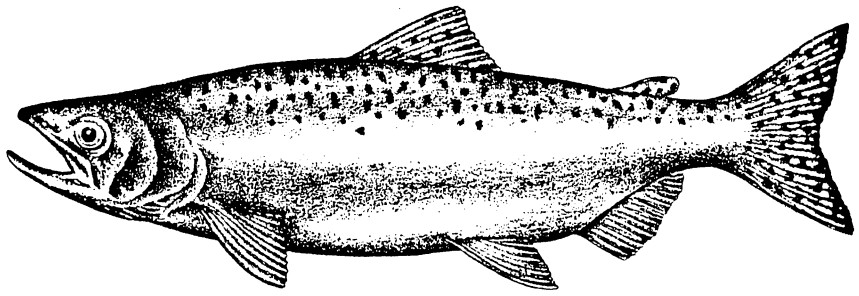
- *Oregon Wild Fish Policy* (Oregon Department of Fish and Wildlife). This policy formally recognizes the need for habitat-based, wild, and natural fish production.

- *Willamette Basin Fish Management Plan*, 1988 (Oregon Department of Fish and Wildlife). A key feature of this plan is a section that emphasizes the importance of maintaining fish habitat to ensure fish populations remain at high levels.

Inadequate information

Inventory of quantity and quality of aquatic habitat suitable for spawning, rearing and feeding of salmonid Management Indicator Species.

Smolt density coefficients derived from site specific studies.



Determine thresholds of sediment and turbidity above which negative effects on fish and fish habitat occur.

Determine the role of food sources from Class III and IV streams on Class I and II habitat.

Determine the influence of gravel stability on the survival of salmonid eggs and fry.

Determine the amount of instream large woody material necessary to meet objectives for fish production.

Assess the results of stream rehabilitation projects on fish population dynamics.
Bull Trout habitat, populations, distribution, and other characteristics as described in the "Research Needs" section of "Biology of the Bull Trout" Willamette National Forest, 1989.

Environmental Consequences Of The Alternatives On Wildlife

A diverse array of wildlife species reside on the Forest. More than 170 avian species, 64 mammalian species, and 30 amphibian and reptilian species use habitats found on the Forest for all or a significant portion of their life history needs. Numerous physical, biological, and environmental factors interact at stand and landscape levels causing the number of individuals within populations to fluctuate over time. These fluctuations can be natural or caused management activities. Management activities have direct, indirect, and cumulative effects on wildlife populations and their habitats.

Particular species have been chosen as management indicator species (MIS). Management indicator species represent a broad group of species dependent on, or associated with, similar habitat conditions. The primary assumption used in the indicator species concept is that by managing for viable populations of indicator species, the viability of all other species that require similar habitats will be maintained. This group of wildlife species serves as one measure of vertebrate diversity across the forest.

A discussion on the selection of MIS and the habitats they represent is presented in Chapter III, Wildlife.

Direct and Indirect Effects of the Alternatives on Wildlife

Diversity of Vertebrate Species - All of the alternatives, except No Change, have been designed to provide for a diverse mix of wildlife habitats capable of sustaining viable populations of native and desirable non-native vertebrate species. Some wildlife populations are directly impacted during management activities such as timber harvest, road construction, mineral extraction, and fire. Small mammals, reptiles, amphibians, and nesting bird species are most likely to be directly impacted because of their limited mobility. Significant population loss throughout the Forest would rarely occur as a direct effect of management activities, but localized segments of the population could be lost or isolated. Management activities involving the release of species could directly increase populations in localized areas. Examples would include transplanting elk or release of peregrine falcons.

Indirect impacts to wildlife species are more subtle and vary greatly depending on the amount of habitat loss, change, or disturbance. Changes in habitat composition, structure, and distribution results in subsequent shifts of species composition and population densities within the Forest as well as off the Forest. Some species are migratory, using habitat on the Forest during breeding seasons and then moving to other locations during winter months. Others, such as elk, migrate from higher portions of the Forest to discrete wintering grounds on other portions of the Forest. In addition, a species' habitat requirements may change through the year, with nesting or calving requiring one type of habitat, while feeding or protection from the weather may require another.

The No Change Alternative (NC) does not incorporate the provisions of the National Forest Management Act (NFMA) requiring diversity of animal communities be maintained and maintenance of habitats for well distributed viable populations of vertebrate species. Wildlife populations are at greatest risk in Alternative NC. Habitat provisions in the current forest management plan (NC) would meet Recovery Plan requirements for federally listed threatened and endangered species.

All alternatives except NC, rely on the MIS strategy to meet the diversity intent of NFMA. The selection of MIS species is described fully in Chapter III. Each alternative results in different habitat characteristics and distribution.

Management Requirements for habitat quality, quantity, and distribution for MIS are met in Alternatives A, J, K, and W (PA). Alternatives D and L provide habitat levels which exceed Management Requirements

(MRs). Alternatives J, W (PA), D, and L, respectively, provide increasing protection for special and unique habitats reducing the risk of losing species diversity.

Northern Bald Eagle: Threatened Species - The northern bald eagle is federally listed as a threatened species. As identified in the Pacific States Bald Eagle Recovery Plan (1986), the population recovery objective for the Forest is 20 pairs of bald eagles. Protection and enhancement of bald eagle habitat must include consideration of nest sites (current, future,and replacement), roost sites, and foraging areas.

Chapter III, Wildlife, describes the habitat requirements and Recovery Plan objectives for the bald eagle. Figure IV-16 displays bald eagle habitat by alternative.

Management activities proposed in all alternatives that would directly impact bald eagles are timber harvest, road construction and maintenance, and recreation developments. Allowing these activities to occur in and around occupied territories could directly impact bald eagles by causing them to avoid or abandon nest sites, roost sites, or foraging areas (Anthony, 1990 personal communication).

Indirect effects could also occur, impacting the potential recovery of the bald eagle. Indirect effects to bald eagles include management practices that reduce habitat suitability by harvesting potential nesting or roosting habitat, result in significant reductions in potential food resources, or allow disturbance in key use areas, causing abandonment or precluding establishment of a territory.

Alternative NC (No Change) would comply with the Threatened and Endangered Species Act of 1973, as amended, and the Pacific States Bald Eagle Recovery Plan. Bald eagle habitat would be managed to meet established Management Requirements (MRs). Alternatives A and K manage bald eagle habitat at the MR level. Alternatives J, W (PA), D, and L increase the potential for population recovery. Alternative W (PA) would increase protection around potential and existing nest sites to at least 125 acres and would require biological evaluations of all activities occurring within 1.1 miles of eleven major water bodies with known or high potential for bald eagle territories. Alternative J would manage for the same number of sites as Alternative W (PA), but the potential nest sites would average 30 acres in size. This is smaller than recommended for protection of nest areas (Anthony 1989). Alternatives W (PA), D and J provide protection of additional potential nest sites above that required in the Recovery Plan and would include habitat provisions as recommmended by Anthony (1989) and McAllister et.al.(1989). Alternative L impacts the fewest acres of old growth habitat, thus would provide the highest amount of nesting and roosting habitat throughout the Forest.

Alternatives W (PA), D, and L provide the most potential for long-term recovery of the bald eagle. Emphasis on timber harvest, road construction, and developed recreation sites combined with minimal protection of potential territories in Alternatives NC, A, K, and J would result in lower probability that long-term recovery objectives would be achieved or maintained.

Table IV-16. Prescribed Management Level for Bald Eagle Habitat

	Alternatives						
	NC (No Change)	K	A	J	W (PA)	D	L
Habitat Acres Associated with Existing Pairs [1]	150	150	150	150	625	625	625
Acres Potential Habitat [2]	480	480	480	570	2375	2825	2825
TOTAL							

[1]These acres reflect roosting and foraging habitat known to be utilized by the existing pairs of bald eagles as well as specific nest sites.
[2]Habitat identified is around key feeding areas and potential nest sites, not formally surveyed.

Peregrine Falcon: Endangered Species - The peregrine falcon is federally listed as an endangered species. In the Pacific states, peregrine falcons nest almost exclusively on cliffs, usually near water and an abundant prey source. Although there are no known pairs of peregrine falcons on the Forest, they do nest in similar habitats on adjacent Forests. Twelve sites have been identified on the Forest as high potential nest sites by the Oregon Department of Fish and Wildlife (ODFW). They are located on rock cliffs having horizontal ledges for nesting.

The peregrine falcon is particularly sensitive to disturbance near the nest cliff during the breeding season. If human activities are occurring throughout the nesting area, the entire territory may be abandoned, and the pair may not nest (Hickey 1942, Fyfe and Olendorff 1976). Use of the organochlorine pesticides, particularly DDT, was the greatest factor contributing to the decline of the peregrine falcon (USFWS 1982).

Timber management activities can indirectly affect peregrine falcon recovery potential by impacting special and unique habitat such as meadows, hardwood stands, marshes, and bogs which often support high populations of birds used as a food resource. Timber harvest may provide additional prey populations by creating openings preferred by many of the peregrine's prey species. Silvicultural practices such as vegetation control using herbicides that reduce vegetation diversity and structure could reduce the potential population of birds within the openings. Where this occurs within a potential territory of a peregrine falcon, adverse indirect effects to recovery objectives could occur.

All of the alternatives meet the minimum habitat protection requirements of the Pacific Coast Recovery Plan for the American Peregrine Falcon. The most limiting factor for meeting recovery objectives on the Forest is the low population densities with the Pacific States recovery zone. Alternatives NC, A, and K would result in aggressive timber harvest and roading programs, with the least emphasis on maintaining habitat diversity. These alternatives would have the greatest potential to affect peregrine falcon recovery. Alternatives D, W (PA), L respectively, would place increased emphasis on maintaining vegetation and habitat diversity and would provide the highest potential to meet or exceed Recovery objectives.

Northern Spotted Owl: Ecological Indicator Species - As an ecological indicator of mature and old growth forest habitats, the northern spotted owl represents those vertebrate communities associated with late stages of forest succession. See Wildlife in Chapter III for a more detailed description of northern spotted owl habitat.

Management activities are most likely to directly impact spotted owls during the breeding and nesting seasons. Road building and timber harvest occurring between February 1 and September 30 have the highest potential for direct impacts. Noise caused by road construction machinery, skyline logging systems, blasting, and felling trees would cause significant disturbance near nest trees and natal areas (Forsman 1989, personal communication). Felling of trees may cause mortality to nestlings or fledglings not yet old enough to disperse away from the disturbance. Miller (1989) found most juvenile spotted owls stayed within natal areas an average of 104 days after fledging. Dispersal of juvenile spotted owls began in September.

Recreation activities are less likely to cause direct impacts unless high use trails and campsites are located within natal areas. Adult spotted owls have the ability to disperse from disturbance activities and have a low probability of being directly impacted. Spotted owls are relatively easy to locate and approach, making them susceptible to harassment or destruction by people.

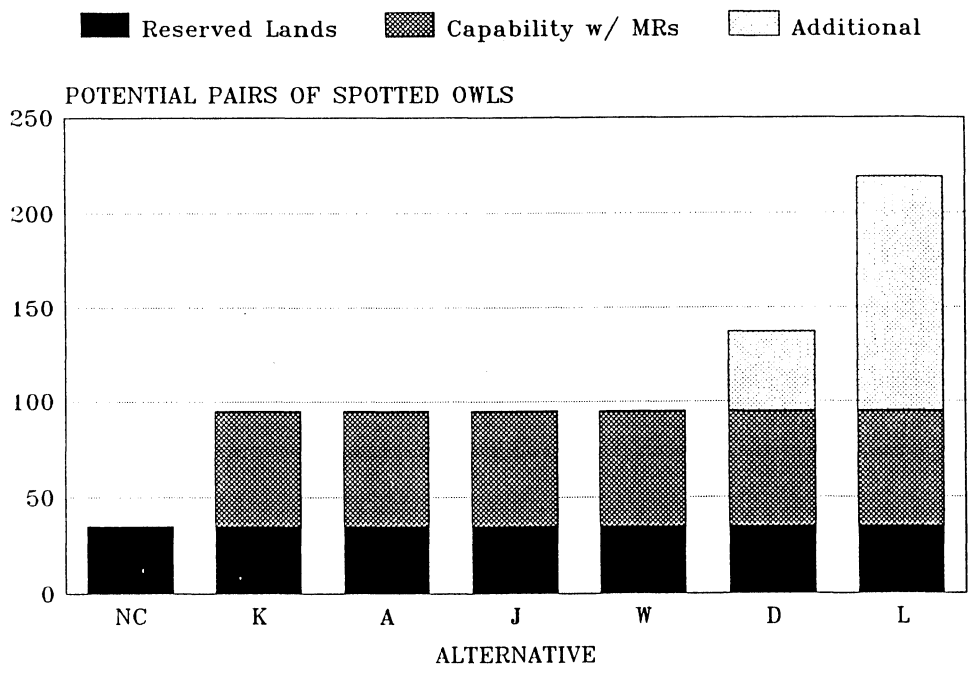
Indirect effects of the proposed alternatives to northern spotted owls are extensive. Changes in habitat quality, quantity, and distribution would result from land allocations and management activities. Impacts to prey bases, competition and predation from species adapted to early successional or edge habitats, and fragmentation of suitable habitat will result in long-term reduction of spotted owl populations (Thomas et al. 1990). The primary land management activities causing indirect effects occur as a consequence of harvesting mature and older trees, road construction, fire, mineral development, silvicultural practices, and vegetation management. Conversion of old-growth and mature forests to managed plantations eliminates many vegetation attributes needed to support those species associated with existing mature and old growth forests. Silvicultural strategies involving maintenance of vigorous stands and harvest rotations less than 200 years have a low potential as replacement habitat in the future because of the lack of canopy layers, snags, and down logs which typically describe preferred habitat of spotted owls (USDA Forest Service, FSEIS 1989). Figure IV-17 displays the amount of mature and old-growth forests that occurred on the Forest when timber harvest began in about 1940, the current condition, and the amount remaining at the end of each future decade, by alternative. Effects of fragmentation on suitable habitat are not represented.

Past and current intensive timber management activties including timber harvest and road construction have resulted in a highly fragmented landscape. The impact this has had on the spotted owl population is unknown. Future consequences of these acivities, as represented by Alternative NC, would include a rapid decline in habitat followed by a probable decline in the spotted owl population. Concern for the future viability of the spotted owl has led to a proposal to protect the northern spotted owl under the Endangered Species Act by listing it as Threatened and Endangered throughout its range.

In compliance with the Record of Decision (1989) and Amendment to the Region 6 Guide for the northern spotted owl, suitable habitat will be provided to maintain habitat capable of supporting a viable population in Alternatives A, K, J, W (PA), D and L. All alternatives, except NC, meet or exceed MRs for the establishment of a Forest-wide spotted owl habitat network. The habitat capability for spotted owls would increase above the MR in Alternatives D and L. Protection of spotted owl habitat in Alternatives D and L would increase the number and distribution of suitable habitat islands and would reduce the risk of isolating small populations of spotted owls. Figures ***** and ***** display the estimated impact to spotted owls and their habitat by alternative.

All alternatives would provide habitat capability for 35 pairs of spotted owls in "reserved" lands such as Wilderness. Fifteen pairs have been verified as occurring in wilderness areas since 1985. An additional 60 pairs would be present within the Forest-wide SOHA network. Alternative D would provide habitat capability for 137 pairs and Alternative L would provide habitat capability for the full inventory of 219 verified pairs of spotted owls. The population of spotted owls on the Forest could continue to decline

in all alternatives. Only Alternative L provides timber harvest rotations and harvest levels which may allow the population level to stay near current densities and possibly increase over the long-term.



Alternatives have direct and indirect effects on spotted owls, and the species represented by them, in proportion to their emphasis on harvest of existing mature and old growth forests, road building, and other resource extraction activities. Additional impacts are caused in alternatives that minimize allocation for watershed protection, scenic values, recreation opportunities in primitive or semi-primitive settings, and retention of dead and down woody material.

All alternatives have similar potential for adverse consequences from wildfire at the current condition. Over time, the potential for severe adverse consequences would increase as fire resistant mature and old growth stands are converted to young, even aged plantations susceptible to severe fire damage. As fragmentation of fire resistant stands occurs and as stands become smaller islands within the managed landscape, the potential for direct adverse effects to spotted owls and their habitat would increase.

Prescribed fire and wildfire may adversely impact spotted owls where smoke inundation occurs in natal areas or when slash burns escape harvest unit boundaries into suitable spotted owl habitat. Alternatives that harvest the most acres of land would have a proportional increased risk of adverse consequences. Analysis of the number of wildfires reported on the Forest indicates most fires occur as a result of escaped slash burns, or other human activities assiciated with increased access resulting from timber harvest. Refer to Air Quality and Vegetation sections in Chapter IV for a more detailed discussion on causes and effects of fire.

The potential for adverse direct or indirect effects on spotted owls for all proposed Forest activities, ranked from most to least impact, would be Alternative NC, K, A, J, W (PA), D, and L, respectively.

[1]Values reflect estimates for the number of pairs that the habitat is capable of supporting.
[2]NA = Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. These differences are described in Chapter II of the FEIS as part of the discussion of the No Change Alternative.
[3]Current habitat capability is 187 pairs based on 152 pairs verified and 35 potentially suitable sites not formally surveyed.
[4]After the 5th decade, it is assumed that old-growth stands of timber will remain only in the Allocations withdrawn from timber harvest.

Pileated Woodpecker: Ecological Indicator Species - The pileated woodpecker represents those wildlife species associated with mature and old-growth forests of the true fir, true fir/Douglas fir, Douglas fir/western hemlock, and Douglas fir vegetation series. The habitat requirements are broader than those identified for the spotted owl. The size of trees available for cavity excavation determines habitat capability and is used to determine the forest vegetation series that comprise suitable pileated woodpecker habitat on the Forest. The size and number of snags used for nesting and roosting have been documented by Mannan (1982) and Mellen (1987) for the Douglas fir forests west of the Cascade Range.

Distribution of contiguous forest stands containing high numbers of large, standing, dead trees is a limiting factor for future population potential. Chapter III, Wildlife, contains a complete discussion of the MR for pileated woodpeckers.

Fire and felling of trees during breeding seasons are the primary activities likely to result in direct impacts to pileated woodpeckers. Most management activities directly impact the availability and distribution of habitat, and indirectly influence changes in populations densities.

Management activities that harvest mature and old-growth trees, increase forest fragmentation, and result in landscapes dominated by managed stands less than 100 years old would have the greatest impacts on nesting and roosting habitat of pileated woodpeckers. Forests less than 100 years old would not have developed the size, number, and distribution of snags required for viable populations of pileated woodpeckers. Some sites have a lower potential for tree growth and considerable more time could be required for development of suitable nesting and roosting habitat.

Snags, downed trees, and large green trees also serve as important sources of food for pileated woodpeckers. As unmanaged stands with these characteristics are harvested and managed on rotations of less than 100 years, pileated woodpecker habitat on the Forest would diminish. Managed stands with trees greater than 14 inches dbh and canopies 40 or more feet tall, begin to provide habitat for dispersal and foraging (Mellen 1987). Suppression of trees during forest devlopment results in some tree mortality or insect outbreaks. These occurrences provide recruitment of dead and dying trees throughout the successional development of forest stands. Trees within managed stands on this Forest could begin to provide snags of adequate size for nesting and roosting at about 120 years of age. Forest-wide, harvest rotations of at least 150 years would be required to allow recruitment of adequate numbers and sizes of snags. Use of shelterwoods while foraging has also been documented, but pileated woodpeckers show an avoidance for early seral forest stands (Bull 1989, personal communication).

Because pileated woodpeckers forage extensively on insects such as carpenter ants and insect larvae, pest management activities that reduce these insects populations or use "sanitation" techniques involving the removal of dead or dying trees adversely affects prey bases critical to insectivorous species.

Wildfire has historically created high numbers of dead and defective trees in forest landscapes. Trees killed or injured by wildfire have lower resistance to insect or fungal invasion and provide long-term recruitment of snags, down woody material, and defective tree habitat. Prescribed fire could provide a similar function in managed stands, however, current procedures and activities associated with the control, suppression, and mop-up of prescribed fire and wildfire used in slash burning or control of wildfire could result in a net decrease in snag recruitment and retention.

Salvage of hazard trees, snags, and down trees within road rights-of-way causes additional loss of habitat. The impacts of salvage associated with road maintenance and use increase as the number of miles of road maintained increases.

For all alternatives, with the exception of Alternative NC, pileated woodpecker habitat would be provided to maintain viable populations. Figure IV-10 displays the impacts to suitable pileated woodpecker habitat over time, by alternative. Alternative L would provide the highest number of habitat acres, followed by Alternatives D, W (PA), J, A, L, and NC, respectively. Alternatives L and W would provide management strategies for replacing pileated habitat acres, using extended rotations with retention of large green trees to simulate conditions found in native, unmanaged stands. Alternative D would provide the second highest habitat capability, but would not provide the dispersal corridors prescribed in Alternatives W (PA) and L. Pileated woodpeckers and their habitat would be at highest risk in Alternatives NC, A, and K, respectively.

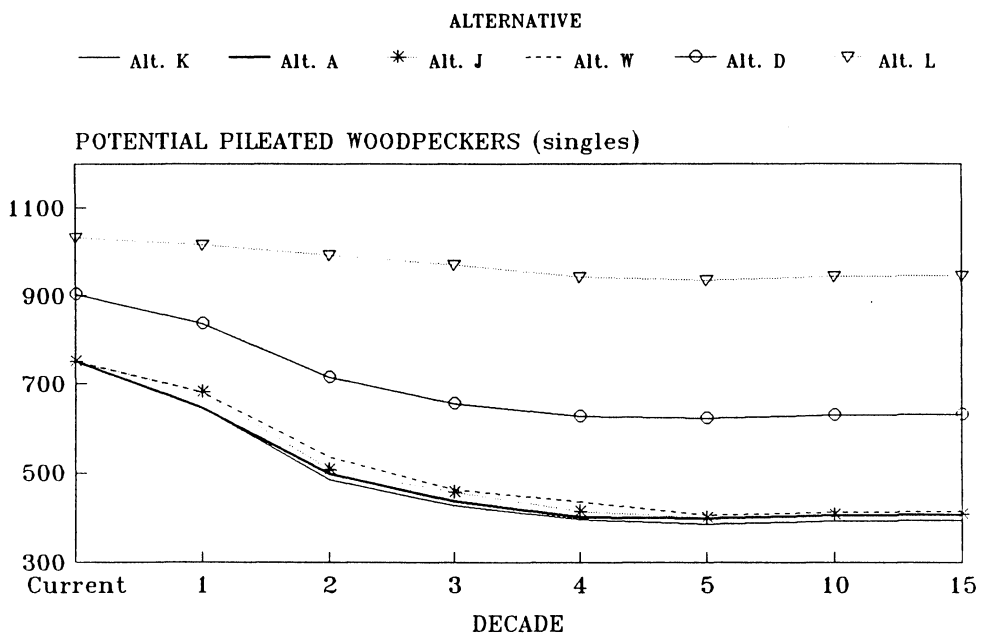

Table IV-18 displays the potential population of pileated woodpeckers on the Forest by alternative. The potential population number was derived from a combination of habitat capability provided in reserved lands, spotted owl habitat areas, pileated woodpecker habitat areas, and general forest. Each spotted owl habitat area is assumed to provide enough habitat for a pair of pileated woodpeckers. Reserved lands and general forest were evaluated to determine the amount, distribution and quality of suitable pileated woodpecker habitat. The analysis process is described in Appendix B.

Table IV-18. Prescribed Management Level of Pileated Woodpecker Habitat [1]

	Alternatives						
	NC (No Change)	K	A	J	W (PA)	D	L[2]

[1]Values reflect estimates for the number of individuals that the habitat is capable of supporting.
[2]NA - Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. These differences are described in Chapter II of the FEIS as part of the discussion of the No Change Alternative.

Potential population trends, projected over 15 decades, indicate that pileated woodpecker populations would remain at or above the MR level in all alternatives, but NC. These trends assume no catastrophic events result in the loss of habitat network sites. Loss of network habitat areas would increase isolation of populations. The effect this would have on viability of pileated woodpeckers is unknown. Studies of other nonmigratory, large, long lived birds indicate there may be cause for long-term viability concern with the strategy used in development of the Management Requirements for pileated woodpeckers (Thomas et.al. 1990).

Marten: Ecological Indicator Species - Marten is the management indicator species (MIS) for wildlife that utilize mature and old-growth forests of true fir, mountain hemlock, True fir/Douglas fir, Douglas-fir/hemlock, and Douglas fir vegetation series. Marten are secretive, nocturnal mammals and are not readily observed. Marten have historically been trapped for their fur. ODFW regulates the harvest of marten populations.

Marten are highly mobile, and direct effects on populations would most likely occur as a result of trapping, or loss of young during timber harvest operations.
Timber harvest, fire, and road construction have the greatest direct effect on marten habitat. These land management activities will impact habitat distribution and suitability resulting in indirect effects to population densities.

Martens utilize mature and old-growth forest types as primary habitat, but they disperse through, and hunt in, early seral stands having greater than 50% crown closure, high numbers of downed trees, and snags. Chapter III, Wildlife, contains a discussion on marten habitat and the MR for maintaining viable populations.

In Alternative NC, marten habitat may not be provided at levels needed to maintain viable populations. Habitat quality and distribution outside reserved lands (Wilderness, Research Natural Areas, etc.) would become a limiting factor. Populations would become isolated and overall population viability would decline as timber harvest and road construction fragment the landscape, reducing habitat capability.

All alternatives, except NC and L, use a combination of spotted owl, pileated woodpecker, and marten habitat areas to provide a network of well distributed mature and old-growth conifer habitat throughout the Forest. Habitat islands provided in the MR for pileated woodpecker and marten habitat areas may not be large enough to provide for breeding pairs of marten (Irwin 1987). The function of the habitat areas could be limited to provided "stepping stone" habitat for dispersing juveniles or adults seeking unoccupied territories located within larger habitat islands found in SOHAs or reserved lands. Where suitable habitat exists on lands available for timber production and is contiguous with designated habitat, habitat quality and quantity for breeding pairs would be present until those areas are fragmented or harvested.

Figure ***** displays the effect of timber harvest on the amount of suitable marten habitat available on the Forest, by alternative. Alternative L has the least effect on marten habitat because it harvests the fewest acres per decade, and provides extended rotations for recruitment of mature forest habitat. Relative impacts to marten habitat, thus population potential, listed in order of decreasing effect are Alternative NC, K, A, J, W (PA), D, and L, respectively.

Alternative W (PA) provides a well distributed habitat network with some provision which exceed the MR. The preferred alternative (W) would provide direction for maintaining 340 acres of managed stands meeting forage and dispersal requirements contiguous with 160 acres of protected mature or old-growth habitat for each habitat area. Protection of riparian corridors for dispersal and foraging, protection of special and unique habitats, and Forest-wide S&Gs for maintaining moderate to high amounts of large down material in managed stands would be emphasized. These factors increase the potential for well distributed, viable marten populations in Alternative W (PA).

Alternative D increases the number of spotted owl habitat areas. These additional sites were placed to provide larger habitat islands and increase the Forest-wide distribution of mature and old growth habitat. Marten habitat capability would be increased as as a result. Dispersal corridors are limited, and this could reduce interaction within the marten population Forest-wide.

Table IV-19 displays the projected effects to marten populations of the alternatives considered. These population estimates are based on habitat capability which includes an assessment of forest fragmentation, habitat availability within reserved and nonreserved lands, and distribution of habitats.

Table IV-19. Prescribed Management Level of Marten Habitat [1]

	Alternatives						
	NC (No Change)	K	A	J	W (PA)	D	L[2]
Marten Habitat Areas	NA[3]	100	100	100	100	100	--

[1]Values reflect estimates for the number of individuals that the habitat is capable of supporting.
[2]NA - Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. These differences are described in Chapter II of the FEIS as part of the discussion of the No Change Alternative.

Primary Cavity Excavators: Ecological Indicator Species - Dead and defective trees provide a unique habitat type for a diverse array of species. Associated with these decaying wood habitats are a wide variety of plants, animals and microorganisms essential to the nutrient cycling in the forest ecosystem. Maintenance of a dead and defective component in the forest provides a habitat requirement for many species that can not be filled by any other component of the forest. Loss of this component would result in a large loss in wildlife diversity.

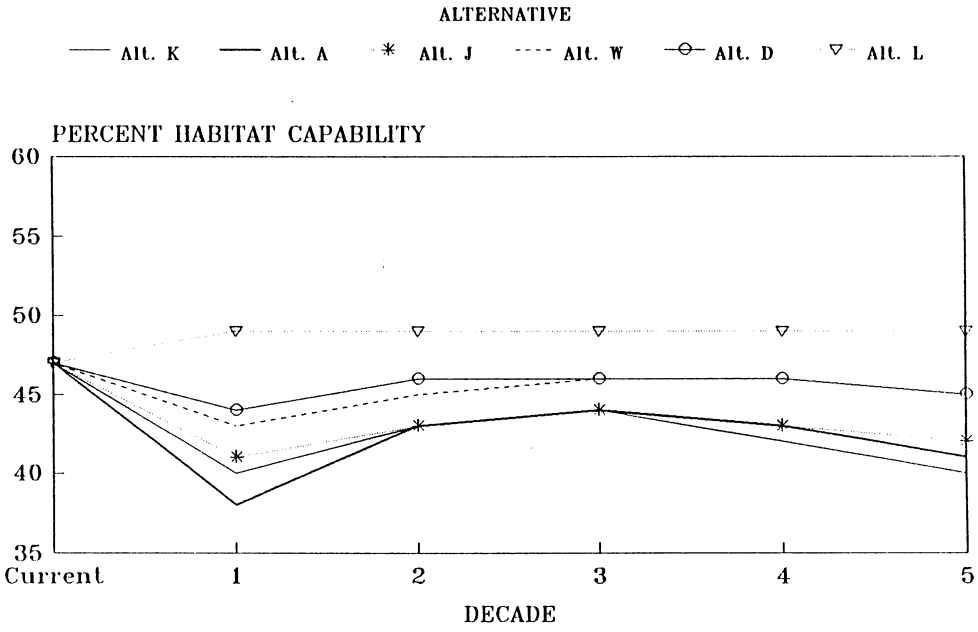
Dead and defective trees provide essential habitat for species referred to as primary cavity excavators (PCE) and secondary cavity users. Primary cavity excavators are those wildlife species that excavate cavities for nesting and roosting. Secondary cavity users are those wildlife species that use cavities created by PCE species for their life history needs. Many insectivorous species use dead and defective

trees as foraging substrates, regardless of whether they require cavities for nesting or roosting. Chapter III, Wildlife, provides a discussion on wildlife species dependent on dead and defective trees. Potential consequences to primary cavity excavator populations are assumed to indicate potential impacts to all species dependent on dead and defective trees.

Direct effects to species requiring dead and defective trees occur primarily as result of tree harvest during reproductive seasons. Cutting of hollow trees or trees containing cavities would cause direct mortality to nesting or denning species.

Activities such as timber harvest, firewood cutting, prescribed burning, and pest management have the greatest potential for adverse impacts to dead and defective tree habitat. Direct loss of habitat caused by management activities would indirectly influence population levels.

Pest management activities that focus on control of insect populations could deplete the forage resource, or cause poisoning if toxicants are used. Recruitment of dead and defective trees is often a direct result of insect damage. Pest control activities will result in reduced availability of replacement snags. The effects of pest management activities on insectivorous species cannot be inferred from assessments of habitat availability. Individual projects would need to be evaluated for environmental consequence of the specific pest management activity.



Although fire can consume snags and down logs which serve as forage and nesting habitat, it can also increase snag numbers and damage live trees, lowering their resistance to insect or fungal invasion. Of primary concern are the activities associated with the control, suppression, and mop-up of prescribed fire and wildfire. Historically, fire control resulted in the loss of high numbers of snags. This continues to be a concern in managed stands where fire is prescribed as a post harvest activity to meet specific resource objectives. Fire as a post harvest treatment has been used on most harvest acres and is proposed to be used on most harvested acres through the first decade.

The greatest impact to dead and defective tree habitat results from timber harvest. Salvage of dead and dying trees has occurred throughout most roaded subwatersheds. Salvagable dead trees are used as a component of the allowable sale quantity in all alternatives. Salvage within road rights-of-way results in an area approximately 100 feet on either side of roads being devoid of snags. Salvage activities would directly reduce the potential population of primary cavity excavators on lands available for timber production by 20% forestwide (Smith 1990). Few snags were left on areas harvested and burned in the past. This reduced potential populations of primary cavity excavators by an additional 35%. Retention of trees within harvest units has improved in recent years and would be required in all alternatives, except NC.

Some forest vegetation series may not have the biological capability to support 100% of potential populations because of the small size of trees available for cavity excavation. On this Forest, mountain hemlock stands may not achieve the 18 inch diameter required to support all species of cavity excavators identified on the Forest. Current habitat capability for potential populations of primary cavity excavators is 45%.

Alternatives NC and A have the most adverse effect on dead and defective tree habitats. Management direction in Alternatives J, K, and W (PA) provides for well distributed habitat within all harvest units, and would result in a moderate decline in habitat conditions. Retention of dead and defective tree habitat would be increased in Alternatives D and L causing the least impact to primary cavity excavator habitat.

Figure IV-12. Habitat Capability for Primary Cavity Excavators [1]

[1]Values reflect estimates for the number of snags available for use by primary cavity excavators (in thousands of snags).
[2]NA - Data Not Available; could not be reasonably estimated, or compared to other Alternatives, since Alternative NC (No Change) is based on a significantly different set of assumptions than the other Alternatives, and could not be modeled with the current Willamette National Forest FORPLAN model. These differences are described in Chapter II of the FEIS as part of the discussion of the No Change Alternative.

Roosevelt Elk and Black-tailed Deer: Featured Species - Special emphasis has been placed on Roosevelt elk and black-tailed deer because of their economic and recreational importance. Recreational activities related to hunting, viewing, and photographing deer and elk result in significant contributions to local economies. Chapter II describes the projected outputs for deer and elk by alternative. A discussion on the habitat requirements for healthy, productive populations is presented in Chapter III.

Deer and elk use a wide variety of forest and non-forest vegetation types throughout the Forest. Most individuals and herds are migratory using higher elevations during summer months and lower elevations during winter. Migratory routes are often traditional with the same routes used year after year. Special and unique habitats such as meadows, marshes, bogs, and talus slopes are critical during specific times of the year.

Roosevelt elk are more sensitive to habitat changes and disturbance than deer, and therefore have more restrictive habitat needs. Thus, habitat requirements for elk are assumed to meet the requirements for deer as well. Elk were used as an indicator of habitat capability for deer in assessing the potential effects of the alternatives.

Hunting and poaching are two activities occurring on the Forest which have great direct effect on deer and elk populations. Severe winter weather with accumulations of deep snow also directly impact population levels, potentially causing significant population reductions. Large catastrophic fires cause some deer and elk mortality, but rarely result in significant population losses.

Management activities indirectly affect populations levels by directly impacting habitat suitability. The design, size, and placement of harvest units within a given landscape can be either beneficial or detrimental. Harvest of mature and old growth forests reduces cover quality, making deer and elk more susceptible to environmental extremes in summer and winter (Brown 1985). Timber harvest provides openings and edge habitats preferred by deer and elk for foraging. Alternatives NC, K, and A have the most potential to adversely affect cover quality Forest-wide because of high timber harvest levels and reduced emphasis on protection of optimal cover. Increasing emphasis would be placed on providing optimal cover (mature and old growth forest stands) in Alternatives J, W (PA), and D by protecting optimal cover on winter ranges, and protection of mature and old growth stands for other resource values including visuals, dispersed recreation, special interest areas, old-growth groves, special wildlife habitats, and riparian areas. Alternative L provides the the most acres of optimal cover, however distribution of forage openings would limit overall capability to produce deer and elk.

Presence of roads can have adverse effects on deer and elk. Open roads reduce the use of openings by deer and elk, increase potential for harassment and poaching, and reduce escapement of mature bulls during hunting seasons. Alternatives that harvest the highest number of acres have the most potential for adverse effects due to development and use of open roads. Specific habitat enhancement measures such as access management, gates and barriers, and vegetation retention can be implemented to mitigate road system development. Additional mitigation measures are described in the section of Chapter IV titled Mitigation Measures for Wildlife. Alternative D provides the highest emphasis on reducing the effects of roads followed by Alternatives L, W (PA), J, K, A, and NC respectively.

Fire affects deer and elk habitat by creating openings and influencing the vegetative species available for forage. Sprouting and growing vegetation in burned areas often has increased forage quality. Prescribed fire and wildfire create a high quality seed bed for the establishment of preferred forage species. In some cases, noxious weed species invade burned areas and result in a net decrease in the availability of forage (Smith 1979). All alternatives provide the same level of wildfire suppression. Prescribed fire is used in all alternatives and would result in similar effects on forage quality in harvest units (Wisdom et al 1986).

Recreation use in some areas would reduce the habitat quality for deer and elk. Hunted populations of elk are sensitive to the presence of people. Campsites and trails near or through meadows and marshes could adversely affect deer and elk use of these critical fawning, calving, and foraging areas. All alternatives have potential to impact elk and deer use of areas, however, Alternatives NC, A, K, and J provide few primitive or semi-primitive recreation opportunities outside of wilderness. This would increase the potential for impacts from high recreation use where special protected habitats occur. Alternative L, D, and W (PA), respectively, provide high to moderate opportunities for spreading recreation use Forest-wide.

Winter recreation has the potential to significantly impact deer and elk on winter ranges. Energy balances are critical during the winter period. Harassment of deer and elk by skiers, snowmobilers,

campers, and hikers can cause disturbed animals to burn energy reserves that they may not be able to replace, depending on environmental conditions and the quality of habitat on the winter range. The consequence of high energy loss could result in population reductions through death, reduce birth rates, and poor survival of young the following spring. Alternative D provides the most habitat emphasis on protecting deer and elk winter range areas, followed by Alternatives L, W (PA), J, A, K,and NC, respectively.

Silvicultural and vegetation management practices influence the quality of deer and elk habitat. Reforestation and stocking control allow rapid recruitment of hiding cover (20 years) and thermal cover (40 years) following timber harvest. The long-term development of optimal cover is a function of time and would require estimated rotation lengths of 170 years or more. Precommercial thinning and vegetation management, involving cutting of brush, usually result in large accumulations of debris, leaving the treated area unsuitable for several years after treatment. In some plant community types, vegetative management activities that open the canopy by cutting brush improve forage availability by inducing basal sprouting. This practice has been used successfully on the Forest.

Vegetation management activities using herbicides are of special concern. Plants most preferred by deer and elk are most susceptible to being eliminated from treated stands. Elimination of preferred forage resources would increase the potential for severe damage to crop trees. Some concern exists as to the toxic nature of various herbicides. Little evidence exists as to toxic levels for deer and elk, however some toxic compounds are known to be stored in the internal organs and fat tissues. The Region 6 FEIS for Managing Competing and Unwanted Vegetation (1988) includes a discussion on the potential health hazards of using pesticdes.

All alternatives use intensive management techniques on all lands available for timber production. Potential for adverse effects from silvicultural and vegetation management activities would increase as the number of acres intensively managed for timber production increases. Potential for adverse effects to deer and elk also exist if too few acres are harvested and managed. Alternatives NC, K, and A have a high potential for adverse effects. Alternatives J and W have a potential for adverse effects, but like Alternative D, provide significant opportunities to use silvicultural and vegetation management techniques to develop high quality deer and elk habitat. Alternative L could have adverse effects on deer and elk as harvest levels are reduced and forage producing openings become limited Forest-wide.

Cumulative Effects of the Alternatives on Wildlife and Wildlife Habitat

Diversity of Vertebrate Species - Protection of special and unique habitats reduces the risk of adverse cumulative effects to those wildlife populations whose life history needs are not fully covered by Management Requirements. Alternatives listed in order of increasing risk of adverse cumulative effects to diversity are L, D, W (PA), J, A, K, and NC.

Alternatives W (PA) and L provide full protection of riparian ecosystems emphasizing the value of wildlife habitat in riparian corridors for foraging, nesting, denning, dispersal, and long-term connectivity between habitat islands.

Alternatives NC, K, and A would cause significant declines in habitat diversity by the fifth decade. Managed stands dominated by a few conifer species would dominate the forest landscape, resulting in isolation of protected habitat types and populations within three decades. Alternatives NC, A, K, and J result in high risk to special and unique habitats when they occur within or adjacent to stands suited for timber production.

Northern Bald Eagle: Threatened Species - Alternatives NC, A, K, and J have the greatest potential for adverse cumulative impact on habitat quality within 1.1 miles of major water bodies identified as potential bald eagle nesting, roosting, and foraging habitat. Protection of 40 acres for potential nest sites, while harvesting all other potential habitat reduces the probability that new territories would be established in the Recovery Zones. These alternatives would have the lowest potential for meeting recovery objectives and maintaining bald eagle nesting and roosting habitat in the long-term.

Alternative L and W (PA) would provide for the replacement of old-growth habitat over time in some Management Areas, thus loss of existing or potential nest sites through catastrophic events such as wildfire or windthrow would not limit long-term recovery potential.

All alternatives encourage developed recreation sites along the lakes, reservoirs, and rivers, creating significant potential for disturbance to existing territories and could preclude establishment of new territories along some designated water bodies. Only occupied territories which receive additional consideration due to site specific Bald Eagle Management Plans have a high probability for long-term viability. Mitigation Measures (Chapter IV) include conducting biological evaluation on all activities which would effect bald eagles. These measures are intended to minimize the adverse consequences associated with developed recreation sites.

Alternatives W (PA), D, and L would reduce the overall emphasis on roading and timber harvest,and would increase the protection of potential bald eagle territories. These alternatives would provide the highest potential to meet or exceed Recovery Plan objectives over the planning period.

American Peregrine Falcon: Endangered Species - Cumulative effects to peregrine falcons result as a consequences of changes in habitat conditions for prey species or impacts to the structure or microhabitat of nest cliffs. Because peregrine falcons feed extensively on songbirds, management activities that reduce habitat diversity or involve the use of toxicants have some probability of adverse cumulative impacts to recovery of the species.

Alternatives that reduce habitat diversity by converting the landscape to intensively managed conifer plantations with little structural or plant diversity, would have long-term negative indirect cumulative impacts. Peregrine falcons that would nest on the available cliffs may not have access to abundant bird populations required to sustain a viable population. Alternatives W (PA), D, and L, respectively, would have the highest probability of providing the habitat diversity and protection needed for recovery of peregrine falcon populations.

Alternatives NC, A, K, and J will create an abundance of openings that would provide foraging habitat as harvest levels remain high. Low emphasis on providing vegetative diversity within intensively managed stands, limited protection of special and unique habitats, and a landscape subjected to numerous intensive silvicultural treatments reduces the probability of providing the diversity of habitats or abundant bird populations needed to meet and exceed long-term recovery objectives for peregrine falcons.

Northern Spotted Owl: Ecological Indicator Species - Suitable spotted owl habitat will be restricted to reserved lands, lands unsuited for timber production, and lands subject to constrained harvest rates, by the fifth decade in all alternatives except L. Reduced rates of harvest occur in visual corridors and dispersed recreation management areas, 5% to 10% per decade. Spotted owls inhabiting these islands of suitable habitat will be at increased risk of eventually becoming isolated pairs or individuals. Alternative W provides a strategy to reduce habitat fragmentation, but harvest rates would eventually result in the same cumulative effect. Alternatives A, K, J, and W (PA) vary only in the rate at which direct loss of habitat results in declining populations. Alternatives W (PA), D, and L, respectively, would maintain increased potential for maintaining habitat capability above MRs through the fifth decade.

Dispersal of spotted owls through fragmented landscapes and across large expanses of unsuited habitat will increase the risk of mortality, as individuals attempt to locate unoccupied habitat islands. Fewer suitable acres of habitat Forest-wide, and limited distribution of habitats needed for nesting, feeding, and roosting, could result in increased adult mortality rates and decreasing juvenile survival. Dispersal opportunity would be highest in Alternative L and Alternative W (PA). Alternative L maintains high levels of suitable habitat Forest-wide. The preferred alternative (W) places management emphasis on riparian resources, visual corridors, and retaining many of the vegetation attributes of existing unmanaged stands (residual green trees, snags, and down logs) in managed stands. These strategies provide increased dispersal opportunity.

The potential for severe adverse consequences from escaped slash burns or wildfire increases over time. Landscapes dominated by young, even aged stands with inclusions of mature or old growth islands will be more susceptible to crown fires and catastrophic loss of suitable habitat islands. Increased amounts of small dead and downed woody debris left untreated in harvest units increases the potential for fire ignition within individual managed stands during the decade following harvest. Large down woody material maintains a high moisture content and will not necessarily increase the risk of wildfire.

The potential to replace of network habitat areas following catastrophic events would be very limited in Alternatives NC, A, J, K, and W (PA) by the third decade. Alternatives D and L provide protection above the MR level, and would provide some opportunity to replace lost habitat.

Pileated Woodpecker: Ecological Indicator Species - Based on habitat capability assessments, potential populations of pileated woodpeckers would decline in all of the alternatives, except L. Most habitat loss will occur during the first five decades. After the fifth decade only those lands allocated to no harvest, or rotations longer than 150 years, would contain suitable roosting or nesting habitat. Alternative D provides the second highest long-term capability, but dispersal between habitat islands could result in a high juvenile mortality rate. Alternative W (PA) provides travel and distribution corridors with a high degree of structural diversity. Potential for successful dispersal between habitat islands would be highest in Alternatives L and W (PA), respectively.

Only Alternative L provides for significant recruitment of suitable mature and old growth habitat in the future. All other alternatives intensively manage most lands suitable for timber harvest on rotations less than 120 years. Although much of the landscape should be suited for dispersal and foraging (age classes greater than 50 years) there is no allowance for replacement stands of suitable nesting habitat in the event of catastrophic event in the habitat islands provided for spotted owls and pileated woodpeckers.

Marten: Ecological Indicator Species - The long-term cumulative effects of the alternatives on the Forest's capability to support a viable population of marten is displayed in Figure IV-11. The rate of decline of the potential population following habitat loss is unknown. The cumulative effects assessment assumed a one decade lag between loss of habitat and subsequent decline in population. This assumption was used because of the likelihood that adult marten would survive in marginal habitat, however, recruitment to the population would be lost as habitat suitable for reproduction diminishes.

Connectivity and distribution of habitat on lands available for timber harvest would not be maintained after the third decade in any alternative but L. The Forest has evaluated the time over which options for minimizing habitat fragmentation can be maintained in Alternative W (PA). After the third decade all planned harvest would have to come from forest stands that were protected in the previous decades. Habitat suitable for dispersal of marten would diminish in all alternatives except L and W (PA). Dispersal capability in Alternative L results from low harvest levels. Alternative W provides habitat features of

snags and downed logs Forest-wide at levels capable of providing replacement habitat dispersal and foraging.

After Decade 5, mature and old-growth forest stands would be found primarily on lands unsuited for timber production in all alternatives, except L. These areas include reserved lands, spotted owl, pileated woodpecker and marten habitat areas, special and unique habitats, special interest areas, forested stands on unsuited soils, roadless lands, wild and scenic river corridors, and riparian areas. The number of acres in these allocations varies by alternative, but the rate of harvest applied to the lands suitable and available for timber production would have the same cumulative effect within five decades. Little opportunity would exist to replace habitat lost as a result of catastrophic events.

Potential population trends, projected over 15 decades, indicate that marten populations would remain viable, and suitable habitat would be provided at or above the MR level, in all alternatives, but NC. These trends assume no catastrophic events result in loss of habitat network sites required to maintain suitable habitat distribution and population capability. Loss of these areas would increase isolation of populations. The effect this would have on the viability of marten is unknown.

Primary Cavity Excavators: Ecological Indicator Species - Figure IV-12 displays the cumulative effects of timber harvest on potential populations of cavity excavating species. All alternatives cause a continued decline in distribution, quality, quantity, and recruitment of dead and defective tree habitat. Alternatives D and L provide the highest long-term habitat capability; unit and subwatershed objectives would provide habitat objectives for 60% of potential populations. Alternatives NC and A cause habitat conditions to decline to threshold levels for minimum viability. Habitat capability also decline in Alternatives J, K, and W (PA), but should stabilize near levels capable of supporting 40% potential populations.

Roosevelt Elk and Black-tailed Deer: Featured Species - Management prescriptions for high, moderate, and low habitat emphasis are common to all alternatives. The alternatives vary as to the amount of Forest area managed at each of the three emphasis levels.

Some areas designated for high emphasis would not achieve the habitat effectiveness standards within the first decade. Conversely, areas that are currently above the Forest-wide standards set for low emphasis may not decline to those levels. The current condition of the Forest most closely resembles the Forest-wide standards set for moderate emphasis. The cumulative effects of the proposed management practices would result in an overall decline in habitat capability in Alternatives NC and K. Alternatives A, J, W (PA), L, and D, respectively, provide for increasing habitat capability over time.

The effects of the alternatives, with the exception of Alternative NC, on potential deer and elk populations are evaluated using a population index which is linked with the habitat effectiveness variables described in Chapter III, Wildlife. The habitat effectiveness variables are cover quality, forage quality, open road density, and size and distribution of cover and forage. Cumulative effects are expressed in terms of potential populations of deer and elk when the habitat conditions for one of three levels of habitat emphasis are met.

Cumulative effects on potential populations were calculated based on the number of winter range acres managed at each emphasis levels. High emphasis winter range contributes habitat capability for potential populations of 2 elk and 10 deer per 100 acres. Moderate emphasis winter range contributes habitat capability for potential populations of .8 elk and 4 deer per 100 acres. Low emphasis winter range contributes habitat capability for a potential population of .1 elk and .5 deer per 100 acres. A full description of this modeling process can be found in Appendix B.

Mitigation Measures for Wildlife

Mitigation measures that reduce the effects of disturbing activities to wildlife and their habitats include Forest-wide Standards and Guidelines (S&Gs) for wildlife, prescriptions, operational practices applied during project planning and/or implementation and post-project activities designed to accelerate restoration of desired habitat conditions or attributes. The following discussion of MRs applies to all alternatives with the exception of Alternative NC.

Bald Eagle -- Management Area S&Gs consistant with Recovery Plans objectives reduce the potential for adverse impacts to bald eagles and their habitat. Forest-wide require biological evaluation of proposed activities within potential bald eagle habitat. Mitigation includes establishing protection zones around nest sites, seasonal restrictions to reduce human disturbance during critical times such as breeding, nesting, and fledgling periods, and reducing or eliminating conflicting activities in and around forage areas.

Peregrine Falcon -- Forest-wide S&Gs reduce the potential for adverse impacts to peregrine falcons. Direction includes the protection of potential nest sites, protection of special and unique habitats, and biological evaluation of activities which may affect peregrine falcon habitat.

Spotted Owl -- Standards and Guidelines established in Amendment to the Pacific Northwest Regional Guide were followed to ensure appropriate size and distribution of spotted owl habitat areas (SOHAs) throughout the Forest. All SOHA acres were removed from lands suited for timber production. No harvest will be allowed within the SOHA boundaries. Additional protection is provided for pairs of spotted owls located outside SOHAs through the use of Forest-wide S&Gs.

Pileated Woodpecker -- Management requirements for pileated woodpecker habitat are met by establishing Management Area direction. This direction is provided in the S&Gs specific to the management area.

Marten -- Management requirements for marten are met by establishing Management Areas direction. This direction is provided in the S&Gs specific to the management area.

Primary Cavity Excavators -- Forest-wide S&Gs incorporate management requirements that will provide sufficient number, distribution, and size of dead and defective trees to maintain habitat for snag dependent species capable of supporting 40% of potential populations within each subwatershed.

Deer and Elk -- Habitat management focuses on cover quality, forage quality, security, and size and distribution of cover and forage. Management emphasis varies depending on the alternative. Direction for meeting habitat effectiveness values within emphasis areas is provided through Forest-wide S&Gs.

Monitoring questions have been prepared to evaluate the implemantation and effectiveness of the S&Gs. Validation monitoring has been proposed to address the assumptions used to predict effects to habitat and populations.

Information needs have been documented to address the need for inventories and research pertaining to specific plants, wildlife, and habitats.

Relationships with Other Agency Plans or Policies for Wildlife

Management for peregrine falcons will be in accordance with the Pacific Recovery Plan for the American Peregrine Falcon (1982) and the Endangered Species Act of 1973, as amended. In a cooperative effort

with the ODFW, 12 potential peregrine nest sites were identified. If presence of a nesting pair is verified, the Forest will proceed to develop site specific management plans for the area in cooperation with the USDI Fish and Wildlife Service and Oregon Department of Fish and Wildlife.

Management of bald eagles and their habitat will be in accordance with the Pacific States Bald Eagle Recovery Plan. Additional requirements for management of occupied territories will be based site specific management plans developed in cooperation with the U.S. Fish and Wildlife Service and Oregon Department of Fish and Wildlife.

Under all alternatives habitat for the spotted owl will be provided on Federal lands adjacent to the Forest. The Mt. Hood, Umpqua, and the Deschutes National Forests along with the Salem and Eugene BLM Districts will provide habitat linkages. The private lands adjacent to the Forest have been heavily harvested and will provide little to no spotted owl habitat within the planning horizon. The contribution of spotted owl habitat on private lands within and adjacent to the Forest is expected to be minimal as old-growth stand characteristics will not be achieved on planned harvest rotations.

Under all alternatives, with the exception of Alternative NC, a systematically spaced distribution of marten and pileated woodpecker habitat will be provided on the Forest in coordination with adjacent Forests to ensure proper distribution of habitat. Private lands within and adjacent to the Forest have been heavily harvested and are expected to provide little to no marten or pileated woodpecker habitat within the planning period.

Region Six policy directs management of Primary Cavity Excavator Habitat to exceed 40% biological potential (FSM 2600). ODFW recommends 60% biological potential as the appropriate management level for primary cavity excavators. All alternatives, except NC and A, meet the Region 6 objectives, with Alternatives D and L meeting the 60% objective. Potential populations were not determined for Alternative NC.

Both the ODFW and the Forest are currently involved in a cooperative agreement to determine elk population trends, herd composition, and habitat use through an elk collaring and monitoring program. Alernatives were designed to evaluate the potential for meeting ODFW population benchmarks for deer and elk.

Incomplete or Unavailable Information on Wildlife

Territory size and habitat use of pileated woodpeckers and marten within the Cascades Province of Oregon.

Dispersal distances between habitat areas required to ensure long-term population viability for all Management Indicator Species.

Inventories of Sensitive species populations throughout the Forest.

Availability, distribution, recruitment, and fall down rates of dead and down trees in managed and unmanaged forest stands.

Biological role of old-growth Douglas fir forests in the winter survival of deer and elk populations.

Quality and amount of forage produced in seral stages of plant community development with and without treatment with prescribed fire.

Environmental Consequences Of The Alternatives On Recreation

Recreational settings occur throughout the Forest and provide a range of recreation opportunities. Changes in the characteristics of these settings affect the recreational experience of the Forest visitor. Recreation settings for both developed and dispersed use are affected by a number of management activities including those that alter plant and wildlife habitat, remove vegetation, expose soil, alter landforms, change water levels, and increase or decrease access to the National Forest land.

Numerous dispersed recreational settings are located throughout the Forest, from the densely forested areas of the Western Cascades to the meadows and alpine lakes of the Cascade Crest. Over 1,286,000 acres provide a broad range of potential dispersed recreation opportunities, in addition to those available in Wilderness. Dispersed recreation users are attracted to the Forest because of road and trail access, the presence of fish and wildlife, the scenic quality of the landscape, and its diversity of recreation settings.

People are drawn to the developed recreation sites in the Forest for many of the same reasons, including accessibility, availability of facilities, proximity to water, and attractiveness of their surroundings. Developed sites range from ski areas where facilities are provided to enhance recreational experiences and user comfort, to developed primitive campsites where facilities are provided only for the protection of basic resources. Although developed sites are relatively small, distinctly defined areas where facilities are provided for concentrated public use, the characteristics of adjacent areas also contribute to the quality of a developed recreation setting.

Direct and Indirect Effects of the Alternatives on Recreation

The management areas proposed by the alternatives will determine the location and type of recreational settings that will be available in the future. The proposed alternatives will affect recreation settings, trails, and the level of use of both dispersed and developed recreation opportunities. This will affect the capability of the Forest to meet present and projected demand for various types of recreation experiences. Alternative levels of recreation program funding also have an impact on the quantity, quality, and utility of recreational settings, especially as related to changes in the Recreation Opportunity Spectrum (ROS) inventory acres and resultant use capacity of the Forest. The capacity of recreational settings to sustain projected levels of demand is measured in Recreation Visitor Days (RVDs).

Dispersed Recreation Settings - Settings for dispersed recreation are primarily affected by activities that alter the physical character of the landscape, such as road construction, timber harvest, and mineral and energy development. The extent to or manner in which the landscape is altered will affect each ROS setting differently.

Semiprimitive settings, both motorized and nonmotorized, are affected to the greatest extent by landscape altering activities. In the roaded natural and roaded modified setting, road construction and timber harvest are normal occurrences; however, setting activities are designed to ensure a specified level of scenic quality and recreation experience. Although semiprimitive motorized and nonmotorized settings can absorb small, carefully designed alterations, activities typically associated with roaded natural and roaded modified settings would preclude satisfaction of user needs for isolation, solitude, and primitive type recreation in these settings. In addition the influences of road construction and timber harvest activities in near proximity to semiprimitive settings can reduce the effective size of these settings. Also the presence of noise and the visibility of timber harvest operations detract from and thus can further diminish this experience opportunity.

The effect on settings for dispersed recreation is illustrated by the disposition of each ROS class setting in the alternatives. Depending on which management areas are applied in the alternatives, all or part of a given ROS Class may be managed for an opportunity that is different than its inventoried potential. Table IV-21 displays how each inventoried ROS setting would be managed by alternative.

Table IV-21. Effects on Inventoried Dispersed Recreation Opportunity Settings

ROS Inventory			Alternatives [1]						
Classes	Acres	Proposed Management	NC	K	A	J	W	D	L

		Total	100	100	100	100	100	100	100

[1] Values are percent of inventoried non-Wilderness ROS acres.

Semiprimitive Non-motorized - Alternative K has the greatest effect on semiprimitive nonmotorized (SPN) recreation settings. In this alternative 82% of the SPN is proposed for management as roaded natural (RN) and roaded modified (RM) opportunities. The SPN settings managed for RN and RM opportunities will, in 5 to 10 years, be altered dramatically by roads and harvest units, and thus unable to provide for user needs of isolation, solitude, and primitive type recreation in an un-modified natural environment. Alternatives D and L maintain 61% and 62% respectively the Forests inventoried SPN settings.

Semiprimitive Motorized - Of all the alternatives, D and L have the most favorable effect on semiprimitive motorized (SPM) recreation settings, maintaining 61% and 75% respectively. Alternatives D and L, through management area allocations that provide both motorized and nonmotorized use in undeveloped areas, also maintain 74% and 75% of inventoried SPN settings, respectively. Alternatives NC, K, and A propose management of between 61% and 77% of the Forest's semiprimitive motorized recreation setting for roaded natural and roaded modified opportunities; while this change from unroaded

opportunities to roaded recreation does not preclude motorized use, it does limit dramatically off-road vehicle use opportunities in undeveloped settings.

Roaded Natural - Inventoried roaded natural settings are affected most adversely in Alternatives NC, K and A as between 59% and 71% of this opportunity setting is proposed to be managed as a roaded modified setting. The frequency and design characteristics of management activities in the roaded modified setting will result in an obviously altered, rather than a natural appearing landscape, typical of the roaded natural setting. Alternatives D and L would have the most favorable effect on the roaded natural setting as they maintain 65% and 68% respectively, of the Forest's inventoried potential.

Roaded Modified - Opportunities for recreation use in a roaded modified setting are maintained to a significant extent of inventoried potential (80%-96%) in all alternatives except, Alternative L. Minor amounts of this inventoried opportunity setting are proposed for management as roaded natural and semiprimitive settings. Alternative L proposes that 74% of the RM setting would be managed as RN, SPM and SPN settings.

Oregon Cascades Recreation Area (OCRA) - The OCRA is a unique recreation setting within the Forest that provides semiprimitive recreation opportunities. The OCRA was established by the Oregon Wilderness Act of 1984 to conserve and protect a wide array of natural resources and landscape attributes, and provide for use of both developed and dispersed recreation settings including motorized access and use opportunities. The portion of the OCRA managed by the Forest encompasses the Timpanogas Basin, located 45 miles southeast of Oakridge, Oregon.

While the alternatives have no effect on the location of boundaries, or the size of the OCRA, they do effect how the area is proposed to be managed. Effects on the environment of the area are expected to be minor as no programmed timber harvest or road construction is permitted. Effects to the physical resource are anticipated primarily from human use, such as soil displacement, compaction of camp areas, trampling of ground cover vegetation, and increased littering. The degree of effect on the resources would vary among the alternatives. Alternatives that permit motorized use of the area will have a greater effect on the recreation setting of the OCRA than those that exclude such use. Table IV-22 displays OCRA proposals for managing motorized and nonmotorized use in each alternative.

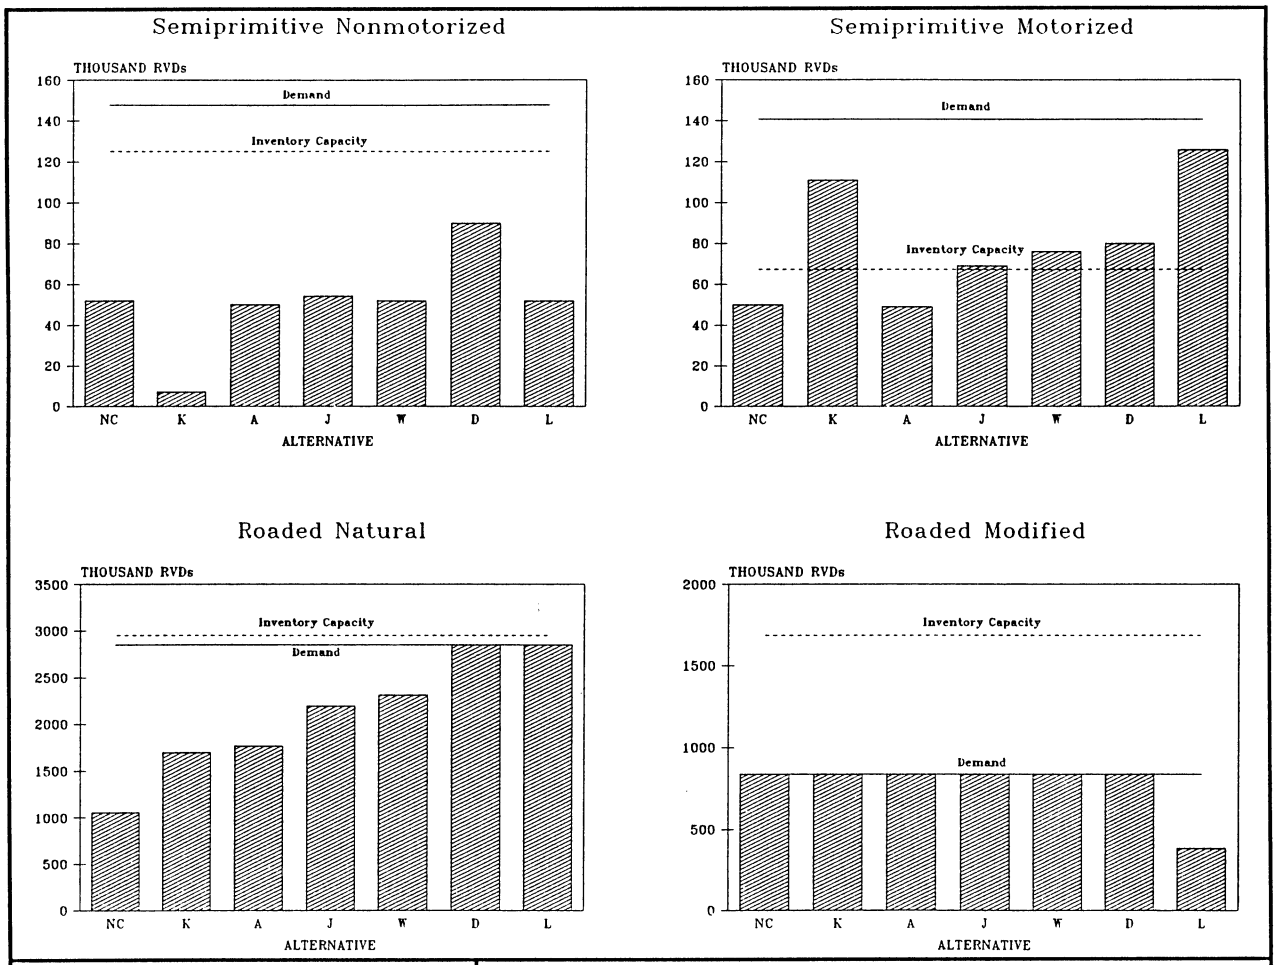
Alternatives K and L are expected to have the least effect on the physical resources of the OCRA as motorized use is excluded from the area, except in winter under Alternative K. The greatest potential effect to the area's resources is expected from Alternatives NC and A as motorized use is permitted throughout the OCRA. Effects of Alternatives J, W (PA) and D are expected to occur primarily in motorized trail zones and dispersed camping areas.

Dispersed Recreation Use and Demand - Dispersed recreation use Forest-wide currently totals 1,480,900 recreation visitor days (RVDs). User demand for this form of recreation use is expected to increase to 3,980,600 RVDs by the year 2040. The Forest's inventoried capacity to accommodate future use exceeds expected use levels in 2040 by 21%. Although total use in dispersed recreation activities may not be particularly sensitive to changes in management allocations, use that is dependent on a specific recreation setting would,however, be affected by such changes in the alternatives.

RVD outputs for the NC Alternative are not available for comparison on an ROS class basis. However, outputs for total dispersed recreation use for the NC Alternative are shown and compared with other alternatives in the Resource Program section of Chapter II.

Table IV-22 Management Options for Motor and Nonmotor Use of the OCRA [1]

	Alternatives						
	NC	K	A	J	W	D	L
UNDEVELOPED AREAS							
All Seasons	M/N	N/S	M/N	N/S	N/S	N/S	N
TRAIL ZONES [2]	M/N	N/S	M/N	M/N	M/N	M/N	N
All Seasons							



[1]M/N = Motorized and Nonmotorized use.
N = Nonmotorized use.
N/S = Nonmotorized use with winter only motorized use.
[2] The Pacific Crest National Scenic Trail is closed to motorized use all year.

Because of the changes to settings for dispersed recreation described above and illustrated in Table IV-21, the Forest's ability to satisfy user demand for semiprimitive and roaded natural settings is limited in some alternatives. However, future demand for roaded modified opportunities is fully satisfied in all alternatives. Figure IV-13 illustrates the extent to which each alternative would satisfy user demand for each ROS setting.

The public's desire for use in semiprimitive nonmotorized recreation settings is best provided for in Alternative D. This alternative proposes to supply 61% of expected user demand in the year 2040. Alternative K has the greatest effect on supplying semiprimitive nonmotorized use opportunities by accommodating 6% of the demand expected in the year 2040. Other alternatives supply between 34% and 35% of future demand.

User demand for semiprimitive motorized recreation opportunities is provided for to the greatest extent in Alternatives K and L. Alternative L supplies 89% of demand while Alternative K provides 79% of 2040 demand. Alternatives J, W (PA) and D provide between 50% and 57% of use expected in the fifth decade (2040). Other alternatives provide between 34% and 35% of 2040 demand.

Figure IV-13 Effects on Dispersed Recreation Use [1]

			Alternatives [1]						
ROS CLASSES	**2040 RVD**	**Demand[2]**	**NC[3]**	**K**	**A**	**J**	**W**	**D**	**L**
Semiprimitive Nonmotorized	Demand	147.8	35	5	34	37	35	61	35
Semiprimitive Motorized	Demand	140.9	36	79	35	50	54	57	89
Roaded Natural	Demand	2,852.7	37	59	62	77	81	100	100
Roaded Modified	Demand	839.2	100	100	100	100	100	100	100

[1] Alternative outputs are percent of 5th decade RVD demand provided.
[2] Values are in thousands of RVDs.

The Forest's ability to satisfy demand for semiprimitive motorized and nonmotorized use in any of the alternatives is limited by inventoried capacity. Forest capacity is about 85% of demand for nonmotorized use and 31% of demand for motorized use. To satisfy 2040 demand for semiprimitive motorized and nonmotorized use, would require rehabilitation of roaded natural and roaded modified settings over a period of 30 to 50 years.

The public's desire for roaded natural recreation settings is accommodated at a high level in Alternatives J, W (PA), D and L. Alternatives D and L supply 100% of 2040 demand while Alternatives J and W (PA) accommodate 77% to 81% of future demand. The lowest response to public demand for this recreation setting is provided by Alternative NC by supplying 37% of 2030 demand. Other alternatives provide between 59% and 62% of future demand for the roaded natural setting.

Public demand for use of roaded modified opportunities in the year 2040 is fully satisfied in all alternatives.

Trails - Management areas, each with specific goals and standards applied in the alternatives, will have differing effects upon the trails located within them. However, groups of management areas may be expected to have some common characteristic effects on Forest trails. The most significant effects of management area activities on nonwilderness trails are due to timber harvest and road construction. Trails which traverse management areas having a high incidence of timber harvest and road construction are more subject to the effects of replacement and bisection by roads, and the encroachment of management activities on the visual experiences of trail uses than management areas with a lower incidence of these activities.

The removal of trees along trails through various harvest methods and associated post harvest practices will alter the basic character of trail settings and may displace trail use. During harvest and post harvest operations affected trail segments will become impassable or destroyed. The felling of trees, yarding, and residue treatment activities can block access of users and destroy or disturb trail surfaces. These effects will typically result in closures of affected trail segments, trail relocations and reconstruction of disturbed trail surfaces.
Road construction continues to have the greatest effect on the Forest trail system. As the Forest road network expands, more and more trails will be bisected or replaced. Bisection of trails interrupts an otherwise continuous trail-related experience or opportunity of both motorized and nonmotorized use. Often roads that bisect trails result in a shortened distance to a trail's destination. Trail replacement through road construction often results when a new road actually occupies the same grade and alignment of a trail, obliterating any evidence of its existence and providing access to the same destination.

A further consequence of replacement and bisection of trails, is the loss of trail related recreation opportunities and displacement of trail users. Extension of the Forest's road system has and may continue to shorten access and attract more use to many special areas and natural features resulting in increased compaction, displacement, and erosion of trail surfaces. In addition, as trail mileage is reduced from bisection and replacement, competition among mountian bikers, hikers, motorized trail bike users, and pack and saddle users for exclusive use is likely to increase.

Actual impacts to trails from timber harvest and road construction will be on a site specific basis. Effects cannot be determined until locations of harvest units and road segments are known. However, by comparing for each alternative the miles of Forest trails in management areas that permit timber harvest and road construction, with proposed harvest areas, the relative potential effect of each alternative can be assessed.

To illustrate the relative effect each alternative has on the Forest's existing trail system, management areas have been grouped into three categories, based upon their potential to affect trails. Table IV-23 illustrates the effects of the alternatives on trails based on these management area groupings.

Table IV-23 Effects on Existing and Potential Forest Trails in Miles

		Alternatives						
Effect Category [1]		NC	K	A	J	W	D	L
High	Existing	314	343	278	200	77	136	28
	Potential	38	83	83	171	231	204	315
Moderate	Existing	236	243	221	207	243	178	186
	Potential	199	121	193	160	171	133	127
Low	Existing	164	128	215	307	394	400	500
	Potential	315	348	276	221	150	215	110
TOTAL	Existing	714	714	714	714	714	714	714
	Potential	552	552	552	552	552	552	552

[1] **High** = Management areas with normal harvest levels and attendant road construction.
Moderate = Management areas with reduced harvest levels and limited road construction.
Low = Management areas with no programmed harvest and no road construction.

As illustrated in Table IV-23 each alternative will affect exisiting and potential miles of trails differently. Generally, alternatives that include more trails and potential trail locations within management areas that exclude or permit only low levels of timber harvest or road construction will maintain trail corridor environments in natural or natural appearing conditions. Alternatives J, W (PA), D and L maintain between 307 and 500 miles of existing trails and between 171 and 315 miles of potential trails locations in management areas that assure the protection of trail related values and experiences. Other alternatives, such as NC, K and A propose maintain 164 and 215 miles of existing trails and between 38 and 83 miles of potential trail locations in a similar manner.

Opportunities for mountian bike use, hiking, pack and saddle use, and trail bike use would be increased in some alternatives through construction of new trails. Alternatives W (PA) and D propose construction of 60 and 68 miles of new trails respectively, while Alternatives J and L propose 40 miles each. Alternatives NC, K, and A propose no new trail construction.

Off-Road Vehicles - The primary areas of off-road vehicle (ORV) use in the Forest include Santiam Pass, Willamette Pass, and the Oregon Cascades Recreation Area. Other areas of use include the upper reaches of the Middle Fork of the Willamette drainage and, during drawdown periods, the mud flats of Lookout Point and Hills Creek reservoirs. The proposed alternatives vary in their effect on the availability of recreation settings for ORV use. Since each management area either permits, restricts, or excludes ORV use, the type and distribution of management areas in each alternative will affect directly the location and amount of area to be provided for ORV opportunities. Management area 14a (General Forest) provides the greatest amount of area for this type of use opportunity. Table IV-24 illustrates the status of ORV opportunities in each of the proposed alternatives.

Table IV-24 Effects on Off-Road Vehicle Opportunities [1]

	Alternatives [1]						
	NC	K	A	J	W	D	L
Open	69	63	61	59	57	54	38
Restricted	1	7	6	6	6	5	3
Closed	30	30	33	35	37	41	59
TOTAL	100	100	100	100	100	100	100

[1] Values reflect percent of total Willamette National Forest acreage.

Management areas or portions of areas that restrict ORV use typically limit use during specified periods to reduce conflict with other uses and protect resources. Access to some areas of the Forest is controlled by season to avoid impacts to highly erosive soils, big-game calving and winter areas, threatened and endangered species habitats, and other types of seasonally dependent recreation use.

A reduction in the amount of area or miles of trail available to ORV use and subsequent displacement of use has several effects. Expected effects on remaining ORV areas include higher per acre use densities and increased potential of resource impacts. The potential for conflict among users is also expected to increase, particularly in those areas highly suited to some forms of nonmotorized recreation use such as cross-country skiing.

Alternatives NC and K increase from 2% to 8% the amount of Forest area open to ORV use over current levels. All other alternatives decrease the amount of Forest area available for ORV use from 2% to 23% below current levels.

Developed Recreation - Alternatives may affect developed recreation settings in three basic ways: by the elimination of sites, by the manner in which individual sites are maintained, and by the type of management that is proposed to surround individual sites.

The elimination or closure of some developed sites may affect other sites. The users of sites proposed for closure will be displaced into other developed sites, or will seek alternative experiences in undeveloped dispersed sites. Subsequent effects include: the possible overuse of other developed sites, the loss of a preferred user experience, and the increased potential of human-caused wildfire in dispersed camping sites. In addition, an increase in litter, human waste, vandalism, and related effects can be expected in dispersed sites.

An increase in the number of sites will provide for a growing demand for some forms of developed recreation, tend to reduce overcrowding and overuse of existing sites, and offer a more diverse range of opportunities. Table IV-25 illustrates the number of sites proposed by management sector in each of the alternatives.

Table IV-25. Effects on Developed Recreation Opportunities [1]

		Alternatives [1]						
Management Sector	Current Inventory	NC	K	A	J	W	D	L
Public Sector	174	174	214	174	178	199	188	174
Private Sector	30	30	44	30	41	36	34	30
TOTAL	204	204	258	204	219	235	222	204

[1] Values are expressed as number of sites.

As illustrated in Table IV-25, the alternatives would affect the availability of both public and private sector sites. Alternatives K, J, W (PA) and D increase the total number of developed sites by 54, 15, 13, and 18 respectively, over current inventory levels. Alternatives NC, A, and L propose maintainingdeveloped sites at current levels. In addition to increases in total number of new sites among some alternatives, the emphasis between public versus private sector management shifts among some of the alternatives. Alternatives K, J, W (PA), and D propose increasing the number of developed recreation sites to be managed by the private sector from 30 to 44, 41, 36, and 34 respectively.

Actual management of individual sites is based upon their assigned service level for operation and maintenance. The level of service assigned is based on use capacity, site protection needs, and seasonal demand for public use. Sites assigned to a less than standard service level of maintenance, as compared with sites that are managed at the standard service level, will not be provided with law enforcement patrols, garbage pickup, potable water, grounds cleanup and brushing, or sign maintenance. However, safety hazards will continue to be minimized and no fees will be charged for use of less than standard service sites. The frequency of other site maintenance activities, such as sanitation, will be reduced from a daily to a weekly occurrence.

Likely consequences of these actions include a potential increase in rodent populations, reduction in aesthetic appearance of sites, and the need for users to pack out their own garbage, and provide their own water and toilet supplies. Table IV-26 illustrates the relationship of less than standard service sites to standard service sites in each alternative.

Table IV-26. Proposed Management of Developed Recreation Settings

		Alternatives [1]						
Operation and Maintenance Levels	Current Inventory	NC	K	A	J	W	D	L
Standard Service	122	122	176	122	137	153	140	122
Less than Standard	82	82	82	82	82	82	82	82
TOTAL SITES	204	204	258	204	219	235	222	204

[1] Values are in number of sites.

As illustrated in Table IV-26, the alternatives would affect the operation and maintenance levels of developed recreation settings. Operation and maintenance levels of developed sites change only for the standard service level among the alternatives.

Alternatives K, J, W (PA), and D all increase the number of sites to be managed at the standard service level. Increases over current levels range between 15 and 54 sites. Alternatives NC, A, and L maintain standard service site management at current levels. The number of sites to be maintained at a less than standard service level remain the same among all alternatives.

Timber harvest and road construction activities in areas surrounding developed sites could affect the setting of those sites and the experience of users if activities affect the developed area or if users venture beyond the sites into the surrounding landscape. In either case, harvest activities can change the character of the surrounding area in a manner that may preclude experiences and opportunities typically associated with developed site use, or in the vicinity of developed sites, such as hiking, fishing, sightseeing and nature study.

Road construction and harvest activities could result in increased sedimentation affecting fish habitat and fishing quality. These activities can also result in a heightened sense of industrial activity in the area from increased noise levels and, therefore, a reduction in the quality of the overall recreation experience.

The alternatives provide a high degree of protection for the settings of both existing and proposed developed recreation sites from surrounding management influences. Most sites are surrounded by management areas that permit only low levels of harvest and road development and, are therefore, buffered from the normal effects of forest industrial operations. Alternative K provides the least protection for developed settings from surrounding influences, while alternatives D and L provide the most.

The effects of the alternatives on the Forest's ability to satisfy user demand in the future is based on the total number of sites provided and their inherent use capacity. Furthermore, the ability of the Forest to provide for some increases in types of developed recreation use, such as downhill skiing, is based on whether new development or expansion of existing sites is proposed. Table IV-27 illustrates the total number of developed sites to be provided by each alternative and the percent of expected 5th decade (2040) demand they would provide.

Table IV-27. Effects on Managed Sites and User Demand

		Alternatives [1]						
Category	Current Inventory	NC	K	A	J	W	D	L
Existing Sites	204	204	204	204	204	204	204	204
Proposed Sites	0	0	54	0	15	31	18	0
TOTAL SITES	204	204	258	204	219	235	222	204
RVD DEMAND [2]	57%	57%	100%	57%	62%	69%	63%	57%

[1] Values are expressed as number of sites.
[2] Alternative values are in percent of 2040 RVD demand; 4,481,300 RVDs.

As indicated in Table IV-27, Alternatives A, J, and L supply between 57% and 62% of developed recreation demand expected in the year 2040, while Alternative K provides 100%; W (PA), 69%; and L, 85% of expected future demand.

Within the spectrum of developed recreation opportunities that the public desires, downhill skiing is the most significant in terms of required facilities, capital investment, and development area; however, it represents only about 3% of the total estimated demand for developed recreation use. Projected annual user demand for downhill skiing in 2040 (117,100 RVDs) is accommodated with existing facilities. However, permit areas for both Hoodoo Ski Bowl and Willamette Pass Ski Area have been enlarged to develop additional capacity to provide expanded opportunities during peak use periods, currently limited by installed lift capacity. All alternatives provide for expansion of Hoodoo Bowl and Willamette Pass Ski areas.

Cumulative Effects on Recreation

As natural settings are altered through timber harvest and road construction, the capacity of the Forest to provide some types of dispersed recreational settings and experiences is diminished. The greater the shift from unroaded recreation to roaded recreation in the alternatives, the greater the cumulative effect on semiprimitive (motorized and nonmotorized) recreation opportunity settings. Alternative K will have the greatest effect on this type of setting as only 21% of potential will be provided. Alternative D would have the least effect as 71% of inventoried potential will be maintained. Other alternatives would maintain between 32% and 66% of the Forest's semiprimitive opportunity settings.

Another effect of managing recreational settings is that over time, some characteristics of developed sites are lost as a consequence of recreational use and maintenance, and sites take on a "well groomed" appearance. This effect, coupled with limited new site development, would narrow the range of developed recreation setting opportunities by stratifying them at a high level of development

Alternatives NC, A, and L have the greatest effect by narrowing the range of developed recreation settings available for public use. Alternatives K, J, W (PA) and D have the least effect, as they increase the total number of sites and broaden the range of available developed recreation settings.

As road construction and timber harvest activities are implemented over several decades, they have the potential to affect an increasing amount of trail mileage. The effects of bisection and replacement

are greatest in alternatives NC, K, and A. Alternatives W, D, and L are likely to have the least effect as fewer miles of trail are exposed to future road construction and timber harvest activities.

Mitigation Measures for Recreation

The quality of recreational settings in the Forest would be managed in all alternatives through the application of standards and guidelines which apply to all management activities. Relative to the type and level of recreation use, mitigation measures consist of a broad scope of actions that avoid, minimize, rectify, reduce, or compensate for environmental impacts.

The effects of intensive Forest management activities, such as noise and visibility of activities and equipment adjacent to semiprimitive settings can be mitigated by: limiting the proximity of roads; modifying the extent or nature of proposed activities; and scheduling activities during periods of low public use.

Transportation systems and roads affect access to and impacts on both dispersed and developed recreational settings in the Forest. Uncontrolled off-road vehicle (ORV) use increases the risk of degrading the recreational experience because of damage to vegetation both within and adjacent to designated use areas. The risk of damage can be lessened through area controls and public contact. Area improvement and rehabilitation plans and projects can be developed and implemented by groups of ORV users.

In some situations, the effects of crowding on campsites and trail systems can be reduced by dispersing recreation use into other areas where timber harvest is not active. Road closures in these areas can make additional settings available to recreationists who do not object to hiking and camping where there is evidence of harvest activity.

To maintain semiprimitive experiences, group sizes would be regulated, campfires may be limited to designated areas, and visitor contacts would be made by Forest officers to ensure compliance with established management standards and permit requirements.

Losses of trail systems as a result of timber harvest can be offset by alternate ways of locating and scheduling road construction and the cutting of harvest units. In some areas there is also the potential for relocating trails, rehabilitating older, nonmaintained trails, or rehabilitating trails in place after timber harvesting is complete to supplement access.

Increased use of trails and dispersed campsites where there are no sanitary facilities would be accompanied by increased levels of human waste. If trails or dispersed campsites are located near water features, the risk of reduced water quality is increased. The location and magnitude of this effect is lessened by backcountry ranger contact with users, toilet facilities to protect resources and human health and safety, and if necessary, area closures.

As a result of providing recreational opportunities in a visually appealing and safe forest setting, there are impacts on vegetation and timber resources. In developed sites, selected silvicultural practices would be utilized to protect vegetation from insects and disease, perpetuate healthy vegetation, and establish viable vegetative cover. Diseased or hazardous trees located in recreation sites or along trails may be removed for the safety of Forest users.

Because dispersed activity can significantly disturb soil, duff, litter layer, and vegetation, Forest guidelines for all the alternatives set standards for dispersed campsites and prohibit camping within a 100 feet from lakes, streams, trails and key features. The use of camping sites near streams or lakes concentrates fishing pressure, decreases fishing success, and reduces riparian vegetation by trampling. Increased

motor vehicle activity and/or use of pack and riding stock near water courses and lakes can cause erosion, sedimentation, and degradation of fish habitat. These effects can be mitigated by limiting times of use to avoid periods when the ecosystem could be unacceptably damaged. Mitigation could also include site rehabilitation, seasonal and permanent road and/or area closures, and restrictions on dispersed campsite locations.

Developed recreation sites are vulnerable to both costly vandalism and overuse, which can adversely effect facilities, soils, vegetation, and aquatic resources. Measures used to mitigate these impacts, if they occur, include site rehabilitation, re-distribution of use into underutilized sites, scheduling shorter use seasons, raising fees, and concentrating funding on cost effective developed sites. Proposed recreation sites, as in Alternatives K, J, W (PA), and D, would have comprehensive and detailed plans prepared in accord with requirements specified in Forest Service Manual 2330 (Recreation Management) before construction or expansion would occur.

Relationships With Other Agency Plans or Policies for Recreation

State and local planners, and members of the private sector, recognize the importance of recreational settings to both the tourist industry and the local economy. In response, some local communities are beginning to promote year around tourism as a means of diversifying their economic base. The State Tourism Council is also pursuing destination point futures for Oregon. Toward this end some communities may become increasingly dependant upon the Forest and it's varied resources to attract visitors.

Although none of the alternatives are in conflict with current Army Corps of Engineers plans, proposed changes in reservoir water levels for Hills Creek and Lookout Point reservoirs by the Army Corps of Engineers may conflict with existing or potential recreation activities and developments. Each proposal will be fully evaluated in regards to the recreation setting on a case by case basis.

Consultation is also made with other agencies such as the Oregon State Division of Parks and Recreation, the Oregon Department of Fish and Wildlife, and the State Historic Preservation Office regarding the management of existing or potential recreational settings. While the effects of implementing any of the alternatives are not expected to conflict with the majority of the objectives identified by these constituencies, a high level of public contact and coordination between the Forest Service and others will be maintained.

Incomplete or Unavailable Information

Information on the factors affecting user demand or activity preferences is insufficient to project or estimate future use levels for recreation activity types and as a basis to effectively scheduling the delivery of recreation services, facilities or opportunities for public use.

Environmental Consequences Of The Alternatives On The Social And Economic Setting

The social and economic environment that surrounds the Forest will be affected as a consequence of implementing any of the proposed alternatives. Change will occur through various direct and indirect effects on the communities, industries, and people that rely on the Willamette for employment, recreation, and other goods and services.

The intent of the Forest Service management was stated shortly after the turn of the century as "the greatest good for the greatest number in the long run." It essentially means that the National Forests were established not for any single group, industry, or individual, but rather for the present and future benefit of the people of the United States. This sort of utilitarian philosophy has been the guiding principle of National Forest management ever since. Thus both local and national issues and concerns are considered in Forest Service policies and decision-making.

Management of Forest resources affects many of the people and communities in Lane, Linn, and Marion counties which make up the Forest's primary area of influence. The alternatives, which show different combinations of management options, will have certain impacts or effects on people who are employed by the Forest Service, those who work under contract for the agency, and businesses that use or renew the many resources of the Forest. The counties receive monies equivalent to 25% of the gross timber receipts (50% on O&C land timber) in lieu of taxes that could be generated from the National Forest land. The counties also receive 25% of the total revenues derived from other resource uses on the Forest, including campground receipts and grazing fees. The Forest also has a direct effect on recreation users, including individuals, families, and organized groups. These people use the Forest for a wide variety of recreation opportunities that vary from Wilderness to developed campgrounds and resorts. The opportunities for participating in these leisure activities vary by alternative.

The socioeconomic environment is affected by changes which are subtle and quite often difficult to measure. These are indirect impacts which include expected changes in secondary employment due to changes in direct employment. Thus, the car dealer or grocery store may be affected by changes in the number of sawmill or Forest Service workers that are employed. Likewise, the employment and projects partially supported by the county monies will have indirect impacts that are real, but difficult to quantify. Feelings of satisfaction with the local area influence citizens beliefs, attitudes, and enjoyment of their work and leisure activities. These are considered to be indirect because of the many other factors that may influence the people in an area more directly. These include home mortgage interest rates, availability of work, hourly wages or salaries, family ties, savings, and amount of leisure time.

The range of alternatives shows considerable variation in the resource outputs that can have an impact on the socioeconomic environment. For example, in one alternative the amount of timber to be sold could be 75% less than current volumes while available recreation opportunities increase. Effects would include a reduction in total jobs and county revenues and potential increases in recreation use if the alternative were implemented. The secondary impacts would also be estimated in terms of the types of businesses that rely on income from timber processing employees, as well as aspects of the community that would benefit through an increase in recreation visits to the Forest.

Effects of the Alternatives on the Social and Economic Setting

There are several basic factors that vary by alternative, with respect to their impact on the socioeconomic environment. They are: (1) jobs, which are heavily influenced by the amount of timber sold and subsequently harvested; (2) income, which is affected by dollar flows throughout the county; (3) payments

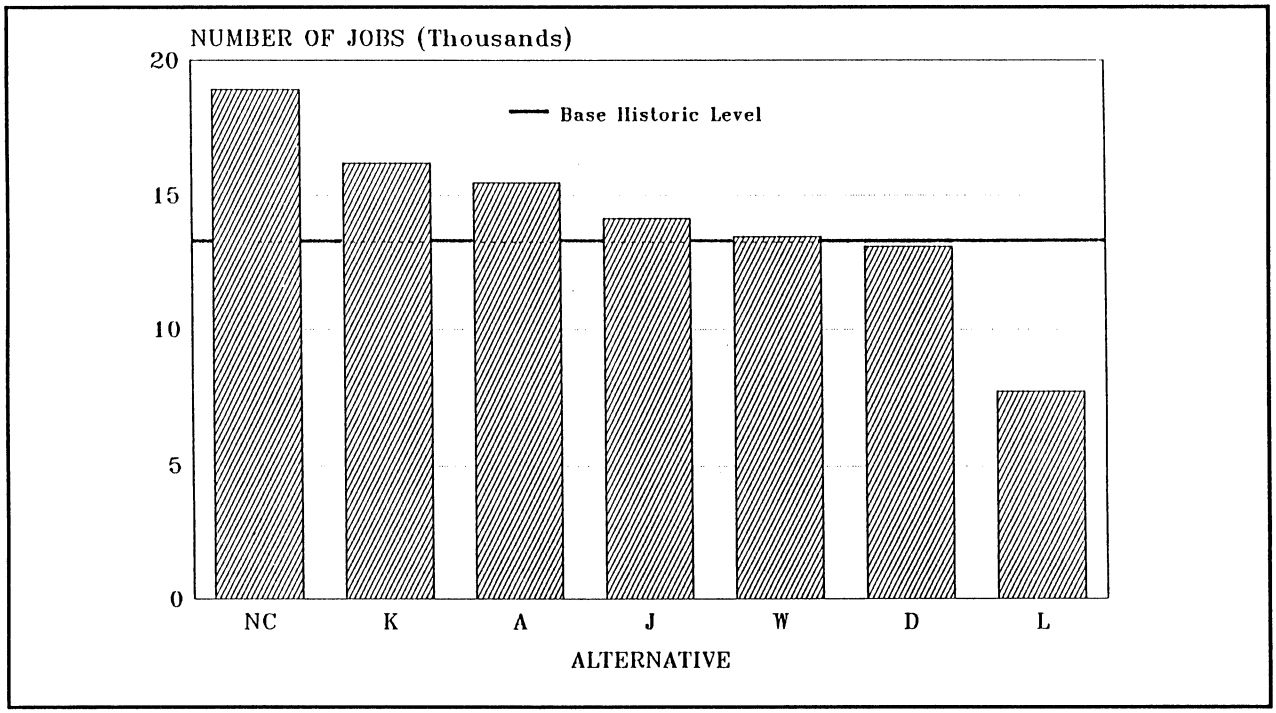
to the counties which affect county funding, especially for schools and roads; (4) lifestyles, reflected in the amount of recreation opportunities or traditional Native American uses; and (5) community cohesion, which reflects the amount or type of natural resource or Forest management issues which pull together or split the communities.

In addition to the factors that vary by alternative, there are several national social equity concerns that do not vary by alternative. As a public agency, the Forest is committed to the management and development of an organization reflective of the national diversity found in the public we serve. The Federal Small Business Administration (SBA) procedures encouraged small businesses to bid for Forest Service contracts and timber sales. Another Federal program provides for minority and women owned business contracting and encourages participation in the Forest contracting program. The timber sale bidding process allows businesses to be competitive in an open setting.

Federal Equal Employment Opportunity (EEO) and Affirmative Action policies and programs guarantee and encourage equal access to and participation in all Federal resource and employment opportunities. Federal EEO programs include Special Emphasis Programs which advocate the employment and upward mobility of women and minorities in the U.S. Department of Agriculture--Forest Service. These EEO Programs include the Federal Womens Program; the Hispanic Employment Program; the Native American Program; the Human Resource Program, and the Volunteer Program.

Jobs - The Forest has the potential to affect the total number of jobs in its area of influence (Linn, Lane, and Marion Counties) as a result of the mix and level of goods and services provided in each alternative. The assumption in estimates of job impacts is that other supply and demand factors affecting the "markets" for Forest products and uses are constant. This assumption becomes more tenuous the further out in time projections of effects are made. For example, the amount of timber offered for sale by the Forest is not, and will not be, the only factor to affect the number of jobs in the timber industry. Timber supply and demand, thus the number of jobs in the wood products industry are influenced by numerous factors including worker productivity, union and non-union wage and benefit agreements, interest rates for home mortgages and business loans, modernization of the mills, closing of mills that cannot make a profit, import and export levels, production and shipping costs, regional competition, private and public land harvest levels and policies, volatility of the lumber, plywood, and chip markets, and estimating what the availability and price of raw materials and finished products will bring. The analysis of effects in this FEIS is on the comparison of potential first decade changes in the number of jobs for each alternative relative to a base historical level. The base historical level is based on the time period 1980 to 1989.

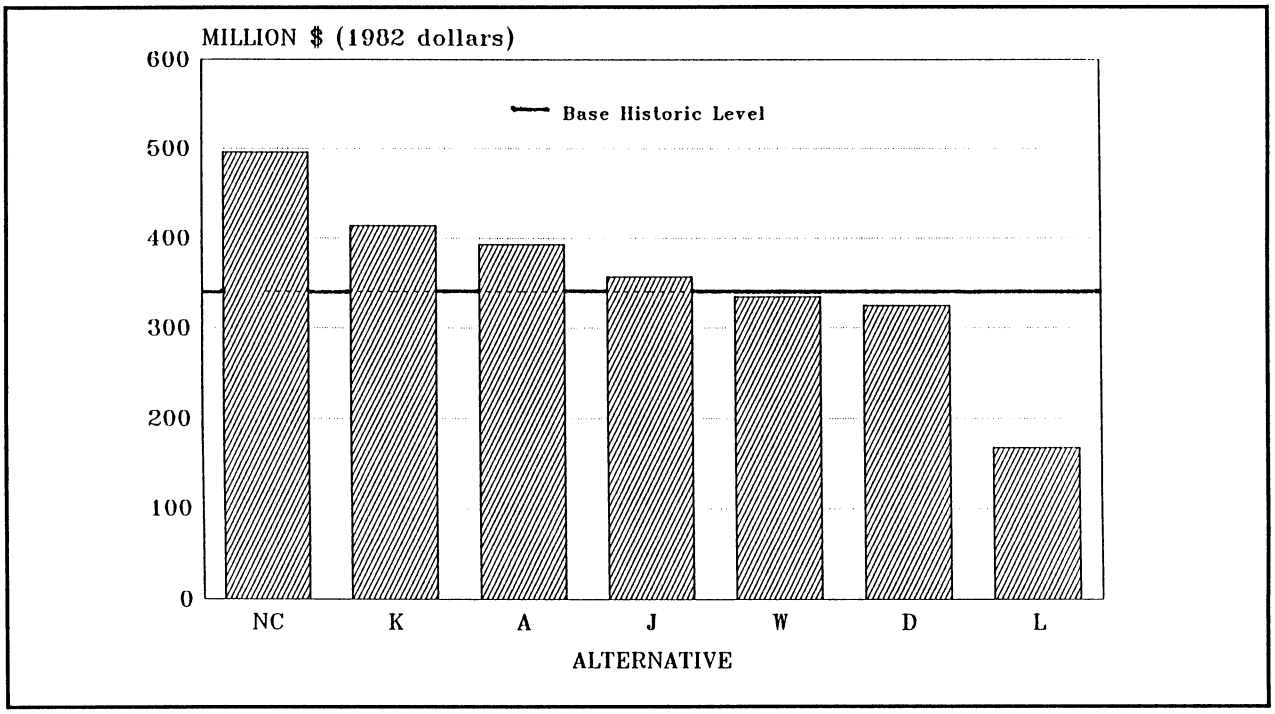
The number of jobs associated with each alternative was estimated using an input-output model called IMPLAN. In this model, job estimates are a function of changes in final demand resulting from changes in output levels. Changes in output or activity levels initiate expenditures in various sectors of the local economy which trigger the change in jobs and income. On the Forest, job and income effects are based on changes in four major outputs: the amount of timber volume expected to be harvested, recreation use, payments to counties, and Federal government expenditures.



The following discussion of potential changes in jobs will focus on changes in the total number of jobs. To estimate the potential changes in jobs and income associated with each alternative, a base level was established for each output. This base represents a multi-year average of historic output levels between 1980 and 1989. The average number of jobs during this period was 13,257. For more detail regarding assumptions, methods of analysis and alternative outputs refer to Appendix B, *Social Impact Assessment.*

Alternative NC would provide the greatest amount of jobs, approximately 5,654 jobs more than the base level. This reflects a projection of the potential yield for timber in the current Forest Plan (1977) which is significantly higher than the amount actually harvested over the base period. The timber harvest level in the NC Alternative was calculated with a different set of assumptions than were the other alternatives. For more details see Chapter II, *Comparison of Alternatives*.

Alternative K would provide the most jobs relative to the historic level, with nearly 2,945 additional jobs in the first decade. Most of these jobs are related to increased timber harvest. Alternative A would also provide a very high number of jobs with first decade job increases approximately 2,218.

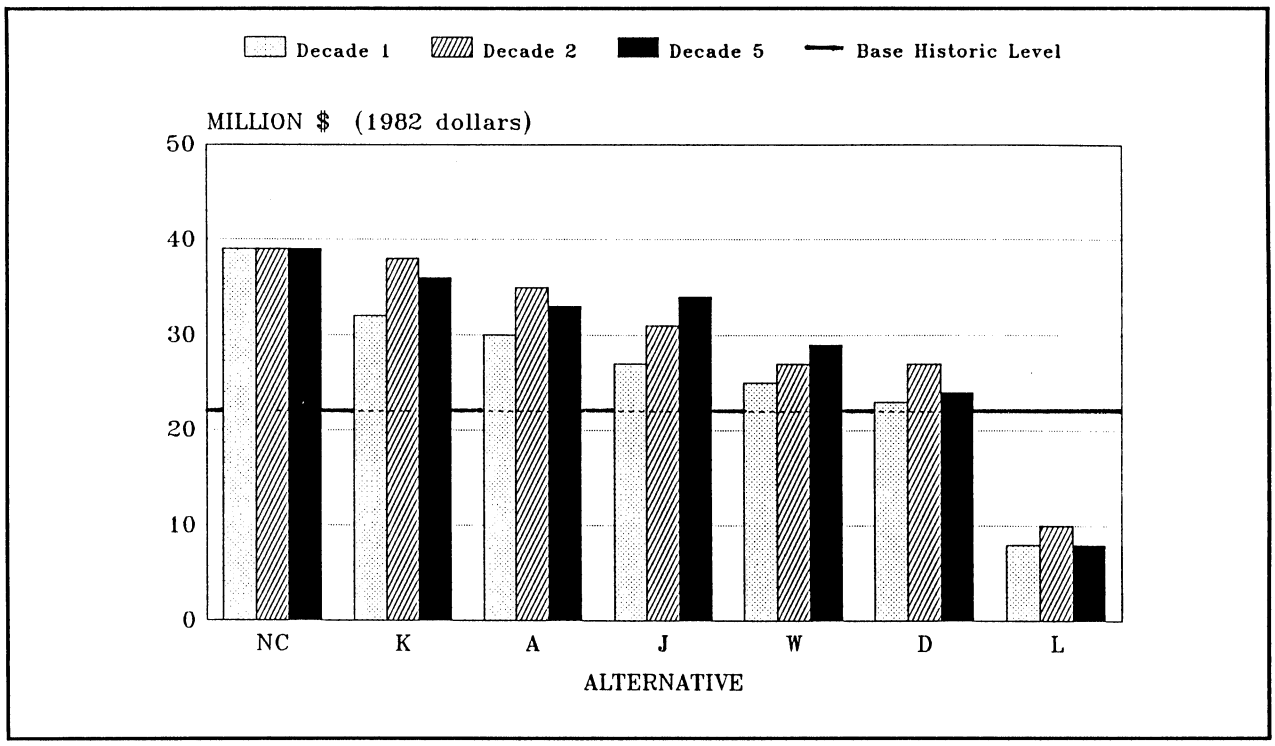


Total employment in the first decade would increase above the historic level in all alternatives except D and L. Total jobs in the first decade would be reduced by almost 167 in Alternative D and 5,499 in Alternative L. These reductions occur primarily because of reduced timber harvest volumes. Though a net increase in jobs is expected, Alternatives J and W would cause a loss of 272 and 815 jobs, respectively, in timber related employment. Recreation related jobs are expected to offset many jobs lost in timber related employment. All alternatives would provide more recreation-related jobs or jobs primarily in the lodging and food industries. Figure IV-20-1 displays the total jobs by alternative and the base historic level. The table associated with Figure IV-20-1 also shows the changes in jobs by alternative relative to the historic base level and relative to the NC Alternative.

Figure IV-14 Total Jobs

Income - Income was also estimated for the first decade with the IMPLAN model and compared to the historic level. Alternatives NC, K, A, and J would increase total income for the first decade. Alternatives W and D would have an income level below the historic level, while total income for Alternative L would fall to 50% of the historical base average. Decreases in total income for Alternative W, D, and L can be best accounted for by the relative decreases in timber related employment. Figure IV-15 displays the total income by alternative and the average base historic level (1980-1989).

Figure IV-15. Total Income



Payments to the Counties - Dollar payments to the counties are based on the 25% formula for uses of National Forest land and resources that generate income for the Federal government. These funds, by law, are to be only used for roads/highways and public schools, while the Oregon and California (O&C) land revenues (which are 50%) can be used for any purpose. The vast majority of these payments come from timber harvests. Thus, when there is a reduction in Forest receipts, the counties must find other sources of revenues to maintain the same funding levels for school and road programs. This could decrease the money available for other programs.

It is recognized that a thorough analysis of the effects resulting from increasing or decreasing timber supply requires an assumption that timber values fluctuate on demand. For example, alternatives that provide reduced timber harvest levels may generate more dollars per unit measure than alternatives producing higher timber harvest levels. However, the complexities involved in estimating supply and demand are beyond the scope of the analysis done by the Forest. The analysis in this FEIS assumes timber values remain constant regarless of supply.

Payments to counties would be above the historic average in Alternatives NC, K, J, and W in the first decade. The returns for Alternatives NC, K and A would be the highest of all alternatives, while in

Alternatives D and L, they are the lowest. Alternative W would be above the historic average (1980-1989). These amounts directly reflect the projected level of timber harvest by alternative and expected value of stumpage. Figure IV-16 displays estimated payments to counties for the first, second, and fifth decades.

Figure IV-16 Payment to Counties

Lifestyles - Lifestyles could be influenced in an alternative by the amount of recreation, hunting, fishing, and visual quality. In terms of the recreation and leisure opportunities on the Forest, all alternatives increase recreation emphasis, with Alternatives K, J, W, and D providing additional new developed sites. All the alternatives provide a wide range of dispersed recreation activities but vary their emphasis as related to diversity of opportunity. Alternatives NC, and A place a moderate emphasis on semiprimitive motor and nonmotorized activities, while Alternative K provides primarily roaded natural and roaded modified recreation opportunities with a minor amount of area provided for semiprimitive opportunities. Alternatives J, W, D, and L provide the most diverse range of recreation opportunities among the alternatives.

With respect to Wilderness, Alternatives W, D, and L provide the highest quality experience opportunities, and the least amount of use during the planning horizon, as a response to conditions of resource damage and over-use in some Wildernesses. Alternative J also provides for higher quality opportunities over current conditions through lower overall Wilderness use levels. Alternatives K and A maintain the current uses and quality of Wilderness and provide for the same levels of expected use in the future.

Alternatives NC, K, and A would maintain the current trail systems while Alternatives J, D, and L provide 40 miles of new trail construction and Alternatives W and D provide at least 60 miles of new trail construction.

Deer and elk hunting opportunities would vary significantly between alternatives. NC would reduce habitat capability for deer and elk and could cause limited opportunity to hunt deer and elk. Alternative K and A would reflect current opportunities the first decade and then decrease in future decades. Alternatives J, W, L, and D, respectively, would increase opportunities to hunt deer and elk as populations respond to habitat conditions.

Fishing opportunities on the Forest will vary considerably through the alternatives, with both anadromous and resident fish use highest in Alternatives W, D, and L. Alternatives K, A, and J will have the same level of resident fish use, but Alternative J has the highest anadromous fish use of the three and Alternative K the lowest. Anadromous fish use in all alternatives is expected to increase in the second decade and then level off. Resident and anadromous fish use was not estimated for the NC Alternative.

Firewood availability for home heating in the first decade will be lowest in Alternative L. Alternatives K, A, J, and W will have similar firewood opportunities. The most firewood will come from Alternative NC. Firewood availability will remain constant in the second decade except for a slight increase for Alternative D. By the fifth decade firewood availability will decrease by more than 50% for all alternatives except J and W which will have decreases of 27% and 41%, respectively.

Community Cohesion - Community cohesion could be affected by the amount of land available for specific resource uses, especially timber harvest, old growth, undeveloped areas, and pending decisions regarding spotted owl protection. It is expected that polarization (issues which split the community) would increase as alternatives approach the extremes in terms of acres allocated to one or more of these uses. In alternatives that address key resource issues with similar emphasis, it is expected that community cohesion would be present but not in the degree found in the extreme alternatives. However, with the total reduced timber sale/harvest levels in almost all alternatives, as well as related issues such as the continued controversy over the amount of protection for the spotted owl and old growth, it is expected that a high degree of polarization will continue for several years, perhaps until the next planning period. The following discussion addresses those issues expected to most effect the degree of polarization in communities.

Alternatives D and L provide the least amount of acres available for timber harvest activities on the Forest, with Alternative L about two-third of the current level. Alternatives J and W also have fewer acres allocated to timber harvest than in the Current Plan (same as Alternative A), whereas Alternatives NC and K have more acres for timber harvest than the current level.

Old-growth acres will be reduced in all alternatives over time. Alternative L provides the most old growth in all decades, and Alternative D provides the next highest. Alternatives NC, K, A, and J provide a low amount, with Alternative NC having the lowest of all the alternatives. Old growth in Alternatives W and D have more than Alternative A in the first decade, with Alternative D being just above Alternative W by the fifth decade.

Spotted owl habitat will also vary with Alternative L protecting the most owl sites (184), followed by Alternative D (102). Four Alternatives (K, A, J, and W) are at the Management Requirement (MR) level plus some additional owls present in Wilderness. Alternative NC does not protect any owl sites outside of Wilderness or other protected areas; therefore, the NC Alternative provides the least habitat areas of any alternative since MRs are not included.

Alternative L maintains the most (85%) inventoried roadless areas in an undeveloped condition. Alternatives D and W provide somewhat lower amounts but each has more than 50% of the total inventory assigned to unroaded prescriptions. Alternatives A, J, NC, and K maintain less than half of the roadless areas in an undeveloped condition with Alternative K maintaining the least (15%).

Cumulative Effects of the Alternatives on the Social and Economic Setting

The cumulative effects of an alternative on the socioeconomic environment are quite difficult to estimate. One basic problem is that job impact data, especially secondary effects, are dated or nonexistent (1977 base updated to 1982). There is good data on counties and large cities, but for smaller towns the information is incomplete. Another factor is that the severe recession of the early 1980's has fundamentally changed the economy of affected counties and especially the smaller towns and industries. This occurred in spite of the fact that the sale (but not harvest) of Forest timber and recreation opportunities remained constant.

In terms of cumulative effects, Forest timber volumes for sale may have little influence on any one mill, for example an owner can purchase from Bureau of Land Management and private woodlot owners to get additional supply. They can also purchase logs from the Umpqua or Siuslaw National Forests. Or, at the owners choice, they can increase or reduce the size of the mill operation, sell the operation to another company, or simply close the mill. All of these have occurred in the last decade and few, if any, of the changes to companies or communities can be tied directly to the sale of Willamette National Forest timber.

The yearly timber harvest level, rather than the sale level, and production in the mills depends on economic factors outside the control of the Forest. These external factors include, but are not limited to, interest rates, housing starts, marketing of products (including demand for products, bid prices on resources, product pricing, and availability of foreign markets), domestic and foreign competition, international tariffs, and exchange rates. Additional factors that affect companies and individuals that use Forest resources, which employ thousands of people in the primary area of influence, include capital investments (including plant modernization), profits, losses, as well as wages, benefits, and working conditions for employees, structure of the companies/corporations, tax rates and breaks, efficiency of the company operations, and productivity of the workers.

Other timber and recreation suppliers (Bureau of Land Management, Oregon State Forestry, private industry, and woodlot owners) play important roles in the jobs, income, dollar returns, lifestyles, and community cohesion in the affected counties. Cumulative social and economic impacts are most effected by external business decisions rather than most variations shown in the Forest Alternatives.

Mitigation Measures for the Social and Economic Setting

Management of the Forest's natural resources affect many of the people and surrounding communities. Recently disputes over old-growth forests and spotted owl habitat has resulted in the reduce sale of timber and consequent reductions in natural resource payments to counties for road and school budgets. Resource dependent communities are also threatened by changing policies in Congress and Federal land management agencies. In response to growing concern over the economic vitality of communities the Forest Service serves and the pressure and change taking place in natural resource management, Region 6 has recently adopted a proposal designated the "Pacific Northwest Strategy".

The Pacific Northwest Strategy is a regional effort of the Forest Service to form partnerships focused on helping resource-dependent communities prepare for and achieve their desired future. The intent

of the Pacific Northwest Strategy is to assist resource-dependent communities in preparing and managing their future by:

- Developing future community leadership,
- Strengthening basic education,
- Establishing a sense of community pride, ownership, and belonging,
- Actively incorporating family, children, and youth,
- Identifying needs and resources,
- Assuming ownership responsibilities to local jurisdictions by all land ownerships.
- Creating partnerships and networks,
- Coordinating among local, State and Federal efforts.

Relationships with Other Agency Plans or Policies for the Social and Economic Setting

Bureau of Land Management (BLM) - Coordination between the BLM and the Forest Service is occurring at the BLM State Office and Forest Service Regional Office regarding planning efforts of both agencies. In addition, coordination occurs between the BLM-Eugene District and BLM-Salem District and the Forest. In terms of socioeconomic effects, the common area of concern between the agencies is the distribution of Federal monies due to the presence of Federal lands in each county. For the Forest, the distribution of Federal monies to the counties depends almost entirely on the timber harvested and the amount of National Forest and O&C Lands in each county.

State Forestry Program for Oregon (FPFO) - The Oregon Department of Forestry (ODF) has developed, in conjunction with the State Board of Forestry, the "Forestry Program for Oregon". At one point, a key to this program for the Forest was the output levels assigned to the various land "owners" (state, private, industrial, and federal) required to accomplish the coordinated programs envisioned.

The volume figure previously given the Forest as an objective, however, is no longer considered an accurate reflection of the objectives for the FPFO or an objective for the Forest to consider in its implementation of the Plan (State Forester letter, March 21, 1990). The target represents data that were collected over a decade ago and that were published based on a situation that existed in January, 1980. The Program has been re-focused on the intent of Oregon's forestry programs rather than on a comparison of numbers. The ODF recognizes that there are legal constraints the Forest must abide by in setting harvest levels.

The objectives of the new FPFO relevant to the Forest Plan and FEIS are:

1. Preserve the forest landbase of Oregon and assure practical forest practices that conserve and protect soil productivity, and air and water quality by:
    - Developing land use recommendations that recognize that forests are dynamic and most forest uses are compatible and that emphasize the integration of forest land uses;

- Encouraging federal agencies to maintain as large and as stable a commercial forest landbase as possible and to minimize future withdrawals from this landbase;

- Recommending that habitat should be managed based upon sound research data and the recognition that forests are dynamic and most forest uses are compatible over time; and

- Cooperatively establishing forest management standards and regulations for the protection of necessary habitat that are based upon the best knowledge available and that are consistent with responsible forest management.

2. Promote the maximum level of sustainable timber growth and harvest on all forest lands available for timber production, consistent with applicable laws and regulations and considering landowner objectives by;

    - Promoting timber growth and harvest on public lands in a manner consistent with the governing statutory direction while seeking to meet Oregon's timber needs through the application of enlightened land and resource management.

    - Supporting the use of intensive timber management practices where professionally, environmentally, and economically sound.

    - Supporting federal policies and initiatives that provide sufficient funding for forest management and timber sale programs on federal land.

3. Encourage appropriate opportunities for other forest uses, such as fish and wildlife habitat, grazing, recreation and scenic values on all forest lands, consistent with landowner objectives by;

    - Encouraging a full range of recreational opportunities on both public and private lands consistent with landowner objectives.

    - Promoting adequate funding for the full implementation, operation and maintenance of forest recreation facilities, including campgrounds, trails, etc., on public forest lands allocated for forest recreation.

4. Devise and use environmentally sound and economically efficient strategies to protect Oregon's forests from wildfire, insects, disease, and other damaging agents by;

    - Encouraging cost-effective federal fire management policies that emphasize planned ignitions over natural ignition fires and that consider impacts to the state's fire protection program.

    - Encouraging that federal plans which develop and implement fire suppression policies be coordinated with the state.

    - Promoting the effective use of integrated pest management as a coordinated approach to pest control actions.

Table IV-10 in the Vegetation section of this Chapter, illustrates how acres are allocated under each alternative to full yield or partial yield.

State of Oregon Land Conservation and Development Commission (LCDC) - The State of Oregon has mandated a county planning program. At this time, the Counties of Lane, Linn, and Marion have completed their LCDC plans. Lane County is currently in the process of revising their plan with respect to the uses of primary and secondary forest land. An Oregon statute requires that the County plans be coordinated with all levels of government (ORS 197.015(5)). In addition, LCDC Goal Number 2 requires that "City, county, state, and federal agency and special district plans and actions related to land use shall be consistent with the comprehensive plans of cities and counties and regional plans." The guidelines for this goal include the following statement: "During the preparation of their plans, federal, state, and regional agencies are expected to create opportunities for review and comment by cities and counties." Review of the primary county plans and proposals for revision has occurred at the Ranger District and Supervisor Office levels on the Forest. In addition, the Forest has consulted with the counties regarding the DEIS and Proposed Forest Plan and has remained in contact with County Commissioners through meetings and periodic mailings of planning newsletters.

The counties in the Forest's primary area of influence are concerned about the economic well-being of their businesses and citizens as well as the overall livability of the area. Objectives associated with these concerns are not always complimentary and result in the need to seek a balance between competing interests at all levels of planning.

Incomplete or Unavailable Information on Communities

Predictions of effects were made with the most current information available. The following topics which effect these predictions require additional information to allow more accurate predictions:

- Future social and economic trends that would influence local communities. For example, the effects of forest timber supplies on local commnities might by amplified or offset by changes in the national and international demand for wood products, advances in mill technology, log export restrictions, and incentives for timber supplies from other land owners. Also, the aesthetic ties between the forest and the communities would be influenced by demographic and economic trends of the local population.

- Future management and resource outputs on lands other than the Forest.

- Community specific information on effects.

- Data on nonlinear relationships between resource outputs and jobs/income.

- Changes in the relationship between forest outputs and jobs and income that have occuryed during the latest national economic cycle.

Environmental Consequences Of The Alternatives On Scenery

The scenic importance of a Forest area is based upon its proximity to travelways and use areas, its relative attractiveness, and the concern users have for scenic quality. Although the degree of visitor sensitivity to the visual environment is difficult to quantify, many people expect to see a naturally appearing landscape in the Forest environment.

All of the alternatives contain activities that change the natural appearance of the Forest by reshaping landforms or altering the vegetative cover of the landscape. Activities associated with timber harvest generally have the most widespread consequence, though road construction, building, and site development also affect scenery. Significant activities introduce line and color changes that contrast with the natural landscape. These physical changes have the potential to dominate a scene and alter its esthetic value.

There are ten viewshed areas in the Forest which are used to display the likely consequences of the proposed alternatives. The effects of the alternatives are estimated by first determining the level of visual quality to be provided, and secondly, by comparing that level of proposed visual quality with the Existing Visual Condition (EVC) of each viewshed.

In the alternatives, each viewshed is allocated to several management areas. Each management area is assigned a Visual Quality Objective (VQO). These VQO descriptions are described in detail in Chapter III, Scenery. The assigned VQOs are designed to manage both long and short term visual effects and range from preservation to maximum modification. Each proposed alternative will vary in its effects based on the amount of area allocated to each management area within specified viewsheds.

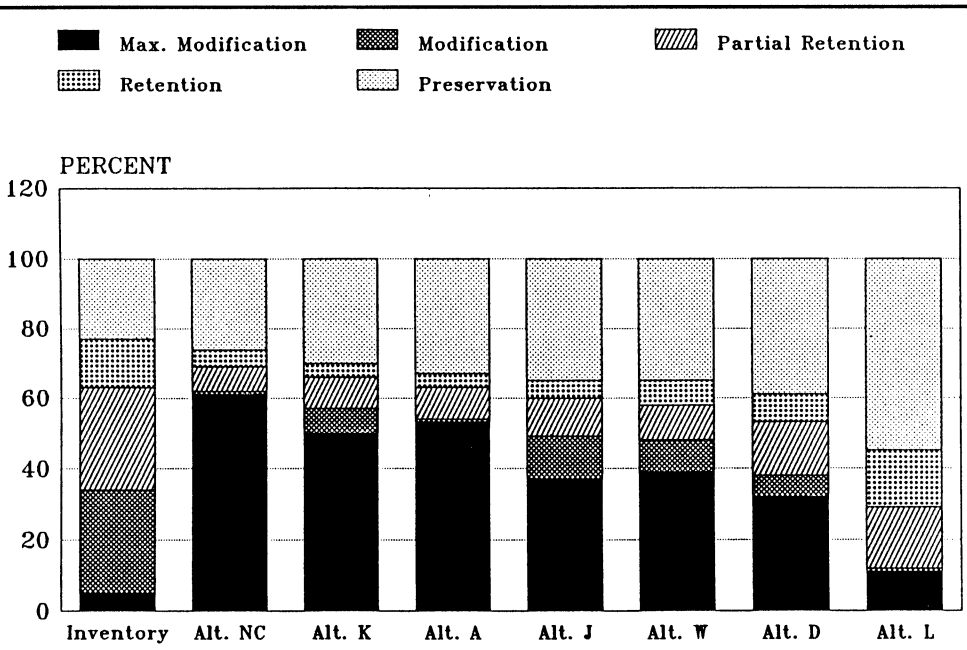
The amount and distribution of each VQO, in aggregate, determines the level of proposed visual quality in each viewshed. The aggregate visual quality proposed for each viewshed is compared with its existing visual condition to determine the expected effects of each alternative.

The EVC of each viewshed is expressed in degrees of apparent landscape alteration. EVC categories include naturally appearing, slightly altered, moderately altered, and heavily altered. Effects that each alternative have on viewsheds are expressed as changes from current EVC levels.

Direct and Indirect Effects of the Alternatives on Scenery

The most obvious and significant effects on scenery are from vegetation and landform alterations typically associated with such resource management activities as timber harvest, road construction, recreation facility development, and mineral exploration. These activities have the potential to alter the natural attributes of landform, vegetation patterns and textures; create stark and dramatic contrasts of exposed soil surfaces with surrounding vegetation; and introduce structural features, such as buildings, utility structures, and electronic towers into the natural landscape. The clearcutting and shelterwood methods of tree removal create openings in the Forest canopy resulting in distinct contrasts between exposed soil and the surrounding landscape. These created openings will vary in their effects on scenery depending on their size, shape, location, and proximity to other openings. Created openings that exhibit attributes of scale, edge effect, shape, and location characteristic of natural openings in the surrounding landscape will have more favorable effects on scenery. Openings that are geometric in shape and large in size relative to natural openings in the surrounding landscape will have an adverse effect on scenery.

Road construction also creates linear openings in the Forest canopy. Roads, primarily in mid-slope locations in steep terrain, often result in the exposure of cut and fill slopes and tree boles, creating an unnatural line effect in the landscape that is usually permanent.



Minerals and energy development activities have the potential to affect scenery to a greater extent than the combined effects of timber harvest and road construction. In addition to tree removal and road construction, minerals or energy development could include significant landform alteration. Effects would also occur from the presence and use of drilling and processing equipment and related facilities. The actual effect of minerals and energy development is unknown however, and can only be determined once a mineral development project is proposed.

The effect of recreation site construction on scenery is minimal except for ski areas. The removal of trees for downhill ski runs, base facilities and structures, and access roads can have the visual effect of several large harvest units. However these effects can be minimized through skillful planning and facility design (USDA Forest Service Agricultural Handbook No. 617, 1984). The visual effects of management activities are most pronounced in landscapes with a homogeneous appearing forest canopy, steep slopes, and light colored soils.

The alternatives have varying effects on scenic quality as a result of the type and distribution of the proposed management areas and their associated activities. In general, alternatives emphasizing the production of market goods provide less Forest area managed for high levels of scenic quality. Areas inventoried as retention and partial retention, which are proposed for management as modification and maximum modification objectives, would change dramatically in appearance. Management activities that result in landform and vegetation alterations would change the scenic quality of these areas from natural appearing to moderately and heavily altered landscapes. The middle ground areas within major viewsheds are the areas most sensitive to this effect, as they are typically inventoried as partial retention.

Table IV-28 provides a Forest-wide comparison of alternatives and their effect on scenery as measured against inventoried VQOs. As illustrated, there would be an increase in the amount of area managed for preservation as a consequence of implementing any of the proposed alternatives. However, lands to be managed for retention, partial retention, and modification VQOs would decrease from inventory levels in all alternatives except Alternative L, in which lands managed for a Retention VQO would increase 2% over inventory levels. The amount of Forest land proposed to be managed as maximum modification in all the alternatives is between 2 and 12 times greater than currently inventoried as maximum modification.

Table IV-28. Forest-wide Effects on Inventoried Visual Quality Objectives

Visual Resource Inventory			Alternatives [1]						
Objectives	Acres	Percent	NC	K	A	J	W	D	L

Maximum Modification	80,841	5	61	50	53	37	39	32	11
TOTAL	1,675,408	100	100	100	100	100	100	100	100

[1]Expressed as percent of Inventoried Visual Quality Objective acres.

Alternatives L and D propose management of most viewshed middlegrounds as retention and partial retention while Alternatives NC, K, and A, propose management of most viewshed middlegrounds for modification and maximum modification visual quality. Alternatives J and W (PA) propose management of viewshed middleground areas primarily for modification and partial retention objectives.
Table IV-29 illustrates the changes in visual quality proposed by the alternatives for each viewshed.

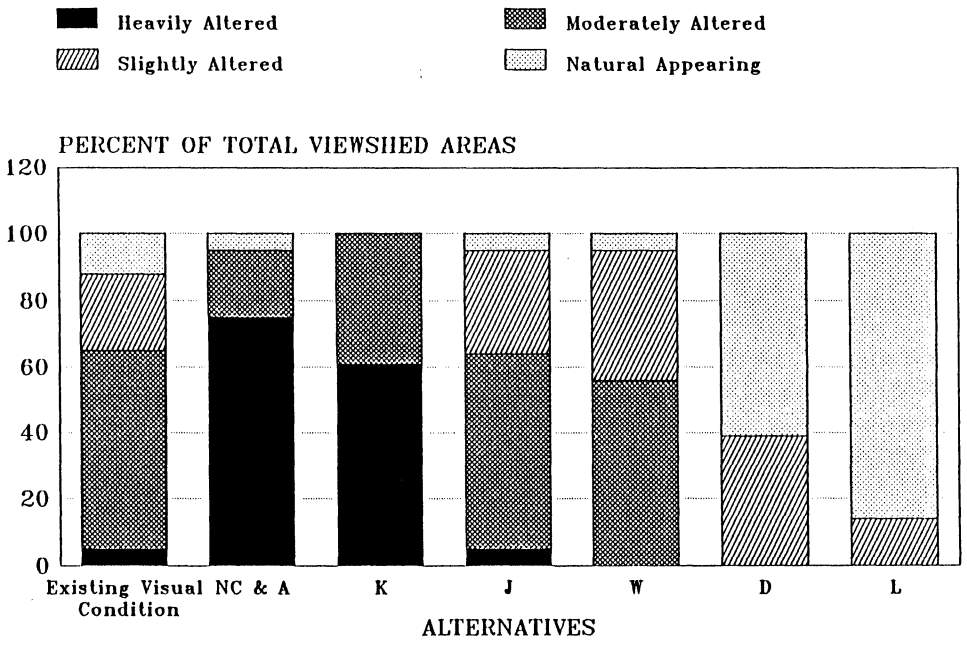
The amount of area assigned to each VQO in each viewshed has a major effect on the future visual condition. If the amount of area assigned to preservation, retention, and partial retention VQOs in a viewshed is increased over current amounts, particularly in middleground areas, it is likely that the EVC would be maintained or improved in the viewshed over the long-term. However, if acreages assigned to these VQOs remain the same or decrease from current levels, the scenic quality of a viewshed is expected to become more altered in appearance in the near-future (10-20 years).

The proposed VQO changes of the alternatives, as illustrated in Tables IV-28 and 29, would have the effect of altering the existing visual condition of Forest viewsheds. Based on EVC ratings; the amount of area assigned to each VQO; the distribution of each management area in relation to important travel routes, use areas and sites; and the rate of programmed harvest associated with each management area the expected future visual condition of each viewshed is determined. Table IV-30 summarizes the effect of each alternative on the scenery of each Forest viewshed.

Table IV-30. Expected Changes to Existing Visual Conditions of Forest Viewsheds

Existing Visual Condition			Alternatives						
Viewshed	Acres [1]	EVC Rating [2]	NC	K	A	J	W	D	L
Little North Santiam	12,222	1	3	4	3	3	2	1	1
Breitenbush	32,357	4	4	4	4	4	3	2	2
North Santiam	63,926	3	4	4	4	3	2	1	2
South Santiam	53,006	2	4	4	4	2	2	1	2
McKenzie	103,131	3	3	3	3	2	2	1	1
North Fork/South Fork	81,033	2	4	4	4	3	3	2	1
Fall Creek	30,929	1	4	4	4	2	3	2	1
Willamette	102,747	3	4	3	4	3	3	1	1
Waldo	26,706	1	1	3	1	1	1	1	1
Middle Fork	83,250	3	4	4	4	3	3	2	1



[1] Acreages include non-National Forest land.
[2] 1 = Natural Appearing.
2 = Slightly Altered.
3 = Moderately Altered.
4 = Heavily Altered.

In Alternative D and L the existing visual conditions of all viewsheds would be maintained or improved with one exception. The Fall Creek viewshed would become slightly altered in Alternative D.

Alternative W (PA) maintains or improves the EVC, and hence, the natural appearance of all but two viewsheds. In Alternative W (PA) both the Little North Santiam and the Fall Creek viewsheds would change from natural appearing to slightly altered conditions. Alternative J also maintains or improves conditions of most viewsheds. This Alternative maintains the EVC of six viewsheds and proposes to improve conditons of the McKenzie viewshed. The EVC of the Little North Santiam, Fall Creek and Willamette viewsheds would become altered under this alternative.

In Alternatives NC, K and A, existing visual conditions of Forest viewsheds are expected to diminish. All viewsheds in these alternatives, except one, would remain or become moderately or heavily altered. The Fall Creek viewshed in Alternative NC and A would be maintained in a natural appearing condition. The generalized effect of the alternatives on the Forest's existing visual condition is summarized in Figure IV-17.

Figure IV-17. Expected Changes to Visual Conditions of Forest Viewsheds

Existing Visual Condition			Alternatives [1]						
Condition Class	**Acres**	**Percent**	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Natural Appearing	69,857	12	5	0	5	5	5	61	86
Slightly Altered	134,039	23	0	0	0	31	39	39	14
Moderately Altered	353,054	60	20	39	20	59	56	0	0
Heavily Altered	32,357	5	75	61	75	5	0	0	0
VIEWSHED TOTALS	589,307	100	100	100	100	100	100	100	100

[1] Alternative values are in percent of total viewshed acres

Cumulative Effects on Scenery

While a single activity may only affect its immediate surroundings, many activities over several years or decades would affect the scenic quality of the Forest as illustrated in Figure IV-17. This effect has even greater consequence in areas where private or other public agency land is adjacent to the Forest. Areas with large blocks of intermingled ownership may display these effects most significantly. It is assumed that private landowners having a large timber inventory will harvest timber and will not maintain the landscape in a natural appearing condition. These areas within and adjacent to National Forest lands will be seen from some travel routes, recreation roads and trails, high vista points, and from aircraft. This "checkerboard" effect will be most apparent in the North Santiam, South Santiam, and Middle Fork of the Willamette drainages and to a lesser extent in the McKenzie drainage and around the community of Oakridge.

Alternatives NC, K and A would have long-term cumulative effects of altering viewsheds at a rapid rate due to the amount of land allocated to general forest and associated harvest levels. The NC Alternative would have a more dramatic effect than K or A on viewshed conditions. This alternative makes available more acres of the general forest in viewshed areas and proposes their harvest at an increased rate. Alternatives J and W (PA) would also result in long-term effects to the appearance of Forest viewsheds. The most significant effect would occur from shifts in EVCs to expected future conditions of some viewsheds. Generally, Alternative J would maintain or improve the existing condition of most viewsheds and lower conditions of a some others. Alternative W (PA) would improve conditions of appearance for four viewsheds, maintain conditions of four, and lower conditions of two others.

Alternatives D and L would have the least cumulative effect on the scenery as these alternatives emphasize the maintenance or improvement of scenic quality within all viewsheds of major travel corridors.

Mitigation Measures for Scenery

The appearance of the landscape will change as management activities are implemented to fulfill Forest Plan objectives. Several published visual resource handbook guides, such as "National Forest Landscape Management, Volumes 1 and 2", specify mitigation methods for scenery, many of which are included in the standards and guidelines of the Forest Plan.

In scenic viewshed corridors, timber harvest areas will be shaped to blend with the terrain to minimize contrast with the character of the existing landscape. Roads will be seeded along steep cutbanks and screened by vegetation. Along critical roads, trails, streams, lakes, and dispersed sites timber harvest units may be restricted in size. In selected management areas, the latitude of vegetative management activities is restricted. For example, harvest levels may be reduced, or complex logging systems and/or stringent cleanup procedures may be required to achieve scenic objectives.

Recreational settings in particular are managed with visual objectives that reflect the concerns of recreational users and expected levels of recreation use. Dispersed camping areas are to be set back from lakes, streams, trails and key interest features to disperse the effects of recreational activity. Developed sites have the potential to contrast dramatically with their surroundings; these potential contrasts are partially mitigated through the use of professional site planning and landscape design skills as well as through the use of native or natural appearing materials and use of "earth tone color" paints and stains. Vegetative screens and/or dispersed or buried facilities may provide adequate mitigation, though in some cases, visual constraints could eliminate certain types of developed site construction.

Relationships With Other Agency Plans or Policies for Scenery

In some viewsheds there may be differences between the Forest Service objectives and those of adjacent landowners or other land management agencies, such as the State of Oregon and Bureau of Land Management. The Forest coordinates with a number of other agencies to ensure that visual resource quality is maintained along state and federal highways, around reservoirs, and around utility lines and electronics sites. To identify potential conflicts and further coordination between other agencies and the Forest Service, a number of operation and maintenance plans are reviewed, including those of the Army Corps of Engineers, Eugene Water and Electric Board, Bonneville Power Administration, the State Department of Transportation, and the Oregon Department of Fish and Wildlife. County zoning actions and adjustments would also be reviewed during project planning.

Incomplete and Unavailable Information

Inventories used in scenic resource management are in need of updating to incorporate the most recent research on human perception and scenic quality expectations of Forest visitors.

Digital terrain data of the Forest landscape is needed for use in visual simulations of proposed landscape altering activities.

Environmental Consequences Of The Alternatives On Wild And Scenic Rivers

The Wild and Scenic Rivers Act of 1968 (Public Law 90-542 as amended) established a method for providing federal protection for certian of our remaining free-flowing rivers, and preserving them and their immediate environments for the use and enjoyment of present and future generations. Rivers are included in the system so that they may benifit from protective management and control of development for which the Act provides.

Numerous river corridors in the Forest draw increasing numbers of users annually because of their special attributes and some have gained both State-wide and National attention. At this time there are 2 designated National Wild and Scenic Rivers, 2 designated Wild and Scenic Study Rivers, and 4 designated State Scenic Waterways within the Forest. The McKenzie River and the North Fork of the Middle Fork of the Willamette River are designated as included in the National System and Blue River and the South Fork of the McKenzie are designated as Study Rivers. Rivers designated as State Scenic Waterways include: Little North Santiam; McKenzie, South Fork of the McKenzie; and North Fork of the Middle Fork of the Willamette Rivers. In addition, all or portions of 8 rivers on the Forest have been determined eligible for Wild and Scenic River status. Table IV-31 displays the designation status of Forest rivers. A discussion of each river listed in Table IV-31 is included in Appendix E together with a tabular listing of river mileage, corridor acres, "outstandingly remarkable" values and potential river classification.

Direct and Indirect Effects of the Alternatives on Wild and Scenic Rivers

The setting of a wild and scenic river provides for a wide range of recreational opportunities which are enhanced by the river's free-flowing condition and "outstandingly remarkable" values and the quality of its surrounding environment. Activities that could affect river values include timber harvest, road and bridge construction, prospecting and mineral extraction, geothermal development, expansion of hydroelectric generating facilities, and development of private land in the area. Environmental changes in river corridors resulting frome these activities could limit a rivers future consideration for inclusion into the National Wild and Scenic Rivers system.

The location and extent of the effects of the alternatives on eligible and designated study river values is relative to the particular management area(s) applied to river corridors. Management areas that emphasize timber harvest, provide for road construction, permit mineral extraction, and allow for hydroelectric or geothermal development have a high probability of altering potential WSR values. Management areas that limit road development, timber harvest rates, and adjust harvest unit designs commensurate with a high level of scenic quality (retention VQO), will typically maintain resource values of river corridors consistent with Scenic or Recreation river classifications. Management areas that prohibit timber harvest and all development, except for low impact recreational facilities, are expected to preserve potential WSR environments in their current condition.

Table IV-31. Designation Status of Forest Rivers[1]

River Name	National WSR	State Scenic Waterway	National WSR Study River	Eligible Rivers
Little North Santiam River		X		X
South Fork Breitenbush River				X
Breitenbush River				X
North Santiam River				X
Quartzville Creek				X
Middle Santiam River				X
South Santiam River				X
McKenzie River	X	X		
Blue River			X	
South Fork McKenzie River		X	X	
NF of the MF Willamette River	X	X		
Middle Fork Willamette River				X

[1]See also Appendix E for a disscussion of each river and a display of corridor acreage, river mileage, river values, and potential classification.

Although none of the alternatives recommend that Congress designate additional Forest rivers as included into the National Wild and Scenic Rivers system, all alternatives, execpt the NC Alternative, specify measures to preserve free-flowing conditions, and protect "outstandingly remarkable" scenic, recreational, geologic, fish, wildlife, historical/cultural, biological and ecological values of all designated, study and eligible rivers. Protection of these rivers and their associated values is extended until a river is determined un-suitable for inclusion into the National System.

Through interim protection of these river values potential WSR corridors would be managed to provide opportunities for a broad range of river oriented recreation activities, such as boating, rafting, fishing, hiking and camping. Other activities, including road construction or timber harvest, would be permitted with these corridors providing that such activities would not lower a rivers potential WSR classification or affect it's eligibility for inclusion into the National System.

Alternative NC is the only alternative that fails to protect the free-flowing conditions and the "outstandingly remarkable" values of eligible rivers in the Forest from development activities. Eligible rivers in this alternative are protected to the extent that scenic management areas overlay these potential WSR corridors as well as through the application of riparian management standards. Protection from road construction, mineral extraction or hydroelectric development consistent with potential WSR classifications is not, however afforded in this alternative. This alternative does however provide protection of designated WSRs and study rivers in accord with the requirements of the Wild and Scenic Rivers Act. Table IV-32 provides a summary of the amount and extent of designated, study and eligible rivers corridors to be protected in each alternative.

Table IV-32 Wild and Scenic River Protection Status

		Alternatives						
River Designation[1]	**Units**	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Wild and Scenic Rivers	Rivers	2	2	2	2	2	2	2
	Miles	55.0	55.0	55.0	55.0	55.0	55.0	55.0
	Acres	17,459	17,459	17,459	17,459	17,459	17,459	17,459
W & S Study Rivers	Rivers	2	2	2	2	2	2	2
	Miles	34.2	34.2	34.2	34.2	34.2	34.2	34.2
	Acres	10,944	10,944	10,944	10,944	10,944	10,944	10,944
Eligible for W & S Status	Rivers	0	8	8	8	8	8	8
	Miles	0	122.2	122.2	122.2	122.2	122.2	122.2
	Acres	0	41,927	41,927	41,927	41,927	41,927	41,927
TOTALS	Rivers	4	12	12	12	12	12	12
	Miles	89.2	211.4	211.4	211.4	211.4	211.4	211.4
	Acres	28,403	70,330	70,330	70,330	70,330	70,330	70,330

[1] The Little North Santiam River, McKenzie River, South Fork of the McKenzie River, and the North Fork of the Middle Fork of the Willamette River are also designated as State Scenic Waterways.

In all alternatives, however to a lesser extent in NC the all river corridors will retain the appearance of an old-growth forest through the limiting the size of created openings, extending harvest rotation lengths, and use of uneven-aged havest systems when vegetation management activities are undretaken.

Campsites within these river corridors would remain accessible from existing public roads and other improvements with these corridors, such as signing and parking areas, when planned would be designed to enhance user experience and protect resources in accordance with the requirements of the Wild and Scenic River Act. Construction of dams and development of a river's hydroelectric potential would not be permitted in any alternative, except the NC Alternative. This protection would be extended until a river has been determined unsitable for WSR status.

Cumulative Effects on Wild and Scenic Rivers

As natural settings are altered, the capacity of the Forest to provide wild and scenic river settings would be diminished. Although demand for recreation river experiences may increase, opportunities to protect river values consistent with Wild and Scenic River classification will be forgone or limited.

Mitigation Measures for Wild and Scenic Rivers

The designation of eligible or study rivers as included into the National Wild and Scenic Rivers System has the potential to increase levels of recreation use and subsequent effects on river environments. Historical data from the Rogue Wild and Scenic River display this trend (RIM, Rogue River National Forest, 1970-1985). To prevent degradation of resources and maintain the quality of recreation experiences, standards and guidelines provide for the establishment of carrying capacities for managing use levels and mitigating effects. The effects of crowding on campsites and trail systems can be reduced

by substituting facilities and dispersing recreation use. Access to river corridors, provided by the construction and maintenance of signs and trails, will govern the location and degree of effects to these areas from public use.

Some management practices can be employed to ensure that effects of vegetation manipulation remains subordinate to the general scene of the area. These practices include: adjustments in the size and location of timber harvest units and created openings; the regulation of harvest rates; the use of uneven-aged management practices, such as group selection or individual tree selection; handpiling and burning of harvest debris; immediate reforestation of disturbed sites; and locating roads to be visually inconspicuous from the river surface and riverbanks.

Relationships with Other Agency Plans or Policies for Wild and Scenic Rivers

Designation of eligible or study rivers as included into the National Wild and Scenic Rivers system could affect private land use and development. Effects would include compliance with county zoning regulations as well as stipulations of scenic easements. Stipulation may limit vegetation management practices, and establish requirements regarding maintenance and development of private lands. Geothermal resource use and development on private land could be subject to additional constraints similar to those constraining geothermal development on public land.

The current objectives of the Oregon State Scenic Waterways System are not in conflict with the effects of any of the proposed Alternatives. Four rivers in the Forest, the Little North Fork of the North Santiam, the McKenzie, the South Fork of the McKenzie, and the North Fork of the Middle Fork of the Willamette River and Waldo Lake are included in the Oregon State Scenic Waterways System. Their important features of these rivers, such as, water purity, natural trout populations, and plant and animal diversity will continue to be protected through the application of standards and guidelines specified in the Forest Plan. Continuing coordination with the Oregon State Parks Division and the Oregon State Marine Board will be conducted to assure compliance with State regulations for access, use and management of designated rivers. In addition, cooperative efforts will continue with these agencies of the State as participants in suitability studies of eligible and designated study rivers and in the development of river management plans for designated Wild and Scenic Rivers on the Forest.

Inadequate Information

All essential information was available for assessing WSR eligibility of Forest rivers.

Environmental Consequences Of The Alternatives On Roadless Lands

Roadless lands are defined as inventoried areas of undeveloped Federal land within which there are no improved roads maintained for travel by motorized vehicles intended for highway use. The roadless area inventory does not include the Oregon Cascades Recreation Area (OCRA), established Wilderness, or areas non-contiguous to Wilderness that are less than 5,000 acres in size. Due to these existing areas, there will always be, as a minimum, 23% of the Forest in a roadless condition.

The Forest, prior to release of the DEIS, and following passage of the Oregon Wilderness Act of 1984, had 31 inventoried roadless areas that totaled 210,207 acres. During the period 1984-1987 and the period following release of the DEIS (1987-1989), management activities were being implemented in many of these areas. A recent assessment of inventoried roadless area conditions indicates that 38,200 acres have been affected by management activities since the 1984 inventory was completed. The roadless area inventory currently includes 31 areas that total 172,007 acres in parcels that are at least 5,000 acres in size, except where contiguous to established Wilderness, smaller areas are included. The disposition of these lands has become an important public issue.

In the current planning cycle, these roadless lands are available for a range of multiple resource uses including those of timber production, fish and wildlife habitat, research, recreation, and in one instance Wilderness. The timber on roadless lands has a commodity value and has the potential to contribute to both the economic and social pattern of local communities. Roadless lands also have the potential to provide settings for recreation, and opportunities to interweave the physical environment with particular social factors such as isolation, remoteness, and personal challenge.

An important consequence of the alternatives is whether or not these lands will remain in an unroaded condition, and whether they will meet the minimum requirements for future Wilderness consideration by Congress. Allocation of roadless areas to some uses requires development. These uses include timber harvest, road construction, and special uses such as expansion of existing ski areas and mining exploration. Development activities may affect how people perceive environmental qualities such as naturalness and isolation.

Roadless land is also proposed for some uses which require only partial development. These would include areas allocated to retention and partial retention visual quality objectives, and semiprimitive motorized and nonmotorized recreation areas that permit timber harvest. In these areas, there will be a slower rate of change, and effects will be managed to shorten the time of recovery to natural appearing conditions. In some cases, roadless conditions can also be re-created by limiting the kind of management activities allowed in an area and letting it revert, in time, to a condition where roads and other past alterations are apparent.

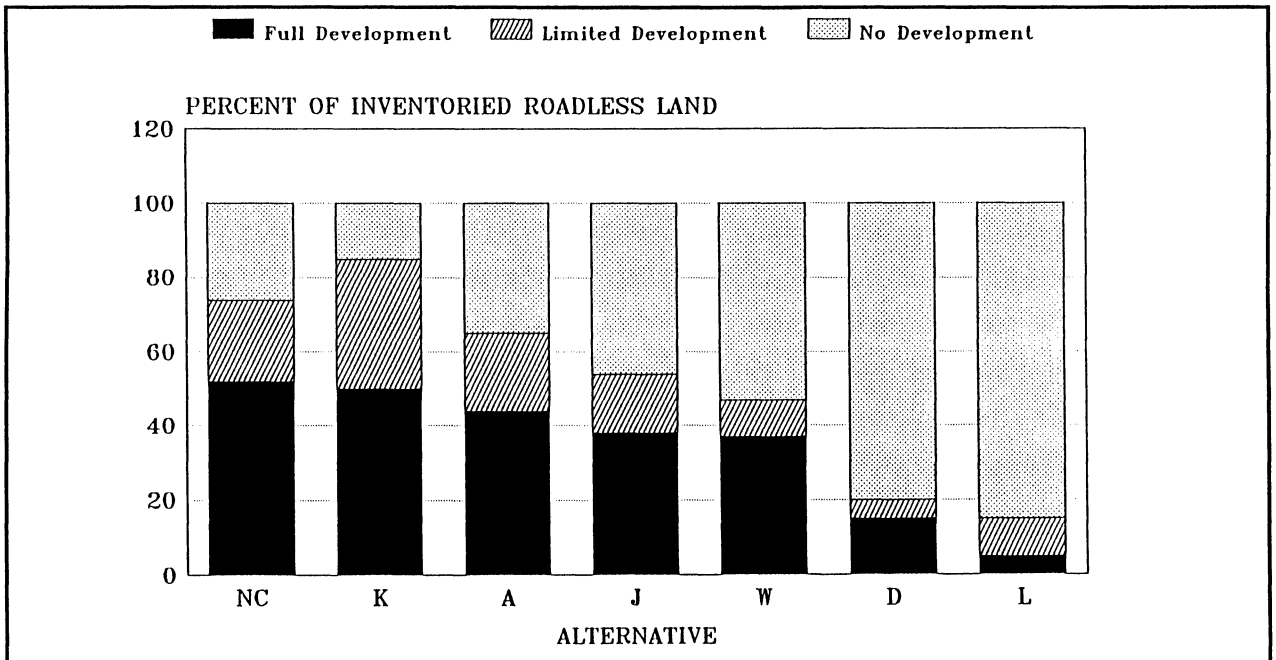
Direct and Indirect Effects of the Alternatives on Roadless Lands

As a consequence of implementing any of the proposed alternatives, there would be effects to roadless lands in the Forest. In all alternatives some roadless areas would become developed through road construction, timber harvest, recreation facility development, or mineral exploration and development, while other areas would remain in an undeveloped condition. The extent of development or maintenance of an undeveloped condition of roadless lands is determined by the type of use to which areas are allocated.

Alternatives that favor development of most roadless areas (Alternatives NC, K, A, J, and W (PA)) would diminish the Forest's capacity to satisfy future demand for uses dependent on roadless conditions.

In addition, the option to evaluate roadless lands for Wilderness in the next cycle of Forest planning would be limited. The allocation of roadless lands to development activities typically results in alteration of the landscape, vegetation patterns, and size and shape of individual areas. Changes of this nature limit the potential of an area to provide isolation, solitude, and primitive recreation experiences and hence its suitability for future Wilderness evaluation.

Although development of roadless areas would preclude future Wilderness evaluation and other recreation uses, it would provide for other values and benefits. Development of roadless areas would support maintenance of historic harvest levels, employment of wood products workers, and community stability. In addition, development activities would provide increased forage for big-game animals and habitat for other species.



In alternatives that maintain significant portions of most roadless areas (Alternatives D and L), it is likely that greater amounts of future demand for uses dependent on roadless conditions such as semiprimitive recreation could be satisfied. In these alternatives, and to a lesser extent in Alternatives J and W (PA) the Wilderness evaluation option would be retained for many areas for the next cycle of Forest planning. Opportunities for isolation, solitude, and primitive recreation would be maintained in some inventoried roadless areas.

The allocation of roadless areas to uses that do not permit the extraction or removal of priced commodities, such as wood products and minerals, can affect the economic base and social patterns of dependent communities. Employment levels of wood products workers would likely be affected. However, habitats for some wildlife species would be favored, such as species utilizing mature and old-growth timber habitat.

The location and magnitude of these effects are relative to the amount of total roadless land allocated to full development, limited development or no development. As indicated by Table IV-33, Alternatives D and L would maintain between 80 and 85% of all inventoried roadless land respectively in an undeveloped condition while Alternative K maintains 15%. Alternatives NC, A, J, and W (PA) would maintain between 26% and 53% of the Forests roadless land in an undeveloped condition.

As indicated in Table IV-33, Alternative L is the only alternative that recommends the inclusion of roadless land in the National Wilderness Preservation System; Alternative L proposes the study and designation of 169,360 acres of roadless land, including the 6,292 acre Mt. Hagan area, as Wilderness.

Table IV-33. Effects on Roadless Lands [1]

	Alternatives [1]						
Effect Categories	**NC [2]**	**K**	**A**	**J**	**W**	**D**	**L**
Full Development	52	50	44	38	37	15	5

[1]This area is divided into several parts for purposes of description in Appendix C.
[2]The Mt. Hagan area is recommended for Wildernes in Alternative L.

Cumulative Effects on Roadless Lands

The cumulative effect on roadless lands is relative to the extent of their development in the alternatives from both the activities on the Forest and those of adjacent land owners. Each alternative proposes different levels of development for different amounts of the inventoried roadless areas. The proposed development of areas, whether full or limited would alter the roadless condition of each area gradually through time. As roads are constructed and timber sale units are harvested, roadless areas would be altered in size and shape. In addition roadless areas adjacent to other land ownerships are subject to the external influences of their management. These effects would alter the potential of individual areas to provide wilderness quality experiences and opportunities in the future.

Areas of 5,000 acres or larger, maintained in an undeveloped condition, would be available for consideration as Wilderness in the next cycle of land management planning. Roadless lands that are allocated to limited development uses would be developed 30-50% slower than areas to be fully developed. This slower rate of development could maintain the current roadless condition of some areas depending on: access strategies, such as helicopter or other aerial harvest systems; project location and design; and implementation schedules. Areas included in the full development category are not expected to remain roadless much beyond 2010.

Mitigation Measures for Roadless Lands

On roadless land proposed for limited development, there will be a slower rate of change than on intensively managed lands, and impacts can be managed to shorten the time of recovery to natural conditions. Where roadless lands have been allocated to scenic uses, timber harvest is reduced to 5-7% of the area per decade. Cutting units will be designed to reflect the vegetative patterns of the characteristic landscape. Three major methods of mitigating effects to roadless lands are: the allocation lands to non-development uses; the use of aerial harvest systems without the construction of roads; and a general development strategy that limits harvest access and activities to the perimeter of individual areas where feasible.

Relationship With Other Agency Plans or Policies for Roadless Lands

There are no conflicts with the proposed allocation of roadless lands in the alternatives with the plans or policies of other agencies.

Incomplete or Unavailable Information

Detailed location and extent of scheduled road construction and timber harvest for the period 1991 through 2000.

Environmental Consequences Of The Alternatives On Wilderness

The environmental qualities of naturalness and solitude will continue to characterize designated Wilderness, although as a consequence of implementing any of the proposed alternatives there will be change, within acceptable levels, in some aspects of Wilderness settings. Wilderness will continue to provide a range of recreation opportunities that interweave the physical and biological features of water, air, soil, geology, vegetation, fish and wildlife with particular social factors such as isolation, remoteness and personal challenge.

The Wilderness Act of 1964 states that Wilderness is to be managed in such a manner "devoted to the public purposes of recreational, scenic, scientific, educational, conservation and historical use" only to the extent that the essential wilderness character of the area is protected. Managers are faced, therefore, with the problem of accommodating human use yet preserving an area's wilderness quality.

Given that any use of the environment produces at least some impact, managers must identify where, and to what extent, varying degrees of change are appropriate and acceptable within wilderness settings. This is accomplished through the use of the Wilderness Resource Spectrum (WRS) system. Wilderness settings are characterized within the WRS as Pristine, Primitive, Semiprimitive and Transition classes. For a description of WRS classes refer to Chapter III, Wilderness.

Changes in WRS classifications result primarily from resource conditions affected by the amount and type of user activities and the inside of designated Wilderness. Although activities, such as timber harvest, can cause localized effects near wilderness boundaries, the most significant effects on wilderness settings are relative to access and the amount and type of recreation use that a particular area receives.

Roads provide access to wilderness settings, and trails facilitate and organize recreation use within designated Wilderness. Trails allow people to take advantage of primitive and un-confined types of recreation opportunities. An extensive trail system can result in fewer contacts between users but could cause increased effects to physical and biological aspects of the environment. Increased access can also cause overuse of desirable campsites and attractions. For example, pack and saddle users need water and meadow areas for maintaining their stock, and tend to utilize large campsites. Commercial outfitters and guides may introduce large groups to some wilderness settings, affecting the solitude and isolation of individuals or smaller groups of users.

Each Wilderness within the Forest displays a range of WRS conditions. For example, at major entry points to wilderness, such as Obsidian Trailhead in the Three Sisters Wilderness, use levels are relatively high, with frequent contact between parties. Areas of Wilderness, such as Obsidian Trailhead, would be classified in the Transition WRS class and resource effects would be moderately evident. Elsewhere, within Forest Wildernesses there are places where few people visit and natural conditions remain undisturbed. The Pristine WRS classification would apply to these undisturbed areas. Between these opposing ends of the WRS are the Primitive and Semiprimitive classes, which apply to the intermediate conditions of use and resource quality of wilderness.

Direct and Indirect Effects of the Alternatives on Wilderness

Three factors that vary by alternative with respect to their consequences on Wilderness are: the recommendation of adding acreage to the Wilderness Preservation System; the establishment of WRS management classes and their subsequent projected recreation use; and increased access through road construction and harvest activities along Wilderness boundaries.

Of the proposed alternatives, only Alternative L, recommends lands for Wilderness designation or study. This alternative proposes 169,360 acres of roadless land, including the Mt. Hagan roadless area for study or inclusion in to the National System. This would result in a total of 550,200 acres of Wilderness in this alternative. Congressional legislation would be needed to establish the areas in this alternative as designated Wilderness. A considerable investment of time and money expended on a research project in the Mt. Hagan area would be forgone if the area were designated as Wilderness. In 1981 research personnel began collecting pre-treatment data on channel conditions, vegetation, stream ecosystem, and soil. This pre-treatment data is valuable in establishing a baseline from which to evaluate later treatments. The location of the project is in an undisturbed low elevation drainage near the proposed Hagan Block RNA. The RNA would serve as a control for the treatment area. Undisturbed low elevation areas such as this are not common and this research project would contribute to knowledge of cumulative effects of riparian management.

Designation of WRS classes within each Wilderness allows for management of Wilderness settings for differing experiences and recreation use capacities. The capacity appropriate to each setting is measured by "persons at one time." The capacity to provide for Wilderness use is determined by the amount and distribution of each WRS Class included in each alternative. All of the proposed alternatives provide for Wilderness recreation use within their respective WRS capacities except Alternative NC. Alternative NC does not employ the WRS as a management system. Table IV-35 illustrates the amount of each WRS Class and respective RVD output for the period 1991-2000 provided in each alternative.

Table IV-35. Effects on Wilderness Resource Spectrum Acres and Visitor Days

		Alternatives						
WROS Class	**Units**	**NC [1]**	**K**	**A**	**J**	**W**	**D**	**L**

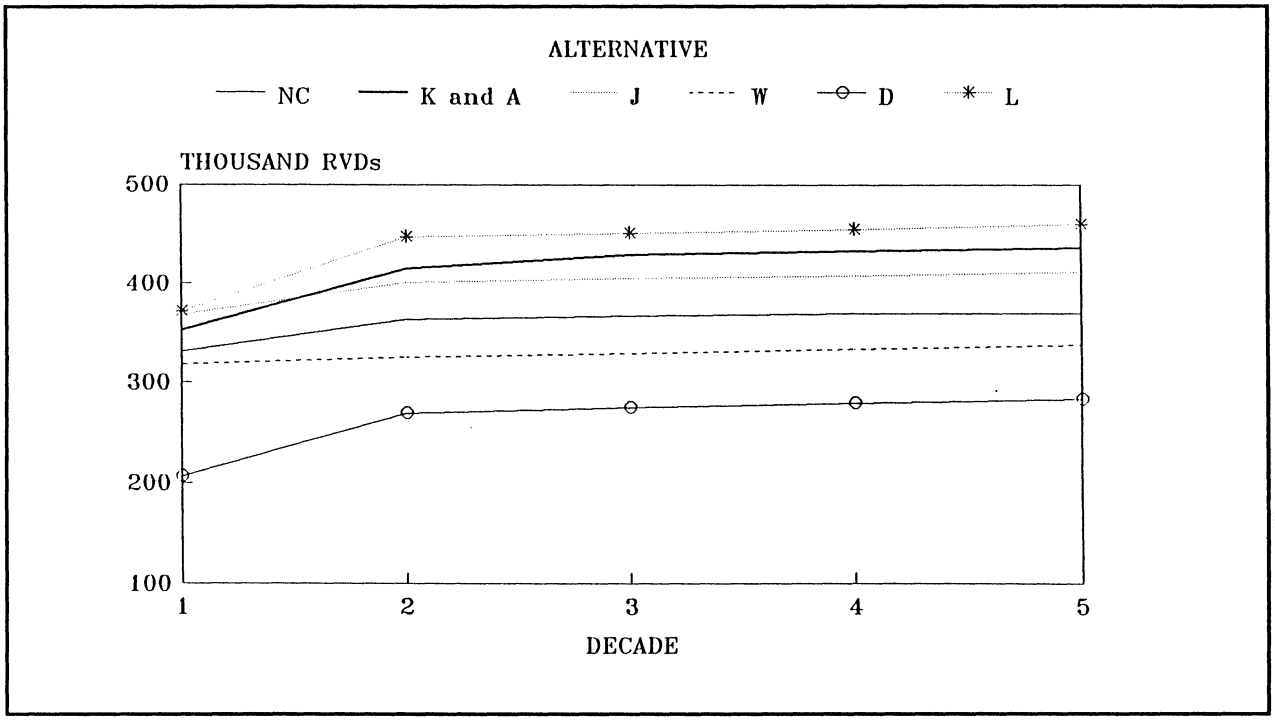
TOTAL	MAcres	380.8	380.8	380.8	380.8	380.8	380.8	550.2
	MRVDs	330.7	352.1	352.1	368.0	318.1	207.2	370.5

[1] Wilderness Resource Spectrum Classes are not applicableto the No Change Alternative.

As illustrated in Table IV-35, Alternatives D and L will provide the highest quality Wilderness experiences; Alternative D by virtue of re-allocating inventoried Semiprimitive Class areas to the Primitive Class and the Transition Class areas to the Semiprimitive Class, thus reducing use levels of Wilderness; and Alternative L through the proposed designation of additional Wilderness. In Alternatives K and A WRS Classes are maintained as currently inventoried. In Alternative J management of interior WRS Classes of each Wilderness is re-allocated from Transition to the Semiprimitive Class. In Alternative W(PA), WRS Classes are also adjusted to improve the quality of Wilderness experience to be provided



and to enhance the conditions of wilderness resources. In the NC Alternative wilderness use opportunities are un-differentiated by WRS Class.

Each alternative, except the No Change Alternative, provides for a range of Wilderness use opportunities through the distribution of WRS Classes. Total Wilderness use varies among the alternatives over a five decade planning horizon based on the distribution of these WRS classes. Figute IV-18 illustrates the amount of expected Wilderness use by decade for each alternative.

Although Alternatives W, D, and L provide the highest quality Wilderness experience opportunities, they also provide the least amount of use during the planning horizon. These alternatives, through variation in the distribution of WRS acres, propose to alter use levels in Wilderness areas where use has been typically high and where resource conditons fail to comply with limits of acceptable change (LAC). Likely consequences of these alternatives include the displacement of former Wilderness users into nonwilderness areas. The recovery of natural processes and conditions is also expected in areas where heavy use has compacted soil, trampled vegetation, and altered surface runoff patterns.

Alternative J also provides for higher quality opportunities over current conditions through variation of WRS Class acres and with use limitation in some WRS Classes to lower over-all Wilderness use levels. Alternatives K and A, however, maintain current inventory acres for each WRS Class and provide for the same levels of expected future use. These alternatives would not provide for recovery of Wilderness resource conditions in areas where over-use has affected Wilderness values.

Figure IV-18. Effects on Wilderness Use by Decade

The response of the alternatives to user demand (905 MRVDs) in the fifth decade of the planning horizon varies directly in relation to how WRS acres are distributed within Wilderness in each alternative. The alternatives provide for projected future use of Wilderness as follows: Alternative NC, 41%; K, 48%, A,48%, J,46%; W, 37%; D, 31%; and L, 51%.

No new trail construction is proposed in any of the alternatives. Trail construction activities would alter vegetation along the trail corridor, disturb soil surfaces, and change water runoff patterns along steep slopes, and although localized in effect, would lower the WRS Classification of the area within which it occurs.

Effects on nonwilderness trails have potential consequences for Wilderness. Alternatives that emphasize timber harvest, and propose development of most roadless areas, will affect nonwilderness trail opportunities, displacing current users into substitute areas. Expected consequences to Wilderness include: an increase in demand for trail related use; a need to perform trail maintenance or reconstruction more frequently; and a need to regulate user access to Wilderness to assure maintenance of use and resource conditions consistent with the Wilderness Act and Wilderness management area S & Gs. Alternatives NC, K, A, and J are expected to have the greatest effect on Wilderness as they retain the least amount of roadless land and Alternatives W, D, and L have the least as they maintain more roadless land or expand Wilderness use opportunities.

Other activities, external to Wilderness, that have potential to effect the Wilderness environment, its integrity, and its use, include road construction and timber harvest. Road construction and timber harvest can have a dramatic effect on both the amount and character of Wilderness use. Locating roads and harvest units along or in near proximity to the Wilderness boundary can increase the number of possible entry points, result in user developed trail systems, and increase access to areas of high public interest and use. In addition, harvest areas can alter the wind firmness of adjacent Wilderness timber stands, and may reduce scenic quality experiences of adjacent areas as viewed from within Wilderness. Alternatives that emphasize timber harvest, such as NC, K, A and J are expected to have the greatest incidence of these effects, while W, D and L will have fewer.

Cumulative Effects on Wilderness

There are cumulative effects on Wilderness as a consequence of any of the proposed alternatives. One such effect is the designation or nondesignation of lands as Wilderness by Congress. Approximately 22% of the Forest is currently designated Wilderness. This has the effect of preserving a wide range of natural resources in their natural condition. In Wilderness, water, vegetation, soil and air quality will be maintained in a natural state. The non-designation of suitable lands may result in the development of such land and over time may become unsuitable for future Wilderness consideration. Another effect on Wilderness is the development, such as timber harvest and road construction, that may occur adjacent to Wilderness boundaries. This effect will result in physical changes that over a period of time can influence the type or quality of experience opportunities to be provided in Wilderness and alter the microsite conditions along Wilderness boundaries. Typically, without some form of use limitation, improved access could result in a greater number of visitors entering the Wilderness at more locations, adversely affecting the type of user experience currently being provided or intended. In addition continued Wilderness use at current levels could result in the permanent loss of essential Wilderness character in some locations of individual Wildernesses.

Mitigation Measures for Wilderness

Wilderness settings will be managed in all alternatives except NC through the application of standards and guidelines which apply to all management activities. Management of wilderness in the No Change

Alternative will be accomplished through existing wilderness management plans and current polices. Mitigation measures consist of a broad range of actions that avoid, minimize, rectify, reduce, or compensate for environmental effects.

If recreation use exceeds capacities, or the levels of acceptable environmental change established for any specific WRS class within a Wilderness, specific actions will be taken to reduce unacceptable use levels. These actions may consist of a permit systems, closure of specific areas with in Wilderness, access restrictions, and closures of roads or trails leading to points of entry. In addition, and as a prerequisite to other actions, user education and public contact can would be used to assist in the prevention of misuse and overuse of the Wilderness environment and related resource degradation. The establishment and monitoring of LAC factors for various elements of the Wilderness resource will aid in reducing effects on the environment. The LAC (U.S. Department of Agriculture--Forest Service 1985) process gives primary attention to acceptable existing Wilderness conditions and prescribing actions to protect or achieve those conditions. If the conditions are exceeded, action is taken to bring them into an acceptable range.

In areas that are characterized by concentrated use, mitigation measures will ensure maximum use and enjoyment within wilderness management standards. Typical areas of high use are arterial trail corridors, areas where major trails intersect, converge, or lead to places of high interest or destination, and staging areas or trailheads. Management Area 1a typifies this high use on 14,482 acres in Alternatives K and A. In this WRS class group sizes are larger; more groups will encounter each other; and, where they occur in this class, more campsites would be visible.

To maintain the essential character of Wilderness, group sizes, encounters with other parties, and intervisibility of campsites will be limited, and campfire sites will be designated if resource damage indicates a need. Dispersal of camps from each other and from attractive features within the Wilderness will reduce effects of concentrated use. To manage high intensity use and resource degradation camping may be prohibited in specific areas to facilitate recover of natural conditions (see Mitigation Measures under Vegetation). These and other measures may be found in the S & Gs included in the Forest Plan.

Although all prescribed burning in western Oregon will be scheduled for times when winds are expected to disperse smoke concentrations, smoke and haze may be evident in the airshed over or adjacent to Wilderness. The Clean Air Act and its 1977 Amendments mandate air quality and visibility protection for the Diamond Peak, Three Sisters, Mt. Washington and Mt. Jefferson Wildernesses. New Wildernesses established under the Oregon Wilderness Act of 1984, to date have not been redesignated visibility protected Class I Areas. Additional mitigation measures for reducing the impacts of prescribed burning on Wilderness air quality values include the scheduling of burning to avoid high Wilderness recreation use periods; increasing wood utilization on harvest units; and decreasing suspended particulate emissions production from slash burning (See also the discussion on Air in this Chapter).

During the past 40 to 50 years, fire suppression efforts have generally suppressed fires in the Wilderness at a smaller size than free-burning natural fires. Because of this change in the fire regime there has been some increase in forest residues, although the buildup has not generally reached a critical level in the western Cascades. Over time however, this may develop into a greater problem and larger, more intense wildfires could be expected in the future. The longer fire is kept out of these areas, the more the vegetation develops towards a climax seral stage with higher accumulations of natural dead and down material. Prescribed burning may be considered in Wilderness where necessary to perpetuate natural ecosystem succession without threatening public safety or adjacent nonwilderness lands. For additional information on prescribed burning and fire suppression in the Wilderness see Section 5, Fire.

Relationships with Other Agency Plans or Policies for Wilderness

Coordination with other agencies is an ongoing process to ensure that users and rights afforded them by the Wilderness Act are provided without impairment of Wilderness values. Examples include: the fish stocking program of Oregon Department of Fish and Wildlife (ODFW); taking mineral samples by the U.S. Geological Survey; and collecting water samples by the Environmental Protection Agency.

The Forest and the Confederated Tribes of the Warm Springs Indian Reservation are working together to resolve trespass issues on the Reservation which is bordered by the Mt. Jefferson Wilderness. Forest visitors and commercial users initiating day or overnight use may inadvertently cross the Forest boundary onto the Reservation and risk citation for trespass. Public information about management policy and regulations to Forest users in the Mt. Jefferson Wilderness will be a focus of the cooperative management effort.

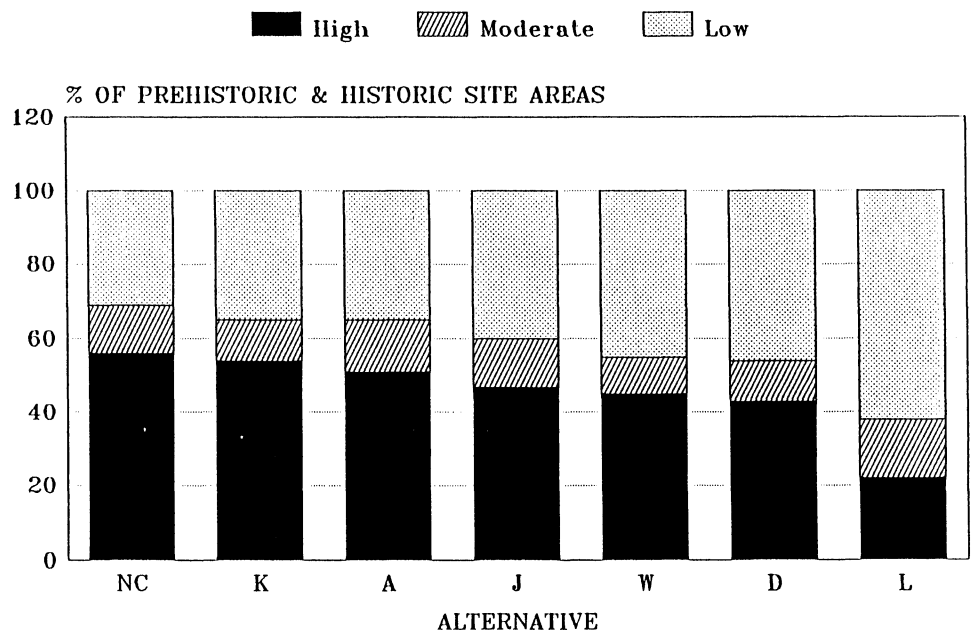
Inadequate Information

Information regarding both the physical capacity of Wilderness resources to accommodate specific types of use and the factors relating to the social capacity specific to the Forests 8 Wildernesses, including the amount, duration, type, purpose and point of entry of Wilderness use is inadequate for the purposes of affective wilderness planning and management.

Environmental Consequences Of The Alternatives On Artifacts And Sites

Human use of land and resources now encompassed within the Forest boundary extends over a period estimated to be at least 8,000 years. The physical remains of prehistoric, Euro-American, and early Forest Service administrative use are documented throughout the Forest. Artifacts and sites include rock quarry sites, open lithic sites, rock shelters, religious sites, wagon roads, homesteads, mines, cabins, trails, administrative buildings and structures. These cultural resources are a unique, fragile, and nonrenewable feature of the environment and are recognized by a number of historic preservation laws, regulations, and policies. The probability of exposing or damaging artifacts and sites increases as lands are used in activities that modify the landscape.

Potential impacts to artifacts and sites are relative to the amount and location of ground disturbing activities proposed by the alternatives. All of the alternatives contain activities that reshape landforms or alter the vegetative cover of the landscape. Activities associated with timber harvest generally have the most widespread consequence to artifacts and sites throughout the Forest. Road construction, and building and site development, also have the potential to generate significant impacts, however on a more localized basis.



While ground disturbing events can damage artifacts or archeological sites, they also provide opportunities for identification of previously unknown cultural properties. In heavily vegetated environments, the removal of understory and forest duff may provide the only means of locating artifacts. Direct and indirect effects may be natural, project related, or the consequence of public use. Natural processes that affect artifacts and sites include weathering, insect infestation, erosion, moisture, tree fall, trampling by wildlife, and fire. Natural effects may increase in significance when coupled with the effects of human activities but may also generate additional opportunities for discovery and enhancement.

Direct and Indirect Effects of the Alternatives on Artifacts and Sites

The effects of the alternatives on cultural artifacts and sites is assessed for both known sites and for areas where the occurrence of sites is probable. To facilitate analysis of potential impacts, management areas are grouped into three categories of potential effect; high, moderate, and low. (See Figure IV-19 for an explanation of potential effect categories). The greater the number of known or potential sites or areas having frequent and extensive modifications of the environment (moderate to high effect), the greater the risk of adversely affecting artifacts and sites. Activities such as timber harvest and road construction have the most significant effect. Effects on artifacts and sites range from disturbance, destruction, or loss of part or all of the resource, to modification of the surroundings of a site such that its contextual integrity is destroyed.

Timber harvest activities are expected to have the greatest potential to damage artifacts and sites because of the extent of ground disturbance. Timber harvest activities will cause considerable disturbance to surface and subsurface soil profiles in localized areas, such as landings, skid trails, and within harvest units. The repeated use of heavy equipment in these areas to fell trees, and yard and pile logs can result in the disturbance, displacement, or crushing of cultural artifacts and sites.

Figure IV-19. Effects on Known Artifacts and Sites

	Alternatives [1]						
Level of Effects [1]	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
High	56	54	51	47	45	43	22
Moderate	13	11	14	13	10	11	16
Low	31	35	35	40	45	46	62
TOTAL	100	100	100	100	100	100	100

[1]Values are in percent of total prehistoric and historic site areas.
[2]**High** - High potential for major alteration of the environmental setting of significant sites; high potential for disturbance of currently unidentified sites. Opportunities for the identification of new sites, however, is also the greatest at this level.
Moderate - Moderate potential for alteration of the environmental setting of significant sites; motorized recreational use increases threats to unprotected sites; substantial opportunity for interaction of the public with cultural resources.
Low - Low potential for impact from land modifying activities; timber harvesting limited; motorized recreational use constrained; primary effect of wilderness management will be to standing structures, but overall these constitute a small proportion of the cultural resorces in the Wilderness. Less emphasis on identification of new sites; more opportunities for preservation of sites in place.

Road construction activities such as excavation, grading, and filling have the greatest potential to effect sites through ground disturbance. Roads tend to be located in areas where artifacts and sites are most frequently found, such as river valleys and terraces, topographic benches, and ridge systems. Because of the magnitude of disturbance, road construction is expected to have the potential to cause the greatest damage to artifacts and sites. However, cultural resource inventories conducted prior to proposed road construction also provide opportunities to locate previously unknown sites that would otherwise go un-discovered.

The magnitude of effect that each alternative has upon known sites and areas of probable occurrence is determined by the amount of coincidence each potential effect category has with the area of known cultural resource sites, and with each of three cultural resource occurrence frequency classes. Figures IV-19 and Table IV-36 illustrate the effect that each alternative has on artifacts and sites.

As illustrated in Figure IV-19 the potential effect on known prehistoric and historic sites and artifacts is variable among the alternatives. In Alternatives NC, K, A, and J, 60% to 69% of the area occupied by prehistoric and historic sites is within management areas that either have a high or moderate potential to effect cultural artifacts and sites. Alternative L is expected to have the least effect as only 38% of the known site areas is coincident with management areas having high or moderate potential to disturb, displace, or damage artifacts and sites. In Alternatives W (PA), and D 54-55% of the know site areas is coincident with management areas having high to moderate potential effects.

In addition to potential effects to known artifacts and sites, the alternatives have the potential to effect Forest areas where the frequency of sites ranges from high to low. Table IV-36 illustrates the effects of the alternatives on the site occurrence frequency areas of the Forest.

Table IV-36 Effects on Artifacts and Sites by Occurrence Frequency Class

		Alternatives [1]						
Occurrence Frequency Class	**Level of Effect [2]**	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
High Frequency (393,254 ac.)	High	47	50	47	45	43	37	18
	Moderate	21	20	21	18	10	18	10
	Low	32	30	32	37	47	45	72
	Total	100	100	100	100	100	100	100
Moderate Frequency (133,675 ac.)	High	74	68	74	67	60	59	29
	Moderate	9	8	9	7	4	9	9
	Low	17	24	17	26	36	32	62
	Total	100	100	100	100	100	100	100
Low Frequency (1,246,590 ac.)	High	53	46	53	52	42	43	18
	Moderate	8	7	8	8	4	8	7
	Low	39	47	39	40	54	49	75
	Total	100	100	100	100	100	100	100

[1]Values are in percent of area.
[2]**High** - High potential for major alteration of the environmental setting of significant sites; high potential for disturbance of currently unidentified sites. Opportunities for the identification of new sites, however, is also the greatest at this level.
Moderate - Moderate potential for alteration of the environmental setting of significant sites; motorized recreational use increases threats to unprotected sites. Future management options are varied; substantial opportunity for interaction of the public with cultural resources.
Low - Low potential for impact from land modifying activities; timber harvesting not permitted; motorized recreational use constrained; primary effect of wilderness management will be to standing structures, but overall these constitute a small proportion of the cultural resorces in the Wilderness. Less emphasis on identification of new sites; more opportunities for preservation of sites in place.

The alternatives are clustered into three groups in respect to their consequences on areas having high and moderate occurrence of cultural sites. Group one, Alternative L allocates the smallest amount of these frequency classes to management areas having high and moderate effects, and thus minimizes potential, yet characteristic, effects from industrial forest operations. Group two, Alternatives NC, K,

A, and J allocate the most area to uses with either high or moderate potential to effect cultural artifacts and sites. Group three, Alternatives D, and W (PA) in respect to area affected, allocates significant areas having high and moderate occurrence of cultural sites to management areas have high to moderate effects although less than Group two.

Assessments to predict accurately the consequences of the alternatives on cultural artifacts and sites is very limited since the actual number, location, and significance of all the cultural resources in the Forest is unknown. It is, however, useful to estimate potential consequences by quantifying the amount of ground disturbing activity generated by the alternatives. Actual impacts to cultural resources within any of the frequency classes will mainly be a result of timber harvest and road construction activity. These activities will occur in management areas having potentially high to moderate effects. Table IV-37 illustrates the predicted amount of ground disturbance due to timber harvest and miles of road construction that will occur in the high and moderate effect categories.

Table IV-37 illustrates the amount of Forest area to be harvested during the next five decades as well as the miles of new road to be constructed. The effect of these activities on known artifacts and sites, as well as areas of high and moderate frequency of site occurrence varies by alternative and by decade. It is evident from this information that effects beyond the second decade will result primarily from timber harvest activities rather than road construction. By the end of the fifth decade effects related to roads will be a consequence of road reconstruction.

Table IV-37. Expected Ground Disturbance on Artifacts and Sites [1]

	Alternatives						
Time Period	**NC [2]**	**K**	**A**	**J**	**W**	**D**	**L**
1st Decade							
M Acres	NA	125.7	120.6	101.8	91.0	98.9	33.1
Miles	NA	550	500	450	400	300	120
2nd Decade							
M Acres	NA	126.4	121.2	100.0	93.6	99.5	27.6
Miles	NA	90	130	70	70	50	40
3rd Decade							
M Acres	NA	116.7	112.5	83.1	80.5	83.0	21.9
Miles	NA	90	70	60	60	30	20
4th Decade							
M Acres	NA	105.3	99.7	87.1	80.7	83.4	28.9
Miles	NA	80	50	40	50	10	10
5th Decade							
M Acres	NA	118.1	115.7	82.0	81.3	85.1	23.2
Miles	NA	40	50	40	20	10	10

[1]Ground disturbance is from acres of timber harvest and miles of road construction.
[2]Data for the No Change Alternative is not available. However, acres harvested and miles of road to be constructed and related effects for this alternative are expected to be similar to Alternative K.

Cumulative Effects of the Alternatives on Artifacts and Sites

The artifacts and sites on the Forest are part of a rapidly diminishing, nonrenewable resource base. The combination of impacts from past landscape modifications, private development, vandalism, and natural deterioration have destroyed much of this record. The exact extent of the loss and the range of site types affected cannot be determined since there were no cultural resource inventories or records preceding most of these activities prior to about 1975. Thus there are few opportunities today to mitigate the cumulative effects of the past. Once destroyed, a cultural resource cannot be replaced. This points to the need for even more careful consideration of cultural resources in the future.

The existing cultural resource compliance process requires that the cumulative effects to cultural resources of any proposed action taking place on National Forest land be considered during project planning. Potential adverse effects can be avoided or mitigated through a variety of measures. Some impacts can be mitigated through scientific data recovery. However, data recovery (excavation) is inherently a destructive process, especially if it is spurred by the need to essentially "salvage" sites in advance of ground disturbing projects such as timber harvest. Data recovery plans address current research questions by using current theories and techniques. But such projects may also destroy data that would be needed in the future when new theories and techniques are developed, thus enhancing the value of remaining sites.

In addition, there is no adequate compensation for the physical loss of some sites. These are resources which, in part, are aesthetically significant and convey, by their existence in place, a special human link with the historic past. For example, the images evoked by the prehistoric carving on a rock outcrop or a rustic cabin are just as strong, and possibly stronger, in a young child as in a trained scholar. The cumulative effects of the various alternatives on these types of resources cannot be mitigated.

Mitigation Measures for Artifacts and Sites

Mitigation measures are specified in the S & Gs included in the Forest Plan and implemented through the Forest-wide cultural resource program. This program integrates inventory, evaluation, protection, and enhancement of cultural resource values into all Forest management activities of a ground disturbing nature.

An important step in the preservation and protection of artifacts and sites is a systematic inventory well in advance of Forest management activities. Prior to any ground disturbing activities the Forest will identify, evaluate, and mitigate impacts to all National Register eligible sites and artifacts that may be affected by a project. On a site specific basis, the ultimate decision whether to practice avoidance of a site or to carry out mitigation measures in lieu of avoidance will be based on both the nature and uniqueness of the cultural values at the site, and the costs of the desired mitigation measure. If excavation is determined to be the appropriate response, a Data Recovery Plan is prepared and implemented by professional archeologists in consultation with the State Historic Preservation Office and reviewed by the Advisory Council on Historic Preservation.

Proposed roads, trails, timber sale units, and other project boundaries can generally be adjusted without additional cost or inconvenience, if the need is determined during the early planning stages of the project. This eliminates effects or threats to cultural sites while encouraging "business as usual" with respect to other management activities. Frequently, activities may be carried out around a cultural site with minimal disturbance through creation of protective buffer zones, use of special technologies, or reduction of the actual area of ground disturbance.

Mitigation measures for cultural resources often include a combination of practices, particularly as they are applied to timber harvest operations. For example, when logs are yarded to a landing area the full suspension of logs substantially reduces or avoids disturbance to the ground surface. Full suspension, in combination with directional felling of trees away from the cultural site, and monitoring of the harvest activities by trained cultural resource technicians, can provide nearly full protection to the cultural resource site.

Where tractor logging is planned, the restriction of the overall number of skid trails and a designated system of trails are utilized to reduce effects. In previously harvested areas, existing skid trails are used wherever possible. The concept of designated skid trails has been successfully tested in soil compaction studies but the concept is likewise applicable to cultural resources (Froelich et al. 1981).

The use of a buffer between equipment and the ground surface may be suitable where there are no above ground structural remains. Recent studies on the Winema National Forest have tested the concept of logging over snow as an effective method of protecting cultural resources (Frances Philipek, personal communication). The results indicate some success as long as the soil characteristics, snow depth and moisture content, slope, and air temperature meet certain criteria. The location of the landings, the method of subsequent slash piling, and careful administration of the timber sale contract to see that specialized criteria are met, are crucial to the success of this technique.

On occasion it is impossible or economically unrealistic to avoid completely, a cultural site, particularly during road construction or reconstruction operations. Where there are no above ground structural features or remnants, crushed aggregate or other materials may be applied to protect the cultural site. The unavoidable loss of an historic cultural resource site can be mitigated by mapping, photo documentation or scaled drawing prior to project implementation. Normally, this documentation is done to the standards of the Historic American Building Survey (HABS) or the Historic American Engineering Record (HAER), whichever is applicable. This process is one of the more common measures preceding the removal of historic properties. In the case of linear features, such as historic ditches, wagon roads, highways, railroad grades, and so forth, a combination of thorough documentation of the feature with preservation of a designated segment may be acceptable.

In some cases, it may be appropriate to excavate archaeological resources. Specific criteria are considered including the significance of the property, the cost of data recovery and the scope of the project. Guidelines specified in the Forest Service Manual are followed and the excavation may be contracted out to a consulting archaeologist. Enhancement and interpretation of cultural sites present an opportunity for increased public education and awareness, although occasionally public use may result in the destruction of cultural properties because of vandalism, relic collecting, theft, and carelessness. Protective measures include directing public use away from sites, maintaining the confidentiality of specific prehistoric site locations, and periodic monitoring of sensitive areas.

Relationships With Other Agency Plans and Policies for Artifacts and Sites

Whenever a significant/eligible cultural resource site is located within the area of a projects potential environmental effect, the Forest Service must consult with the State Historic Preservation Office (SHPO) to determine whether the project will have an effect on the values of the site that qualify it for the National Register of Historic Places. If the project will affect the site, then the Advisory Council on Historic Preservation must be given the opportunity to comment on the project prior to its approval. This consultation process is defined in 36 CFR 800, and fulfills the requirements of Section 106 of the National Historic Preservation Act of 1966, as amended.

Consultation has and will continue to occur with the Confederated Tribes of the Warm Springs, Grand Ronde and Siletz, and the Cow Creek Band of the Umpqua. Consultation and coordination with Native American Tribes regarding the affected environment of the Willamette National Forest has resulted in a greater awareness of a American Indian cultural heritage, values, and issues. Consultation has focused on the site testing program with requests for information about areas of historical, traditional, and cultural use on the Forest. When a site of significance is discovered, Native American Tribes will be consulted and involved immediately. No burial sites have been located on the Forest to date.

Inadequate Information

Current inventories of cultural resources are incomplete regarding the number, location and significance of artifacts and sites in the Forest, thus, limiting through evaluation of potential effects of alternative Forest management proposals on cultural resources.

Environmental Consequences Of The Alternatives On Special Interest Areas, Old Growth Groves And National Natural Landmarks

There is currently one established Special Interest Area (SIA), Lamb Butte Scenic Area, 28 designated Old Growth Groves (OGGs), and no National Natural Landmarks (NNLs) in the Forest. The Forest inventory of potential Special Interest Areas shows 49 areas, totaling 36,960 acres that could be classified as cultural, zoological, geological, botanical, scenic, or recreation areas. A current inventory of OGGs includes 38 areas totaling 7,496 acres. The inventory of potential National Natural Landmarks includes 21 areas, totaling 39,652 acres, nearly half of which are preserved within Congressionally designated Wilderness.
Because these types of areas also provide recreation opportunities, they affect the capability of the Forest to meet present and projected demand for various types of dispersed or developed recreation settings. The designation of special, restricted use areas also affect the capability of the Forest to provide other recreational opportunities and services.

Areas that are designated under these three categories as a result of implementing one of the proposed alternatives will be managed either in a natural or developed condition where appropriate to accommodate access for use and enjoyment of individual areas. Generally, development areas will receive improvements for viewing and interpreting special features and resources.

Certain types of activities or developments adjacent to existing or within potential SIAs, OGGs, or NNLs sites could result in disturbance to the specific values to be protected, studied or enjoyed. In the remaining nonestablished areas, future designation may be precluded by resource development activities such as timber harvest or road construction, or natural events such as fire, flood, or overuse by wildlife.

Direct and Indirect Effects of the Alternatives on Special Interest Areas, Old Growth Groves and National Natural Landmarks

The most significant effect upon the potential SIAs, OGGs and NNLs is whether areas are preserved or not. For areas that are preserved only the incidental effects associated with recreation development, use, or natural processes are anticipated.

For areas allocated to uses that alter the conditions of individual areas or their surroundings, the values or features of interest would be potentially lost or impaired. The degree of loss or impairment is relative to the extent of development associated with each management area to which potential SIAs, OGGs or NNLs are allocated.

The disposition of potential SIAs, OGGs and NNLs in the alternatives is summarized in Tables IV-38, IV-39 and IV-40. As indicated by the figures below, Alternatives W (PA), D, and L would preserve the characteristics and values associated with 84% to 100% of the potential SIA acreage. In Alternatives NC, K, A, and J between 12% and 68% of the potential acres would be allocated to uses that preserve their special features or natural qualities. In Alternatives NC, K, and A, the characteristics and values of potential Special Interest Areas would be either impaired or lost on 32% to 88% of the inventoried acreage.

Lamb Butte, the only established Special Interest Area in the Forest, is subject to the influences of adjacent timber harvest and road construction along it's western boundary in Alternatives NC, K, A and J. However, adjacent activities would primarily affect scenic quality of the surrounding area rather than the physical resources of Lamb Butte. All other alternatives propose complementary forms of management in the area surrounding Lamb Butte Special Interest Area.

Table IV-38. Effects on Potential Special Interest Areas

	Alternatives						
Development Category [1]	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Low	12	24	27	68	93	84	100
Moderate	50	18	43	14	5	5	0
High	38	58	30	18	2	11	0
TOTAL	100	100	100	100	100	100	100

[1] Degree of effect associated with development category in percent of inventory acres:

Low = Preserves conditions and values.
Moderate = Activities may impair conditions or values.
High = Activities may result in the loss of conditions or values.

As indicated in Table IV-39, Alternatives J, W (PA), and L would preserve the characteristics and values associated with 70% to 95% of the potential OGG acreage. In Alternatives NC, K, A, and D between 30% and 66% of the potential acres would be allocated to uses that retain the special qualities and outstanding features of Old Growth Groves. In Alternatives NC, K, and A, the characteristics and values of potential Old Growth Groves would be either impaired or lost on 61% to 70% of the inventoried acreage.

Table IV-39. Effects on Potential Old Growth Groves

	Alternatives						
Development Category [1]	**NC**	**K**	**A**	**J**	**W**	**D**	**L**
Low	30	31	39	70	95	66	73
Moderate	17	11	17	7	0	4	19
High	53	58	44	23	5	30	8
TOTAL	100	100	100	100	100	100	100

[1] Degree of effect associated with development category in percent of inventory acres:

Low = Preserves conditions and values.
Moderate = Activities may impair conditions and values.
High = Activities may result in the loss of conditions and values.

The effects of the alternatives on potential NNLs as indicated in Table IV-40 include: preservation of between 91% and 100% of the inventoried area in Alternatives W (PA), D, and L, and the impairment or loss of NNL features and natural qualities in 27% to 34% of the inventoried areas in Alternatives NC, K, A, and J. There are no areas proposed by the alternatives for inclusion into the National Park Service National Natural Landmarks System. In Alternatives W, D, and L most all of the potential NNLs would be coincident with formally established research areas, Wilderness, Wild and Scenic Rivers, and areas proposed for designation as Special Interest Areas, Old Growth Groves, and semiprimitive recreation areas.

Table IV-40. Effects on Potential National Natural Landmarks

	Alternatives						
Development Category [1]	NC	K	A	J	W	D	L
Low	70	66	71	73	91	95	100
Moderate	22	25	22	24	4	3	0
High	8	9	7	3	5	2	0
TOTAL	100	100	100	100	100	100	100

[1] Degree of effect associated with development category in percent of inventory acres:

Low = Preserves conditions and values.
Moderate = Activities may impair conditions and values.
High = Activities may result in the loss of conditions and values.

Cumulative Effects on Special Interest Areas, Old Growth Groves and National Natural Landmarks

As natural settings are altered through timber harvest and road construction, the capacity of the Forest to provide some types of Special Interest Areas, Old Growth Groves and National Natural Landmark settings is diminished. This is particularly true of potential areas not designated as SIAs, OGGs or NNLs in any of the alternatives and whose attributes are not preserved by similarly protective management area allocations. The special features and attributes of these areas will likely be altered during the planning horizon through intensive Forest management activities. In addition, changes to vegetation patterns, surface drainage, and soil horizons on land adjacent to established SIAs, OGGs or NNLs, may over a period of time affect the natural processes of individual areas. Catastrophic events such as fire and flooding could destroy the values within both potential and designated Special Interest Areas, Old Growth Groves and National Natural Landmarks.

Mitigation Measures for Special Interest Areas, Old Growth Groves and National Natural Landmarks

Special Interest Areas, Old Growth Groves and National Natural Landmarks will be managed principally for public recreation use, study, and enjoyment. Recreational use is permitted when there is no conflict with protection of distinctive characteristics; use will be restricted only to the extent necessary to protect unusual features. Mitigation measures to reduce impacts from vandalism or overuse include public education, rehabilitation, displacing users into less utilized sites, and closing areas. Diseased or hazardous trees located in high use areas or along trails will be removed for the safety of Forest users.

Relationships with Other Agency Plans or Policies for Special Interest Areas, Old Growth Groves and National Natural Landmarks

The effects of implementing any of the alternatives are not expected to conflict with current objectives of State and local planners. Agencies such as the State Oregon Division of Parks and Recreation and the State Historic Preservation Office are consulted regarding the management of areas such as SIAs, OGGs and NNLs. The State Tourism Council is pursuing destination point features in Oregon. As interest among public agencies and private entrepreneurs in developing the State's tourist industry increases, there may be a consequent increase in interest in establishing SIAs, OGGs and NNLs as visitor destination points.

Incomplete or Unavailable Information

Assessments of resource capacity of individual areas to accommodate recreation use and related activites without impairment of special values or features.

Environmental Consequences Of The Alternatives On Research Natural Areas And The H.J. Andrews Experimental Forest

As land use and resource utilization intensify, the need for research involving the climatic, geologic, and biologic systems of the forest environment is expected to become greater. With the ever greater demand for the various uses of land, both public and private, more knowledge is necessary to protect and keep these lands productive. On the Forest, areas have been selected and/or proposed as Research Natural Areas which are representative of cells (habitats, communities, organisms, etc.) deemed important elements in the Pacific Northwest coniferous biome.

Research Natural Areas supply ecological reference points and provide experimental controls for assessing the results of activities in managed areas of the Forest. The four Research Natural Areas are currently used to preserve a representative natural situations including the subalpine mountain meadows, subalpine bogs, noble fir stands on mountain ridges, and old-growth Douglas-fir/western hemlock forests of the Western Cascades. These areas are also used by amateur botanists and biologists, and academic institutions.

Popular Research Natural Areas are vulnerable to disturbance as a result of vegetative trampling or removal of specimens. In addition to the four existing Research Natural Areas, five additional areas have been identified as potential RNAs. If these areas are allocated to other uses, future opportunities to establish these areas as RNAs may be limited or forgone. (See Chapter III, Research Natural Areas and H.J. Andrews Experimental Forest for detailed descriptions of these areas.)

While there are no additional Experimental Forests proposed for the Forest, the management of the H.J. Andrews Experimental Forest (HJA) will continue to meet specific research needs through a joint effort of the Pacific Northwest Forest and Range Experiment Station and the Forest. Research in the HJA focuses on the ecology and management of coniferous forests and watersheds in the Douglas-fir region. Projects have studied the effects of timber harvest and roads upon land stability, site productivity, sediment yields, and water quantity and quality within the old-growth Douglas-fir forest environment, old-growth, and eco-system functioning.

Direct and Indirect Effects of the Alternatives on Research Natural Areas and H.J. Andrews Experimental Forest

The research activities in the H.J. Andrews Experimental Forest (HJA) are often designed specifically to alter vegetation, landform, wildlife habitat, soil or water. In this respect, timber harvest and road building activities are induced for the purpose of study and research. These induced effects may be viewed as adverse in an environmental sense although they are desired and essential in a research context.

In addition to changes that may result from research purposes, minor changes in conditions are expected a consequence of natural events such as wind, fire, insect, and disease within the HJA and RNAs. Extensive timber harvest on the perimeter of these areas could reduce the effective size of some of the included habitats.

The Spotted Owl Habitat Areas located in the HJA could restrict some of the activities necessary for conducting research in all alternatives, except the NC Alternative.

As a consequence of implementing any of the proposed alternatives there would be impacts to potential RNAs. The location and magnitude of these effects are relative to the number of areas allocated as RNAs in each alternative and the disposition of the remaining areas not allocated as RNAs.

Table IV-41 illustrates the acreages of individual RNAs provided in each alternative.

Table IV-41. Research Natural Area Acreage

	Alternatives						
Area Name	NC	K	A	J	W	D	L
Middle Santiam 1	1,152	1,152	1,152	1,152	1,152	1,152	1,152
Three Creeks	--	--	--	512	725	--	--
Wildcat Mountain	1,003	1,003	1,003	1,003	1,387	1,003	1,003
McKenzie Pass 1	--	--	--	1,088	1,130	1,088	--
Hagan Block	853	--	853	1,280	1,280	1,280	--
Olallie Ridge	725	725	725	725	725	725	725
Torrey-Charlton 1	2,048	2,133	2,048	2,112	2,133	2,133	--
Gold Lake Bog	469	469	469	469	469	469	469
Rigdon Point	--	--	--	427	469	427	--
TOTALS	6,250	5,482	6,250	8,768	9,470	8,277	3,349

[1] RNAs that are wholly or partially within established Wilderness.

Table IV-42 displays the distribution of acreages of established and potential RNAs by development categories for each alternative.

The effects on potential RNAs allocated to other than RNA uses is based upon whether the allocated uses would result in no development, limited development, or full development of inventoried areas. Allocation of areas to full or limited development would preclude their use for baseline studies of undisturbed environments.

Table IV-42. Effects on Research Natural Areas

	Alternatives						
Development Categories	NC [2]	K	A	J	W	D	L
No Development	79	69	79	94	100	96	94
Limited Development	7	1	7	2	0	0	1
Full Development	14	30	14	4	0	4	5
TOTAL	100	100	100	100	100	100	100

[1]Includes Middle Santiam RNA within the Middle Santiam Wilderness, the western portion of the Torrey-Charlton RNA within Waldo Lake Wilderness, and a portion of the McKenzie Pass RNA within the Three Sisters Wilderness.

[2]Values are in percent of total acres of potential and established RNAs.

Many of the RNAs provided by the alternatives are surrounded by proposed uses that buffer or otherwise limit effects from the use or management of adjacent lands. All but two RNAs in Alternatives NC, A, and J; four in Alternatives K and W (PA); three in Alternative D; and one in Alternative L are surrounded by uses that buffer or otherwise limit effects from adjacent management activities. Several un-buffered RNAs would be subject to the potential effects of adjacent management such as timber harvest and road construction on adjacent lands.

In some of the alternatives, research potential woull be lost due to development of some areas for resource utilization activities, such as road construction and timber harvest. In Alternatives NC, K, and A, between 21% and 31% of the potential RNA acreage is proposed for resource development. Alternatives J, W (PA), D and L would retain between 94% and 100% of the Forest's inventoried RNA potential in an undisturbed condition.

Cumulative Effects of the Alternative on Research Natural Areas and H.J. Andrews Experimental Forest

The nondesignation of areas as RNAs and subsequent alteration of their conditions over a period of time would result in an eventual loss of research potential. Losses, over time, because of nondesignation would be relative to each areas research potential as described in Chapter III.

Mitigation Measures for Research Natural Areas and H.J. Andrews Experimental Forest

The primary form of mitigation of undesirable effects is boundary identification of individual areas. Areas are generally defined as "closed systems" such as a complete subdrainage or ridge top to avoid contributions of effects such as displaced soil or water runoff from adjacent areas.

In some instances, the intensity of activities on adjacent land is expected to be modified to protect values within the research areas. In the case of RNAs, the establishment report, prepared for each area, sets forth an area objective of maintaining the ecosystems within the boundaries in a natural state of succession.

Other measures include the prohibition of timber harvest, transportation, and utility corridors; withdrawal from mining and mineral leasing; the discouragement of recreation use; and erecting barriers such as fences to exclude domestic stock if necessary. Trails necessary for research projects will be constructed, reconstructed, and/or maintained to the minimum standard required for projects and to provide basic resource protection.

Relationships With Other Agency Plans or Policies for Research Natural Areas and H.J. Andrews Experimental Forest

The HJA is managed according to an Intra-Agency Agreement with the PNW F&RES. Periodic local site committee meetings are held with the PNW, the Forest, and OSU and other interested scientists to plan and discuss on-going research and administrative activities

There are no conflicts between the effects of the alternatives on the Experimental Forest and established Research Natural Areas and the plans of others agencies. There are no conflicts with management of lands of other ownerships and the H.J. Andrews Experimental Forest or established and proposed

Research Natural Areas. A conflict could arise with the Research Natural Area committee if a potential RNA in the Forest is the only area that could fill a research cell need, and is not proposed for establishment.

Incomplete or Unavailable Information

An inventory of existing conditions of proposed RNAs as affected by historic use and natural events.

Environmental Consequences Of The Alternatives On Transportation Systems

The Forest has a developed road transportation system that allows the flow of timber and minerals to local communities. The transportation system also allows access to major portions of the Forest for timber harvest, hunting, fishing, sight seeing, and numerous other activities. Management of resources and programs effects the existing transportation system and determines the need for further development, maintenance, reconstruction and use of roads.

Direct and Indirect Effects of the Alternatives on the Transportation System

Soil and Geology - Soil properties, rock properties, and topography have direct effects on transportation (road) facilities. Availability, location, design, construction, maintenance, reconstruction, and cost of roads are effected by the geological characteristics of the Forest.

The existing Forest development road system is effected similarly in allalternatives. A portion of the road system is on stable soil and rock subgrades. The affect of the stable soil and rock subgrade on the road system is a generally stable road with few, if any, mass movement failures. Other portions of the road system are on moderately stable, unstable, or very unstable soil and/or rock subgrades. The natural effects on roads of the less stable soils/rocks is an increased incidence of road failure and an increased need for road maintenance. Mass soil movements could result in loss of roadbeds. The frequency of roadbed failure would be higher on less stable soils, especially where sideslopes exceed 50%. Loss of roadbed restricts or prohibits the availability of access, either through restriction of road width, or complete loss of the road in the area of mass soil movement. Road reconstruction is required more frequently, and it is more costly on unstable soils. Road maintenance is also more costly on less stable soils.

Road surfaces are typically constructed and surfaced with local rock materials. The quality of rock on the Forest varies widely by locality and geology. Roads surfaces in areas of volcanic breccias and tuffs, generally, are easily degraded by traffic and weather. In order to provide a serviceable road for timber harvest, road surfaces constructed of volcanic breccias and tuffs usually require a greater depth than those made from andesites and basalt materials. The additional depth of surfacing increases the cost over the average cost of constructing new roads. The rapid degradation of breccias and tuffs also requires frequent addition of rock to maintain adequate surface standards. The structural strength of breccias and tuffs is less than that of the andesites and basalts, and could result in a road surface that is driveable during only summer months. All alternatives propose roads in areas of andesite and basalt as well as breccias and tuffs. The alternatives proposing the most road miles, Alternatives NC, K, and A will have the highest proportion of new roads of the adesite and basalt materials. Alternatives J, W, and D will have an approximately like proportion of new road in breccias/tuffs and andesite and basalts. Alternative L will have the largest proportion of new road surfaces of the breccias and tuffs.

New roads would be effected by the soil, rock, and topography that the roads are located on. The significance of the effects are proportional to the number of miles constructed in each alternative. Alternatives with the highest number of new road miles will have the highest number and highest percent of new road miles on unstable and very unstable soils. The natural occurance of mass movements impacting roads will be highest for Alternatives K, A, and NC. Mass soil movements effecting new roads will occur at moderate intervals for Alternatives J, W, and D. In Alternative L the occurance of mass soil movements effecting new roads will be lowest in total numbers, but not necessarily in number of occurances per mile of road. A moderate number of occurances is expected in Alternative L.

Timber - Timber management would have direct and indirect effects on the existing road system and on new roads in all alternatives.

Timber harvest creates a demand for low standard roads to gain access to timber harvest sites and to haul timber from the harvest sites off the Forest. Most road construction on the Forest is in response to timber access needs. The alternatives with the highest allowable sale quantities, require the greatest number of miles of new low standard road construction.

Timber haul has physical direct effects on roads. Repeated truck trips create wear on road surfaces, and can lead to the eventual failure or a need to reconstruct road surfaces. Alternatives NC, K, and A result in the highest rate of wear on the highest number of miles of road. Alternatives J, W, and D create an amount of haul volume that is less than has been produced during the last few years. The haul volumes in Alternatives J, W, and D will produce a moderate rate of wear on a majority of the road system. Alternative L will create a lower amount of timber haul volume than the other alternatives. The rate of wear on road surfaces due to timber haul under Alternative L will be low to moderate and will occur on fewer miles of road than for the other alternatives.

Timber haul also has indirect effects on roads in the Forest. Alternatives that produce the greatest quantities of timber haul, also create the largest amounts of cooperative road maintenance funds which are collected from timber purchasers to be used on Forest roads. Therefore, under alternatives with high haul volumes (NC, K, and A) more funds are available for road maintenance. This results in a higher percentage of road miles being adequately maintained to the required standards. Alternatives J, W, and D produce less cooperative road maintenance funds than have been historically collected. This would result in increased need for congressional budget funds for maintaining roads at historic levles. Reduced haul over roads could reduce the need for maintenance or result in reduced road maintenance or limited access in some areas if no replacement funds are provided. Alternative L would result in a greater proportion of the road system being closed to travel, and reduced maintenance on the remaining road mileage.

Recreation - Recreation use on the Forest creates demand for roads to accomodate public travel. The type of recreation use creates different kinds of affects on the road system. Higher recreation volumes create a demand, generally, for higher standard roads(two lane or wide single lane, higher travel speeds, open to public travel, smoother roadway surfaces, greater visibility, etc.)

Driving for pleasure creates the highest demand of any recreation use for roads open to public travel. Alternatives NC, K, A, J, and W create the highest amounts of dispersed recreation, a portion of which, is associated with driving for pleasure. Demand for roads open for public use creates safety concerns and results in a need for higher standard roads that are well maintained. Alternatives D and L will produce the lowest demands for driving for pleasure experiences, and therefore, create fewer needs for safety, roads open to the public, or higher constructed and maintained standards.

Developed recreation creates demands for higher standard roads to and in develped recreation sites. Alternatives J, W, and D create new developed recreation sites and will require a small number of new miles of high standard road construction associated with these sites. Traffic generated by these new sites would add to the traffic volume on roads leading to developed sites from major highways. Safety concerns would increase on these roads and could increase the need for reconstruction on some roads.

Hunting use has a varying effects on roads. Hunting increases the amount of travel on the road system during a portion of the year. However, public demand for a quality hunting experience, especially elk hunters, requires that some roads be closed to motor vehicle travel during the hunting season.

Wildlife - Management requirements for management indicator species including bald eagles, peregrine falcon, northern spotted owl, pileated woodpecker, Roosevelt elk, and marten could have direct affects on the road system. Protection of these species often requires that roads be closed during certain seasons of the year, may prohibit new road construction, or limit the season of other types of road activity. Alternatives D and L protects the most acres of bald eagle, spotted owl, marten, Rooosevelt elk and pileated woodpecker habitat. These Alternatives would have the potential to prohibit or restrict the most road activities. Alternative W protects somewhat less acres of habitat, therefore would prohibit somewhat fewer road activities. Alternatives NC, K, A, and J have the least potential of effecting use or construction of roads.

Cumulative Effects of the Alternatives on the Transportation System

Soils and Geology - Over time the cumulative affects of soils and geology on roads are similar to their direct and indirect affects. Mass movements will continue to occur on road locations as a result of natural instability of the landscape. Sometimes these mass movements will cumulatively neccessitate reconstruction or relocation of a road facility. Often, though, maintenance will continue to be adequate in providing the needed road facility over time. Road surfacing continues to break down over time, and is lost through erosion processes. Cumulatively road surfacing composed of breccias and tuffs will need frequent replacement, and may neccessitate other types of road surfacing when these are cost effective.

Timber - Timber harvest and haul cumulatively affect the road system. Alternatives producing the highest timber harvests will have the greatest need during the planning horizon for an extensive and well maintained road system. Alternative L producing the least timber harvest and haul volume will have the least need during the planning horizon for an extensive and well maintained road system. over time, Alternative L, will have the affect of lowering the maintenance requirements, closing more roads, keeping more roads in a minimum level maintenance category, and may result more miles being removed from the transportation system than other alternatives.

Recreation - Recreation is projected to increase over time on the Forest. Cumulatively, recreation needs, especially driving for pleasure, and developed recreation, will require a certain number of roads constructed and maintained to a high standard over time.

Wildlife - Cumulative affects of wildlife over time on roads are that certain areas of the Forest will continue to prohibit roads, thus restricting access. Hunting pressures will continue to increase, and may have the result of more roads being closed to motor vehicle travel in future decades than is planned in the first decade. This affect, however, is not known with any certainty.

Mitigation Measures for the Transportation System

Standards and Guidelines represent mitigating measures for the transportation system. Design and construction methods incorporating sound geotechnical practice partially mitigate that affects of soil and geology on roads. Slope stabilization, retaining walls, locations avoiding known areas of instability, geotechnical investigation, and surface stabalization measures are all examples of mitigating measures currently being used on the Forest, and that will continue to be used for any of the alternatives.

Relationships with Other Agency Plans or Policies for Transportation Systems

Cooperative agreements and Memorandums of Understanding with Bureau of Land Management, State of Oregon, counties, and private concerning roads will need to be considered in the implementation

of the Forest Plan. State agency direction concerning elk management will affect road closures. The Forest borders other National Forests; cross haul occurs from timber harvest on these forests and shall be considered in the location, design, construction, maintenance, and management of roads. Any potential reconstruction of the Waldo Lake Road will entail cooperation with the Deshutes National Forest.

Incomplete or Unavailable Information

Traffic data on the Forest is incomplete. Selected roads have had traffic surveilance data generated. Most data is at least three to four years old.

Effects of elk management on roads is insufficient at this time. Long-term research is currently being conducted in Eastern Oregon that may provide sufficient bases for road management.

Environmental Consequences Of The Alternatives On Minerals and Energy

Regulation of mineral and energy activities on the Forest is shared with the Bureau of Land Management (BLM). The demand for access to Forest lands for the purpose of mineral and energy exploration and development is expected to increase over the long term. Requests for access will be processed in a timely manner as prescribed by applicable laws, regulations, and policies.

Implementation of management activities requires the expenditure of energy. The amount of energy used varies by alternative although it is not possible at this time to quantify the energy requirements.

Direct and Indirect Effects of the Alternatives on Minerals and Energy

Land allocations and access development vary by alternative. Alternatives with more restrictive land allocations would place higher emphasis on the protection of scenic values, dispersed recreation values, water quality, special and unique habitats, wildlife habitat. Access would be less developed in alternatives emphasizing these values because lands available for timber harvest would be reduced.

Opportunities for exploration and development of minerals and energy would be greatest in Alternatives NC, A, K, and J, respectively. Alternatives W, D, and L, respectively would place increasing emphasis on scenic values, wildlife habitat protection, recreation, water quality, and other nonconsumptive resource values and would result in decreasing opportunity for mineral and energy development.

Direct and indirect energy requirements would be affected by all alternatives.
Direct energy requirements would include those required for timber harvest, road construction and maintenance, and administrative travel. Alternatives would require energy expenditure in proportion to the timber harvest levels and intensity of timber management. Indirect energy requirements include processing wood products and transport of products to mills and consumers. The energy requirements for the alternatives, ranked in order of increasing requirements would be NC, K, A, J, W, D, and L.

Cumulative Effects on Minerals and Energy

As mineral and energy development occurs, there would be a decrease in the availability of area open for exploration. The removal of minerals from the Forest depends on demand. Alternative L would have the highest potential to restrict mineral and energy development over the long term followed by Alternatives D, W, J, A, K, and NC, respectively. These effects would be caused by management areas prohibiting or highly restricting development and access.

The use of energy to implement the alternatives increases over time all Alternatives except L. The increased energy requirements result from the need to access steep, rough terrain, use increasingly complex timber harvest systems, and intensive timber management practices such as pre-commercial and commercial thinning, control and management of competing vegetation, application of fertilizers, and increased mitigation or enhancement activities needed to maintain water quality, fish habitat, wildlife habitat, and recreation facilities.

Mitigation Measures for Minerals and Energy

Forest-wide standards and guidelines (S&Gs) and management area S&Gs have been developed to provide direction for mineral and energy exploration, development, extraction, and rehabilitation.

Relationships With Other Agency Plans or Policies for Minerals and Energy

U.S. Department of Agriculture, Forest Service recommendations to the BLM regarding the availability of lands for mineral leasing are based on whether development activities could be implemented on Forest lands and meet the management requirements of the Forest Plan. Every application for leasable minerals requires site specific review of environmental effects. Standards and special permit stipulations are used to direct project activities.

Regulation of mining and drilling administered by the Department of Geology and Mineral Industries (ORS Chapters 516,517, and 520). Activities permitted on the Forest will be conducted in compliance with established rules.

Fill and removal operations conducted by the Forest will meet permit requirements of the Division of State Lands (ORS Chapters 274, 517, and 541).

RELATIONSHIP BETWEEN LOCAL SHORT-TERM USES OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY

This Section addresses the effects of the Preferred Alternative (W) on long-term productivity. Forest resource management is a long-term venture and maintaining or maintaining the capacity of the land to provide resource outputs is a primary long-term objective. Short-term uses affect quality of life for the public. Primary examples on this Forest are timber harvest and recreation. The relationship between the short-term uses in the Preferred Alternative (W) and the long-term productivity of the Forest are discussed below.

Long-term productivity changes as a result of various management practices on the Forest. Forest management practices will have direct, indirect, and cumulative effects on the economic, social, and biological environment.

Soil and water are two key factors in ecosystem productivity, and these resources will be protected to avoid damage which could take many decades to rectify.

Wood fiber production will be increased as some of the older stands are harvested and converted to faster growing second growth stands. Timber rotations are normally over 80 years and are managed for long term sustained yield capacity. Silvicultural practices such as the use of commercial tree thinning will also generate measurable long-term gains in wood fiber production.

Opportunities for dispersed recreation use, including hiking, camping, fishing, hunting, snowmobiling, sightseeing and cross-country skiing will be maintained and increased for future generations. Activities planned on the Forest change the setting these activities occur in, but will not reduce the long term potential of the Forest to provide recreation opportunities.

The management of fish and wildlife habitat is designed to maintain viable, well distributed populations of existing native and desired non-native vertebrate species throughout the Forest planning area. The abundance and diversity wildlife species depends on the quality, quantity, and distribution of habitat, whether used for breeding, feeding, or resting. Seven individual species of birds and mammals, one group of birds, and two groups of fish have been selected as management indicator species (MIS). MIS are used to represent the habitat requirements of all fish and wildlife species found on the Forest. By managing habitats and populations of indicator species, the other species associated with the same habitat will also benefit. The Preferred Alternative (W) provides additional emphasis on maintaining long term habitat diversity by protecting special and unique habitats associated with riparian areas, marshes, bogs, meadows, talus slopes, and cliffs.

While some forest management practices reduce long term productivity by causing soil erosion or loss of habitat critical to fish and wildlife species, the desired future condition of the Forest is to maintain integrated ecological functions. For example, timber management activities such as clearcutting, roading, and prescribed burning alter the natural appearing landscape and have adverse impacts on the water quality, soil productivity, and interior forest habitat values. These impacts will be reduced by riparian protection standards, use of Best Management Practices for road construction, retention of snags and large down woody material in harvest units, and protection of large tracts of older forest habitat distributed within the managed forest landscape. In visual corridors, long-term effects of management activities will be avoided or mitigated to meet landscape management objectives.

The Preferred Alternative (W) provides management direction for the Forest for the next ten years. The management area prescriptions and standards and guidelines (S&Gs) specified in the Forest Plan are designed to ensure long-term productivity. These S&Gs will be monitored to ensure that long-term productivity of the Forest ecosystems will be maintained or improved. Details of the monitoring program are found in Chapter IV of the Forest Plan.

IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

This Section addresses the irreversible and irretrievable commitments of resources which would be involved in the Preferred Alternative (W).

An "irreversible loss of resources" results from a decision to use or modify non-renewable resources such as cultural resources or minerals, or resources that are renewable only over a long period of time. Measures to protect natural resources that could be irreversibly affected by management practices are incorporated in Forest-wide S&Gs of the Final Forest Plan and in the mitigation measures discussed in Chapter IV of the FEIS.

The irreversible disturbance of some types of cultural artifacts and sites is likely as a consequence of management activities. This would be especially true for subsurface sites that cannot be located through surface surveys. Even with mitigation, unanticipated or unavoidable disturbances can result in the loss of cultural values.

The removal of mineral or energy resources is an irreversible loss of resources. The utilization of rock resources for road construction would be an example. Actual commitment of mineral resources on the Forest will depend upon demand and mining industry exploration and development proposals.

In unroaded areas, development activities such as timber harvesting and road construction associated with harvest, recreation, or other purposes, will irreversibly reduce the potential amount of area that could be designated as a part of the National Wilderness Preservation System, managed as a Research Natural Area, or managed for other purposes requiring natural characteristics.

An irreversible loss also occurs when stands of old-growth and mature timber are harvested or removed for the construction of roads, campgrounds, ski runs, or other purposes. Old-growth stands provide key wildlife habitat and are also valued for ecological and esthetic reasons. Because old-growth stands take over 200 years to develop, the commitment of this resource to certain uses is reversible only over a long period of time.

High intensity fires can also cause irreversible losses to soil productivity by causing loss of soil structure, volatilization of nutrients, and accelerated soil erosion.

An irretrievable commitment of resources is a use of resources that is lost because of land management objectives. This represents opportunities foregone for the time that the resource cannot be used. Under multiple-use management some irretrievable commitments of resources are unavoidable due to the mutually exclusive relationship between some resources.

An irretrievable commitment of resources is the loss of timber management opportunities within designated Wilderness or other areas where timber production is prohibited or restricted. Another is the loss interior, old growth forest habitat where the management objective for an area is maximizing wood fiber production.

Some long-term uses of the land cause an irretrievable loss of soil productivity. Examples of these uses include the establishment of arterial and collector roads, administrative sites, and/or developed recreation sites.

PROBABLE ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED

Implementation of the Preferred Alternative (W) on the Forest will result in some adverse environmental effects which cannot be avoided. The application of the management prescription (S&Gs) is intended to limit the extent and duration of these effects. Mitigation is reflected in the management prescriptions and mitigation measures are discussed within each section in Chapter IV of this document. Although the formulation of the Preferred Alternative (W) included avoidance of potential adverse environmental effects, some adverse impacts to the environment which cannot be completely mitigated are expected to occur.

Some adverse effects are of a transitory type. For example, air quality will diminish on a recurring though temporary basis, due to the use of prescribed fire. Most significant impacts will be from burning of debris resulting from timber harvest. Even though S&Gs require prescribed burning to be scheduled for times when weather conditions will provide for smoke dispersion, the presence of smoke and haze over or adjacent to the Forest will detract from people's expectation of clean air. Timber hauling and recreation traffic on untreated roads, and the operation of internal combustion engines, will have localized and temporary adverse effects on air quality where these activities occur.

The natural landscape will appear altered by timber harvest, particularly where logging activity is highly visible from travel routes. Burning of harvest units, and their blackened appearance will also be apparent. These adverse effects will eventually be reduced by growth of vegetation. Other impacts on the natural appearance of the landscape include roads and structures which are highly visible despite efforts to blend them with land forms and mitigate the effect by landscaping.

In unroaded areas, development activities such as timber harvesting, and road construction associated with harvest, recreation, or other purposes will have an adverse effect on the potential future management of these areas as designated Wilderness, as Research Natural Areas, or for other purposes requiring natural characteristics.

Disturbance, displacement, or loss of fish and wildlife may occur as a consequence of habitat loss and increased human activity in project areas. Roads and their associated use impact fish and wildlife due to human activities associated with new access into areas previously unroaded. Improved access into areas that previously had low standard roads would have similar effects.

Both the amount and distribution of mature and old-growth stands will be reduced through implementation of the Preferred Alternative (W). Since some wildlife species rely on habitat conditions provided by old-growth stands, a reduction in the populations of some wildlife species can be expected. As old-growth and mature timber stands are converted to young conifer plantations, the capability of the Forest to provide optimal cover for deer and elk will be reduced.

Ground disturbing activities will temporarily increase silt loads in some streams. This could displace fish, reduce anadromous and resident fish reproductive success, and alter aquatic invertebrate populations. In addition, a loss of fish habitat will occur at road crossings of streams. The portion of a stream bed occupied by a culvert or other structures will be lost as fish habitat.

Mineral and energy development may have unavoidable adverse effects on other resources. The scope of these impacts depends upon the location and type of activity proposed by industry. The approving of operating plans for locatable minerals and requiring surface resource stipulations for leasable minerals, will assist in the management and mitigation of these activities.

Fire hazard and resistance to control will increase subsequent to timber harvest and thinning operations as a result of increased accumulations of forest residues. Wildfire risk will increase where access results in more people using an area during and after management activities. Some of this risk will be mitigated by early detection, suppression, and prevention programs. Long-term increases in fuel hazard will be mitigated through fuels management activities that are responsive to resource management objectives.

Adverse effects will result from increasing recreation use and intensive Forest management activities such as timber harvest, road construction and maintenance, developed recreation, and development of other facilities. These adverse effects include disturbance to native vegetation; soil compaction; reduced water quality; increases in noise levels; disturbance to wildlife populations and their habitat; air pollution from campfire smoke, prescribed fire, and vehicle exhaust; and increased potential for human conflict.

PREPARERS

Interdisciplinary Team

The following is a listing of the Interdisciplinary Team members. These are the current members of the core group and other primary participants. Information regarding qualifications (education and experience) and involvement in the preparation of the Forest Planning Documents is included.

Kenneth Adee, GIS Coordinator

Education: B.A. Philosophy; M.F. Forestry; Post graduate studies in Quantitative Ecology.

Experience: 14 years with Forest Service as Research Forester; Sale Preparation Forester; Planning Team's applications programmer; developed the software for the PLOT-7 mapping system.

Role: Provided GIS analysis of vegetative inventory and old growth acreage estimates.

Rolf Anderson, Planning and Programming Staff Officer

Education: B.S. Forest Management/Forestry; M.S. Management.

Experience: 32 years with Forest Service as Timber Management Assistant; Oregon Dunes NRS Ranger Program Analyst; Planning Staff Officer.

Role: Managed the overall Willamette N.F. land and resource management program since 1981.

Norm Barrett, Assistant Biologist

Education: B.A. Botany/Zoology; B.S. Wildlife Biology.

Experience: 9 years with Forest Service as wildlife biologist and technician.

Role: Assisted in the analysis of wildlife data and documention.

Margaret Beilharz, Hydrologist

Education: B.S. Ecosystems Analysis.

Experience: 12 years with Forest Service in Silviculture; District Hydrologist; Assistant Forest Hydrologist.

Role: Adapted analysis methodology for water and soil resources. Provided evaluation of water quality, soil productivity effects.

Elaine Bernat, Cartographic/Planning Technician

Education: B.A. Art; B.L.A./M.L.A. Landscape Architecture.

Experience: 10 years in landscape architecture, graphics, and mapping systems. Assisted in the preparation of the Willamette National Forest 1979/80 viewshed study. Assisted in the development of the data base graphics production and computer maps for use in the DEIS and Forest Plan since 1981.

Role: Assisted in the data management of mapping systems used for Forest Plan documents. Provided graphics support for final documents.

Sara Buckmaster, Transportation Planner

Education: B.S.C.E., Graduate Study in Forest Engineering.

Experience: 10 years with Forest Service as Civil Engineer; Forest Transportation Planner.

Role: Provided technical input as transportation system and effects.

Brad Burmark, Supervisory Operations Research Analyst

Education: B.S. Forest and Range Management, M.S. Forest and Range Management.

Experience: 10 years with Forest Service as Operations Research Analyst, Supervisory Operations Research Analyst. Provided economic analysis and budgets for FEIS and Forest Plan.

Role: Overall coordination of FORPLAN, Implan, and GIS input to planning process.

Peter Eberhardt, Cartographic/Planning Technician

Education: B.S. Geography 1981.

Experience: 8 years with Forest Service as Resource Data Manager (development of the PLOT-7 mapping system).

Role: Managed mapping system and Forest database used to develop the Forest Plan and analysis of alternatives. Coordination production of Forest Plan maps.

Neal Forrester, Strategic Planner

Education: B.S.F., Forest Management; M.S., Forest Management.

Experience: 15 years with Forest Service as Timber Sale Administrator, Silviculturist, Timber Planner, and Planning Team Leader.

Role: Interdisciplinary Team Leader, provided overall leadership and coordination in the development and preparation of the Forest Plan documents.

Miles Hemstrom, Area VI Ecologist

Education: B.A. Biology; Ph.D. Plant Ecology.

Experience: 10 years with Forest Service as Area Ecologist on Willamette and Siuslaw NFs.

Role: Provided input on analysis of vegetative data for old growth determinations and effects of alternatives on ecological systems.

David Hicks, Writer/Editor

Education: B.S. Forest Management/Forestry.

Experience: 20 years with Forest Service in Timber Management, Planning, and Land Management Planning.

Role: Developed analysis of resource effects on roadless areas in Appendix C of FEIS.

Dave Hill, Planning Records Coordinator

Education: B.A.; J.D.

Experience: 10 years with Forest Service as Law Clerk and Land Law Examiner; Personnel Management Specialist; Claims Specialist; Supervisory Program Analyst.

Role: Assisted in documentation of public comments and responses in FEIS. Responsible for planning records systems.

Al Johnson, Forester

Education: B.S. Forest Management.

Experience: 12 years with Forest Service and Bureau of Land Management in land management planning, timber sale preparation and administration, and hydrology.

Role: Provided technicial support for resource data computer analysis, assisted in documentation of water and soil resources.

Charlene R. Johnson, Editorial Assistant and Document Coordination

Education:	College course work in office skills, technical document editing, and computer systems.
Experience:	11 years with Forest Service in timber data processing and editing technical documents.
	23 years in private industry as bookkeeper, office manager, secretary.
Role:	Coordinated document preparation and editing for FEIS.

Robert Longcore, Landscape Architect

Education:	B.S. Landscape Architecture; M.L.A. Landscape Architecture.
Experience:	20 years as Landscape Architect; 4 years Assistant Professor, School of Environmental Design; 16 years with Forest Service in landscape design and recreation management.
Role:	Provide overall input for recreation, visual management and in Forest Planning process. Coordinated input for Wilderness, roadless areas; Wild and Scenic Rivers, and cultural resources for FEIS.

James Mayo, Timber Planner

Education:	B.S. Forest Management/Forestry.
Experience:	16 years with Forest Service as Presale, Silviculture, and Planning Forester; Timber Planning Assistant.
Role:	Adopted methods for timber yields and inventory in Forest Plan modeling. Provided analysis of timber program and vegetation effects in Forest Plan documents.

Allison Reger, Operations Research Analyst

Education:	B.S. Forest Management/Forestry; M.S. Multiresource Management.
Experience:	2 years with Forest Service as operations research analyst.
Role:	Assisted in developing and evaluating FORPLAN model. Used Implan to develop economic inputs used in FEIS.

Patti Rodgers, Public Affairs Specialists

Education:	Undergraduate work in Fine Arts and Sociology; Social Psychology.
Experience:	20 years with Forest Service in Fire, Timber, Silviculture positions including activities at District and Forest levels.
Role:	Coordinated content analysis of public comments on DEIS, produced newsletters for public updates during development of the Forest Plan.

Mike Scanlon, Operations Research Analyst

Education:	B.S. Forest Management; M.S. Forest Economics.
Experience:	6 years with Forest Service in fire/fuels management and silviculture. 3 years as Operations Research Analyst.
Role:	Responsible for developing and running FORPLAN model for analysis displayed in FEIS.

Steven P. Smith, Wildlife Biologist

Education:	B.S. Science and Range Management.
Experience:	10 years with Forest Service as wildlife biologist.
Role:	Adapted methods for analyzing wildlife resource evaluations in the FEIS including big game, Threatened and Endangered Species, and spotted owl.

Gerald W. Williams, Sociologist

Education:	B.S. Sociology; M.S. General Studies Social Science; Ph.D Sociology.
Experience:	11 years with Forest Service as Sociologist. Involvement in the planning process includes the analysis of social-economic values.
Role:	Provided analysis of social effects in FEIS.

FOREST MANAGEMENT TEAM

Forest Supervisor - Michael A. Kerrick

Deputy Forest Supervisor - Mike Edrington

District Rangers

Lynn Burditt - Blue River
David F. Alexander - Detroit
Rick Scott - Lowell
Randy A. Dunbar - McKenzie
Robert Barstad - Oakridge
Herbert L. Wick - Rigdon
Karen Barnette - Sweet Home

Forest Staff Officers

Rolf Anderson - Planning and Programming
Gloria Brown - Public Affairs
Richard Grace - Recreation
Hank Kashdan - Administration
Harold Legard - Watershed/Soil/Range/Wildlife
Bob Leonard - Timber Management
James Mattiazzi - Engineering
Eurial Turner - Fire and Lands

Other Contributors To FEIS

Mary Bowdon - Writer/Editor
Mandy Cole - Writer/Editor
Joan Cully - Document Preparation
Carl Davis - Cultural Resources
Karen Engelhardt - Graphics Assistance
Reino Jarvi - Document Preparation
Daryl Larson - Computer Assistant
Sue Leatherwood - Document Preparation
Hubert Mapes - Fire/Fuels Management
Roy McNary - Computer Assistant
David O'Guinn - Writer/Editor, Document Production
Mike Ragan - Map production
Susan Sater - Wilderness Management
Del Skeesick - Fisheries Biologist

GLOSSARY

Many of the definitions in this glossary are referenced to the following sources. The sources are identified by a number in parentheses following the definition. This number corresponds to the list below. Some other terms will be referenced to Forest Service Manuals (FSM), Forest Service Handbooks (FSH), or other sources which are too numerous to list. Finally, many other definitions are not referenced, but are those in general use on the Forest.

SOURCE LIST

(1) 36 CFR 219 National Forest Management Act Regulations.
(2) Regional Guide for the Pacific Northwest Region, 1984.
(3) SAF Dictionary of Forestry Terms, 1971.
(4) The Random House College Dictionary, Revised Edition, 1975.
(5) Webster's New International Dictionary, 1957.
(6) Wildland Planning Glossary, 1976.
(7) Webster's Third New International Dictionary, 1981.
(8) Wildlife Habitats in Managed Forests, The Blue Mountains of Oregon and Washington, 1979.
(9) A Glossary of Terms Used in Range Management.
(10) Forest Service Manual or Forest Service Handbook.

A

Abnormally heavy storms - Storms with a 10- to 100-year return period. That is, a 10-year storm occurs on the average of once every 10 years, a 20-year storm occurs on the average of once every 20 years, and so forth.

Access - Usually refers to a road or trail route over which a public agency claims a right-of-way for public use; a way of approach. (4)

Acquired lands - Lands added to the National Forest system by purchase, transfer, or donation under authority of the Weeks Law or related acts. Also, lands obtained by the Forest Service by exchange for other acquired lands.

Acre equivalent - When applied to habitat improvement or improvement structures, this term reflects overall habitat benefits derived. It reflects the zone of influence of the habitat improvement for the target species. For example, a single water development for upland game birds occupies very little space but has an acre equivalent of 160 because it serves 160 acres of bird habitat. A single water structure for big game has a value of 640 because it has a larger zone of influence for the more mobile big-game animals.

Acre-foot - A measure of water or sediment volume, equal to the amount which would cover an area of one acre to a depth of one foot (i.e., 43,560 cubic feet or 325,851 gallons). (6)

Activity - An action, measure or treatment undertaken that directly or indirectly produces, enhances, or maintains forest and rangeland outputs, or achieves administrative or environmental quality objectives (FSM 1309, Management Information Handbook). An activity can generate multiple outputs. (2)

Activity fuels - Fuels generated or altered by a management activity. (10)

Administrative unit - An area under the administration of one line officer, such as a District Ranger, Forest Supervisor, or Regional Forester. (6)

Age class - An interval, usually 10 to 20 years, into which the age ranges of vegetation are divided for classification or use. (3)

Age group distribution - Age class distribution; the location and/or proportionate representation of different age classes in a forest. (3)

Airshed - A geographic area that, because of topography, meteorology, and climate, shares the same air. (2)

Allocation - See *Land use allocation* or *Resource allocation*.

Allotment - See *Range allotment*.

Allowable sale quantity (ASQ) - The quantity of timber that may be sold, from the area of suitable land covered by the Forest Plan, for a time period specified by the Plan. This quantity is usually expressed on an annual basis as the "average annual allowable sale quantity." (6) (1)

All terrain vehicle (ATV) - A vehicle characterized by its ability to negotiate most kinds of terrain, by virtue of traction devices such as wide tracks, large, low-pressure rubber tires and/or four-wheel drive.

Alternative - One of several policies, plans, or projects proposed for decision making. (2) (10)

Amenity - An object, feature, quality, or experience that gives pleasure or is pleasing to the mind or senses. The terms "amenity values" or "amenity resources" are typically used in land management planning to describe those resources for which monetary values are not or cannot be established (such as clean air and water, or scenic quality).

Anadromous Fish - Those species of fish that mature in the sea and migrate into streams to spawn. Salmon, steelhead, and searun cutthroat trout are examples.

Analysis area - A delineated area of land subject to analysis of: (1) responses to proposed management practices in the production, enhancement, or maintenance of forest and rangeland outputs and environmental quality objectives, and (2) economic and social impacts. (FSM 1905) Tracts of land with relatively homogeneous characteristics in terms of the outputs and effects that are being analyzed in the FORPLAN model. (SEIS Appendix B, Section entitled Analysis Areas)

Analysis of the Management Situation (AMS) - A determination of the ability of the planning area to supply goods and services in response to society's demand for those goods and services. (1)

Animal Unit Month (AUM) - The amount of forage required by one mature (1,000 lb.) cow or its equivalent for one month (based upon average forage consumption of 26 lbs. dry matter per day). (6)

Animal Month is one month's use and occupancy of the range by one animal. For grazing fee purposes, it is a month's use and occupancy of range by one weaned or adult cow with or without calf, bull, steer, heifer, horse, burro, or mule, or 5 sheep or goats. Forage consumption by other animals is converted to AUM's from animal months by the following factors:

mature cow	=	1.0 AUM	mature sheep	=	.2 AUM
one horse	=	1.2 AUM's	cow/calf	=	1.32 AUM
ewe/lamb	=	.3 AUM			

Annual sale quantity - The quantity of timber that may be sold annually from the area of suitable land covered by the Forest Plan.

Anomalies - A deviation from the common rule, type, or form. An incongruity or inconsistency. (4)

Appropriated Funds - Monies authorized by an act of Congress which permit Federal agencies to incur obligations and to make payments out of the U.S. Treasury for specified purposes.

Aquatic ecosystems - Stream channels, lakes, marshes or ponds, and the plant and animal communities they support.

Aquifer - A geological formation or structure that contains water in sufficient quantity to supply needs for water development. (6)

Artifact - An object made or modified by humans. (4)

Assigned values - Monetary values given to nonmarket resources, based on estimates from comparable market transactions. For example, the benefits of dispersed recreation are given assigned monetary values for their production.

Available forest land - Land which has not been legislatively or administratively withdrawn by the Secretary of Agriculture or Forest Service Chief from timber production.

Average Daily Traffic (ADT) - The average 24-hour volume of traffic, being the total volume of traffic during a stated period divided by the number of days in that period. (6)

B

Background - In visual management terminology, refers to the visible terrain beyond the foreground and middleground where individual trees are not visible, but are blended into the total fabric of the stand. Also a portion of a view beyond three to five miles from the observer, and as far as the eye can detect objects. (6)

Bald Eagle Management Areas (BEMA's) - Areas managed for the protection of the threatened and endangered bald eagle. BEMA's provide nesting and roosting habitat for the bird on each plot.

Basal area - The area of the cross-section of a tree stem near the base, generally at breast height and inclusive of bark. (3)

Base sale schedule - A timber sale schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than the long-term sustained yield capacity. (This definition expresses the principle of nondeclining flow.) (1)

Basic resource - One of the principal resources; a resource upon which the production of other resources is dependent; e.g., the production of vegetation is dependent upon basic resources such as soils and water.

Benchmark - The analytical basis from which the alternatives were developed. The use of assessed land capability as a basis from which to estimate the effects of alternative patterns of management on the land. (6)

Benchmark - Reference points that define the bounds within which feasible management alternatives can be developed. Benchmarks may be defined by resource output or economic measures.

Benefit (Value) - Inclusive terms used to quantify the results of a proposed activity, project or program expressed in monetary of nonmonetary terms. (10) Also:

1. *Direct benefit.* A primary benefit that responds to specified objectives of the policy, program, project, or expenditure. (10)

2. *Induced benefit.* A primary benefit that is incidental to the objectives of the policy, program, project, or expenditure. (10)

3. *Primary benefit.* A benefit accruing to resource owners from a primary output and that may be direct or induced or may be a residual asset. Primary benefits are components of net public benefits. (10)

4. *Secondary benefit.* A benefit accruing to parties other than the resource owners, including effects on local, Regional, and national economies and on consumers of outputs. Secondary benefits are not necessarily included in net public benefits. (10)

Benefit/Cost ratio - A measure of economic efficiency computed by dividing total discounted primary benefits by total discounted economic costs. (10)

Best Management Practices - A practice or combination of practices that is determined by a State (or designated areawide planning agency) after problem assessment, examination of alternative practices, and appropriate public participation, to be the most effective, practicable (including technological, economic, and institutional considerations) means of preventing or reducing the amount of pollution generated by nonpoint sources to a level compatible with water quality goals (Federal Register, Volume 40, No. 230 dated 11/28/75).

Big game - Large mammals hunted for sport. On the National Forest these include animals such as deer, elk, antelope, and bear. (8)

Big game summer range - A range, usually at higher elevation, used by deer and elk during the summer. Summer ranges are usually much more extensive than winter ranges. (8)

Big game winter range - A range, usually at lower elevation, used by migratory deer and elk during the winter months; usually more clearly defined and smaller than summer ranges. (8)

Biological control - A method to control insect populations or tree diseases through the use of applied technology. Also used in noxious plant control. (3)

Biological Growth Potential - The average net growth attainable in a fully stocked natural forest stand. (1)

Biological potential - The maximum production of a selected organism that can be attained under optimum management. (8)

Biomass - The total quantity (at a given time) of living organisms of one or more species per unit of space (species biomass), or of all the species in a biotic community (community biomass).

Board foot (BF) - The amount of wood equivalent to a piece of wood one foot by one foot by one inch thick. (3)

Board foot/cubic foot conversion ratio - Both board foot and cubic foot volumes can be determined for timber stands. The number of board feet per cubic foot of volume varies with tree species, diameter, height, and form factors. A specific factor by species is applied to the cubic foot FORPLAN outputs to give board foot estimates.

Broadcast Burn - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for reduction of fuel hazard or as a silvicultural treatment, or both.

Browse - Twigs, leaves, and young shoots of trees and shrubs on which animals feed; in particular, those shrubs which are used by big game animals for food. (6)

Brush - A growth of shrubs or small trees usually of a type undesirable to livestock or timber management.

Bureau of Land Management (BLM) - An agency within the Department of the Interior, with land management responsibility for the Public Domain lands.

Buyback and Defaulted Timber Sales - In 1984, the Federal Timber Payment Modification Act was enacted by Congress. It allowed private companies to return timber sales not economical to harvest after payment of a fee to the government. The sales returned under the conditions of this Act are

known as "buyback" sales. A timber sale is considered "defaulted" if it is not in compliance with the terms of the contract by the contract termination date. Defaulted sales are also returned to the government.

C

Cable logging - Refers to methods used to skid or pull logs to a central landing or collection area by a cable connected to a remote power source. (6)

Canopy - The more-or-less continuous cover of branches and foliage formed collectively by the crown of adjacent trees and other woody growth. (3)

Capability - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices and at given levels of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils and geology, as well as the application of management practices, such as silviculture or protection from fire, insects, and disease. (1)

Capability area - Geographic delineations used to describe characteristics of the land and resources in integrated forest planning. Capability areas may be synonymous with ecological land units, ecosystems, or land response units. (10)

Capital formation - As used in IMPLAN is defined as the value of purchases from sectors both inside and outside the Region used by individuals, governments, and industries in the area as investment (land, plant, and equipment used in production processes). (10)

Capital Investment - An input that increases the stock of natural or manmade resources (assets) needed to maintain or increase the flow of outputs in the future. Benefits resulting from capital investments are normally recouped in excess of 1 year. (10)

Capital investment - Activities that create or improve capital assets to obtain benefits occurring during several planning periods. (10)

Carrying capacity - 1) The number of organisms of a given species and quality that can survive in, without causing deterioration of, a given ecosystem through the least favorable environmental conditions that occur within a stated interval of time. 2) In recreation, refers to the number of people that can occupy an area for a given social and experience goal. 3) In range, refers to the maximum stocking rate possible on a given range without causing deterioration to vegetation or related resources. (3)

Cavity - The hollow excavated in trees by birds or other natural phenomena; used for roosting and reproduction by many birds and mammals. (2)

Channel or Stream Scour - Erosion of the channel bottom caused by high flows of water, loss of channel stability, or debris torrents.

Characteristic landscape - In reference to the USDA Forest Service visual management system; the overall impression created by a landscape's unique combination of visual features (land, vegetation, water, structures), as seen in terms of form, line, color and texture; synonymous with "visual landscape character." (6)

Chargeable Volume - All timber volume included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on regional utilization standards. (10)

Clearcutting - The cutting method that describes the silviculture system in which the old crop is cleared over a considerable area at one time. Regeneration then occurs from (a) natural seeding from adjacent stands, (b) seed contained in the slash or logging debris, (c) advance growth, or (d) planting or direct seeding. An even-aged forest usually results. (3)

Climatic regimes - A generalized climatic classification which applies to a specific land area; generally that area can be expected to experience that kind of climate in any given year.

Climax - The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition. (6)

Climax Species - Those species that dominate a climax stand in either numbers per unit area or biomass.

Closure - An administrative order restricting either location, timing, or type of use in a specific area.

Coastal Douglas-Fir Zone - The area west of the crest of the Cascade Mountain Range in the States of Oregon and Washington.

Code of Federal Regulations (CFR) - A codification of the general and permanent rules published in the Federal Register by the Executive departments and agencies of the Federal Government. (1)

Coho Smolt - Young coho salmon which are ready to migrate to the sea.

Commercial Forest Land - Land that is producing, or is capable of producing, crops of industrial wood and (1) has not been withdrawn by Congress, the Secretary of Agriculture, or the Chief of the Forest Service; (2) land where existing technology and knowledge is available to ensure timber production without irreversible damage to soil productivity or watershed conditions; and (3) land where existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be obtained within 5 years after final harvesting.

Commercial thinning - Any type of tree thinning that produces merchantable material at least equal in value to the direct costs of harvesting. (3)

Commodities - A transportable resource with commercial value; all resource products that are articles of commerce. (6)

Common varieties - Nonmineralized sand, gravel, stone, etc. (See *Mineral materials.*)

Community Cohesion - The degree of unity and cooperation within a community in working toward shared goals and solutions to problems.

Community stability - A community's capacity to handle change without major hardships or disruptions to component groups or institutions. Measurement of community stability requires identification of the type and rate of proposed change and an assessment of the community's capacity to accommodate that level of change. (10)

Compaction - The packing together of soil particles by forces exerted at the soil surface, resulting in increased soil density.

Composite - In reference to planning for special areas under the Land and Water Conservation Act of 1965, an area identified as having unique recreation and/or fish and wildlife values.

Composite Plan - A documented analysis which, at one time was required to justify the use of Land and Water Conservation Funds for acquisition of private lands within a designated composite.

Condition class - 1) Timber: a grouping of timber strata into size-age-stocking classes for Forest planning. 2) Range: one of a series of arbitrary categories used to classify range conditions, usually expressed as excellent, good, fair, or poor. (9)

Congressionally Classified and Designated Areas - Areas that require congressional enactment for their establishment, such as National Wildernesses, National Wild and Scenic Rivers, and National Recreation Areas.

Constraint - In FORPLAN, a limit (either ceiling or floor) which may be placed on the level of inputs to or outputs from a forest.

Consumptive use - A use of resources that permanantly reduces the supply, such as mining. (See also *Nonconsumptive use.*) (6)

Conversion period - The duration of a change from one silvicultural system to another or from one tree species to another. (3)

Core Area - An area (as related to the spotted owl) encompassing at least 300 contiguous acres of old growth suitable for nesting and reproduction. The area consists of a pair's territory, in part, the nest site, and principal roost areas.

Corridor - A linear strip of land identified for the present or future location of transportation or utility rights-of-way within its boundaries. (1)

Costs -

1. *Direct cost.* A cost that directly contributes to the production of the primary outputs of an activity, project, or program. (10)

2. *Economic cost.* Total fixed and variable costs for inputs, including costs incurred by other public parties and, if appropriate, opportunity costs and cost savings. (10)

3. *Fixed cost.* A cost that is commited for the time horizon of planning or the decision being considered. Fixed costs include fixed ownership requirements, fixed protection, short-term maintenance, and long-term planning and inventory costs. (10)

4. *Investment cost.* A cost of creating or enhancing capital assets, including costs of administrative or common-use transport facilities and resource management investments. (10)

5. *Joint cost.* A cost contributing to the production of more than one type of output. (10)

6. *Non-Forest Service cost.* A cost of investment and operating activities paid by cooperators or other non-Forest Service agencies which are part of Forest Service management programs, or which contribute to the outputs included in the analysis. (10)

7. *Opportunity cost.* The value of a resource's foregone net benefits in its most economically efficient alternative use. (10)

8. *Unit cost or cost per unit.* Total cost of production divided by the number of units produced. (10)

9. *Variable cost.* A cost that varies with the level of controlled outputs in the time horizon covered by the planning period or decisions being considered. (10)

Cost, Capital Investment - The cost of manmade structures, facilities, or improvements in natural resources used as inputs in production processes to produce outputs over one or more planning periods. (FSM 1905)

Cost effective - Achieving specified outputs or objectives under given conditions for the least cost. (6)

Cost efficiency - The usefulness of specified inputs (costs) to produce specified outputs (benefits). In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values, but are achieved at specified levels in the least costly manner. Cost efficiency is usually measured using present net value, although use of benefit-cost ratios and internal rate-of-return may be appropriate. (1)

Cost sensitivity analysis - A type of analysis done to estimate how a particular problem's solution would change if the costs were increased or decreased.

Council on Environmental Quality (CEQ) - An advisory council to the President established by the National Environmental Policy Act of 1969. It reviews federal programs for their effect on the environment, conducts environmental studies, and advises the President on environmental matters. (Abstracted from the National Environmental Policy Act of 1969, as Amended.)

Cover/forage ratio - The mixture of cover and forage areas on a unit of land, expressed as a ratio. The optimum cover/forage mix for deer on summer range is 60:40.

Created opening - An opening in the Forest created by the silvicultural practices of: final removal harvest of shelterwood; clearcutting; seed tree cutting; or group selection cutting. (2)

Crown height - In a standing tree, the vertical distance from ground level to the base of the crown, measured either to the lowest live branch whorl, or to the lowest live branch (excluding shoots arising spontaneously from buds on the stem of a woody plant), or to a point halfway between. (3)

Cubic foot (CF) - The amount of timber equivalent to a piece of wood one foot by one foot by one foot. (3)

Culmination of mean annual increment (CMAI) - The age at which average annual growth is greatest for a stand of trees. Mean annual increment is expressed in cubic feet measure, and is based upon expected growth according to the management intensities and utilization standards assumed in

accordance with 36 CFR 219.16(a)(2)(i) and (ii). Culmination of mean annual increment includes regeneration harvest yields and any additional yields from planned intermediate harvests. (10)

Cultural resource - The remains of sites, structures, or objects used by humans in the past--historic or prehistoric. (2)

Cumulative effects or impacts - Cumulative effect or impact is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or nonfederal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. (40 CFR 1508.7 - these regulations use effects and impacts synonymously.)

Cutting cycle - The planned lapse of time between successive cuttings in a stand. (6)

D

Data - Any recorded measurements, facts, evidence, or observations reduced to written, graphical, tabular, or computer form. The term implies reliability, and therefore provides an explanation of source, type, precision and accuracy. (6)

Debris Slide - A shallow landslide of soil, rock, and organic material that occurs on steep slopes.

Debris Torrent - A large debris slide that is charged with water and confined to a steep stream channel. Debris torrents may travel several thousand feet.

Decadent (stands) - Decaying; deteriorating. (4)

Decision Criteria - Essentially the rules or standards used to evaluate alternatives. They are measurements of indicators that are designed to assist a decision maker in identifying a preferred choice from an array of possible alternatives.

Deer winter range - See *Big game winter range.*

De facto outputs - Resource outputs produced from lands not necessarily being managed or allocated for the specific production of these outputs. De facto resource outputs are most commonly recreation and wildlife opportunities. For example, an area may not be allocated to emphasize recreation management and, in fact, may be scheduled for timber harvest in a later decade. However, the area can usually continue to provide recreation opportunities until it is entered for harvesting.

De facto supply - In dispersed recreation, those acres that are available for timber harvests but not entered.

Deferred rotation - Deferred grazing; deferred utilization; withholding livestock from a range to allow the forage to reach a certain stage of growth, stocking, and vigor for those species that govern utilization. (3)

Demand - The amount of an output that users are willing to take at a specified price, time period, and condition of sale. (10)

Demand Analysis - A study of the factors affecting the schedule of demand for an output, including the price-quantity relationship, if applicable. (10)

Department of Energy (DOE) - A department of the Executive branch of the Federal Government which oversees national matters involving the development and use of energy.

Departure - A schedule which deviates from the principle of nondeclining flow by exhibiting a planned decrease in the timber sale and harvest schedule at any time in the future. (10)

Dependent communities - Communities whose social, economic, or political life would change in important respects if market or nonmarket outputs from the National Forests were substantially decreased.

Designated Area (Air Quality) - Those areas delineated in the Oregon and Washington Smoke Management Plans as principal population centers of air quality concern.

Design standard - Approved design and construction specifications used mainly for recreation facilities and roads--includes specified materials, colors, dimensions, etc.

Desirable Residual Vegetation - The remaining vegetation after application of harvest cutting methods that meets management area objectives. The vegetation may be trees, shrubs, grass, or a combination.

Developed recreation - Recreation that requires facilities that, in turn, result in concentrated use of an area. Examples of developed recreation areas are campgrounds and ski areas; facilities in these areas might include roads, parking lots, picnic tables, toilets, drinking water, ski lifts, and buildings. (2)

Developed recreation site - Relatively small, distinctly defined areas where facilities are provided for concentrated public use; e.g., campgrounds, picnic areas, swimming areas, and downhill ski areas. (6)

Diameter at breast height (d.b.h.) - The diameter of a tree measured 4 feet 6 inches above the ground. (6)

Discount rate - An interest rate that represents the cost or time value of money in determining the present value of future costs and benefits. A "real" discount rate is one adjusted to exclude the effects of inflation. (6) (10)

Discounting - An adjustment, using a discount rate, for the value of money over time so that costs and benefits occurring in the future are reduced to a common time, usually the present, for comparison. (6) FSM 1905

Dispersed recreation - A general term referring to recreation use outside developed recreation sites; this includes activities such as scenic driving, hiking, backpacking, hunting, fishing, snowmobiling, horseback riding, cross-country skiing, and recreation in primitive environments. (2)

Distance zone - One of three categories used in the Visual Management System to divide a view into near and far components. The three categories are: (1) foreground, (2) middleground, and (3) background.

Diversity - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. (2) (1)

Douglas-Fir Type - An association of tree species in which Douglas-fir is recognized as one of the principal seral species.

Draft Environmental Impact Statement (DEIS) - The draft statement of environmental effects which is required for major federal actions under Section 102 of the National Environmental Policy Act, and released to the public and other agencies for comment and review. (6)

Dry Ravel - The slow to very rapid gravity driven movement of dry soil. Dry ravel usually occurs when the organic materials in the surface few inches of the soil are severely altered by fire. Dry ravel is most likely where soils are medium to coarse textured and slopes are over 60% gradient.

Duff - Organic matter in various stages of decomposition on the floor of the forest. (4)

E

Early forest succession - The early stage or condition of a plant community that occurs during its development from bare ground to climax. (6)

Economic efficiency - The usefulness of inputs (costs) to produce outputs (benefits) and effects when all costs and benefits that can be identified and valued are included in the computations. Economic efficiency is usually measured using present net value, though use of benefit-cost ratios and rates-of-return may sometimes be appropriate. (10)

Economic growth - Increased economic output in real terms over time. (6)

Economic impacts -

1. *Direct economic impact.* Effects caused directly by forest product harvest or processing or by forest uses. (10)

2. *Indirect economic impact.* Effects that occur when supporting industries sell goods or services to directly affected industries. (10)

3. *Induced economic impact.* Effects that occur when employees or owners of directly or indirectly affected industries spend their income within the economy. (10)

Ecosystem - An interacting system of organisms considered together with their environment; for example, marsh, watershed, and lake ecosystems. (2)

Edge - An area where plant communities meet or where successional stages or vegetation conditions within the plant communities come together. (2)

Effects - Environmental changes resulting from a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused

by the action and are later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density, or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Effects and impacts as used in this FEIS are synonymous. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic quality, historic, cultural, economic, social, or healthy effects, whether direct, indirect, or cumulative. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial. (40 CFR 1508.8, 2)

Electronic sites - Areas designated for the operation of equipment which transmits and receives radio signals (excluding television aerials and antennas) for individual pickup of programming, and passive reflectors.

Employment - Labor input into a production process, measured in the number of person-years or jobs. A person-year is 2,000 working hours by one person working year long or by several persons working seasonally. (10)

Endangered species - Any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range. Plant or animal species identified by the Secretary of the Interior as endangered in accordance with the 1973 Endangered Species Act. (6)

Ending Inventory Constraint - The standing volume left in the inventory at the end of the planning horizon. The constraint insures that there is enough standing inventory at the end of the planning horizon to perpetuate long-term sustained yield capacity harvest levels on a nondeclining flow basis.

Environmental Analysis - A comprehensive evaluation of alternative actions and their predictable short- and long-term environmental effects, which include physical, biological, economic, social, and environmental design factors and their interactions. (2)

Environmental Assessment - The concise public document required by the regulations for implementing the procedural requirements of the National Environmental Policy Act. (40 CFR 1508.9, 2)

Environmental Impact Statement (EIS) - A statement of the environmental effects of a proposed action and alternatives to it. It is required for major federal actions under Section 102 of the National Environmental Policy Act (NEPA), and released to the public and other agencies for comment and review. It is a formal document that must follow the requirements of NEPA, the Council on Environmental Quality (CEQ) guidelines, and directives of the agency responsible for the project proposal. (6)

Environmental Protection Agency (EPA) - An agency of the Executive Branch of the Federal Government which has the responsibility for environmental matters of national concern.

Ephemeral draw - A drainage way which conveys surface water for short periods of time in direct response to snowmelt or rainfall runoff.

Erosion - (1) The wearing away of the land surface by running water, wind, ice, or other geologic agents, including such processes as gravitation creep; or (2) detachment and movement of soil or rock

fragments by water, wind, ice, or gravity. The following terms are used to describe different types of erosion:

Accelerated Erosion - Erosion which is much more rapid than natural erosion, with the increase in erosion rate resulting primarily from the influence of human activities, or, in some cases, of other events that expose mineral soil surfaces, such as wildfire.

Gully erosion - The erosion process whereby water accumulates in narrow channels, and over short periods, removes the soil from this narrow area to considerable depths, ranging from 4 inches to as much as 75 to 100 feet.

Rill erosion - An erosion process in which numerous small channels less than 4 inches deep and 6 inches wide are formed.

Sheet erosion - The removal of a fairly uniform layer of soil from the land surface by runoff water.

Estuary - A semiclosed body of water which has a free connection with the open sea. The sea water in an estuary is measurably diluted with fresh water from streams, rivers, or ground water.

Eutrophic - Of habitats, particularly soils and water, that are rich or adequate in nutrients. (3)

Even-aged management - The application of a combination of actions that results in the creation of stands in which trees of essentially the same age grow together. Managed even-aged forests are characterized by a distribution of stands of varying ages (and, therefore, tree sizes) throughout the forest area. The difference in age between trees forming the main canopy level of a stand usually does not exceed 20 percent of the age of the stand at harvest rotation age. Regeneration in a particular stand is obtained during a short period at or near the time that a stand has reached the desired age or size for regeneration and is harvested. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands. (1)

Even-aged stands - Stands in which all trees are of about the same age. (A spread of 10 to 20 years is generally considered one age class.) Cutting methods producing even-aged stands are clearcut, shelterwood, or seed tree systems.

Exchange reserved - Lands which have been added to the National Forest System by exchange under the General Exchange Act for reserved/proclaimed National Forest System Lands.

Existing visual condition (EVC) - An inventory of existing visual impacts as seen from sensitive travel corridors or use areas; measures visual changes to the landscape caused by natural or human activities.

Exports - As used in IMPLAN are defined as outputs or products produced but not consumed or used in production of other outputs in the impact area. Includes both exports to other areas of the U.S. and international exports. (10)

Extensive Forest Management - A low investment level of management on regulated timberlands that requires initial harvest, regeneration, and final harvest. Some precommercial thinning may be done to prevent stagnation and disease buildup.

Extirpation - Eradication; extermination. (5)

F

Fault - A ground surface fracture or fracture zone along which there has been a displacement of one side with respect to the other. (6)

Fault scarp - An abrupt change in surface elevation resulting from earthquake activity. Fault scarps may vary from as little as a few inches to two or three thousand feet.

Fawn rearing habitat - Areas used regularly by female deer for fawn raising; optimum fawning habitat includes low shrubs or small trees under an overstory of about 50% closure, usually located on slopes of less than 15 percent where vegetation is succulent and plentiful in June, and water is available within 183 meters. (8)

Feral - Non-native species, or their progeny, which were once domesticated but have since escaped from captivity and are now living free. (6)

Final cut - See *Final removal harvest.*

Final Environmental Impact Statement - The final version of the statement of environmental effects required for major federal actions under section 102 of the National Environmental Policy Act. It is a revision of the draft environmental impact statement to include public and agency responses to the draft. (6)

Final removal harvest - The removal of the last seed bearers or shelter trees after regeneration is established under a shelterwood system. (6)

Fire management - All activities required for protection of resources from fire and for the use of fire to meet land management goals and objectives. (6)

Fisheries habitats - Streams, lakes, and reservoirs that support fish populations.

Flood plain - The lowland and relatively flat area adjoining inland waters, including, at a minimum, that area subject to a one percent or greater chance of flooding in any given year. (2)

Forage - All browse and nonwoody plants that are available to livestock or game animals and used for grazing or harvested for feeding. (6)

Forb - Any herb other than grass. (7)

Foreground - A term used in visual management to describe the portions of a view between the observer and up to 1/4 to 1/2 mile distant. (6)

Forest and Rangeland Renewable Resources Planning Act of 1974 - An Act of Congress requiring the preparation of a program for the management of the National Forests' renewable resources, and

the preparation of land and resource management plans for units of the National Forest System. It also requires a continuing inventory of all National Forest System lands and renewable resources. (6)

Forest land - Land at least 10 percent occupied by forest trees or formerly having had such tree cover and not currently developed for nonforest use. Lands developed for nonforest use include areas for crops, improved pasture, residential, or administrative areas, improved roads of any width, and adjoining road clearings and powerline clearings of any width. (1) (10)

Forest Program - A forest program is the summary or aggregation of project or activity information that makes up an integrated (multifunctional) course of action for a given level of funding on a National forest that is consistent with the Forest plan.

Forest-Range Environmental Study (FRES) levels - Various range management intensities developed to reflect the degree of range utilization. FRES levels measure the amount of native forage available to livestock for consumption under these different intensities. Developed in a Forest Service report entitled "The Nation's Range Resources -- A Forest-Range Environmental Study," Forest Resources Report No. 19.

Forest Service Handbook (FSH) - For Forest Service use, directives that provide detailed instructions on how to proceed with a specialized phase of a program or activity. (10)

Forest Service Manual (FSM) - A system of manuals which provides direction for Forest Service activities.

Forest system roads - Roads that are part of the Forest development transportation system, which includes all existing and planned roads as well as other special and terminal facilities designated as Forest development transportation facilities. (See arterial roads, collector roads, and local roads.)

Forest Type - A classification of forest land based upon the tree species presently forming a plurality of basal area stocking in live trees.

Formally dedicated area - An area of the Forest set aside for a specific use by virtue of a formal ceremony or congressional designation.

FORPLAN - A linear programming system used for developing and analyzing forest planning activities. (10)

Free-to-Grow - A term used by silviculturists to indicate that trees are free of growth restraints, the most common of which is competing over-topping vegetation.

Fuel break - A zone in which fuel quantity has been reduced or altered to provide a position for suppression forces to make a stand against wildfire. Fuel breaks are designated or constructed before the outbreak of a fire. Fuel breaks may consist of one or a combination of the following: natural barriers, constructed fuel breaks, constructed barriers. (6)

Fuel management - The practice of planning and executing the treatment or control of living or dead vegetative material in accordance with fire management direction. (10)

Fuel treatment - The rearrangement or disposal of natural or activity fuels (generated by management activity, such as slash left from logging) to reduce fire hazard. Fuels are defined as both living and dead vegetative materials consumable by fire.

Fuels - Combustible wildland vegetative materials. While usually applied to above ground living and dead surface vegetation, this definition also includes roots and organic soils such as peat. (10)

Full-service management - Management of developed recreation sites to furnish the full range of amenities and maintenance for the public enjoyment. Management objectives are based on site capacity, site protection needs, seasonal demands for public use, and desired levels of service to enhance visitor's experience and convenience and provide optimum maintenance.

Furbearing species - See *Game species*.

G

Game species - Any species of wildlife or fish for which seasons and bag limits have been prescribed and which are normally harvested by hunters, trappers, and fishermen under state or federal laws, codes, and regulations. (6)

Genetic seedlings - Tree seedlings from a genetically superior seed source. The seeds are collected from trees displaying exceptional form and raised in nurseries before outplanting. The seedlings usually have faster growth rates than naturally regenerated seedlings.

Geomorphology - The science that deals with land and submarine relief features of the earth's surface and seeks a genetic interpretation of them, using the principles of physiography in its descriptive aspects and dynamic and structural geology in its explanatory phases. (6)

Geothermal - Of or pertaining to the internal heat of the earth. (4)

Goal - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad, general terms and is timeless in that it has no specific date by which it is to be completed. Goal statements form the principal basis from which objectives are developed. (2) (1)

Goods -

1. *Nonmarket good*. An output that is not normally exchanged for money in a market. Usually no market has evolved because ownership of the good is not clear, exclusive use is not possible under current laws, or it is not possible to consistently define good. (10)

2. *Public good*. An output for which it is impractical to impose a charge, either because it must be supplied to all if it is supplied to one or because the costs of collection and control exceed likely revenue. (10)

Goods and services - The various outputs, including on-site uses, produced from forest and rangeland resources. (2,1)

Grass/forb - An early forest successional stage where grasses and forbs are the dominant vegetation.

Group selection cutting - See *Uneven-aged silvicultural systems.*

Growing season - That part of the year when temperature and moisture are favorable for vegetation growth.

Guideline - An indication or outline of policy or conduct; i.e., any issuance that assists in determining the course of direction to be taken in any planned action to accomplish a specific objective. (2)

Guzzler - A device for collecting and storing precipitation for use by wildlife or livestock. Consists of an impenetrable water collection area, a storage facility, and a trough from which animals may drink. (9)

H

Habitat - The place where a plant or animal naturally or normally lives or grows. (2)

Habitat Capability - The estimated ability of an area, given existing or predicted habitat conditions, to support a wildlife, fish or plant population. It is measured in terms of potential population numbers.

Habitat diversity - The distribution and abundance of different plant and animal communities and species within a specific area.

Hardwood - A broad-leaved flowering tree.

Harvest Cutting Method - A combination of interrelated actions whereby forests are tended, harvested, and replaced. The combination of management practices used to manipulate the vegetation results in forests of distinctive form and character. Harvest cutting methods are classified as even-aged and uneven-aged.

Harvest dispersion (factor) - The dispersion of cutting units over the land base in order to meet clearcut size limitations, or other resource constraints. An example of a harvest dispersion constraint is: no more than 25 percent of an analysis area may be harvested in one decade.

Headwaters - The upper tributaries of a river. (4)

Herbaceous - An adjective describing seed-producing plants that do not develop persistent woody tissue, but die down to ground level at the end of the growing season.

Hiding cover - Vegetation that will hide 90 percent of an adult deer or elk from the view of a human at a distance of 200 feet or less. The distance at which the animal is essentially hidden is called a "sight distance."

High-site timbered lands - A relative measure of resource productivity.

Historic site - Site associated with the history, tradition, or cultural heritage of national, state, or local interest, and of enough significance to merit preservation or restoration. (6)

Hydrology - The scientific study of the properties distribution and effects of water in the atmosphere, on the earth's surface, and in soil and rocks.

I

ID Team - See *Interdisciplinary team.*

Impacts - See *Effects.*

IMPLAN - A computer-based system used by the Forest Service for constructing nonsurvey input/output models to measure economic input. The system includes a data base for all countries in the U.S. and a set of computer programs to retrieve data and perform the computational tasks for input/output analysis. (10)

Imports - As used in IMPLAN are defined as purchases of products for use in production of other products and for final consumption from outside the impact area. Includes both imports from other areas of the U.S. and international imports. Competitive imports are the same as local domestic products which are not produced in quantities sufficient to meet local demands or which obtain a share of the local market formerly supplied by local producers. Noncompetitive imports are products not produced locally. (10)

Improved genetic stock - Group of plants (trees) that have been improved genetically (4).

Income - Employee compensation, profits, rents, and other payments to households. (10)

Indicator species - See *Management indicator species.*

Indirect outputs - Outputs caused by an action, but which are later in time or farther removed in distance, although still reasonably foreseeable. (See *Effects.*)

Individual (single) tree selection - See *Uneven-aged silvicultural systems.*

Induced outputs - Outputs in the private sector induced by the direct outputs produced on the Forest. (6)

Influence zone - See *Zone of influence.*

Input/output analysis - A quantitative study of the interdependence of a group of activities, based on the relationship between inputs and outputs of the activities. The basic tool of analysis is an input-output model for a given period that shows simultaneously for each economic sector the value of inputs and outputs, as well as the value of transactions within each economic sector. It has especially been applied to estimate the effects of changes in Forest output levels on local economic activity. (3)

Instream flows - A prescribed level (or levels) of streamflow, usually expressed as a stipulation in a permit authorizing a dam or water diversion, for the purpose of meeting National Forest System management objectives.

Integrated pest management - A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are studied and weighed. The information considered in selecting appropriate strategies includes the impact of the unregulated population on various resource values, alternative regulation tactics and strategies, and benefit/cost estimates of those alternative strategies. Regulatory strategies are based on sound silvicultural practices and ecology of the pest-host system, and consist of a combination of tactics such as timber stand improvement plus selective use of pesticides. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable. (2) (1)

Integrated resource management - A management strategy which emphasizes no resource element to the exclusion or violation of the minimum legal standards of others. (FSM 1905)

Intensive grazing management - Grazing management that controls distribution of cattle and duration of use on the range, usually by fences, so parts of the range are rested during the growing season. (See also *Quality extensive management*; *Quality intensive management*.)

Intensive management (intensive forest management) - A high investment level of timber management
that includes use of precommercial thinnings, commercial thinnings, genetically improved stock, and control of competing vegetation. (2)

Interdisciplinary Team (ID Team) - A group of individuals with different training assembled to solve a problem or perform a task. The team is assembled out of recognition that no one scientific discipline is sufficiently broad to adequately solve the problem. (6)

Intermediate cutting - Any removal of trees from a stand between the time of its formation and the regeneration cut. Most commonly applied intermediate cuttings are release, thinning, improvement, and salvage. (6)

Intermingled Ownerships - Lands within the National Forest boundaries or surrounded by National Forest lands that are owned by private interests or other government agencies.

Intermittent Stream - A stream that runs water in most months, but does not run water during the dry season during most years.

Interpretive services - Visitor information services designed to present educational and recreational values to Forest visitors to enhance their understanding, appreciation, and enjoyment of the Forest.

Intertie - A link between two points, objects, or concepts. (5)

Inventory data and information collection - The process of obtaining, storing, and using current inventory data appropriate for planning and managing the Forest. (6)

Irretrievable - Applies to losses of production, harvest, or commitment of renewable natural resources. For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible. (10)

Irreversible - Applies primarily to the use of nonrenewable resources, such as minerals or cultural resources, or to those factors that are renewable only over long time spans, such as soil productivity. Irreversible also includes loss of future options. (10)

Issue - A point, matter, or question of public discussion or interest to be addressed or decided through the planning process. (See also *Public issue.*) (2)

L

Land and Water Conservation Fund (L&WCF) - Funds collected from sales of surplus Government real property, motorboat fuels taxes, recreation use fees, etc. which are available to purchase and develop certain qualifying lands for recreational purposes.

Land class - The topographic relief of a unit of land. Land classes are separated by slope, which coincides with the timber inventory process. The three land classes used in the Fremont National Forest Plan are defined by the following slope ranges: 0 to 40 percent; 40 to 60 percent; and greater than 60 percent.

Land exchange - The conveyance of nonfederal land and/or interests in exchange for National Forest System land or interests in land.

Landform - An area of that is defined by its particular combination of bedrock and soils, erosion processes and climatic influences.

Landing - Any place where round timber is assembled for further transport, commonly with a change of method. (3)

Land management - The intentional process of planning, organizing, programming, coordinating, directing, and controlling land use actions. (6)

Landownership pattern - The National Forest System resource land base, in relation to other land ownerships within given boundaries. (2)

Landscape management - The art and science of planning and administering the use of Forest lands in such ways that the visual effects maintain or upgrade human psychological welfare. The planning and design of the visual aspects of multiple-use land management.

Lands Not Appropriate for Timber Production - Includes lands that: 1) are proposed for resource uses that preclude timber production, such as Wilderness; 2) have other management objectives that limit timber production to the point where management requirements set forth in CFR 219.27 cannot be met; or, 3) are not cost efficient over the planning horizon in meeting forest objectives including timber production. (1)

Lands Not Suited (Unsuitable) for Timber Production - Includes lands that: 1) are not forest land as defined in CFR 219.3; 2) are likely, given current technology, to suffer irreversible resource damage to soils productivity, or watershed conditions; 3) cannot be adequately restocked as provided in 36 CFR 219.27(c)(3); or, 4) have been withdrawn from timber production by an Act of Congress, the Secretary of Agriculture, or the Chief of the Forest Service. In addition, Forest lands other than those that have been identified as not suited for timber production shall be reviewed and assessed prior to formulation of alternatives to determine the costs and benefits of a range of management intensities for timber production. (1)

Lands Suitable for Timber Production - Includes all lands not classified as either Not Suited or Not Appropriate for Timber Production.

Landtype - A portion of the Forest mapped in the Siuslaw National Forest Soil Resource Inventory that has a defined arrangement of specific landforms that reacts to management activities in generally predictable ways. Landtypes range from 60 to 600 acres in size.

Landtype Association - A group of landtypes that make up a large portion of the Forest. The landtypes are sufficiently homogeneous to be considered as a whole for modeling the future outputs and effects of planned management activities. Landtype Associations do not usually follow watershed boundaries and are defined on the basis of general similarities in geology, climate, landform and vegetation. Landtype Associations on the Forest range in size from 14,000 to 93,000 acres.

Land use allocation - The commitment of a given area of land or a resource to one or more specific uses--for example, to campgrounds or wilderness. (6)

Leasable minerals - Coal, gas, oil, phosphate, sodium, potassium, oil shale, sulphur, geothermal steam. Also includes other minerals on acquired National Forest Lands. (6)

Least-cost analysis - Determination of the least cost means of attaining specified results. (10)

Level IV Law Enforcement Officer - A Forest Service employee who has graduated from the Federal Law Enforcement Academy and holds a law enforcement commission signed by the Regional Forester. District Level IV officers generally perform other duties as well as law enforcement.

Lifestyle - The characteristic way people live, indicated by consumption patterns, work, leisure, and other activities. (10)

Linear programming - A mathematical method used to determine the cost-effective allocation of limited resources between competing demands when both the objective (e.g., profit or cost) and the restrictions on its attainment are expressible as a system of linear equalities or inequalities. (6)

Locatable minerals - Those hardrock minerals which can be obtained by filing a claim on Public Domain or National Forest System lands reserved from the Public Domain. In general, the locatable minerals are those hardrock minerals which are mined and processed for the recovery of metals, but may also include certain nonmetallic minerals and uncommon varieties of mineral materials. (6)

Logging residues - See *Slash*.

Long-term sustained yield timber capacity (LTSY) - The highest uniform wood yield from lands being managed for timber production that may be sustained under a specified management intensity, consistent with multiple-use objectives. (1)

M

Management Area - An area with similar management objectives and a common management prescription. (1) (10)

Management concern - An issue, problem, or condition which influences the range of management practices identified by the Forest Service in the planning process. (1)

Management direction - A statement of multiple use and other goals and objectives, and the associated management prescriptions, and standards and guidelines for attaining them. (1)

Management emphasis - That portion of a management scheme which receives the most stress or is of the greatest significance or importance. It may be the resources being produced, or it may be the way in which they are produced.

Management indicator species - A species selected because its welfare is presumed to be an indicator of the welfare of other species using the same habitat. A species whose condition can be used to assess the impacts of management actions on a particular area. (8)

Management Information Handbook (MIH) Codes - An accounting system that labels each Forest activity or budget item with a code to identify that activity in a consistent manner. Normally used for budgeting purposes.

Management intensity - The management practices or combination of management practices and associated costs to obtain different levels of goods and services (1). In FORPLAN management prescriptions, a set of activities designed to accomplish a particular management emphasis (see also *Management prescriptions*).

Management practice - A specific activity, measure, course of action, or treatment. (1)

Management prescription - The management practices and intensity selected and scheduled for application on a specific area to attain multiple use and other goals and objectives (1). In FORPLAN, the combination of a management emphasis and associated management intensities with a variety of timing choices for implementation. (2)

Management Requirement (MR) - Minimum standards for resource protection, vegetation manipulation, silvicultural practices, even-aged management, riparian areas, soil and water diversity, to be met in accomplishing National Forest System goals and objectives. (1)

Marginal timber component - Timber on which the income just equals or could just equal the costs of production under a given form of management. (3)

Market - The processes of exchanging a good or service for money or other goods or services according to a customary procedure. A market may occur in a specific place or throughout an area by individual transactions. (10)

Market area - The area from which a market draws or to which it distributes its goods or services and for which the same general price structure and price influences prevail. (10)

Market value - The unit price of an output normally exchanged in a market after at least one stage of production. Market value is expressed in terms of prices as evidenced by market transactions. (10)

Mass movement - A general term for any of the variety of processes by which large masses of earth material are moved downslope by gravitational forces - either slowly or quickly. (6)

Mature timber - Trees that have attained full development, particularly height, and are in full seed production. (3)

Maximum modification - See *Visual quality objective.*

Mean annual increment of growth - The total volume of a tree or stand of trees up to a given age divided by that age. (2)

Mesotrophic - Habitats, particularly soil and water, of moderate nutrient capacity. (3)

Middleground - A term used in visual management to describe the portions of a view extending from the foreground zone out to 3 to 5 miles from the observer. (6)

Mineral entry - The filing of a mining claim upon public domain or related land to obtain the right to any minerals it may contain. (6)

Mineral entry withdrawal - The exclusion of mining locations and mineral development work on areas required for administrative sites by the Forest Service and other areas highly valued by the public. (6)

Mineral materials - Deposits such as sand, stone, gravel, and clay. (6)

Mineral soil - Weathered rock materials usually containing less than 20 percent organic matter. (6)

Minimum level management - FORPLAN term designating lands that will not be actively managed for timber or forage production. Often, these are lands that have high costs and low benefits associated with their management.

Minimum streamflows - A specified level of flow through a channel that must be maintained by the users of streams for biological, physical, or other purposes.

Mining claim - A portion of the public lands which a miner, for mining purposes, takes and holds in accordance with mining laws. (6)

Mitigation - Mitigation includes: (a) avoiding the impact altogether by not taking a certain action or parts of an action; (b) minimizing impacts by limiting the degree or magnitude of the action and its implementation; (c) rectifying the impact by repairing, rehabilitating, or restoring the affected environment; (d) reducing or elimination the impact over time by preservation and maintenance operations during the life of the action; and, (e) compensating for the impact by replacing or providing substitute resources or environments. (40 CFR Part 1508.20)

Mitigation measures - Actions to avoid, minimize, reduce, eliminate, or rectify adverse impacts of management practices.

Model - A representation of reality used to describe, analyze, or understand a particular concept. A "model" may be a relatively simple qualitative description of a system or organization, or a highly abstract set of mathematical equations. (6)

Modification - See *Visual quality objective.*

Monitoring and evaluation - The periodic evaluation of Forest Plan management practices on a sample basis to determine how well objectives have been met.

Mortality - In wildlife management, the loss in a population from any cause, including hunter kill, poaching, predation, accident, and disease. In forestry, trees in a stand that die of natural causes. (8)

Mountain pine beetle - A tiny black insect, ranging in size from 1/8 to 3/4 inch, that bores its way into a tree's cambium and cuts off its supply of nutrients, thus killing the tree.

Multiple Use - The management of all the various renewable surface resources of the National Forest System so that they are utilized in the combination that will best meet the needs of the American people; making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in use to conform to changing needs and conditions; that some lands will be used for less than all of the resources; and harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land and with consideration being given to the relative values of the various resources; and not necessarily the combination of uses that will give the greatest dollar return or the greatest unit output. (1)

Multiplier - A ratio of a measure of total change in income or employment to the direct income or employment change. The measure to total change may be direct plus indirect change (Type I Multipliers); or direct, indirect, and induced change (Type II Multipliers); or direct, indirect, and interactive increased induced demands based on population increase (Type III Multipliers). (10)

Municipal Watershed - A watershed which provides water for human consumption, where Forest Service management could have a significant effect on the quality of water at the intake point, and that provides water utilized by a community or any other water system that regularly serves: 1) at least 25 people on at least 60 days in a year, or 2) at least 15 service connections. In addition to cities, this includes campgrounds, residential developments, and restaurants. (10)

N

National Direction - Statements of missions, goals, and objectives that guide Forest Service planning. (FSM 1905)

National Environmental Policy Act (NEPA) of 1969 - An Act to declare a National policy which will encourage productive and enjoyable harmony between humankind and the environment, to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of humanity, to enrich the understanding of the ecological systems and natural resources important to the Nation, and to establish a Council on Environmental Quality. (The Principal Laws Relating to Forest Service Activities, Agriculture Handbook No. 453, USDA, Forest Service, 359 pp.)

National Forest Land and Resource Management Plan - A Plan which ". . . shall provide for multiple use and sustained yield of goods and services from the National Forest System in a way that maximizes long-term net public benefits in an environmentally sound manner." (1)

National Forest Management Act (NFMA) - A law passed in 1976 as an amendment to the Forest and Rangeland Renewable Resources Planning Act, requiring the preparation of Regional Guides and Forest Plans and the preparation of regulations to guide that development.

National Forest Systems (NFS) - All National Forest lands reserved or withdrawn from the public domain of the United States, all National Forest lands acquired through purchase, exchange, donation, or other means, the National Grasslands and land utilization projects administered under Title III of the Bankhead-Jones Farm Tenant Act (50 Stat. 525, 7 U.S.C. 1010-1012), and other lands, waters, or interests therein which are administered by the Forest Service or are designated for administration through the Forest Service as a part of the system. (16 U.S.C. 1608)

National Recreation Trails (NRT) - Trails designated by the Secretary of the Interior or the Secretary of Agriculture as part of the National system of trails authorized by the National Trails System Act. National Recreation Trails provide a variety of outdoor recreation uses. (6)

National Register of Historic Places - A listing (maintained by the U.S. National Park Service) of areas which have been designated as being of historical significance. The Register includes places of local and state significance as well as those of value to the Nation. (6)

National Wilderness Preservation System - All lands covered by the Wilderness Act and subsequent Wilderness designations, regardless of the governmental department having jurisdiction.

Natural barrier - A natural feature that restricts livestock or wildlife movements, such as a dense stand of trees or a cliff.

Natural regeneration - Reforestation of a site by natural seeding from the surrounding trees. Natural regeneration may or may not be preceded by site preparation.

Net Cash Flow - The difference between the annual receipts of an alternative and costs required to implement that alternative.

Net public benefits - An expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs), whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index. The maximization of net public benefits to be derived from management of units of the National Forest System is consistent with the principles of multiple use and sustained yield. (1)

Net Receipts - Receipts minus costs.

Net returns to the Treasury, Net cash flow - The difference between the total dollar receipts projected for an alternative and the total budget required to implement the alternative.

Nitrogen-Fixing (Nitrogen Fixation) - Conversion of free nitrogen by plants such as red alder into combined forms useful in nutrient cycles and other functions in the biosphere.

No Action Alternative (Alt. A) - This alternative is the "No Action" alternative required by the National Environmental Policy Act. It analyzes the effects of continuing management under direction established by the Fremont National Forest's 1979 Timber Resource Management Plan, using updated timber resource inventories and yield tables. Acres formerly allocated to old growth and stream-side management are replaced by Management Requirement plots in Alternative A, as mandated by the National Forest Management Act of 1976.

No Change Alternative (Alt. NC) - This alternative would implement the Fremont National Forest Timber Resource Management Plan as provided through the 1978 Klamath Basin Working Circle and the 1979 Lakeview Federal Sustained Yield Timber Resource Final Environmental Impact Statements, using the yield tables and timber resource inventories developed for this 1979 Plan. This alternative does not include all management requirements and would not meet the intent of the National Forest Management Act of 1976.

Nominal value - A monetary value relative to time that does not account for the effects of inflation.

Nonchargeable volume - All volume not included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity. (FSH 2409.13)

Noncommodity outputs - Resource outputs that are not normally bought and sold, or cannot be bought and sold, such as air quality or scenic beauty.

Nonconsumptive use - That use of a resource that does not reduce the supply. For example, nonconsumptive use of water includes hydroelectric power generation, boating, swimming, and fishing. (2)

Nondeclining flow - Where the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than the long-term sustained yield capacity. (1)

Nonforest land - Lands that never have had or that are incapable of having 10 percent or more of the area occupied by forest trees; or lands previously having such cover and currently developed for nonforest use. (6)

Nongame species - Animal species which are not hunted, fished, or trapped.

Nonmarket value - The unit price of a nonmarket output normally not exchanged in a market at any stage before consumption; it is thus necessary to impute nonmarket value from other economic information. (10)

Nonmarket valued outputs - Assessed value of a goods or service which is not traded in the market place and has no market value. Because it is not bought and sold, some measure other than price must be used in establishing the value. (6)

Nonpoint source pollution - Pollution whose source is general rather than specific in location. It is widely used in reference to agricultural and related pollutants-- for example, production of sediments by logging operations, agricultural pesticide applications, or automobile exhaust pollution. (6)

Nonpriced outputs - Nonpriced outputs are those for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value. Subjective nondollar values are given to nonpriced outputs.

No Surface Occupancy - A clause used in mineral leases to prevent activities in sensitive areas. Sometimes results in closure of an area and sometimes has little impact if directional drilling can tap resources underlying restricted area.

Noxious weeds - Undesirable plant species that are unwholesome to the range or to animals. (6)

O

Objective - A concise, time-specific statement of measurable planned results that respond to pre-established goals. An objective forms the basis for further planning to define the precise steps to be taken and the resources to be used in achieving identified goals. (1)

Off-road vehicle (ORV) - Vehicles such as motorcycles, all-terrain vehicles, four-wheel drive vehicles, and snowmobiles. (2)

Old-growth deficit - A forest without the excess volume of mature/overmature old-growth trees that could be used to offset reductions in programmed harvest volume resulting from allocation changes.

Old-growth habitat - Habitat for certain wildlife that is characterized by overmature coniferous forest stands with large snags and decaying logs.

Old-growth stand (old growth) - Any stand of trees 10 acres or greater generally containing the following characteristics: 1) contain mature and overmature trees in the overstory and are well into the mature growth stage; 2) will usually contain a multilayered canopy and trees of several age classes; 3) standing dead trees and down material are present; and 4) evidences of man's activities may be present, but do not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand. (2)

Oligotrophic - Lakes characterized by a low accumulation of dissolved nutrient salts, supporting only sparse plant and animal life, and having a high oxygen content, owing to the low organic content. (4)

Open to entry - With respect to minerals management, lands available to occupy under the mining laws.

Operational costs - Those costs associated with administering and maintaining National Forest facilities and resource programs.

Operational Plan - A document approved by the Forest Supervisor which specifies at the project level, implementation of the management direction established in the Forest Plan. (6)

Opportunity - A proposal that is considered in developing alternative activities, projects or programs where an option exists to invest profitably to improve or maintain a present condition.

Output - A good, service, or on-site use that is produced from forest and rangeland resources. See FSH 1309.11 for forest and rangeland outputs codes and units measure. Examples: X06-Softwood Sawtimber Production MBF; X80-Increased Water Yield - Acre Feet; W01-Primitive Recreation Use RVD's. (FSM 1905)

Output, Market - A good, service, or on-site use that can be purchased at a price. (FSM 1905)

Output, Nonmarket - A good, service, or on-site use not normally exchanged in a market. (FSM 1905)

Overbid - To bid more than the appraised value. (4)

Overgrazing - Continued overuse (year after year) creating a deteriorated range.

Overgrazed Range - A range that has deteriorated and may still be deteriorating from its productive potential due to overgrazing.

Overmature timber - The stage at which a tree declines in vigor and soundness, for example, past the period of rapid height growth. (2)

Overstory - That portion of the trees, in a Forest or in a stand of more than one story, forming the upper or uppermost canopy. (3)

Overuse (overutilization) - Utilizing an excessive amount of the current year's growth which, if continued, will result in overgrazing and range deterioration.

Overwood removal - A harvest method that removes the overstory of a two-story stand and leaves the smaller understory for further treatment (thinning or harvesting).

P

Partial Cut - Covers a variety of silvicultural practices where a portion of the stand is removed and a portion is left.

Partial retention - See *Visual quality objective.*

Particulates - Small particles suspended in the air and generally considered pollutants. (See *Total Suspended Particulates.*) (5)

Perennial stream - A stream that flows year round.

Permittee - Any person or business formally allowed to graze livestock on the land of another person or business (e.g.; on state or federal land). (3)

Personal use - Normally used to describe the type of permit issued for removal of wood products (firewood, post, poles, and Christmas trees) from National Forest land when the product is for home use and not to be resold for profit.

Persons-at-one-time (PAOT) - A recreation capacity measurement term indicating the number of people who can use a facility or area at one time. (2)

Pests - Any animal or plant that, during some portion of its life cycle, inhibits the establishment or growth of some other species of plant or animal favored by man.

Phenology - The science dealing with the influence of climate on the recurrence of such annual phenomena of animal and plant life as bird migrations, budding, etc. (4)

Physiographic province - A Region having a particular pattern of relief features or land forms that differs significantly from that of adjacent Regions. (6)

Planned ignition - A fire started deliberately, and controlled to accomplish a resource management objective.

Planning area - The area of the National Forest System covered by a Regional guide or forest plan. (1)

Planning criteria - Criteria prepared to guide the planning process. Criteria applied to collection and use of inventory data and information, analysis of the management situation, and the design, formulation, and evaluation of alternatives. (1)

Planning horizon - The overall time period considered in the planning process. It spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions which would influence the planning decisions (1). In this FEIS and Forest Plan, the planning horizon is considered to be 15 decades.

Planning period - One decade. The time interval within the planning horizon that is used to show incremental changes in yields, costs, effects, and benefits. (1)

Planning records - The body of information documenting the decisions and activities which result from the process of developing a Forest Plan, revision, or significant amendment.

Plan of Operations - A document required from any person proposing to conduct mineral-related activities which utilize earth moving equipment and which will cause disturbance to surface resources or involve the cutting of trees. (36 CFR 228.4)

Pole/sapling - A Forest successional stage in which trees between five and nine inches in diameter are the dominant vegetation. (See also *Size class*.)

Pole timber - Trees of at least five inches in diameter at breast height, but smaller than the minimum utilization standard for sawtimber. (See also *Size class*.)

Policy - A guiding principle upon which is based a specific decision or set of decisions. (FSM 1905)

Potential yield - (*This term is in reference to the 1979 Timber Resource Plan only*.) Optimum sustained yield of timber harvest volume attainable with intensive forestry on available commercial forest land (forest lands able to produce 20 cubic feet of timber per acre per year or more) while considering the interrelationship with other forest resources and uses. Intensive forestry includes planting only with genetic stock, precommercial thinning, commercial thinning and release. Programmable net salvage volume and volume from marginally economical lands are also included (in reference to 155.2 MMBF per year in the 1979 TM Plan).

Practices - Those management activities that are proposed or expected to occur.

Precommercial thinning - The practice of removing some of the trees less than marketable size from a stand so that the remaining trees will grow faster. (2)

Prehistoric site - An area which contains important evidence and remains of the life and activities of early societies which did not record their history.

Preparatory cut - The removal of trees near the end of a rotation, which permanently opens the canopy and enables the crowns of seed bearers to enlarge, to improve conditions for seed production and natural regeneration. Typically done in the shelterwood system. (3)

Prescribed fire - A wildland fire burning under specified conditions which will accomplish certain planned objectives. The fire may result from either planned or unplanned ignitions. Proposals for use of unplanned ignitions for this purpose must be approved by the Regional Forester. (2)

Prescription - A written direction for harvest activities and regeneration methods.

Present net value (PNV) - The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area. (1)

Preservation - A visual quality objective that allows only for ecological changes. (2)

Price - The unit value of an output expressed in dollars. (10)

Price elasticity - A measure of the sensitivity of the quantity of a good or service exchanged to changes in price. (10)

Priced outputs - Priced outputs are those that are or can be exchanged in the market place. The dollar values for these outputs fall into two categories: market or nonmarket (assigned values).

Price-quantity Relationship - A schedule of prices that would prevail in a market for various quantities of the output exchanged. (10)

Price trend analysis - An analysis done to estimate how a particular FORPLAN solution would change if predicted price trends were increased or decreased.

Primitive recreation - Those types of recreational activities associated with unroaded land -- e.g., hiking, backpacking, cross-country travel. (6)

Proclaimed land - Lands reserved from the Public Domain for National Forest purposes by presidential proclamation. (See also *Reserved Land*)

Program - Sets of activities or projects with specific objectives, defined in terms of specific results and responsibilities for accomplishments. (10)

Program Budget - A plan that allocates annual funds, work force ceilings, and targets among agencies. (10)

Program Budget Level - A single, comprehensive integrated program responsive to the Chief's direction that specifies a level of production attainable from a given investment of dollars and other resources. Each budget level represents a complete, full, and independent package within the criteria and constraints identified. (10)

Programmatic Memorandum of Agreement - An agreement between the USDA Forest Service, Pacific Northwest Region, the Oregon State Historic Preservation Office (SHPO), and the Advisory Council on Historic Preservation on the management of two types of cultural resource sites found on the Forest: Depression-era administrative structures and prehistoric lithic scatters.

Programmed harvest - The amount of timber on the Forest that is scheduled for harvesting. The programmed harvest is based on current demand, funding, and multiple-use considerations.

Project - An organized effort to achieve an objective identified by location, timing, activities, outputs, effects, and time period and responsibilities for executions. (10)

Project Design - The process of developing specific information necessary to describe the location, timing, activities, outputs, effects, accountability, and control of a project.

Public Involvement - A Forest Service process designed to broaden the information base upon which agency decisions are made by (1) informing the public about Forest Service activities, plan, and decisions, and (2) encouraging public understanding about and participation in the planning processes which lead to final decision making. (10)

Public issue - A subject or question of widespread public interest relating to management of the National Forest System. (1)

Public participation - Meetings, conferences, seminars, workshops, tours, written comments, responses to survey questionnaires, and similar activities designed and held to obtain comments from the public about Forest Service planning. (2)

Public Participation Activities - Meetings, conferences, seminars, workshops, tours, written comments, survey questionnaires, and similar activities designed or held to obtain comments from the general public and specific publics.

Q

Quality extensive management (QE) - Range management based on low operating and investment costs per acre. (3)

Quality intensive management (QI) - Range management to obtain a high production of livestock through the best techniques of range management. (3)

R

Range - Land producing native forage for animal consumption, and lands that are revegetated naturally or artificially to provide forage that is managed like native vegetation. (6)

Range allotment - An area designated for use of a prescribed number and kind of livestock under one management plan. (6)

Range Environmental Assessment (REA) - An environmental assessment to determine the condition of the range with regard to suitability for grazing, vegetative cover types, potential vegetative communities, condition of vegetation, soil stability, and forage production and utilization.

Rangeland - Land on which the climax vegetation (potential natural plant community) is predominantly grasses, grasslike plants, forbs, or shrubs suitable for grazing and browsing. It includes natural grasslands, savannas, many wetlands, some deserts, tundra, and certain forb and shrub communities. It also includes areas seeded to native or adapted introduced species that are managed like native vegetation.

Range management - The art and science of planning and directing range utilization so as to secure sustained maximum production of livestock, milk, and/or cut forage, consistent with other uses and conserving natural resources. (3)

Raptors - Predatory birds, such as falcons, hawks, eagles, or owls.

Rate of return - The financial yield per unit cost determined as the rate of interest at which total discounted benefits equal total discounted costs. (Internal rate of return is a similar measure appropriate to the benefits and costs that affect private firms or individuals.) (10)

Real dollar value - A monetary value that compensates for the effects of inflation. (1)

Receipts - Those priced benefits for which money will actually be paid to the Forest Service: recreation fees, timber harvest, mineral leases and special use fees.

Receipt shares - The portion of receipts derived from Forest Service resource management that is distributed to State and county governments, such as the Forest Service 25-percent fund payments. (1)

Record of Decision - A document separate from but associated with an Environmental Impact Statement which states the decision, identifies all alternatives, specifying which were environmentally preferable, and states whether all practicable means to avoid environmental harm from the alternative have been adopted, and if not, why not. (40 CFR 1505.2)

Recreation capacity - The number of people that can take advantage of the recreation opportunity at any one time without substantially diminishing the quality of the experience or the biophysical resources. (2)

Recreation Information Management (RIM) - A computer-oriented system for the organization and management of information concerning recreation use, occupancy, and management of National Forest lands.

Recreation opportunity - The availability of choices for users to participate in the recreational activities they prefer within the settings they prefer.

Recreation Opportunity Spectrum (ROS) - A framework for stratifying and defining classes of outdoor recreation environments, activities, and experience opportunities. The settings, activities, and opportunities for obtaining experiences have been arranged along a continuum or spectrum divided into seven classes: Primitive, Semiprimitive Nonmotorized, Semiprimitive Motorized, Roaded Modified, Roaded Natural, Rural, Urban.

1. **Primitive** - Area is characterized by an essentially unmodified natural environment of fairly large size. Interaction between users is very low and evidence of other users is minimal. The area is managed to be essentially free from evidence of human-induced restrictions and controls. Motorized use within the area is not permitted.

2. **Semiprimitive Nonmotorized** - Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present, but would be subtle. Motorized recreation use is not permitted, but local roads used for other resource management activities may be present on a limited basis. Use of such roads is restricted to minimize impacts on recreational experience opportunities.

3. **Semiprimitive Motorized** - Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions use of local primitive or collector roads with predominantly natural surfaces and trails suitable for motor bikes is permitted.

4. **Roaded Natural** - Area is characterized by predominantly natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidence usually harmonizes with the natural environment. Interaction between users may be moderate to high, with evidence of other users prevalent. Resource modification and utilization practices are evident, but harmonize with the natural environment. Conventional motorized use is allowed and incorporated into construction standards and design of facilities.

Recreation Visitor Day (RVD) - A measure of recreation use, in which one RVD equals twelve visitor hours, which may be aggregated continuously, intermittently, or simultaneously by one or more persons. (2)

Recreational river - See *Wild and Scenic river.*

Reduced service management - Management of developed recreation facilities below optimum maintenance standards.

Reforestation - The natural or artificial restocking of an area with forest trees. (2)

Regeneration - The renewal of a tree crop, whether by natural or artificial means. Also, the young crop itself, which is commonly referred to as reproduction. (2)

Region - An area covered by a Regional guide. See FSM 1221.3 for organizational definitions. (10)

Regional Forester - The Forest Service official responsible for administering a single Region.

Regional Guide - The guide developed to meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974, as amended. It guides all natural resource management activities, and establishes management standards and guidelines for the National Forest System lands within a given Region. It also disaggregates the assigned Regional RPA objectives to the Forests within that Region.

Regulations - Generally refers to the Code of Federal Regulations, Title 36, Chapter II, which covers management of the Forest Service. (2)

Rehabilitation - Action taken to restore, protect, or enhance site productivity, water quality, or other resource values over a period of time.

Release - Freeing trees from competition for light, water, and nutrients by removing or reducing the vegetation growth that is overtopping or closely surrounding them.

Removal cut (final cut) - The removal of the last seed bearers or shelter trees after regeneration is established under a shelterwood method. (6)

Renewable Resources - Resources that are possible to use indefinitely, when the use rate does not exceed the ability to renew the supply.

Renewable Resources Assessment - An appraisal of the Nation's renewable resources that recognizes their vital importance and the necessity for long-term planning and associated program development. The Assessment meets the requirements of Section 3 of the Resources Planning Act and includes analyses of present and anticipated uses, demands, and supplies of the renewable resources; a description of Forest Service programs and responsibilities; and a discussion of policy considerations, laws, and regulations.

Research Natural Area (RNA) - An area set aside by a public or private agency specifically to preserve a representative sample of an ecological community, primarily for scientific and educational purposes. In U.S.D.A. Forest Service usage, Research Natural Areas are areas designated to ensure representative samples of as many of the major naturally-occurring plant communities as possible. (6)

Reserved lands - Lands reserved from the public domain for National Forest purposes, and lands which are added to the National Forest System by exchange for reserved National Forest lands. (See *Proclaimed Land*)

Residual stand - The trees remaining standing after some activity such as selection cutting. (2)

Resource - Anything which is beneficial or useful - be it animal, vegetable, mineral, a location, a labor force, a view, an experience, etc. Resources, in the context of land use planning, thus vary from such commodities as timber and minerals to such amenities as scenery, scenic view points, or recreation opportunities. (6)

Resource allocation - The action of apportioning the supply of a resource to specific uses or to particular persons or organizations. (6)

Resource Allocation Model (RAM) - A mathematical model using linear programming which will allocate land to different management prescriptions and schedule implementation of those prescriptions simultaneously. The purpose of the model is to find a schedule and allocation that meets the goals of the Forest and optimizes some objective function, such as "minimize costs."

Resource Management Plan - A Plan developed prior to the Forest Plan that outlined the activities and projects for a particular resource element independently of considerations for other resources. Such Plans will be superseded by the Forest Plan.

Resource Planning Act (RPA) - The Forest and Rangeland Renewable Resources Planning Act of 1974. Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of the act. (2)

Responsible Line Officer - The Forest Service employee who has the authority to select and/or carry out a specific planning action. (1)

Rest rotation - An intensive system of range management whereby grazing is deferred on various parts of the range during succeeding years, allowing the deferred part complete rest for one year. (6)

Retention - See *Visual quality objective.*

Returns to Counties - The portion of receipts derived from Forest Service resource management that is distributed to State and county governments such as the Forest Service 25 percent fund payments.

Right-of-way (R/W) - An accurately located strip of land with defined width, point of beginning, and point of ending; the area within which the user has authority to conduct operations approved or granted by the landowner in an authorizing document, such as a permit, easement, lease, license, or Memorandum of Understanding. (6)

Riparian - Pertaining to areas of land directly influenced by water. Riparian areas usually have visible vegetative or physical characteristics reflecting this water influence. Stream sides, lake borders, or marshes are typical riparian areas. (3)

Riparian Area - Geographically delineated areas, with distinctive resource values and characteristics, that are comprised of aquatic and riparian ecosystems.

Riparian ecosystem - A transition between the aquatic ecosystem, and the adjacent upland terrestrial ecosystem. Identified by soil characteristics and distinctive vegetation communities that require free or unbound water.

Road - A general term denoting a way for purposes of travel by vehicles greater than 40 inches in width.

1. *Forest Arterial Road.* Provides services to large land areas and usually connects with public highways or other forest arterial roads to form an integrated network of primary travel routes. The location and standard are often determined by a demand for maximum mobility and travel efficiency rather than specific resource management service. It is usually developed and operated for long-term land and resource management purposes and constant service. (10)

2. *Forest Collector Road.* Serves smaller land areas than a forest arterial road and is usually connected to a forest arterial or public highway. Collects traffic from forest local roads and/or terminal facilities. The location and standard are influenced by both long-term multiresource service needs as well as travel efficiency. May be operated for either constant or intermittent service, depending on land use and resource management objectives for the area served by the facility. (10)

3. *Forest Local Road.* Connects terminal facilities with forest collector or forest arterial roads or public highways. The location and standard are usually controlled by specific resource activity requirements rather than travel efficiency needs. (10)

Roaded modified (RM) - A classification of the Recreation Opportunity Spectrum that characterizes a predominately altered environment, allowing for noticeable to strongly-evident management activity.

Roaded natural (RN) - A classification of the Recreation Opportunity Spectrum that characterizes a predominately natural environment with evidence of moderate permanent alterations and resource utilization. Evidence of the sights and sounds of people is moderate, but in harmony with the natural environment. Opportunities exist for both social interaction and moderate isolation from the sights and sounds of people. (2)

Roadless Area - Areas studied during the Roadless Area Review and Evaluation process (RARE II) which are roadless and at least 5,000 acres in size.

Roadless Area Review and Evaluation II (RARE II) - The national inventory of roadless and undeveloped areas within the National Forest and Grasslands. This refers to the second such assessment, which was documented in the Final Environmental Impact Statement of the Roadless Area Review and Evaluation, January 1979. (2)

Rotation - Planned number of years between the formation of a generation of trees and its final harvest at a specified stage of maturity. Appropriate for even-aged management only. (6)

Roundwood products - Logs, bolts, or other round sections cut from trees.

Rural - A Recreation Opportunity Spectrum classification for areas characterized by a substantially modified natural environment. Sights and sounds of people are evident. Renewable resource modification and utilization practices enhance specific recreation activities or provide soil and vegetative cover protection.

S

Sale preparation costs - Costs associated with preparing a timber harvest on Forest Service lands for sale to the public; usually include all administrative costs for developing sale layout, writing an Environmental Assessment and selling the timber sale.

Sale schedule - The quantity of timber planned for sale by time period, from the area of suitable land covered by a Forest plan. The first period, usually a decade, of the selected sale schedule provides the allowable sale quantity. Future periods are shown to establish that long-term sustained yield will be achieved and maintained. (1) For planning purposes, the sale schedule and the allowable sale quantity are synonymous for all periods or decades over the planning horizon. (1)

Salvage cuttings - Intermediate cuttings made to remove trees that are dead or in imminent danger of being killed by injurious agents. (10)

Sanitation cuttings - Intermediate cuttings made to remove dead, damaged, or susceptible trees to prevent the spread of pests or pathogens. (10)

Sanitation-salvage treatment - See Salvage cutting; Sanitation cutting.

Satisfactory Range Condition - On suitable range, forage condition is at least fair, with stable trend, and allotment is not classified PC (basic resource damage) or PD (other resource damage).

PC (Basic Resource Damage)

Allotments will be classified as PC when analysis or evaluation indicates that one ore more of the following conditions exist and livestock use on the allotment is or has been a major factor contributing to this condition.

a. Maximum summer water temperatures are elevated above State Standards or other approved criteria on SMU class I or II streams and this is largely due to the loss of shade-producing vegetation in the allotment.

b. Management-induced instability exceeds 20 percent of the total miles of stream (SMU classes I-IV) in an allotment.

c. Gully development of sufficient size to lower the seasonally saturated zone and change the plant community type is occurring.

d. Soil condition rating on 25 percent or more of Key Areas is rated poor or very poor.

PD (Other Resource Damage)

These allotments may or may not have approved allotment management plans (AMP's), but adverse impacts on resources other than the basic soil and water resources are occurring. These impacts are the result of resource management objectives not being met. An allotment will be classified as PD when 10 percent or more of its area meets this criteria. Damage to vegetation is based on use in excess of that planned.

Sawtimber - Trees containing at least one 12-foot sawlog or two noncontiguous 8-foot logs, and meeting regional specifications for freedom from defect. Softwood trees must be at least 9 inches in diameter and hardwood trees 11 inches in diameter at breast height.

Scarified - Land in which the topsoil has been broken up or loosened in preparation for regenerating by direct seeding or natural seedfall. Also refers to ripping or loosening road surfaces to a specified depth for obliteration or "putting a road to bed." (3)

Scenic areas - Places of outstanding or matchless beauty which require special management to preserve these qualities. They may be established under 36 CFR 294.1 whenever lands possessing outstanding or unique natural beauty warrant this classification. (6)

Scenic River Areas - See *Wild and Scenic river.*

Scheduled timber harvests - Volumes and acres programmed for harvest which are within the allowable sale quantity. This does not include salvage and sanitation harvesting.

Scoping process - A part of the National Environmental Policy Act (NEPA) process; early and open activities used to determine the scope and significance of the issues, and the range of actions, alternatives, and impacts to be considered in an Environmental Impact Statement. (40 CFR 1501.7)

Second growth - Forest growth that has become established following some interference, such as cutting, serious fire, or insect attack, with the previous Forest crop. (6)

Sediment - Earth material transported, suspended, or deposited by water. (6)

Seed tree cutting - Removal in one cut of the mature timber from an area, except for a small number of seed bearers left singly or in small groups. (3)

Seedlings and saplings - Live trees less than five inches in diameter at breast height. (See also *Size class.*) (3)

Selection cutting - The annual or periodic removal of trees (particularly mature trees), individually or in small groups, from an uneven-aged forest, to realize the yield and establish a new crop of irregular constitution. (3)

Semiprimitive motorized (SPM) - A classification of the Recreation Opportunity Spectrum, characterized by a predominantly unmodified natural environment in a location that provides good to moderate isolation from sights and sounds of people, except for those facilities/travel routes sufficient to support motorized recreational travel opportunities which present at least moderate challenge, risk, and a high degree of skill testing. (2)

Semiprimitive nonmotorized (SPNM) - A classification of the Recreation Opportunity Spectrum,characterized by a predominately unmodified natural environment of a size and location that provides a good to moderate opportunity for isolation from sights and sounds of people. The area is large enough to permit overnight foot travel within the area, and presents opportunity for interaction with the natural environment with moderate challenge, risk, and use of a high degree of outdoor skills. (2)

Sensitive species - Plant or animal species which are susceptible or vulnerable to activity impacts or habitat alterations. Those species that have appeared in the Federal Register as proposed for classification or are under consideration for official listing as endangered or threatened species, that are on an official State list, or that are recognized by the Regional Forester as needing special management to prevent placement on Federal or State lists. (2)

Sensitivity analysis - A determination of the effects of varying the level of one or more factors, while holding the other factors constant. (6) (10)

Sensitivity level - A measure of people's concern for the scenic quality of the National Forests. Three sensitivity levels are employed, each identifying a different level of user concern for the visual environment.

Level 1 - Highest sensitivity
Level 2 - Average sensitivity
Level 3 - Lowest sensitivity (2)

Separate Suitability Components (SSC lands) - Those forested lands tentatively suitable for timber production that grow less than 20 cubic feet per acre per year of timber but have greater than ten percent occupancy (trees cover more than ten percent of the acre).

Sequential Upper and Lower Bounds - A FORPLAN term referring to the constraint that sets upper and lower limits by which harvest levels can increase or decrease from decade to decade. This constraint constitutes a departure from nondeclining flow and allows the harvest to rise or fall by decade according to the bounds that are set. (See *Constraint.*)

Seral - A biotic community which is a developmental, transitory stage in an ecologic succession. (6)

Shelterwood - The cutting method that describes the silvicultural system in which, in order to provide a source of seed and/or protection for regeneration, the old crop (the shelterwood) is removed in two or more successive shelterwood cuttings. The first cutting is ordinarily the seed cutting, though it may be preceded by a preparatory cutting, and the last is the final cutting. Any intervening cutting is termed removal cutting. An even-aged stand results. (3)

Silvicultural examination - The process used to gather the detailed in-place field data needed to determine management opportunities and direction for the timber resource within a small subdivision of a Forest area, such as a stand.

Silvicultural system - A management process whereby Forests are tended, harvested, and replaced, resulting in a Forest of distinctive form. Systems are classified according to the method of carrying out the fellings that remove the mature crop and provide for regeneration and according to the type of forest thereby produced. (3) (1)

Silviculture - The art and science of controlling the establishment, composition, and growth of forests. (2)

Single-tree selection - See *Individual (single) tree selection.*

Site index - A numerical evaluation of the quality of land for plant productivity, (6) . . .based on the height of dominant trees in a stand at an arbitrarily chosen age. (3)

Site preparation - 1) An activity (such as prescribed burning, disking, and tilling) performed on a reforestation area, before introduction of reforestation, to ensure adequate survival and growth of the future crop; **or** 2) manipulation of the vegetation or soil of an area prior to planting or seeding. The manipulation follows harvest, wildfire, or construction in order to encourage the growth of favored species. Site preparation may include the application of herbicides; burning, or cutting of living vegetation that competes with the favored species; tilling the soil; or burning of organic debris (usually logging slash) that makes planting or seeding difficult.

Site productivity - Production capability of specific areas of land.

Size class - For the purposes of Forest planning, size class refers to the intervals of tree stem diameter used for classification of timber in the Forest Plan data base.

seedling/sapling = less than five-inch diameter
pole/sapling or pole timber = five-inch to nine-inch diameter
sawtimber = greater than nine-inch diameter

Skidding - A general term for hauling loads by sliding, not on wheels, as developed originally from stump to roadside, deck, skidway, or other landing. (3)

Skyline Logging - A system of cable logging in which all or part of the weight of the logs is supported during yarding by a suspended cable.

Slash - The residue left on the ground after tree felling and tending, and/or accumulating there as a result of storm, fire, girdling or poisoning. It includes unutilized logs, uprooted stumps, broken or uprooted stems, the heavier branchwood, etc. (3)

Small game - Birds and small mammals normally hunted or trapped. (2)

Snag - A standing dead tree.

Socioeconomic - Pertaining to, or signifying the combination or interaction of social and economic factors. (2)

Softwoods - Coniferous trees, usually evergreen, having needles or scalelike leaves.

Soil - The portion of the earth's surface consisting of disintegrated rock and humus. (7)

Soil productivity - The capacity of a soil to produce a specific crop such as fiber or forage under defined levels of management. Productivity is generally dependent on available soil moisture and nutrients, and length of growing season.

Soil resource inventory - See *Soil surveys*.

Soil surveys - Systematic examinations of soils in the field and in laboratories; their description and classification; the mapping of kinds of soil; the interpretation according to their adaptability for various crops, grasses, and trees; their behavior under use or treatment for plant production or for other purposes; and their productivity under different management systems. (6)

Soil texture - The relative proportions of the various soil separates in a soil, described by the classes of soil texture. Twelve basic soil texture classes are recognized, such as "loam." The textural classes may be modified by the addition of suitable adjectives when coarse fragments are present in substantial amounts; for example, "stony loam."

Special Interest Areas - Areas managed to make recreation opportunities available for the understanding of the earth and its geological, historical, archeological, botanical, and memorial features. (6)

Special Management Areas (SMA) - Areas of unusual public interest or other significance, e.g.; wilderness, primitive areas, scenic areas, or archeological areas. SMA's do not require formal designation, however, Special Interest Areas do. (10)

Special Use Permit - A permit issued under established laws and regulations to an individual, organization, or company for occupancy or use of National Forest land for some special purpose.

Stand (tree stand, timber stand) - An aggregation of trees or other vegetation occupying a specific area and sufficiently uniform in species composition, age arrangement, and condition as to be distinguishable from the forest or other vegetation or land cover on adjoining areas. (2)

Stand diversity - Any attribute that makes one timber stand biologically or physically different from other stands. This difference can be measured by, but not limited to: different age classes; species; densities; or non-tree floristic composition.

Stand examination surveys - Procedures to collect data on Forest stands.

Standard - A statement which describes a condition when a job is done properly. Standards show how well something should be done, rather than what should be done. (6)

Standards and Guidelines - Principles specifying conditions or levels of environmental quality to be achieved.

Stocking - The degree of occupancy of land by trees as measured by basal area or number of trees and as compared to a stocking standard; that is, the basal area or number of trees required to fully use the growth potential of the land.

Stream Blockage - Accumulation of soil, rock, and organic material deposited in a stream channel by landslides that prevent fish from moving upstream.

Stream Buffer - Vegetation left along a stream channel to protect the channel or water from the effects of logging, road building, or other management activity. (see vegetation leave area)

Stream class - Classification of streams based on the present and foreseeable uses made of the water, and the potential effects of on-site changes on downstream uses. Four classes are defined:

> Class I - Perennial or intermittent streams that: provide a source of water for domestic use; are used by large numbers of fish for spawning, rearing or migration; and/or are major tributaries to other Class I streams.
>
> Class II - Perennial or intermittent streams that: are used by moderate though significant numbers of fish for spawning, rearing or migration; and/or may be tributaries to Class I streams or other Class II streams.
>
> Class III - All other perennial streams not meeting higher class criteria.
>
> Class IV - All other intermittent streams not meeting higher class criteria. (10)

Streamflow - The flow of water, generally with its suspended load, down a well-defined water course. (6)

Streamside Management Unit (SMU) - An area of varying width adjacent to a stream where practices that might affect water quality, fish, and other aquatic resources are modified to meet water quality goals, for each class of stream. The width of this area will vary with the management goals for each class of stream, characteristics of the stream and surrounding terrain, and the type and extent of the planned activity.

Stream Structure - The arrangement of logs, boulders, and meanders which modify the flow of water, thereby causing the formation of pools and gravel bars in streams. Generally, there is a direct relationship between complexity of structure and fish habitat. Complex structure is also an indication of watershed stability.

Stumpage (stumpage value) - The value of timber as it stands uncut, in terms of an amount per unit of volume. (6)

Substantive comment - A comment that provides factual information, professional opinion, or informed judgment germane to the action being proposed. (10)

Successional stage - A stage or recognizable condition of a plant community that occurs during its development from bare ground to climax; for example, coniferous forests in the Blue Mountains progress through six recognized stages: grass-forb; shrub-seedling; pole-sapling timber; young timber; mature timber; old-growth timber. (2)

Suitability - The appropriateness of applying certain resource management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices. (1) (2) (FSM 1905)

Suitable Forest land - Land to be managed for timber production on a regulated basis.

Super pits - Quarry sites that initially contain at least 100,000 cubic yards of better-than-average quality road-surfacing material, usually basalt or andesite.

Supply - The amount of an output that producers are willing to provide at the specified price, time period, and condition of sale.

Supply Schedule (Curve) - A schedule of amounts of an output that producers are willing to provide at a range of prices, at a given point in time and condition of sale. (See Price-Quantity Relationship.)

Suppression - The process of extinguishing or confining fire. (2)

Sustained-Yield of Products and Services - The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System without impairment of the productivity of the land. (1) (6)

T

Technology change - A change in the relationship between inputs and outputs in a production process resulting from the implementation of new technology, or a new application of existing technology. (10)

Tentatively suitable Forest land - Forest land that is producing or is capable of producing crops of industrial wood and: (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; (c) existing technology and knowledge, as reflected in current

research and experience, provides reasonable assurance that it is possible to restock adequately within five years after final harvest; and (d) adequate information is available to project responses to timber management activities.

The Nature Conservancy (TNC) - A private organization whose primary function consists of the acquisition of land which The Nature Conservancy believes should be under management by a public agency. The land usually has some specific environmental or conservation value attached to it; such as a piece of land which fits one of the ecological niches identified as needing to be included in the Research Natural Area program, or has some unique values for wildlife management.

Thermal cover - Cover used by animals to ameliorate effects of weather.

Thinning - A felling made in an immature stand primarily to maintain or accelerate diameter increment and also to improve the average form of the remaining trees without permanently breaking the canopy. An intermediate cutting. (3)

Threatened and Endangered (T&E) species - See *Threatened*; see *Endangered*.

Threatened species - Those plant or animal species likely to become endangered species throughout all or a significant portion of their range within the foreseeable future. (See also Endangered species.) (2)

Tiering - Refers to the coverage of general matters in broader environmental impact statements (such as National program or policy statements) with subsequent narrower statements or environmental analyses (such as Regional or Basin-wide program statements, or ultimately, site-specific statements) incorporating, by reference, the general discussions and concentrating solely on the issues specific to the statement subsequently prepared. (40 CFR 1508.28)

Timber classification - Forest land is classified under each of the land management alternatives according to how it relates to the management of the timber resource. The following are definitions of timber classifications used for this purpose.

1. *Nonforest*--Land that has never supported forests and land formerly forested where use for timber production is precluded by development or other uses.

2. *Forest*--Land at least 10-percent stocked (based on crown cover) by forest trees of any size, or formerly having had such tree cover and not currently developed for nonforest use.

3. *Suitable*--Commercial forest land identified as appropriate for timber production in the forest planning process.

4. *Unsuitable*--Forest land withdrawn from timber utilization by statute or administrative regulation (for example, wilderness) or identified as not appropriate for timber production in the forest planning process.

Timber harvest schedule - See *Sale schedule*.

Timber Management Resource Plan (TM Plan) - A functional resource plan completed in 1979 which established a sale volume to be sold each year based upon an analysis of the most recent resource inventories. This plan was an integrated plan which considered implications to other resources on the Forest.

Timber production - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees to be cut into logs, bolts, or other round sections for industrial or consumer use. For purposes of Forest planning, the term "timber production" does not include production of fuelwood or harvest of unsuitable lands. (1) (2)

Timber Sale Program Quantity - The volume of timber planned for sale during the first decade of the planning horizon. It includes the allowable sale quantity (chargeable volume) and any additional material (nonchargeable volume) planned for sale. Expressed as the average for the first decade.

Timber stand improvement (TSI) - Measures such as thinning, pruning, release cutting, prescribed fire, girdling, weeding, or poisoning of unwanted trees aimed at improving the growing condition of the remaining trees. (2)

Topography - The configuration of a surface including its relief, elevation, and the position of its natural and human-created features. (6)

Total Suspended Particulates (TSP) - Any finely divided material (solid or liquid) that is airborne with an aerodynamic diameter smaller than a few hundred micrometers.

Tractor logging - Any logging method which uses a tractor as the motive power for transporting logs from the stumps to a collecting point--whether by dragging or carrying the logs. (3)

Tradeoff - The combination of benefits and costs which are gained and lost in switching between alternative courses of action. Trade-offs include only those portions of benefits and costs which are not common to all alternative courses of action under consideration. (6)

Transitory range - Land that is suitable for grazing use of a nonenduring nature over a period of time; often found in the openings created by timber harvesting activities. For example, on particularly disturbed lands, grass may cover the area for a period of time before being replaced by trees or shrubs not suitable for forage. (6)

Turbidity - The degree of opaqueness, or cloudiness, produced in water by suspended particulate matter, either organic or inorganic. Measured by light filtration or transmission and expressed in Jackson Turbidity Units (JTU's).

U

Understory - The trees and other woody species growing under a more-or-less continuous cover of branches and foliage formed collectively by the upper portion of adjacent trees and other woody growth. (6)

Undeveloped Area - Portion of the National Forest that is essentially unroaded.

Uneven-aged Management - The application of a combination of actions needed to simultaneously maintain continuous high-forest cover, recurring regeneration of desirable species, and the orderly growth and development of trees through a range of diameter or age classes to provide a sustained yield of forest products. Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes. Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection. (1)

Uneven-aged silviculture systems - The combination of actions that result in the creation of forests or stands of trees, in which trees of several or many ages grow together. Cutting methods that develop and maintain uneven-aged stands are individual tree and group selecting cutting methods:

> Individual tree selection cutting - The removal of selected trees of all size classes on an individual basis.
>
> Group selection cutting - The removal of all trees in groups for regeneration purposes. The size of the group will be small enough in area that all subsequent regeneration will be influenced by the surrounding uncut stand. Cuts are generally .25 - 2.0 acres in size.

Unplanned ignition - A fire started at random by either natural or human causes, or a deliberate incendiary fire.

Unsatisfactory Range Condition - Allotment does not meet criteria for satisfactory condition. (See Satisfactory Range condition.)

Utility corridor - A strip of land, up to approximately 600 feet in width, designated for the transportation of people, energy, commodities, and communications by: railroad, state highway, electrical power transmission (66 KV and above), and/or oil, gas, and coal slurry pipelines 10 inches in diameter and larger; and telecommunication cable and electronic sites for interstate use. (1)

Utilization standards - Standards guiding the projection of timber yields and the use and removal of timber. The standards are described in terms of minimum diameter at breast height, minimum length, and percent soundness of the wood, as appropriate. (1)

V

Variety Classes - Variety Classes are obtained by classifying the landscape into different degrees of variety. This determines those landscapes which are most important and those which are of lesser value from the standpoint of scenic quality.

The classification is based on the premise that all landscapes have some value, but those with the most variety or diversity have the greatest potential for high scenic value.

There are three variety classes which identify the scenic quality of the natural landscape:

Class A - Distinctive
Class B - Common
Class C - Minimal

Vegetation Leave Area - Area of land in which vegetation is left undisturbed in order to provide shade and organic debris to streams, or to prevent the acceleration of natural erosion processes. No regulated timber harvest is planned in these areas.

Vegetative management - Activities designed primarily to promote the health of the crop forest cover for multiple-use purposes.

Vertical relief - A contour variation of the land surface perpendicular in relation to the surrounding land. (3) (4)

Viable Population - A population which has adequate numbers and dispersion of reproductive individuals to ensure the continued existence of the species population on the planning area. (FSM 1905)

Viewshed - Portion of the Forest that is seen from a major travel route, or high use location.

Visual absorption capacity (VAC) - The physical capability of the land to support management activities without significantly affecting its visual character. Rated as high, moderate, and low.

HIGH (H) - High visual capability to absorb change.
MODERATE (M) - Moderate visual capability to absorb change.
LOW (L) - Low visual capability to absorb change.

Visual quality objective (VQO) - Categories of acceptable landscape alteration measured in degrees of deviation from the natural-appearing landscape.

Preservation (P) - Ecological changes only.

Retention (R) - Management activities should not be evident to the casual Forest visitor.

Partial Retention (PR) - Management activities remain visually subordinate to the characteristic landscape.

Modification (M) - Management activities may dominate the characteristic landscape but must, at the same time, follow naturally established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.

Maximum Modification (MM) - Human activity may dominate the characteristic landscape, but should appear as a natural occurrence when viewed as background.

Enhancement - A short-term management alternative which is done with the express purpose of increasing positive visual variety where little variety now exists. (2)

Visual resource - The composite of basic terrain, geologic features, water features, vegetative patterns, and land use effects that typify a land unit and influence the visual appeal the unit may have for visitors. (2)

W

Water rights - Rights to divert and use water or to use it in place.

Water yield - The measured output of the Forest's streams. (6)

Watershed - The entire land area that contributes water to a drainage system or stream. (6)

Watershed Impact Area - Areas within a watershed that are being affected by harvesting, road building, etc. Impact areas are limited to a percent of the total watershed area by the Standards and Guidelines in Appendix D of the DEIS.

Waterside Management Unit (WMU) - See *Streamside Management Unit.* Identical to SMU, except applies to standing water, i.e., lakes, ponds, reservoirs, etc., rather than streams.

Wetlands - Areas that are inundated by surface or ground water often enough to support, and usually do support, primarily plants and animals that require saturated or seasonally saturated soil conditions for growth and reproduction. (E.O. 11990)

Wild and Scenic river - Those rivers or sections of rivers designated as such by congressional action under the 1968 Wild and Scenic Rivers Act, as supplemented and amended, or those sections of rivers designated as wild, scenic, or recreational by an act of the legislature of the state or states through which they flow. Wild and scenic rivers may be classified and administered under one or more of the following categories:

1. Wild River Areas - Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted.

2. Scenic River Areas - Those rivers or sections of rivers that are free of impoundments, with watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

3. Recreational River Areas - Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past. (2) (6)

Wilderness - Areas designated by congressional action under the 1964 Wilderness Act. Wilderness is defined as undeveloped federal land retaining its primeval character and influence without permanent improvements or human habitation. Wildernesses are protected and managed to preserve their natural conditions, which generally appear to have been affected primarily by the forces of nature with the imprint of human activity substantially unnoticeable; have outstanding opportunities for solitude or a primitive and unconfined type of recreation; are of sufficient size to make practical their preservation,

enjoyment, and use in an unimpaired condition; and may contain features of scientific, educational, scenic, or historical value as well as ecologic and geologic interest. (2)

Wildlife and Fish User Day - Twelve visitor hours which may be aggregated continuously, intermittently, or simultaneously by one or more persons.

Wildfire - Any wildland fire that is not a prescribed fire. (See also *Prescribed fire.*) (2)

Withdrawal - A legislative or administrative order removing specific land areas from availability for certain uses.

Wood fiber production - The growing, tending, harvesting, and regeneration of harvestable trees.

Woody Material - Organic materials necessary for stream channel stability and maintenance of watershed condition. It includes large logs and root wads.

Working circle (WC) - A geographic division of the Forest created for administrative or marketing purposes. In this document, the area that is not part of the Lakeview Federal Sustained Yield Unit is sometimes referred to as the Klamath Basin Working Circle and the Lakeview Unit may be referred to as the Lakeview Working Circle. (3)

Working group - A term used for planning purposes to identify and group the major commercial tree species harvested from the Forest. The Fremont National Forest recognizes three working groups: the Pine-Associated working group includes stands of white fir with inclusions of ponderosa pine, incense cedar, lodgepole pine, western white pine, or sugar pine; the Ponderosa Pine working group includes stands which are predominately ponderosa pine; the Lodgepole Pine working group is made up of stands dominated by lodgepole pine. These vegetative classifications are based on the vegetative potential of a site and not necessarily the actual vegetative occupancy of the site. Working groups are further stratified by productivity potential, such as "ponderosa pine-high" and "ponderosa pine-low".

X, Y, Z

Xeric - A dry soil moisture regime. Some moisture is present but does not occur at optimum levels for plant growth. Irrigation or summer fallow is often necessary for crop production. (3)

Yarding - Hauling timber from the stump to a collection point. (2)

Yield tables - Tables that estimate the level of outputs that would result from implementing a particular activity. Usually referred to in conjunction with FORPLAN input or output. Yield tables can be developed for timber volumes, range production, soil and water outputs, and other resources.

Zone of influence - The geographic area whose social, economic and/or environmental condition is significantly affected by changes in Forest resource production or management.

APPENDIX A

ISSUES, CONCERNS, AND OPPORTUNITIES

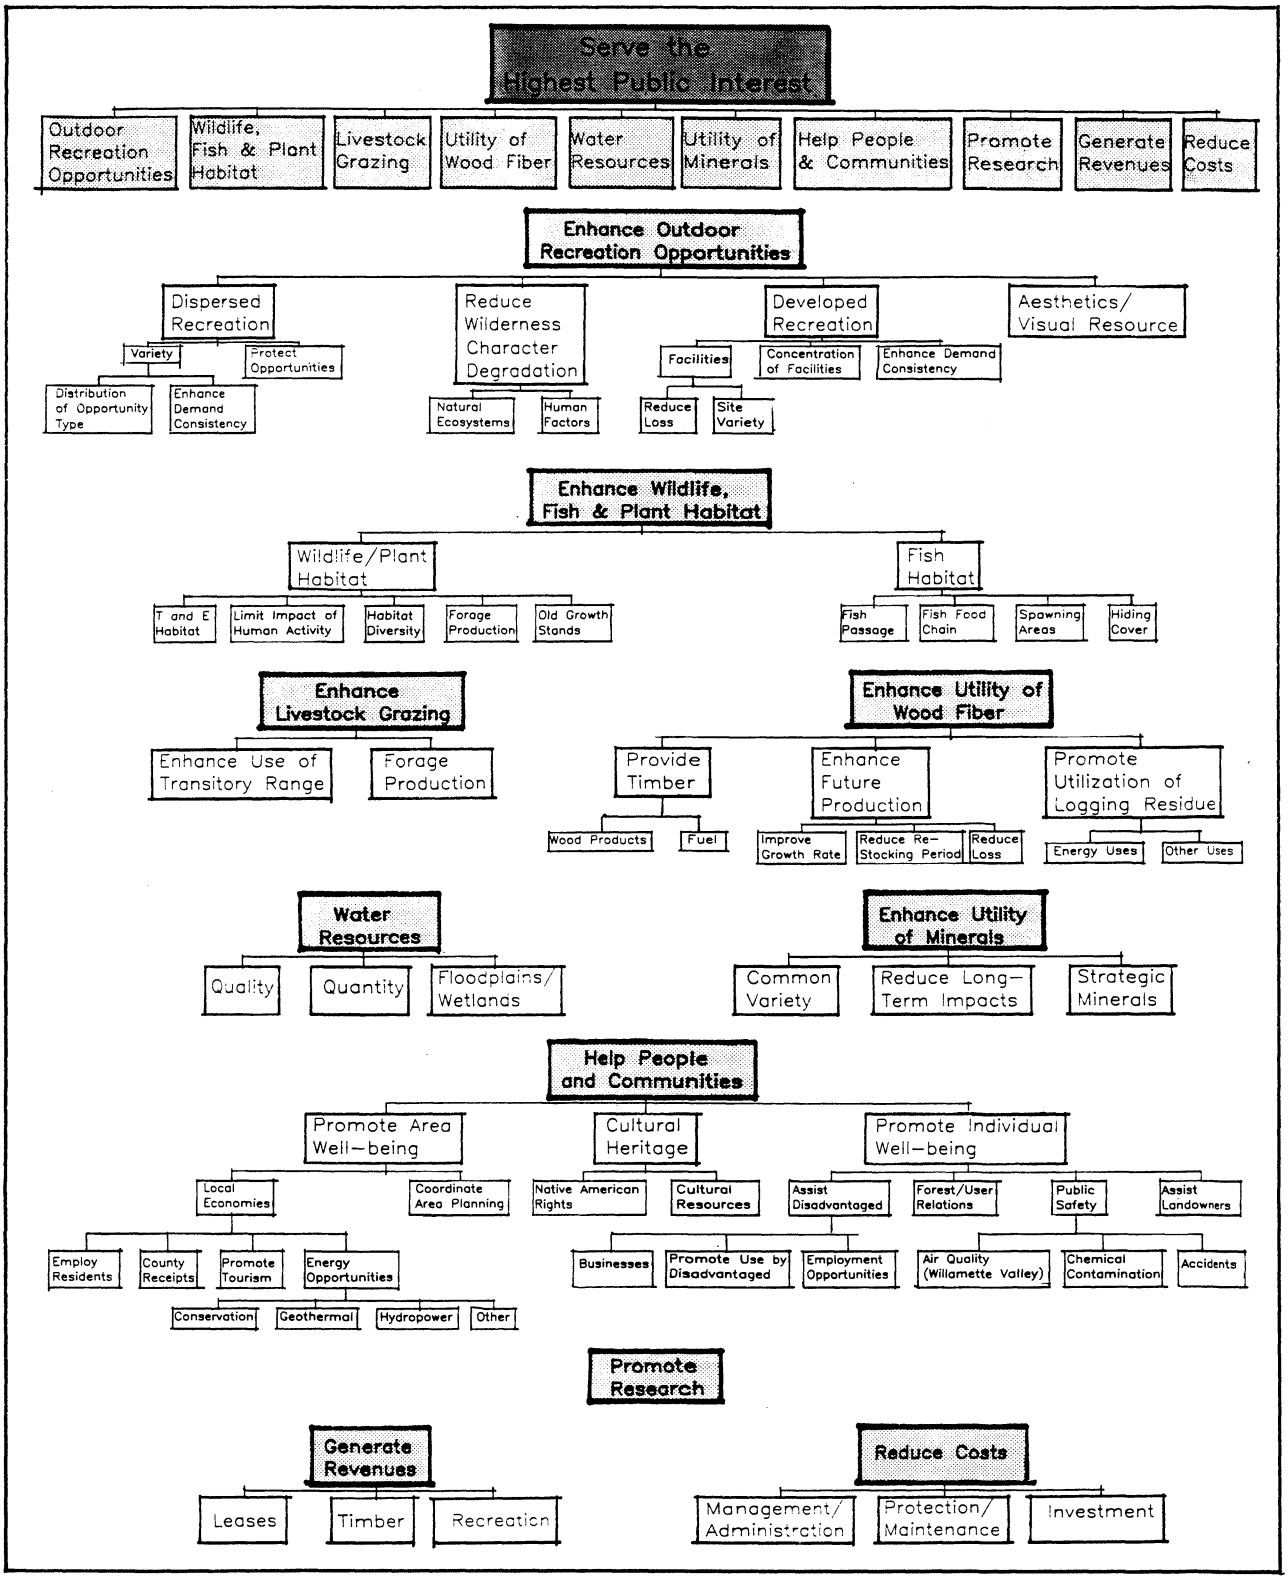
INTRODUCTION

This appendix discusses the:

- Process used to identify the issues, concerns, and opportunities (ICOs) through publication of the Draft Environmental Impact Statement (DEIS).

- Relationships among resources within and between key issues, human interests affected by varying responses to those key issues, refinements and changing focus of public and internal interest about five key issues during the interval between publication of the DEIS and Final Environmental Impact Statement (FEIS); the location in the FEIS and Land and Resource Management Plan (LRMP) where the issues are addressed; and the indicators which can reasonably be used to judge responsiveness to the issues.

- Consultation with others.



The first section is the description of the ICO identification process through publication of the DEIS. This section addresses: how issues were formulated; how their importance and weight were assessed; the criteria used to determine the capability of the Forest Plan to address the issues; the validation and revision of the objectives hierarchy; and a general description of the facets to the issues which could be addressed through allocation of resources available to the Forest.

The second section discusses the major issues and their disposition. It contains three subsections. The first subsection discusses in greater depth certain "key" or major issues which were of relatively greater importance in the selection of a preferred alternative. Those key issues are explored in terms of the relationships between resources both within and between the key issues, as well as in terms of the competing human interests served by varying management responses to those issues. The second subsection briefly discusses refinements to five of the key issues resulting from public and internal input during the interval between the DEIS and FEIS. The third subsection directs the reader to those chapters within the FEIS and LRMP where the issues are given intensive treatment. It also displays the principal indicators and the quantitative measures which can be used to judge responsiveness to the key issues and economics.

The third section describes outreach made to consult with other agencies, groups, and Indian tribes which was in addition to general public involvement activities. These contacts were made because these agencies, groups, and tribes were believed to have special interest or expertise in the forest planning process.

Appendix A bears a special relationship to Appendix I. Readers are encouraged to consult Appendix I for a more complete understanding of the range of the issues, concerns, and opportunities the public believes faces the management of this Forest.

Issues, Concerns, And Opportunities Identification Process

The process of issue identification through the publication of the DEIS began in the fall of 1979. The formal announcement of the intent to prepare an Environmental Impact Statement for a new Willamette National Forest Management Plan was published in the Federal Register and local newspapers.

An initial comprehensive draft of existing and anticipated issues, concerns, and opportunities was circulated on-Forest to Rangers, Staff, and Zone Engineers for review and comment. Several questions and topics were presented under the following subject areas: Protection (Fire, Insects, and Disease); Wilderness Management; Visual Resource; Chemical Use; Human and Community Development; Cultural Resources; Use Permits; Water; Land; Soils; Plant and Animal Diversity; Transportation; Recreation; Timber; Threatened and Endangered Animals; Range; Resident and Anadromous Fish; Riparian; Energy; Geothermal and Other Energy; Minerals, including Common Variety.

The issues, concerns, and opportunities were expressed as objectives, and a hierarchy was developed. Figure A-A-1 is a schematic representation of this hierarchy. At the top appears the broadest, most general objective of Land and Resource Management Planning. Each successive layer further defines the broad purpose. At the bottom the most specific statements of the objectives are expressed. Narrative definitions explaining each of the objectives were reviewed by Forest Service employees who were judged familiar with public opinion to assess the completeness of the objectives hierarchy. Another review by the Forest's Management Team followed.

Next a response packet to solicit public comments was prepared. The packet used the hierarchy as a framework and contained three items. The first was a newsletter explaining the planning process and describing the need for public participation. The second was a booklet discussing the anticipated issues for this round of planning. Facets to these issues were developed from specific statements in the objectives hierarchy and were included in the booklet. The third item was a response form for return to the Willamette National Forest Supervisor's Office. The packets were mailed to over 1,000 names and addresses on the Forest's planning contact list, and another 300 packets were distributed from the various Forest offices and during meetings with various organizations.

The specific issue subject areas listed in the public response packet were:

- *Dispersed Recreation:* To provide a range and a quantity of opportunities.
- *Developed Recreation:* To provide a range and a quantity of opportunities.
- *Wilderness:* To allow for the uninterrupted functioning of the area's natural processes.
- *Aesthetics:* To provide opportunities for a pleasant visual experience for all visitors to the Forest.
- *Wildlife/Plant Habitat:* To provide for plentiful and diverse habitats.
- *Fish Habitat:* To provide habitat for anadromous and other fisheries.
- *Livestock Grazing:* To provide for livestock forage production and the use of the Forest's transitory range.
- *Current Production:* To provide timber in the present decade for wood products.

- *Future Production:* To provide for supplies of timber continuing beyond the current decade.
- *Utilization of Slash:* To promote the use of slash for energy production and other uses.
- *Water Quality:* To provide high quality water for municipal watersheds, fish habitats, and other uses.
- *Water Quantity:* To provide sufficient quantities of water to meet demand.
- *Floodplains/Wetlands:* To provide for the natural functioning and to protect their productivity.
- *Minerals:* To provide for the extraction of common, precious, and strategic minerals.
- *Area Well-Being:* 1. Local Economies: To promote the economic health of local areas.
- *Area Well-Being:* 2. Energy: To facilitate the development of sources of potential domestic energy.
- *Cultural Heritage:* To protect the cultural, historic, and natural aspects of our national heritage. This includes protecting the rights of Native Americans.
- *Individual Well-Being:* To promote public safety and provide assistance to landowners and the disadvantaged.
- *Promote Research:* To promote research in various fields of study by identifying needs and cooperating with researchers.
- *Generate Revenues:* To generate receipts for the Federal general fund.
- *Management Efficiency:* To use cost-effective methods of providing Forest outputs.

Open house sessions were held to explain the issues packet and response forms, as well as opportunities to participate in the Forest's planning process. The open house sessions were informal, offering assistance in preparing response forms and answering questions. The Eugene Open House, November 24, 1980, was attended by 61 people. The Salem Open House, November 25, was attended by 22 people. The Albany Open House, November 25, was attended by 11 people.

Response forms were due back January 2, 1981. 291 forms were returned out of the 1,300 distributed. An additional 41 items of correspondence were submitted and were included in the analysis process.

Through the open house and response packet process, people were asked to rate the importance of the issues, suggest revisions, and give supporting reasons and comments. Figure A-A-2 shows how the public rated the importance of each of the 21 issues.

People were also asked to weigh or rate the relative importance of the issues after they were grouped into 10 resource categories, by allocating a total of 100 points across the 10 categories. Figure A-A-3 presents the results of this exercise.

No formal updating of the relative ratings and rankings of the issues represented in Figures A-A-2 and A-A-3 was conducted for the FEIS. A discussion of what the Forest considers the major refinements

of issues since the early 1980s can be found later in this Appendix in the subsection "Issue Refinement Between the DEIS and the FEIS."

Table T146. Issue Importance [1] (Figure A-A-2)

Issue No.	Issue Subject	Very Important	Fairly Important	Not Important
1.	Dispersed Recreation	44	44	8
2.	Developed Recreation	33	52	11
3.	Wilderness	55	30	12
4.	Aesthetics	33	49	15
5.	Wildlife/Plant Habitat	63	34	6
6.	Fish Habitat	56	37	3
7.	Livestock Grazing	6	28	61
8.	Current Production (Timber)	64	27	6
9.	Future Production (Timber)	84	13	1
10.	Slash Utilization	55	28	14
11.	Water Quality	82	14	1
12.	Water Quantity	42	34	21
13.	Floodplains/Wetlands	49	36	11
14.	Minerals	22	48	24

19	Promote Research	6
20	Generate Revenues	7
21	Management Efficiency	8

[1]Calculated by resource category.

Development of the final list of issues for Regional Forester review and approval involved analyzing the public responses received in early 1981. One step in this analysis involved assessing the capability of the Forest Plan to address each issue:

1. Was the issue or concern within the legal responsibility of the Willamette National Forest?

2. Did the issue or concern pertain to the responsibility of other Federal, State, or local governmental agencies?

3. Could the issue or concern be resolved by the National Forest Management Act (NFMA) planning process?

4. Could the issue or concern be best resolved at the National, Regional, or Forest level?

5. Did the issue or concern affect: (a) Forest land-use patterns, or (b) the nature, quality, or quantity of outputs from the Willamette National Forest?

6. Could the issue or concern be resolved more effectively through other already existing management processes, such as environmental assessments, policy statements, manual supplements, or project work plans?

The final phase of the analysis had as its central theme the goal of validation or revision of the objectives hierarchy from suggestions and comments contained in the response documents.

First, every comment about an issue was read and paraphrased onto lists under appropriate headings. After all responses were listed, each was compared to the descriptions of the most specific statements of objectives from the objectives hierarchy. If the specific statement of objectives adequately described a given response, a code was assigned to the paraphrased comment linking it to the appropriate position within the hierarchy. If no existing specific statement of objectives adequately described a given response, a new description was added to the appropriate section of the hierarchy and the paraphrased comment so coded.

A finalized list of 19 issues was sent to the Regional Office with the accompanying comments:

1. While the final regulations suggest that we do not consider additional areas for Wilderness designation, many of the public expressed their desires that this issue be addressed.

2 The issue of old-growth management is treated under the timber production issues and the wildlife/plant habitat issue.

3. The firewood issue is considered a part of four other issues.

4. The issue of the use of herbicides and chemicals in general is addressed in terms of growth rate, wildlife/plant habitat, water quality, and public safety.

5. Transportation system management is addressed as it relates to access timber, recreation and wilderness, mineral sources, and for the physically disadvantaged.

The result of Regional Office review was modification of the document to incorporate the issue named "Promote Research" as a component of other issues, instead of treating it separately. In October 1981 a document listing the following 18 issues (planning questions with their facets) was published:

1. CURRENT TIMBER PRODUCTION

What emphasis should the Willamette National Forest place on providing timber supplies during the present decade?

FACETS: Production of timber on the shortrun basis involves developing or applying technologies to: improve product utilization in the woods and at point of manufacture (or use as firewood), harvest of difficult or sensitive areas, accomplish reforestation of cutover lands, provide access, and intensify cultural treatments sensitive to environmental concerns.

2. FUTURE TIMBER PRODUCTION

What emphasis should the Willamette National Forest place on providing timber supplies beyond the present decade?

FACETS: The determination of the productive land base, the intensity of applying management practices, and the rate of old-growth harvest are the most important aspects of this issue. Improvements in growth rate (possibly using fertilizers); reducing the restocking period; and limiting losses due to fire, waste, disease, and pests (possibly using pesticides or other chemicals) are additional concerns.

3. LOGGING RESIDUE

What emphasis should the Willamette National Forest place on achieving the utilization of logging residues?

FACETS: Logging residue as an alternative energy source. Maintaining natural decomposition, wildlife habitat, and nutrient cycling are some of the considerations. Recognition of air quality standards, cost-effectiveness, and accessibility are other important concerns.

4. WILDLIFE AND PLANT HABITAT

What emphasis should the Willamette National Forest place on promoting habitat for wildlife and plant species?

FACETS: Habitat richness is the relative degree of ability of a habitat to produce numbers of species of either plants or animals; the more species produced, the richer the habitat (Thomas, J. W., Wildlife Habitats in Managed Forests, USDA Forest Service, Ag. Handbook No. 553, 1979). Management of wildlife and plant habitat requires special consideration for threatened, endangered, and sensitive species, wildlife forage production, old-growth habitat and the impact of human activities upon wildlife and plant communities. Opportunity costs of promoting habitat richness; intensity of Forest management practices (possibly using fertilizers, pesticides, or other chemicals); and coordination with the appropriate Federal, State, and local agencies are additional considerations.

5. AQUATIC HABITAT

What emphasis should the Willamette National Forest place on providing habitat for aquatic species?

FACETS: Providing habitat and quality fisheries requires consideration of fish migration routes, food chains, spawning areas, hiding cover, and water suitability. Opportunity costs of providing and maintaining aquatic habitats; intensity of Forest management practices; and coordination with the appropriate Federal, State, and local agencies are additional considerations.

6. DISPERSED RECREATION

What emphasis should the Willamette National Forest place on providing dispersed recreational opportunities?

FACETS: Providing a range and a variety of dispersed recreation opportunities outside wilderness involves considerations of how much and what types, location, conflicts, and compatibilities among users and uses, and proximity to population centers. In addition, the quality of opportunities to be provided is an important aspect of these considerations.

7. DEVELOPED RECREATION

What emphasis should the Willamette National Forest place on providing a range of developed recreation opportunities?

FACETS: Providing a range of developed recreation opportunities requires consideration of facility types, distribution throughout the Forest, proximity to population centers, and demand patterns. Facility design standards and maintenance levels are important quality considerations.

8. WILDERNESS

What emphasis should the Willamette National Forest place on managing existing wilderness areas?

FACETS: Management proposals for wilderness areas must address the relationships between natural processes and human activities. Resource degradation and the disruption of natural processes are functions of the amount of use, user distribution, and behavior.

9. SCENIC RESOURCE

What emphasis should the Willamette National Forest place on providing a variety of pleasant scenic experiences?

FACETS: While providing other benefits, management of the scenic resource involves considerations of actual treatment, design, and the amount and rate of management activities occurring in the landscape. In addition, important factors to be addressed include specific practices, techniques, and methods, as well as the extent of their applications.

10. WATER PRODUCTION

What quality and quantity of water should the Willamette National Forest produce?

FACETS: Water, as defined in terms of quality and quantity, is influenced not only by natural conditions but by the scope, timing, location, amount, or intensity of management actions. Of these actions the manner in which the riparian zones are treated is very important.

11. ECONOMIC EFFICIENCY

What is the tradeoff between efficient allocation of resources and the production of desired levels of outputs on the Willamette National Forest?

FACETS: The concept of economic efficiency implies a commitment to high quality investments based upon careful consideration of all benefits and costs, many of which are not readily quantifiable. An important aspect of operating in a cost-effective manner is reducing costs; one method may be through the use of increased contracting.

12. LOCAL ECONOMIES

What emphasis should the Willamette National Forest place on providing outputs and services in response to local needs?

FACETS: Maintaining land and resource management options may be more important than the production of a single output. Important considerations in determining the appropriate mix of programs for local economic stability include the amount and distribution of revenues produced by the Forest, the need for diversification of local economies, the relationship between Forest management practices and labor hiring policies, and the amount of preferential treatment given to small businesses.

13. ENERGY

What emphasis should the Willamette National Forest place on the development and conservation of energy sources?

FACETS: Potential sources of energy currently emphasized include hydropower, geothermal, and fuel wood. Additional concerns include conservation of energy in Forest activities and the provision of powerline corridors for energy transmission.

14. INDIVIDUAL WELL-BEING

What emphasis should the Willamette National Forest place on individual well-being?

FACETS: Individual well-being entails civil rights, including Native American rights, public safety (including the safe use of chemicals), employment opportunities, and assistance to landowners and the physically and economically disadvantaged. In addition, opportunities exist to improve access, particularly for the physically disadvantaged, and to make environmental education available to the public.

15. CULTURAL RESOURCES

What emphasis should the Willamette National Forest place on the cultural resources program?

FACETS: The cultural resources program involves the identification, interpretation, and protection of the cultural, historic, and natural aspects of our national heritage.

16. MINERALS

What emphasis should the Willamette National Forest place on the management of mineral resources?

FACETS: The primary aspects are the exploration and the removal of common variety, precious, and strategic minerals, particularly in the next decade. Land reclamation is particularly important for reducing long-term impacts on other resources.

17. AIR QUALITY

What emphasis should the Willamette National Forest place on maintenance of air quality?

FACETS: Air quality concerns include the production of smoke, dust, and other particulate matter and the need to keep particulates from intruding into Class I and Class II areas.

18. LIVESTOCK GRAZING

What emphasis should the Willamette National Forest place on providing for livestock forage production and the use of the Forest's transitory range?

FACETS: Dealing with livestock forage production and transitory range use involves considerations of enhancing use, forage production, and livestock management to avoid impacting other resource values.

MAJOR ISSUES AND DISPOSITION OF ISSUES

Major Issues

By the time of publication of the DEIS, modifications were made to the 1981 list of primary issues. These modifications were made to reflect refinements in public opinion during that interval and to reduce complexity within the planning documents. In some cases closely interrelated issues were grouped together. Examples include consolidating "Aquatic Habitat" into "Wildlife, Fish, and Plant Habitat;" and combining "Current and Future Timber Production" into one issue named "Timber Supply." Other topics, such as Old Growth and Roadless lands, had increased in public interest to such a large degree that they were then being treated as separate issues.

While all of the issues were considered during the development of the DEIS Alternatives, the degree of response to the major ones was of greatest importance in selecting the Preferred Alternative for the Draft Forest Plan. Issues were considered of "major importance" if they were the subject of continually recurring correspondence, individual visits, or meetings involving other public agencies, organized groups and industry, or the public at large. These issues were also often discussed in media reports. The major issues that provided the focus for the DEIS were Dispersed Recreation; Old Growth; Roadless Lands; Scenic Quality; Timber Supply; Water; and Wildlife, Fish, and Plant Habitat.

A brief discussion follows about each of the seven major, or "key" issues which were the subject of special focus in the DEIS. These key issues, with some refinements discussed later in this Appendix, remain the major issues considered in the FEIS and Final Forest Plan. In addition, readers are encouraged

to read Chapters I and III of the FEIS for a more complete discussion of the interrelationships and conflicts among resources.

Dispersed Recreation

Demand for recreation opportunities on the Forest remains high. People are interested in maintaining a wide variety of options for recreation activities. The subject of roaded and unroaded dispersed recreation opportunities carry the greatest potential to vary among Alternatives. There is concern about how the management decisions made in the Forest Plan will increase or decrease these opportunities.

There is continuing, although somewhat less intense, interest in managing for developed recreation, as well. Developed sites are tracked through the process; but they are not treated as a major issues, because there is less land involved and less intensity of public interest. Decisions made regarding developed recreation have a low significance in affecting the overall management of other Forest resources.

Old growth

In the early stages of development of this Forest Plan, the management of old-growth stands was considered part of the timber production and fish and wildlife habitat issues. By the publication of the DEIS, however, increasing public attention had warranted treating it as a separate category despite its particularly strong interrelationships with other issues.

Part of the public sees a need to preserve old growth for its benefits to plant and wildlife habitat diversity, soil and water productivity, and its recreational and aesthetic values. Another segment of the public recommends converting the old growth stands to more vigorously growing second growth stands to support future timber production needs. The amount of the old growth to be harvested in the next decade affects the current timber supply also.

Roadless Lands

Although the Oregon Wilderness Act of 1984 resolved part of the issue concerning Wilderness, interest in some of the Willamette's roadless lands has remained high. "Wilderness" as an issue was rated highly important by the 1981 respondents. In 1983 a reinventory of the roadless lands on the Forest included extensive public involvement, including a 1200-piece mailing and a series of public meetings. The 1984 Act increased the amount of designated Wilderness on the Forest to about 25% of the land base.

The nature of this issue revolves around using these lands for timber production; or to defer harvest to preserve old growth trees, provide habitat diversity, and protect aesthetic values. A "no-harvest" allocation assigned to unroaded areas would also tend to maintain options for future designation as Wilderness. Some people feel that the marketable resources in these areas should be developed; some feel that they should remain undeveloped. Still others feel that some lands currently in a developed condition should be returned to an undeveloped condition, particularly if the lands are adjacent to designated Wilderness.

Scenic Quality

The visual quality of the Forest landscape is of concern to adjacent landowners, travelers, and Forest visitors. Many people prefer not to see evidence of timber harvesting from major highways and popular recreation areas such as trails, campgrounds, and scenic overlooks. Other people, who tend to favor utilization of Forest resources, feel that most visual effects of resource management activities are temporary, so that Visual Quality Objectives should play a reduced role in planning such activities.

Timber Supply (Current and Future Timber Production)

The Forest annually provides the largest amount of timber production in the National Forest System. The amount of timber produced on the Forest therefore assumes some level of national as well as local importance. In addition, since the wood products industry is one of the three major components of the economy of the State of Oregon, concern has also been high for several years about the level of contribution the Forest's timber resource makes to the overall timber supply within the State, as well. In the 1981 survey current and future timber production received the highest weighted importance. Interest has not decreased since then.

Some people feel that the allowable harvest is too high, resulting in unacceptable adverse effects to other resource values. Others believe that the level of harvest should be maintained or increased to provide the raw material to help satisfy needs for wood products and to provide a stablizing force on the economies of local communities which may be highly dependent upon the various wood products industries.

Additional components of the timber supply issue include: logging residues and firewood, harvest schedules and methods, use of herbicides and fertilizer, reforestation, and species mix, and access.

Water Quality and Quantity

Water quality received the second highest rating for issue importance in the 1981 issue development survey. The natural level of water quality on the Forest is generally quite high. Consequently, unlike many of the other issues addressed by the Forest Plan, the concern centers more on minimizing degradation than taking specific actions to enhance the resource over natural levels. Accordingly, much of the treatment given this issue can be found in the Standards and Guidelines and Monitoring sections of the documents.

Water quantity was of less concern than quality, and only slight variations between Alternatives exist. Adequate and consistent water supply for streamflow for fish habitat and domestic uses were of greatest concern.

Wildlife, Fish, and Plant Habitat

The broad issue of habitat represents a complex of concerns about the living components of the Forest. Central to the issue are matters of species survival and maintaining ecological diversity.

Concerns range from continuation of game species for hunting and fishing to preservation of reptiles and insects to threatened, endangered, and sensitive plant species. Differences of opinion arise about the extent and nature of land allocations and mitigation requirements associated with various individual, commercial, and management activities which are needed to assure adequate support for the viability and distribution of the various native species.

Issue Refinement Between The DEIS And The FEIS

The key issues did not change between the DEIS and the FEIS, but some refinements in focus occurred, most notably to five of the key issues. The attempt to be responsive to these refinements ultimately led to analysis of three new alternatives in the FEIS. The five affected key issues are identified with the same descriptors used in the preceeding discussion of major issues.

Dispersed Recreation

A segment of the McKenzie River and the North Fork of the Middle Fork of the Willamette River received Wild and Scenic River designation by Congress in 1988. Congress also required that Blue River and the South Fork of the McKenzie River be studied for their suitability for Wild and Scenic River status. The State of Oregon added two additional rivers to its State Scenic Waterways inventory. Interest in studying additional rivers and their segments for similar designations has intensified.

Special designations of these types affect management practices on the rivers and surrounding lands. Timber harvest, road building, and recreation site development may be constrained or eliminated for some distance from the rivers themselves. Retaining the special values of study rivers pending suitability determination similarly affects the nature and extent of new management activities in those areas until suitability is resolved.

Old Growth

The intensification of public interest surrounding old growth has involved a number of key issues: old growth as forest structure; old growth as a reservoir of timber supply; old growth as an ecosystem providing a unique habitat in support of other plant and animal species. This discussion focuses on old growth as forest structure. Related discussions can be found in the Timber Supply and Wildlife, Fish, and Plant Habitat subsections.

One of the more perplexing aspects to addressing old growth concerns was the apparent lack of unanimity of definition. Some of the more commonly used definitions are the Region 6 definition (Regional Guide), the Pacific Northwest Range and Experiment Station definition (PNW 447), and the definitions proposed by the Wilderness Society and the Society of American Foresters. In order to enhance public understanding of old growth issues, data are analyzed and displayed in the FEIS using several different definitions.

Increased attention has focused on the silvicultural values of old growth structure, including its capability to retain and enhance soil and water productivity. This attention has not limited its scope to preservation of existing stands. Indeed, interest in old growth structure has been instrumental in the development of changing philosophies of site utilization and stand regeneration techniques, known as "the New Forestry" and "New Perspectives Forestry."

Differences in public and professional opinion exist about the extent to which increased preservation of old growth and "New Perspectives" forestry should occur; the specific nature of indicated practices; the best locations in which to undertake the practices; and the attendant risks involved, such as susceptibility to fire and disease.

Timber Supply

The Timber Supply issue intensified to near-crisis proportions during the period between the DEIS and the FEIS. Although the values of harvested timber on the Forest reached all-time highs, the volume sold for eventual harvest dramatically reduced by fiscal year 1989. Much of the reduction in sold volume was in response to court injunctions associated with spotted owl habitat litigation. The current and intermediate term availability of timber from all sources within the State of Oregon achieved high levels of public concern. Central to this concern was the contribution made by the federal sector, particularly in the form of old growth timber.

Ultimately Congress balanced the habitat needs of the spotted owl with the federal supply needs of old growth dependent mills by passing the Northwest Timber Compromise as Section 318 of the Fiscal

Year 1990 Appropriations Act. This legislation was acknowledged not to represent a permanent solution, however. Consequently, the public issues remain for evaluation under the planning process.

In addition, many public comments alerted the Forest to improvements which could be made to the technical analysis of timber availability.

Water Quality and Quantity

Public comments during the response period after publication of the DEIS sent the strong message that many of the alternatives in the DEIS, including the preferred alternative, proposed unacceptable levels of watershed degradation. This did not so much represent a refinement of public concern as it represented a reaffirmation of the intensity with which the concern was held and the need for the Forest to address the issue with greater sensitivity.

Wildlife, Fish, and Plant Habitat

During the interval between the DEIS and FEIS, concerns surrounding plant and animal diversity and habitat preservation intensified. These concerns spanned a wide variety of species, habitats, and management practices. The most notable representatives of these concerns were spotted owl habitat, old growth as a reservoir of a unique and valuable ecosystem, and riparian areas as critical ecosystems.

These issues were central to examining notions such as habitat connectivity and preserving options. In many cases, however, decisions to provide or enhance such connectivity or to preserve options produce reductions in timber supply or suggest relatively more costly harvest techniques.

Disposition Of The Issues

The initial planning concerns, as well as the seven key issues, are discussed in several places throughout the FEIS and in the Final Forest Plan. Figure A-B-1 indicates the chapters in the documents which address the issues. The Alternatives displayed in the FEIS differ primarily in the way they respond to the planning issues. Figure A-B-2 lists the "indicators of responsiveness" which are used to show a quantified level of response. Figure II-E-29 displays the Alternatives' outputs and effects, listed by the key issues.

Table T148. Disposition of Forest Issues (Figure A-B-1)

Planning Concern (Appendix A)	Plan Issue (Chapter 1) (FEIS)	Altenatives (Chapter 2) (FEIS)	Consequences (Chapter 4) (FEIS)	Standards and Guidelines (Forest Plan)
Dispersed Recreation	Yes	Vary by Acres & Management	Yes	Yes

Lands Allocated to a Modification VQO	Thousand Acres
TIMBER SUPPLY	
Allowable Sale Quantity in the 1st Decade	Million Board Feet
Allowable Sale Quantity in the 1st Decade	Million Cubic Feet
Long-Term Sustained Yield	Million Cubic Feet
WATER (Quality and Stream Condition)	
Area with Risk of Adverse Impact Rating (Low, Medium, & High)[1]	Percent in each Rating

ISSUE/Indicator	Unit of Measure
WILDLIFE, FISH, AND PLANT HABITAT	
Habitat Capability for Spotted Owls (Mature/old-growth habitat)	Acres of Habitat Maintained
Habitat Capability for Pileated Woodpecker (Mature/old-growth habitat)	Acres of Habitat Maintained
Habitat Capability for Pine Marten (Mature/old-growth habitat)	Acres of Habitat Maintained
Habitat Capability for Elk (End of 1st Decade)	Ratio Between Percent of High, Medium, Low Emphasis
Habitat Capability for Deer (End of 1st Decade)	Ratio between Percent of High, Medium, Low Emphasis
Special and Unique Habitats	Acres Protected
Bald Eagle Recovery	Number of BEMAs; Acres of Nesting Habitat
Peregrine Falcon Recovery	Number of Potential Nesting Cliffs
Cavity Nesting Habitat	Percent Potential Population Managing for
ECONOMICS	
Changes in Numbers of Jobs in 1st Decade	Number of Jobs
Changes in Income in the 1st Decade	Millions of Dollars
Payments to Counties in the 1st Decade	Millions of Dollars
Net Cash Flows in the 1st Decade	Millions of Dollars
Present Net Value for 15 Decades	Billions of Dollars

[1]See Chapter IV, Water, for further explanation.

CONSULTATION WITH OTHERS

The size and scope of the Willamette National Forest and its location near large municipal centers in the Willamette Valley led to a high level of continuous public contact. Although the discussion below makes no attempt to be exhaustive, it describes many of the organizational contacts which were made in the development of the FEIS and Final Forest Plan. Readers specifically interested in the public comments after publication of the DEIS should read Appendix I.

Agencies And Groups

The Forest worked closely with a number of governmental entities holding special expertise in many diverse disciplines touching forest management. For instance, neighboring National Forests were consulted, particularly on matters of mutual concern where a measure of relative consistency in management treatment of forest resources were desirable. The Environmental Protection Agency, Bureau of Land Management, and the U.S. Fish and Wildlife Service are examples of other federal agencies which were consulted.

Counterpart agencies for the State of Oregon were also consulted, in particular the Oregon Department of Fish and Wildlife, the Oregon State Department of Forestry, the Oregon Department of Environmental Quality, and the Governor's National Forest Planning Team. Consideration was given to the "Forestry Program for Oregon" during alternative development.

Planning documents of various federal and State agencies were available in order to coordinate management where appropriate. County plans for Lane, Linn, Douglas, and Marion counties were reviewed.

Numerous consultations with elected officials of federal, State, and local jurisdictions, or their staff, yielded valuable information about the concerns of their constituencies and provided insight into the major issues surrounding the future management of this Forest. In many instances these consultations included tours and field trips, allowing discussions to be specific.

A series of meetings were held in January and February 1985 to provide an opportunity for participation in the development of resource management options for Alternative formulation. Many of the same individuals and groups that responded during the initial issue development process stayed with the process the entire time. In addition to formally scheduled public involvement activities, the Willamette encouraged continual involvement from groups expressing special interest in the management of Forest resources.

The Oregon Natural Resources Council (formerly Oregon Wilderness Coalition) and its member groups which use the Forest have been active in the Plan's development since 1980, submitting narrative and mapped proposals for land allocations. Some other especially active groups tending to emphasize noncommodity uses of the Forest include the Chemeketans, Old Cascades Wilderness Committee, Waldo Wilderness Council, Cathedral Forest Action Group, Hardesty-Mt. June Council, and Cascade Holistic Economic Consultants. The Mt. Jefferson Snowmobile Club, Oregon Trout, American Alpine Club, Obsidians, Sierra Club, and others have also been involved. Site specific concerns were recorded on a data base map and evaluated during Alternative formulation.

The Forest has also worked with "consensus groups" composed of members of the public and agency representatives to develop management proposals to be analyzed during this round of planning for

several locations on the Forest: Fall Creek, Hardesty Mountain, South Fork of the McKenzie, and Three Creeks.

In the interval between the DEIS and FEIS, the Forest also received valuable advice from a group known as the "Fruitful Discussions Group." This group was comprised of a number of representatives from the environmental community, timber industry, and local government who regularly met to provide advice to the Forest Supervisor in the development of the Forest Plan. While the members of the group recognized that their individual organizational goals frequently differed considerably, the Fruitful Discussions Group worked hard to develop a common understanding of specific issues affecting forest planning and to produce consensus recommendations on those matters where agreement could be reached. Given the range of informed opinion this group represented, the Forest found the group's recommendations very useful in clarifying the issues and narrowing the scope of topics of key concern.

Adjacent landowners and land managers were also included in public involvement activities. Summer homeowners also commented. The Breitenbush Community, Shiny Rock Mining Corporation, and the Willamette Pass Ski Area Corporation contributed input.

The primary industry which was represented during the planning effort was the timber industry, since raw material for wood products is the main commercial commodity available from the Forest. The Associated Oregon Loggers, Industrial Forestry Association, Northwest Timber Association, Western Timber Association, Willamette Timbermen, Oregon Women for Timber, and others have been continually involved. Individual mills and companies have also been represented.

Indian Tribes

There are four Indian Reservations in the vicinity of the Forest. They include the Confederated Tribes of the Warm Springs Reservation, the Cow Creek Band of Umpqua Indians, the Confederated Tribes of Siletz Indians, and tribes of Confederated Grand Ronde Indians. Letters were sent to the tribal council of each respective tribe to inform them that the Forest was preparing a new land management plan. The Forest encouraged participation in the planning process. A letter of this nature was also sent to the Bureau of Indian Affairs, Portland, Oregon.

Through the Willamette Cultural Resource Management Program, the Forest solicited input from the nearby tribes and the Bureau of Indian Affairs. Requested were their issues and concerns related to the Forest, areas on the Forest where the Indian tribes have had historic use, and the magnitude of that use. Historic use can include hunting, fishing, gathering, religious practices, or any other culturally sensitive activity.

An early consultation with Indian tribes in the Pacific Northwest was a series of coordinated meetings held by the Regional Forester in Seattle on November 10, 1981, and other selected locations and dates throughout the Region. Indian concerns generated at these meetings were forwarded to the Forest and incorporated into the planning process. Issues resulting from this interaction included: knowledge of and responsiveness to Native American treaty rights on Forest Service administered lands; responsiveness to cultural resource management laws and regulations including the American Indian Religious Freedoms Act; access to Forest resources for traditional uses and activities, including hunting, fishing, grazing, and gathering; the compatability of maintaining traditional Indian culture and religion with Forest Management programs; and building an atmosphere of trust between Native American leaders, their representatives (including attorneys, planners, and biologists), and Federal agencies.

The Forest, along with other Columbia Basin Forests in the Region contributed to a joint response to the Columbia River Intertribal Fisheries Commission, which requested data on anadromous fish production and habitat. The Columbia River Intertribal Fisheries Commission consists of representatives from the Yakima Indian Nation, Warm Springs Confederated Tribes, Nez Perce Indian Nation, and the Umatilla Confederated Tribes. The Willamette River, which drains the Forest, is confluent with the Columbia River below the Bonneville Dam; fisheries production from the Forest was not as large a concern to the Columbia River Intertribal Fisheries Commission as upper Columbia River fisheries issues.

Representatives from the Forest attended a conference in May 1986 entitled "Perspectives on the American Indian Cultural Heritage: Indians, Historians, and Archaeologists." The conference discussed important issues and concerns from Native Americans about the Cultural Resource Management Program. Issues included the working relationship between archaeologists and the Native American community, the importance of Native American historical and archaeological knowledge to Native Americans, the process the USDA Forest Service implements in the cultural site testing program, the treatment of burial sites, sacred sites and remains, religious sites, and respect and regard for American Indian values and interests.

No Indian burial sites have been found on the Forest. The Forest has worked with the Confederated Tribes of the Grand Ronde Indians to obtain input and involvement in the site testing program to determine the extent and nature of their use of lands on the Forest. In addition, Native Americans at the Native American Student Union on the University of Oregon campus and individuals in the community expressed a desire to establish a sweat lodge for religious practices on the Forest.

Native American Cultural Awareness Days in June 1986 and August 1987 provided a forum for the Confederated Tribes of Siletz Indians, the Native American Special Emphasis Program Coordinator on the Willamette National Forest, and Native American employees on the Forest to present Native American issues, culture, and art.

Informal meetings have occurred at various levels with Native American Tribes and the Forest Service. Site specific issues and concerns have been discussed at the Forest and Ranger District level with Warm Springs Confederated Tribe representatives. A portion of the Mt. Jefferson Wilderness on the Detroit Ranger District borders the Warm Springs Indian Reservation. Annually, Forest Service Wilderness guards and Tribal law enforcement officers meet informally. Trespass onto the Reservation by Forest hikers and commercial operators has surfaced as a concern. Coordination and pursuit of a cooperative management effort in the area is continuing.

Comments Recevied

The following is a nonexhaustive list of groups with whom the Forest met or from whom the Forest received written comments during the planning process:

Federal

Northwest Power Planning Council
U.S. Army Corps of Engineers
U.S. Congress - Representative Peter Defazio
U.S. Congress - Representative Denny Smith
U.S. Department of Energy - Bonneville Power Administration
U.S. Department of Interior - Bureau of Land Management

U.S. Department of Interior - Fish and Wildlife Service
U.S. Environmental Protection Agency
U.S. Senate - Senator Bob Packwood
U.S. Senate - Senator Mark Hatfield

State of Oregon

Department of Energy
Department of Geology and Mineral Industry
Department of Fish and Wildlife
Department of Forestry
Department of Transportation
Land Conservation and Development Commission
Office of the Governor
State Economist

County

Lane County

APPENDIX B

DESCRIPTION OF THE ANALYSIS PROCESS

INTRODUCTION

Planning Situation

One of the primary responsibilities and challenges facing the Forest Service is deciding how best to manage National Forest lands to produce the goods and service desired by the public. Because National Forest lands and the resources they contain are valued by society, commitments to various uses represent significant decisions with far-reaching implications for current and future users.

The NFMA of 1976 (NFMA) directs each National Forest to prepare a comprehensive land management plan. The Forest's major planning goal under NFMA is to provide decision makers with sufficient information to determine the mix of goods, services and land allocations which best resolves the identified public issues in a manner that maximizes net public benefits. Net public benefits are defined as the overall long-term value to the Nation of all outputs and positive effects (benefits), less all associated inputs and negative effects (costs), whether they can be quantitatively valued or not.

The regulations (36 CFR 219) developed under NFMA provide the analytical framework for developing a forest plan. The National Forest Management Act and its regulations also state that the requirements of the National Environmental Policy Act (NEPA) and its regulations (40 CFR 1500-1508) must be applied in this analysis process. The NEPA regulations require that the environmental effects of a proposed action and alternatives to that proposed action must be disclosed in an Environmental Impact Statement (EIS).

The planning problem is a very complex one. This complexity stems from the need to address a variety of interrelated and often conflicting issues by allocating land and scheduling activities in a cost-efficient manner for the entire Forest over a long period of time. The analytical processes and techniques used by the Forest to accomplish this are described in this Appendix.

Changes Between Draft and Final

Based on public comment the estimated effects (Step #6 below), the evaluation of alternatives (Step #7), the preferred alternative recommendation (Step #8) and even some of the formulation of alternatives (Step #5) have been revised for the FEIS. In this Appendix you will find many areas where the analysis process has changed. As you review the analysis process you will find new descriptions under the following topics.

Inventory & Data

- Timber inventory condition classes (updated for harvest)
- Timber age class stratification (young stands and large sawlogs/old growth disaggregated)
- Fertilizer response (increased)
- Spotted Owl inventory data (updated)
- Other mature conifer habitat allocations (modified)
- Soil resource inventory interpretation (corrected)
- Wild & Scenic Rivers (included)

Modeling Assumptions

- Analysis area stratification (revised)
- Allocation zones (moved to analysis areas)
- Limited entry areas (visuals, dispersed recreation, and some riparian) modeled outside FORPLAN
- Technical FORPLAN design (changed)
- IMPLAN model (updated)
- Wildlife, recreation and water quality models (changed)
- Breakage, defect and dead tree habitat factors (revised)
- Relational data base operations (added)

Management Changes

- Allowable sale quantity (salvable dead timber included)
- Alternatives considered in detail (changed)
- Timber prescription set (changed)

The Planning Process

The planning process described in the NFMA regulations consists of ten steps oriented towards a systematic analysis of the complex problems associated with multiple-use forest management. This 10-step process is discussed in Chapter I of the DEIS and is briefly summarized as follows:

1. Identification of purpose and need: Issues, Concerns, and Opportunities (ICO's) - In any systematic approach to problem solving, the first step is to identify the problem. In this step, the interdisciplinary Team (IDT) identifies and evaluates public issues, management concerns, and resource use and development opportunities. What does the public want? What does the Forest Service want? What needs to be done?

2. Planning Criteria - Criteria are designed to guide the collection and use of inventory data and information, the analysis of the management situation and the design, formulation, and evaluation of alternatives. This step sets the guidelines for accomplishing the next 5 steps.

3. Inventory data and information collection - The type of data and information needed is determined in step 2 based on the ICO's. The data is then collected and assembled in a manner meaningful for answering planning problems.

4. Analysis of the management situation - This step is a determination of the ability of the planning area to supply goods and services in response to society's demands. This provides a basis for formulating a broad range of reasonable alternatives.

5. Formulation of alternatives - A broad range of reasonable alternatives is formulated according to NEPA procedures. Alternatives are formulated in a manner which provide an adequate basis for identifying the one that comes nearest to maximizing net public benefits.

6. Estimated effects of alternatives - The physical, biological, economic and social effects of implementing each alternative considered in detail are estimated and compared according to NEPA procedures.

7. Evaluation of alternatives - Significant physical, biological, economic and social effects of implementing alternatives are evaluated with respect to the planning criteria.

8. Preferred alternative recommendation - The Forest Supervisor reviews the IDT's evaluation and recommends a preferred alternative to the Regional Forester who then selects one from the group that is provided. This is identified in the Draft Environmental Impact Statement and displayed as the proposed plan.

9. Plan approval and implementation - The Regional Forester reviews the proposed plan and Final Environmental Impact Statement and either approves or disapproves the plan.

10. Monitoring and evaluation - The plan establishes a system of monitoring at established intervals to determine how well objectives have been met and how closely management standards and guidelines have been followed. Based on these evaluations, the plan will be revised or amended as necessary.

Three distinct phases occur during this process. Planning steps 1, 2, 7, and 8 make up the judgmental or selection phase of the process. These steps are addressed in Chapters I, II, IV and in Appendix A of the DEIS. Steps 9 and 10 are execution steps and are dealt with in or through the proposed Forest Plan. Steps 3, 4, 5 and 6 are analytical steps and are addressed along with other details of the analysis in this Appendix.

INVENTORY DATA AND INFORMATION COLLECTION

Overview

The inventory step in the planning process consists of the collection, development, automation and documentation of data and information needed to address the ICOs and planning criteria identified in Planning Steps 1 and 2. Two basic types of information are needed to facilitate the analysis and development of alternatives. The first consists of information related to the classification of land into categories with unique properties. This classification can be based on land form, existing resources, production capabilities, political or other geographic boundaries, or some other attribute or combination of attributes. This type of information is directly tied to a map base, and to facilitate analysis of the size and complexity of forest planning, is usually handled by a computerized mapping system.

The second type of information is not tied directly to a map but has to do more with how the land responds to various activities applied to it. On a specific piece of ground, management activities and their associated costs result in the production of physical outputs and effects (i.e. yields) and some associated economic benefits and costs. To evaluate the planning problem, physical and economic yields and relationships are developed based on a potential set of management activities or prescriptions which can be applied to land with similar characteristics. This data comes from a variety of sources,

most of which are listed in the last part of this section. The rest of this section will discuss the mapping Data Base and some of the major uses of the vast amount of information assembled for the Land Management Planning process.

Data Base Development

The Forest considered use of several different automated data bases for storage and retrieval of geographic planning information. A grid mapping system, the Mt. Hood National Forest's version of R2MAP, was set up on the University of Oregon's computer and eventually transferred to the Forest's Data General computer system.

After selecting a mapping system, determining an appropriate grid cell size and map scale was necessary to initiate Data Base construction. A one inch to the mile scale was considered appropriate for Forest-wide planning because of the large size of the Forest and much information was already developed at that scale. The size of a grid cell is a function of the size of the two line printer characters used to represent the resource data mapped for that cell. A rectangular cell 1/5-inch by 1/6-inch accommodates two line printer characters. This represents 21.33 acres of land at the one inch to a mile scale.

A grid mapping system organizes the resource data into "layers" of information. This information can be overlaid in different orders and combinations to see the coincidence, correlations, and associations of the various resources for specific locations. The overlay technique provides a unique opportunity for analyzing data. It allows many types of information to be examined simultaneously and in different combinations. It also allows information to be manipulated quickly and accurately. The system accurately tallies acreages and locates those acres spatially.

Some types of information, however, can not be represented well in this mapping system. The 21.33 acre grid cell size makes linear (roads and streams) and small area information (administrative sites) hard to represent. Any spatial representation of these types of information distorts the acreage and a decision has to be made whether acreage or location is the most critical factor. For display maps the location is generally taken as the most critical factor but for analysis maps correct acreage summaries control the decisions.

Using the mapping system for planning influences the form in which data is needed. It also influences the level of resolution, detail and accuracy of the data actually used in planning. Some types of data lend themselves to this format better than others. But the limitations implicit in this are outweighed by the benefit of having all the information in a consistent, easily-used format so that all of it can be considered throughout the analysis and planning process.

The selection of layers to include in the mapping system was based on several factors. The major need for forest planning was the ability to combine basic resource data and geographic locations into analysis areas, and relate those acreages to potential land allocations. Other layers were included to assist in the calculation of costs, yields, effects, conditions, constraint values or acreage adjustments. Table B-1 lists the data layers in the mapping system. The last part of this section summarizes the major data sources for layers in the Forest's Data Base and other types of information used in Forest planning. Additional information on the Forest's Data Base is contained in the paper "Data Base Documentation" which is available in the Forest's planning records.

Toward the end of 1989 the Forest put the "MOSS" Geographic Information System (GIS) on its Data General computer system. Information on the management strategies and "Mature/OverMature Status" inventory were combined in the MOSS system to analyze old growth protection in the FEIS.

Visual Quality Objectives (VQO)	

Major uses of Inventory Data

Analysis Areas and Allocation Zones

The basic resource information and boundaries contained in the data layers of the mapping system are used to define the areas which are analyzed in the planning process. For the Forest, two levels of resource information were needed to adequately represent the planning problem: analysis areas and allocation zones.

Analysis areas represent aggregations of many individual areas which have similar characteristics and respond to management practices and activities in similar ways. The composition of an analysis area is important because it defines the range of management activities appropriate for a given objective and the resultant costs and yields. The analysis model FORPLAN assigns prescription to analysis areas based upon these costs and yields.

Analysis areas are constructed by overlaying several resource layers in the mapping system. These layers or combinations of layers become analysis area identifiers.

Overlaying all of the resources and boundary layers in the mapping system would result in tens of thousands of unique areas. Modeling limitations in FORPLAN require some grouping or condensing to arrive at a manageable number of analysis areas. In the DEIS model, allocation zones (watersheds) were used in concert with forest-wide analysis areas. For the FEIS, the watersheds were included in the analysis area identifiers; but big game winter range, slope class, soil stability and logging suitability were taken out of the analysis areas used by FORPLAN. Where these data were needed, they were included in the information provided to a side model or averaged across the watershed. *The Forest Planning Model* later in Appendix B contains more information on the development and composition of the analysis areas.

Production Coefficients

Analysis of the planning problem requires the development of production functions which are relationships between sets of inputs (i.e., activities and their costs) and outputs, effects, and conditions. The coefficients which represent these relationships were developed in a number of ways and from a variety of sources. In some cases, data representing several years experience were averaged. In other situations, historical data were not available or representative of anticipated practices, so estimates were made.

Computerized models were used to develop certain types of yields (e.g., timber yields from DP-DFSIM and PROGNOSIS). The Forest's grid mapping system (Mt. Hood version of R2MAP) aided in the construction of production coefficients in some cases by providing the acreages of specific categories within other more general categories. The derivation of production coefficients is discussed in more detail later in Appendix B in the Forest Planning Model section titled *Development of Yield Coefficients* and the *Economic Efficiency Analysis* section.

Timber Suitability

The Forest followed a process based on National and Regional direction to determine which lands are unsuitable for timber management. This process included a screen for regeneration difficulty. The Forest's soil resource inventory (SRI) was used to locate areas with potential regeneration difficulty. Unsuited soils became a layer in the Forest's Data Base and were used in defining analysis areas. A data base error was identified in the DEIS interpretation of the Soil Resource Inventory. Correcting the error for the FEIS analysis resulted in the addition of approximately 29,000 acres to the lands tentatively suitable for timber production. The Timber suitability process and results are presented in the FEIS, Chapter III.

Alternative Development and Analysis

Alternatives were developed to meet specific resource objectives or to follow a particular theme. The basic use of inventory data in this step was to accurately reflect the land base and provide the basis for scheduling activities and estimating outputs, costs and effects through the development of production coefficients. Inventories of potential land allocations or management areas were used as a basis for assigning prescriptions in each alternative. The Forest's Data Base greatly facilitated the task of identifying these areas and determining which prescriptions could be applied. This process is described more fully later in Appendix B, in the sections titled *The Forest Planning Model*, and *Formulation of Alternatives*.

Implementation and Monitoring

Inventory data will continue to be essential when the plan moves into the implementation and monitoring phases. Site-specific activities and projects will be scheduled based on the results of the Forest-wide planning process. Changes in the land base due to timber harvest, Congressional mandates and other major developments will guide future activity scheduling. Data collected to monitor activities and their effects will be stored to facilitate mid-course corrections and future analyses. More detail on these steps can be found in Chapter 5 of the Forest Plan.

Summary of Major Data Sources

Major data sources used in the planning process are divided according to mapping system data layers (Table B-1) and coefficient development/estimation of effects.

Mapping System Data Layers

1. The basic **soils** map was developed from the Forest's *Soil Resource Inventory* (SRI) which was conducted in 1971-72 and published in 1973.

2. **Unsuited soils** were identified in a Timberland Suitability study by the Forest's Soil Scientist in 1980 and revised in 1984.

3. Watershed **subdrainage boundaries** were mapped in 1980-81 by District personnel.

4. **Riparian zones** were identified from a "Stream Classification Map" developed in 1972 and revised in 1979.

5. The Forest's most recent **Timber inventory** (1981), subsequent updates (1984 and 1988) and analyses provided the Timber size and type information needed to describe the Forest's timbered vegetation.

6. **Commercial thinning accessibility** information was developed from 1982 topographic maps with updated road information from the transportation planners and Districts. The original mapping was done in 1982 and revised in 1984.

7. **Aerial logging** areas (inaccessible by ground based logging systems) were mapped by District timber staffs in 1982 and revised in 1983.

8. **Spotted Owl Habitat Areas** (SOHAs), each containing a verified pair of owls, have been identified in an on-going field inventory begun in 1979. The distribution and size of the areas has changed several times. For the FEIS a 1500 acre/pair network was developed in 1989.

9. **Winter range boundaries** for deer and elk were provided by District biologists from TRI information adjusted with field knowledge in 1982. The original boundaries in TRI were mapped in 1972 by the Forest Wildlife Biologist. (Updated with District biologists and Oregon Department of Fish and Wildlife input, 1989.)

10. **Pileated woodpecker** and **pine marten habitat areas** were mapped by the planning team wildlife biologist based on Regional Office direction which specified size, distributional and other habitat requirements. (Updated, 1989)

11. **Special wildlife habitat areas** were mapped by District wildlife biologists in 1983. (Updated, 1989)

12. Two existing **bald eagle territories** were mapped as a Threatened and Endangered Species habitat. Potential sites were mapped based on Regional Office criteria contained in a February 9, 1983 memo.

13. **Threatened, Endangered and Sensitive plants** on the Region 6 Sensitive Plant List were mapped based on 1979 and 1980 field inventories.

14. The ability of the Forest to absorb visual change, known as the **Visual Absorption Capability (VAC),** was mapped by the Forest Landscape Architect in 1980.

15. The **slope** map of the Forest was done by the Forest Landscape Architect in 1980 using topographic maps.

16. The VIEWIT Seen Area Program was used by the Forest Landscape Architect to develop **viewshed boundaries** along ten designated highways.

17. The **Existing Visual Condition (EVC)** inventory map which shows the appearance of the Forest at a particular point in time was developed from field inventories and the mapping system in 1984. (Updated, 1989)

18. **Visual Quality Objectives (VQO)** information was extracted from a map containing Composite Visual Quality Standards which were developed through a visual resource inventory in 1974.

19. **Existing developed recreation sites** were mapped based on information in the Recreation Information Management (RIM) System and reviewed and updated by District personnel in 1982 through 1984. (Updated, 1989)

20. **Potential developed recreation sites** were mapped based on information provided by the Districts including the number and kind of sites and size of development. (Updated, 1989)

21. The **types of recreation opportunities** available are described in terms of physical, social and managerial settings in the Recreation Opportunity Spectrum (ROS) System and are based on District inventories conducted in 1981. (Updated, 1989)

22. Mapping of **Wilderness Recreation Opportunity Spectrum** areas was done at a 1983 workshop with District personnel.

23. Transportation planners on the Forest provided information on **transportation collectorshed boundaries** in 1982.

24. **Rock sources for road building** were identified on maps prepared by geotechnical engineers on each Engineering Zone in 1981.

25. Known **mineral resources** on the Forest were obtained from the "Mineral Resource Map of Oregon", a 1984 publication by M. L. Fernes and D. F. Huber.

26. **Land ownership** within the National Forest boundaries was mapped in 1981 based on information in the *Land Status Atlas* and *Land Areas of the National Forest System.*

27. **Administrative boundaries** were also obtained from the two documents listed under land ownership as well as information contained in "Forest Facts, 1980" and Congressional Districts Map (1982).

28. **Wilderness boundaries** were obtained through inventory mapping in 1981 and revised to reflect the additions from the 1984 Oregon Wilderness Act.

29. The boundaries for established and proposed **Research Natural Areas (RNAs)** were taken from the existing Willamette National Forest Land Management Plan (1977) and mapped in 1981. (Updated, 1989)

30. All **roadless areas** identified in Forest plans and RARE II were mapped. Other areas that appeared to meet roadless criteria were also mapped in 1981. All roadless area boundaries were adjusted in 1984 to account for the 1984 Wilderness Act and an additional update was conducted in 1989 to reflect continuing road building and timber sales.

31. The boundaries for **Oregon and California (O&C) Grant Lands, stipulated mining claims, administrative sites and special use permits** were derived from the *Land Status Atlas.* The *Land Use Reporting System* (LUR) and special use permit files were also used as information sources for mapping special use boundaries.

32. The **current Land Management Plan** (1977) was mapped with periodic revisions to reflect allocation and acreage adjustments to the present.

33. **Special Interest Areas, National Natural Landmarks and Wild & Scenic Rivers** were mapped by the planning team in 1983-84 using information from the National Park Service, the Forest's current Land Management Plan, and District and staff input. (Updated, 1989)

34. Information about the known **geothermal resource** was provided by the Lands and Minerals Staff, mapped in 1981 and updated in 1984.

35. The *Land Status Atlas* provided information on **existing hydroelectric sites. Oil and gas lease areas** were obtained from descriptions in applications provided by the Lands and Minerals Staff in 1984.

36. **Prehistoric and historic cultural sites** were mapped in 1982 and updated in 1989.

37. **Trail system** information was obtained from the Trail System Inventory updated by District personnel. (Updated, 1989)

Coefficient Development/Estimation of Effects

1. Codes and definitions for most activities, outputs and effects come from the Forest Service's National Activity Structure Handbook (FSH 1309.16).

2. Timber values were obtained from the Timber Sale Statement of Accounts Data Base and represent the value of Timber harvested from April, 1977 through September, 1983.

3. Other resource values are taken from the 1985 Forest and Rangeland Renewable Resources Planning Act (RPA) Program Update per Regional Office direction (1920 letter of April 27, 1984) and FSM 1971.64.

4. Cost information was developed from multi-year averages of actual expenditure data from the PAMARS Data Base, submission to the 1985 RPA Program Update, and Staff or specialist estimates.

5. Existing stand timber yield tables were developed from volume and growth information by species from the 1981 Forest timber inventory.

6. Managed stand timber yield tables were developed using two growth and yield models: Dynamic Programming Douglas-fir Simulator (DP-DFSIM) for low elevation species and PROGNOSIS for high elevation species.

7. Salvable dead volume coefficients were obtained from the 1981 timber inventory.

8. Percentage increases for volumes (in addition to net green) available from natural stands were developed from Cut and Sold Reports (e.g.,nonchargeable cull and other convertible products) and the Timber Inventory Adjustment Record (e.g., chargeable dead salvage and unregulated).

9. Dispersed recreation capacity coefficients were estimated by Recreation Opportunity Spectrum (ROS) class based on the procedures outlined in the ROS Users Guide (FSH 2309.13).

10. Wilderness capacity coefficients were developed through the use of WRS class standards, Wilderness specific data, and limits of acceptable change (LAC) considerations.

11. The RIM System provided the information needed to determine developed site capacity estimates and was the basis for making recreational use projections for all sites and areas on the Forest by alternative.

12. Social and Economic Statistics and a description of the local economy were obtained from the Forest's Socio-Economic Overview and updated with current figures from the State of Oregon, Employment Division.

13. National and county data files describing local county economies and inter-industry transactions that occur as goods are produced and sold formed the base data used by the input-output model IMPLAN which predicts local economic impacts of alternatives.

14. Road construction rates were developed through computer analyses which generate roading estimates based on variable harvest rates associated with the amount of land available and suited for timber production in each watershed, roadless area, and management area.

15. Erosion production rates based on Willamette National Forest SRI types were developed through a study contracted to the Pacific Northwest Forest Research Station. These rates were then converted to erosion coefficients specific to slope and soil stability classes for use in the planning model.

16. Wildlife and Fish user days (WFUDs) were calculated from historic average proportions of past total use levels which were obtained from the RIM System.

17. Habitat capability for big game was generated by a computer program based on "A Model to Evaluate Elk Habitat in Western Oregon" (Wisdom, et al. 1988)

18. Activity, output, and effect data for the No Change Alternative were in part derived from the current Forest Multiple-Use and Timber Management Plan (1977).

THE FOREST PLANNING MODEL (FORPLAN)

OVERVIEW

Forest planning is a very complex process in which an enormous amount of information must be considered before an alternative management plan can be recommended as the one which best addresses the issues, concerns, and opportunities identified at the outset of the planning process. Because of this complexity, several interrelated computer models and analytical tools have been developed and utilized to help determine the decision space within which alternatives can be developed, and to evaluate their associated outputs and effects.

One of these models is called FORPLAN. The name is an acronym for FORest PLANning model. FORPLAN is a computerized linear programming (LP) model which has its roots in the Resource Allocation model (RAM) and Multiple-Use Sustained Yield Calculations (MUSYC) models. It is composed of a matrix generator, a linear programming solution system (FMPS), and a report writer. Within the bounds of the matrix generator and the FMPS solution package, the user is allowed a great deal of latitude in formulating the mathematical representation of the Forest planning problem to be analyzed. The Forest's modeling analysis was performed with the Version II, DEO-TEST model. The system is maintained and operated on the Department of Agriculture Univac computer at Fort Collins, Colorado and has been adapted for use on MS-DOS based personal computers by the U.S. Forest Service's Rocky Mountain Forest and Range Experiment Station.

The FORPLAN model was specifically designed to help the IDT analyze the economic and production trade-offs associated with the recreation, timber, scenic, old-growth, water, roadless, and wildlife resources, and to help evaluate the extent to which various alternative management scenarios were able to address and resolve the identified planning issues. One key step in the development of the FORPLAN model was to divide the total Forest into analysis areas. Analysis areas are tracts of land with relatively homogeneous characteristics in terms of the outputs and effects that are being analyzed in the FORPLAN model. Their delineations were intended to capture the significant social, biological, and economic differences in the way the land responds to alternative management strategies. The focus of the delineations was upon the planning issues.

In the FORPLAN model, analysis areas were assigned prescriptions in order to achieve the resource management objectives of a particular benchmark analysis or alternative. Prescriptions are directly related to the management areas described in Chapter II. Two major categories of prescriptions were used in the analysis. Management prescriptions contain the standards and guidelines necessary to meet the multiple-use objectives of each management area. These prescriptions are contained within the Proposed Forest Plan document, Chapter IV. The second category of prescriptions, called FORPLAN prescriptions, contain the details necessary to model the management prescriptions in FORPLAN, and to schedule activities in a cost-efficient manner.

FORPLAN prescriptions are combinations of scheduled activities and practices, and their associated outputs and effects. These prescriptions and their range of timing choices are represented as decision variables in FORPLAN. The outputs and effects associated with the prescription choices are represented as mathematical coefficients in the respective decision variables.

FORPLAN prescriptions are represented at three levels within FORPLAN. At the first level, a set of management emphases parallel the management prescriptions. Second, within many management emphases a set of management intensities are represented as choices in the FORPLAN model. These intensities depict different combinations of activities such as timber harvesting, planting, commercial thinning, etc. At the third level, dozens of different timing patterns and rotation ages were provided for most management emphasis-management intensity combinations on timbered lands.

Operation of the FORPLAN model was designed to ensure that prescriptions were selected in a cost-efficient manner. The prescriptions FORPLAN selected depended upon the objective function and the set of constraints used to represent a particular benchmark or land management plan alternative. The objective function is a mathematical equation which shows how the Forest's objective (maximize present net value or maximize timber production, for example) is affected by the variable values explicitly portrayed in alternative management prescriptions. Constraints are mathematical equations which require that a given amount of an input or output variable be achieved. The given amount is also termed the right-hand side (RHS) due to its location within typical linear programming matrix representation. All constraints must be satisfied before an optimal solution to the objective function is reached.

The objective function was usually to maximize present net value (PNV) or maximize the production of timber. These were subject to first satisfying all the specified constraints. Constraints were designed to guarantee the spatial and temporal feasibility of land allocation and harvest scheduling choices in order to achieve the multiple-use objectives of a benchmark or alternative. Once the model had determined that a feasible solution existed by satisfying all of the constraints, it would then search for the set of prescriptions and timing choices which permitted it to optimize the solution according to the specified objective function.

Analysis Process and Analytical Tools Used

As directed in the Planning Regulations (36 CFR 219.12(f)(8)):

> "Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in the alternative."

This direction provided overall guidance to the entire analysis process. The IDT analyzed economic efficiency at several stages of the planning process in order to be reasonably assured that the alternatives developed and displayed in the Draft EIS complied with the intent of this direction. The discussion of the analytical process and tools used will follow this general outline:

1. Analysis prior to FORPLAN,
2. How FORPLAN was used in the analysis,
3. Analysis done in addition to FORPLAN model analysis.

Analysis Prior To FORPLAN

The analysis process began with the identification of issues, concerns, and opportunities. The Forest planning team developed an initial set of issues based on an "objectives hierarchy." This structure of objectives tied together both general and specific resource objectives into an understandable and comprehensive format. These issues were then mailed out to the public. General feedback concerning these issues as well as specific responses on the relative importance of the issues was requested. These responses were then analyzed and relative weights assigned to the issues. The objectives hierarchy

and issue descriptions were then modified, based upon public input, and formed the basis for the final Forest issues.

Once the issues, concerns, and opportunities were identified, the Interdisciplinary Team began to formulate management prescriptions and their associated standards and guidelines. This step was probably one of the most difficult and laborious, and possibly the most important task of the interdisciplinary planning process. Management areas coupled with their respective standards and guidelines provide specific direction for implementation, and serve as a framework for how to use, develop and protect the Forest's resources in a manner consistent with the goals and objectives of the various alternatives.

Since the standards and guidelines provide general, rather than site or project specific direction on how to implement the final Forest Plan, little opportunity was available to calculate a present net value (PNV) or benefit/cost ratio for many of them. However, economic efficiency was a strong consideration throughout their development. For example, standards and guidelines for logging system selection list economic considerations as a major criterion. Similarly, timber haul rates and timing must be cost-effective. Intensive timber management prescriptions call for "obtaining the greatest economic return consistent with other resource requirements."

Much of the analysis prior to FORPLAN involved decisions that needed to be made in the design and construction of the FORPLAN model. Concurrently with the formulation of management areas and the standards and guidelines, the IDT also began to identify the analysis areas that would be used in the FORPLAN model. The Forest's grid cell data base was used extensively to analyze different analysis area combinations that could be used to model and evaluate the production and economic trade-offs between the recreation, roadless, timber, water, scenic, old-growth, and wildlife resources on the Forest. The objective of this exercise for the DEIS analysis was to delineate the analysis areas in such a way as to capture the important variations in the biological and economic characteristics of the land in as few analysis areas as possible.

Many of the decisions that were necessary to reduce the number of analysis areas for the DEIS analysis were made unnecessary through the use of relational data base tools in conjunction with the Forest's grid mapping system. Complete detail was maintained in the analysis areas until after the management strategies were combined and the data processed through the side model, "VISPLAN", developed by the Pacific Northwest Regional Office. VISPLAN provided details on the availability and average volume per acre for lands in all strategies with a limited final harvest entry per decade (up to 12% per decade). Based on VISPLAN output, the analysis areas for all strategies except the "general forest" strategy were collapsed, constraints were written for harvesting limited entry areas, and special yield tables were written to accurately reflect the average volume per acre for harvests in the limited entry strategy areas. Final analysis area delineators were focused upon depicting timber production and economic differences.

Once the final analysis area delineation was settled upon, the next step was to develop the prescriptions for the FORPLAN model. This included the development of timber yield tables, other resource yield coefficients, and the economic costs and benefits associated with each FORPLAN prescription. These prescriptions were designed to enable FORPLAN to analyze the economic and resource trade-offs associated with a particular benchmark or alternative, and to select and schedule prescriptions in a cost-efficient manner.

FORPLAN prescriptions are combinations of scheduled activities and practices, and their associated outputs and effects. These prescriptions and their range of timing choices are represented as decision

variables in FORPLAN. The outputs and effects associated with the prescription choices are represented as mathematical coefficients in the respective decision variables.

FORPLAN prescriptions are represented at three levels within FORPLAN. At the first level, a set of management emphases parallel the management prescriptions. Within many management emphases a set of management intensities are represented as choices in the FORPLAN model. These intensities depict different combinations of activities such as timber harvesting, planting, commercial thinning, etc. At the third level, dozens of different timing patterns and rotation ages were provided for most management emphasis and management intensity combinations on timbered lands.

In designing the FORPLAN model considerable effort was expended in developing the management intensities to be used for each management prescription, and in determining the timing choices to be used for each management intensity. A dynamic programming model, DP-DFSIM, was used to develop timber management regimes that were most efficient in meeting different criteria (e.g., maximum timber volume, and maximum PNV). In addition to these maximums, a wide range of timber yield tables was developed to provide FORPLAN with the harvest scheduling flexibility needed to satisfy the multiple-use objectives of each alternative, and to find the most efficient solution. The complete set of management intensities was also analyzed in terms of present net value on a per acre basis. The final set of intensities selected were based on silvicultural considerations, economic criteria, multiple resource objectives, and the need to provide a wide range of choice for FORPLAN. An entire section, titled *Development of Management Prescriptions and Intensities*, appears later in Appendix B and contains the details of these analyses and the analysis of timing patterns to be allowed.

Another analysis done prior to FORPLAN for some alternatives in the FEIS has been termed the "Spatial Disaggregation Process" (SDP). The same process can be used (depending on the alternatives objectives) to meet hydrologic recovery goals by writing FORPLAN constraints or to measure the effects of timber harvest on hydrologic recovery after FORPLAN has found an optimal solution. The Spatial Disaggregation Process begins with the analysis area information and adds geographically specific data from the mapping system for the factors affecting water quality and the dispersion of created openings. Using this detail, the SDP finds the one most constraining factor for each sub-drainage (there are 454 unique geographically located sub-drainages). When SDP is used to distribute and limit hydrologic recovery, the acres available by sub-drainage are totaled by watershed to generate FORPLAN constraints. When SDP is used to analyze a FORPLAN solution, it estimates the relative risks of violating standards and guidelines for harvest unit location and water quality risks based on hydrologic recovery measures.

FORPLAN Analysis

FORPLAN was used for three principal purposes in the analysis. The first use was to identify the maximum or optimum method of meeting a single objective. This was done primarily in the formulation of benchmarks as part of the Analysis of the Management Situation. The objectives of focus were maximizing present net value (using all values, and using market values only), maximizing timber production, and maximizing recreation opportunities. In all of these benchmarks a review of the implications on the resources not being emphasized was a key concern of the analysis.

The second principal use of FORPLAN was to assess implications of particular policy decisions. This was also primarily done in the context of the maximum PNV benchmark (using all values). In this case, a comparison of FORPLAN results with and without the particular policy feature was used to estimate the impacts associated with the implementation of the policy in question. Among the specific policies examined this way were minimum management requirements (MRs) (including specific comparisons on wildlife MRs, spotted owl MRs, riparian MRs, and spatial dispersion requirements),

departure versus nondeclining flow schedules, limiting first entry rotation ages to 95% of the culmination of mean annual increment, and the impact of different economic assumptions.

The most important use of FORPLAN was in the development of alternatives. Since alternatives are generally multiresource oriented, the FORPLAN model served to identify the most efficient method to achieve, simultaneously, a number of different management objectives. During alternative modeling interaction of constraints was watched closely to ensure achievement and avoid overachievement of the intended objectives of the constraints being modeled. FORPLAN was also used to identify effects of the alternatives on particular areas of resource concern.

The prescriptions FORPLAN selected depended upon the objective function and the set of constraints used to represent a particular benchmark or land management plan alternative. The objective function is a mathematical equation which shows how the Forest's objective (maximize present net value or maximize timber production, for example) is affected by the variable values explicitly portrayed in alternative management prescriptions. Constraints are mathematical equations which require that a given amount of an input or output variable be achieved. The given amount is also termed the right-hand side (RHS) due to its location within typical linear programming matrix representations. All constraints must be satisfied before an optimal solution to the objective function is reached.

The objective function was usually to maximize present net value (PNV) or maximize the production of timber. These were subject to first satisfying all the specified constraints. Constraints were designed to guarantee the spatial and temporal feasibility of land allocation and harvest scheduling choices in order to achieve the multiple-use objectives of a benchmark or alternative. Once the model had determined that a feasible solution existed by satisfying all of the constraints, it would then search for the set of prescriptions and timing choices which permitted it to optimize the solution according to the specified objective function.

Analysis In Addition To FORPLAN

Although many of the outputs and effects displayed in the Draft EIS were calculated directly by FORPLAN, many others were developed through post-FORPLAN modeling processes. Generally, these processes either integrated several factors derived from multiple sources, or required a specific type of disaggregation of model results. The major outputs or effects analyzed by post-FORPLAN processes were fish and wildlife, water, economics, transportation needs, and roadless areas.

The FORPLAN solution was disaggregated to each analysis area and management strategy combination by special report writers maintained by the Pacific Northwest Regional Office and by a data base software package (Paradox) for MS-DOS computers. Coefficients for many of the outputs and effects that were not directly reported by FORPLAN were assigned using relational data base techniques and the SDP was employed to asses the effects of timber harvest levels on hydrologic recovery. Most of the recreation estimates and the economic summaries were calculated using electronic spreadsheets.

Estimation of economic effects also required additional analysis after FORPLAN. The IMPLAN model was used to estimate the effects of the alternatives on county level jobs and personal income. Outputs from FORPLAN, primarily timber and recreation, provided the basic input to IMPLAN. The section titled *Social and Economic Impact Analysis* of this appendix provides more detail on the IMPLAN model. Electronic spreadsheets were used to fully calculate PNV, resource contributions to benefits and costs, and the necessary budgets for benchmarks and alternatives.

Analysis of transportation system needs and of resource outputs and effects within roadless areas both required specific disaggregations of FORPLAN outputs. FORPLAN timber volumes were distributed to transportation "collectorsheds" for estimation of road mileages needed. An electronic spreadsheet was used to derive estimates of outputs and effects within each roadless area.

FOREST PLANNING MODEL

Identification of Analysis Areas

Overview

Analysis areas serve as the basic land stratification in FORPLAN. They help to describe the Forest land base so that different management options can be analyzed. Analysis areas are a part of the basic decision variable used in the linear program (LP). The other component of the decision variable involves the prescription that is applied to the analysis area. A range of prescriptions are defined for each analysis area. The linear program optimizes over all prescriptions to provide the most efficient combination of prescriptions for each analysis area given the constraints.

As the basic land stratification, analysis areas (AAs) serve several functions in FORPLAN.

1. AAs allow the Forest to be stratified so that management prescriptions may be applied based on different land characteristics. These characteristics help in defining appropriate management activities and their associated costs. The land characteristics can also help to predict the effects of undertaking these activities (the resource yields produced and any financial value they may represent).

2. AAs allow the Forest to be stratified so that management activities and/or resource yields may be constrained to specified levels, fluctuations over time, or relative levels (based on other activities or yields).

3. AAs allow the Forest to be stratified so that management activities or resource yields may be summarized and reported by different geographic areas or vegetative conditions on the Forest.

Level Identifiers

AAs are defined by six levels of information. The six levels are mapped and overlayed to form unique, homogeneous units. Each of the six levels will be discussed summarizing the reasons why the resource information was chosen, and its function in the analysis process. All resource inventory maps used in developing analysis areas have been coded into the Forest grid cell map data base at 1-inch equals 1-mile scale. This equates to a grid cell size of 21.33 acres.

Level 1: Watershed - Watershed delineation was chosen as the identifier or information for the first level of Forest stratification. It is a spatial representation of data. The watershed delineation is comparable to the allocation zones used in the DEIS analysis. Some of the specific boundaries were adjusted to follow district boundaries or to more accurately segregate areas with unique hydrologic or geomorphic conditions. This geographic information is used with other FORPLAN identifiers and other map layers to estimate average production coefficients for FORPLAN or other models that are used to estimate outputs and effects.

Level 2: Not Used

Level 3: Not Used

Level 4: Silvicultural Suitability - Level 4 contains a composite of information that shows where commercial thinning and fertilization are feasible. A full range of timber harvest prescriptions were developed from which the FORPLAN model could select. Areas that are suitable for commercial thinning and fertilization opportunities were identified so that the management costs, growth, and timber yields are accurately reflected in each management prescription.

Areas that are considered accessible for commercial thinning are those that can be reached from either an existing or proposed road within the capability of existing logging equipment. This was assumed to occur a given number of horizontal feet from a road depending upon its topographic location:

Valley roads	-	300 feet each side
Ridge top roads	-	1,200 feet each side
Hillside road	-	300 feet uphill/1,200 feet downhill

Transportation plans and information from the Districts were used to map the existing and proposed road network on 1-inch to the mile topographic maps. The area accessible around each type of road was then mapped based on the horizontal width criteria. See "Accessibility for Commercial Thinning" (Megargel 1982) for more information about development of this layer.

Fertilization opportunities were derived from the soil inventory for the DEIS analysis. The assumptions for fertilization response have changed between the DEIS and FEIS. For the DEIS, only the 19 soil types which had been tested for fertilization response were included in the "responds to fertilizer" classification. For the FEIS analysis, all of the predominantly Douglas fir (60% or greater) timber type lands were assumed to "respond to fertilizer" applications. The actual amount of response predicted is taken from fertilizer response predictions in the yield simulator.

Table B-2. Assignment of Timber Management Intensities

	Analysis Area Identifier			
	Accessible		Not Accessible	
	Response	No Response	Response	No Response
T-1A Minimum Investment	X	X	X	X
T-1B Minimum Investment with Early Entry	-	X	-	-
T-1C Early Entry with Fertilization	X	-	-	-
T-2 Moderate Investment	-	X	-	X
A-2 Moderate Investment and Fertilization	X	-	X	-
T-3 Full Stocking Level Control	X	X	-	-
T-4 High Investment	X	-	-	-

X Indicates the timber intensity allowed for the analysis area identifier combination.

Timber management intensities available for selection are based, in part, upon accessibility to commercial thinning and fertilization response. Table B-2 shows which intensities are available according to analysis area identifiers. Management intensities that require fertilization will only be an option in areas that show response. Only areas accessible will have the choice of the management intensities that prescribe commercial thinning. Regardless of which logging system happens to overlap with accessible areas, only skyline systems were used in modeling commercial thinning. The majority of thinning done on the Forest utilizes skyline systems. The yield table analysis (Sanders, et al. 1985) showed that thinning with aerial systems was not economically viable. Thinning using ground-based systems is not commonly used.

The timing of thinning and fertilization depends upon timber type association and size class represented in Levels 5 and 6. The "Timber Yield Table Documentation" (Sanders, et al. 1985) process paper gives a detailed description of yield table development.

Level 5: Timber Type - Analysis of the timber production capabilities of the Forest is dependent upon knowing the status of the existing timber inventory, and of the potential growth a site is capable of producing in the future. The timber type association is an important vegetative stratification used to categorize differences and summarize data.

Timber type associations were taken from the four inch to the mile timber type map developed for the 1981 timber inventory. The inventory sampled plots that were stratified based on the Forest's Aggregated Timber Type Model. The model describes the vegetation conditions of timber stands according to the predominant commercial timber species and size class. Five timber type associations were represented in the sampling model:

1. *Douglas fir/western hemlock* - catch-all category for the western hemlock zone;
2. *Douglas fir/true fir* - stands with some true fir, indicating a cooler site than western hemlock;
3. *True fir association* - catch-all category for silver fir zone, with less than 20% Douglas fir;
4. *Mountain hemlock* - stands dominated by mountain hemlock, no noble fir present;
5. *Lodgepole pine* - pure or nearly pure lodgepole pine stands of any size or stocking.

The "Process Documentation for Timber Resource Inventory" (Sloan et al. 1983) describes the timber typing and inventory in detail.

Timber type associations help determine the economics of timber production since the average dollar return per unit volume harvested differs depending upon the species mix. Timber types are also important in estimating wildlife indicator species populations. The Douglas fir/western hemlock association was used in analyzing the hydrologic condition of watersheds. Existing timber inventory and future growth rates also vary by timber type.

Non-forest areas that are less than 10% tree cover, water, rock, or barrens are identified in the timber type class information. Forest cover types are reported for unsuitable lands, withdrawn lands, and for Douglas fir/hemlock lands on non-National Forest. This information is used for estimating both dead tree habitat and hydrologic conditions for each watershed.

Level 6: Timber Size - The last level in the analysis area stratification includes the existing timber size information. This information was taken from the timber typing done for the 1981 timber inventory.

Five size classes were represented for sampling inventory plots based on the Aggregated Timber Type Model (Sloan, et al. 1983):

1. *Seedlings and Saplings/nonstocked* - 0 to 4.9 inches diameter;

2. *Pole Timber* - 5 inches to 8.9 inches;

3. *Small Sawtimber* - 9.0 inch to 20.9 inches diameter, mainly young growth;

4. *Large Sawtimber* - 21 inches diameter and larger;

5. *Old-growth Timber* - 21 inches diameter and larger, usually over 180 years old. Trees are characterized by deeply furrowed bark, ragged tops, and limb clusters in lieu of individual limbs.

The seedling and sapling size strata was not sampled since the inventory plots were not designed to sample vegetation in this size class. After the field work was done in 1981, empirical timber yield tables were developed for each of the type/size combinations. As the timber yield tables were developed, the mountain hemlock and lodgepole pine components were combined into one size class for purposes of timber yield estimation. The plot information showed a mixture of species within the lodgepole pine type, and since the strata is a mountain hemlock climax type, it was combined with the mountain hemlock poles. The two empirical tables were weighted together based upon the suited acres in each strata.

The inventory analysis showed the per acre yields between the large sawtimber and old growth strata were not statistically different. For the DEIS these two size classes were combined. However, public comment received after the DEIS was released cited the importance of correctly identifying old-growth stand characteristics, and there was some concern that the Forest was losing the ability to identify existing old growth. In response, a new inventory was done with the major objective of identifying stand characteristics. The new inventory was named for the type of stands that were to be sampled and is commonly referred to as the Mature/OverMature Survey (MOMS). The survey data allows identification of old growth based on a variety of possible definitions or stand characteristics.

The timber size information that was delineated for the 1981 inventory was current up to January 1980. To represent a more accurate timber inventory, this was updated twice for the DEIS. The timber size class data was again updated for the FEIS (from 1985 to 1989). Also in response to public comments, the seeds/saps size classes were disaggregated into four 10 year age groups by species, using information in the Total Resource Information (TRI) system and the mapping done as part of the Mature and Overmature survey. Average ages now are 10, 20, 30 or 40 years near the midpoint of the first planning decade (1994). This disaggreagation is used only for the Douglas fir timber types. The true fir association, mountain hemlock and lodgepole pine timber types are represented by one age class for the seedlings and saplings up to 40 years old. More information on the process of updating the timber size class information can be found in the planning records, available for public review at the Forest Supervisor's Office.

The timber inventory established an average site index and age for each type and size strata. The average site index gives an indication of future growth potential. It was used in developing managed timber yield tables. The average age is used to assign appropriate prescriptions for the first decade of the planning horizon. The assigned ages are shown in Table B-3.

Table B-3. Analysis Area Ages

Timber Type	Timber Size	Age in Years
Douglas fir/hemlock	10-year-old	10
	20-year-old	20
	30-year-old	30
	40-year-old	40
	Poles	60
	Small sawtimber	120
	Large sawtimber	180
	Old growth	240
Douglas fir/true fir	10-year-old	10
	20-year-old	20
	30-year-old	30
	40-year-old	40
	Poles	50
	Small sawtimber	160
	Large sawtimber	190
	Old growth	230
True fir	10 to 40-year-old	20
	Poles	140
	Small sawtimber	160
	Large sawtimber	220
Mountain hemlock/lodgepole	10 to 40-year-old	20
	Poles	160
	Large sawtimber	220

The nonstocked component of the seedling and saplings is not identified separately, but it was recognized through a yield falldown applied to managed timber yield tables applicable to this size class. For documentation on identification of physically unsuited lands, see "Willamette National Forest: Timberland Suitability Documentation" (Mayo and Bernat 1984).

Conclusion

For further discussion of the resource layers used in the level identifiers, see "Data Base Documentation" (Bernat 1984). This process document describes how the source maps were derived and coded into the grid cell map system.

The levels of information that make up the analysis areas are composed of basic geographic, soil, and timber stand characteristics. This information serves in applying appropriate prescriptions and in predicting and constraining resource yields to land areas.

Table B-4 shows the final set of analysis area identifiers that were used to represent the Forest in the FORPLAN model.

Table B-4. FORPLAN Identifiers

*LEVEL 1 WATERSHED
10: BLUE RIVER

DEVELOPMENT OF MANAGEMENT PRESCRIPTIONS AND INTENSITIES

Overview

In the FORPLAN model analysis areas were assigned prescriptions in order to achieve the resource management objectives of a particular benchmark analysis or alternative. Prescriptions are directly related to the management areas described in Chapter II. Two major categories of prescriptions were used in the analysis. Management prescriptions contain the standards and guidelines necessary to meet the multiple-use objectives of each management area. These prescriptions are contained within the Proposed Forest Plan document, Chapter IV. The second category of prescriptions, called FORPLAN prescriptions, contain the details necessary to model the management prescriptions in FORPLAN, and to schedule activities in a cost-efficient manner.

The National Forest Management Act (NFMA) regulations define management prescriptions as "management practices selected and scheduled for application on a specific area to attain multiple use and other goals and objectives" (36 CFR 219.3). Management prescriptions consist of a goal statement which establishes the purpose of the prescription, and a compatible set of management practices designed to develop and/or protect some combination of resources, and create or perpetuate a desired condition. The standards and guidelines that form the prescriptions were constructed within the requirements specified in 36 CFR 219.27. These requirements guide the development, analysis, approval, implementation, monitoring and evaluation of Forest Plans with regard to:

- Resource protection;
- Vegetative manipulation;
- Silvicultural practices;
- Even-aged management;
- Riparian areas;
- Soil and water; and
- Diversity.

These prescriptions represent a range of management direction, intensity, practices, standards and guidelines. The IDT included the necessary mitigation measures and resource coordination measures that are required to satisfy economic, legal, and social constraints when implementing these prescriptions. The documentation of these measures are found in the Standards and Guidelines of the Forest Plan.

The prescription development and screening process will be presented in detail in the next two sections. The next section will discuss management prescriptions: the process used to construct them; the goals and objectives of the prescriptions; and a standard and guideline comparison table. Following that is a discussion of the FORPLAN prescriptions: the process used to construct and screen timber options; the effects of assumptions made in the screening process; and the prescriptions used.

Management Prescriptions

The Forest uses 38 different management area themes for this FEIS and Plan. A range of prescriptions were developed to analyze alternate ways of managing the unique resources that exist in each management area. Each prescription was evaluated for its interaction and representation in FORPLAN. As the FORPLAN model was developed, many of the management areas were found to contain standards and guidelines that could be accurately represented with only a few FORPLAN "emphases". Table B-5 shows the relationship between management areas, standards and guidelines, and FORPLAN emphasis.

00	No programmed timber harvest (nontimbered, Unsuitable, withdrawn, etc.)
55	5% of the area available for final harvest in any 10-year period.
77	7% of the area available for final harvest in any 10-year period.
10	10% of the area available for final harvest in any 10-year period.
12	12% of the area available for final harvest in any 10-year period.
TI	General Forest (Greater than 12% available for final harvest in any period).
PD	Nonnational forest.

The process of developing the management prescriptions began with a review of the issues, concerns, and opportunities, which led to the development of prescription options with related goals and objective statements. The IDT used research literature and professional judgement to identify projects which would be consistent with existing policy, legislative direction and the identified goals.

In addition to addressing ICOs, the process of designing management prescriptions was also guided by the following criteria: (1) prescriptions should be achievable and contain realistic practices, (2) they are to be general enough to accommodate the variable site specific conditions on the ground, (3) they should be specific enough for the IDT to develop accurate resource and economic output and effect coefficients, and (4) to the extent practicable, they should be the most cost effective means of achieving the intent of the prescription.

To a large degree the particular structure used represented a consensus judgement about the type and detail of direction appropriate for management areas. Sufficient detail is necessary to resolve problem areas and provide clear direction. Enough flexibility must be preserved to allow for efficient accomplishment of objectives. Improvement of the accuracy and specificity of data and of analysis techniques may allow more specific direction in the future.

Management practices are implemented within each prescription according to the resource management goals of the prescription and the standards and guidelines. A map of the land allocation for each management area is available for each alternative. This map, in conjunction with the associated prescriptions, and the standards and guidelines identifies where activities will take place during the implementation of any one alternative. Table B-5 compares the major standards and guidelines for each management prescription. The goals of each management prescription are summarized below. Chapter IV of the Forest Plan describes them more completely.

Timber Options

FORPLAN prescriptions are combinations of scheduled activities and practices, and their associated outputs and effects. These prescriptions and their range of timing choices are represented as decision variables in FORPLAN. The outputs and effects associated with the prescription choices are calculated for each decision variable.

FORPLAN prescriptions are represented at three levels within FORPLAN. At the first level, a set of management emphases parallel the management prescriptions discussed in the previous section. Within many management emphases a set of management intensities are represented as choices in the FORPLAN model. These intensities depict different combinations of activities such as timber harvesting, planting, commercial thinning, etc. At the third level, dozens of different timing patterns and rotation ages were provided for most management emphasis and management intensity combinations on timbered lands.

A wide range of yield tables that encompassed all practicable combinations of management practices was developed. The dynamic programming option used with the DP-DFSIM model for Douglas fir types greatly aided this process by automatically selecting the optimum timing and level of activities for a given set of criteria. A set of yield tables was then selected for further analysis in FORPLAN. Decisions made based on this FORPLAN analysis resulted is a final set of management intensities and timing choices used as FORPLAN prescriptions. The actual FORPLAN intensities and timing choices for each analysis area are listed in the FORPLAN data sets (part of the Forest Planning Records).

Management intensities developed with DP-DFSIM involved different mixes of reforestation methods, precommercial thinning, fertilization timing, and commercial thin timing. Each combination of activities tested were developed under both a maximum timber volume (MAI) objective function and a maximum PNV objective function. Table B-6 and Table B-7 display the results of these yield tables for Douglas fir/western hemlock and Douglas fir/true fir respectively. More intensive analysis was performed with the Douglas fir/western hemlock timber type than with other types since it occupies over 80% of the suited timber land.

For the true fir and mountain hemlock timber types management intensities were developed with the PROGNOSIS model, involving different mixes of reforestation methods, precommercial thinning, and commercial thinning. Table B-8 and Table B-9 display the results of these yield tables for the true fir and mountain hemlock types respectively.

The number of yield tables used in FORPLAN for the Douglas fir strata was reduced by using DP-DFSIM to analyze all the possible treatment combinations for each objective (maximize volume or present net value). Only the optimum regime for each management intensity was used in FORPLAN. Based on public comment, a prescription that called for one heavy commercial thinning (and consequently led to earlier culmination of mean annual increment and a 60-year rotation) was added to the FEIS analysis. The prescription was chosen by FORPLAN even though it produced a lower mean annual increment and a lower present net value. Both the heavy thinning and the shorter rotation age were valued by FORPLAN for their ability to fill in the harvest schedule during the fifth through seventh decades.

For the true fir and mountain hemlock strata, a range of managed yield tables with various treatment options was developed from the base tables, using PROGNOSIS to determine volumes. Because PROGNOSIS is not an optimization program like DP-DFSIM, many more runs were necessary to determine the optimum regimes. A program called "CHEAPO" was used in conjunction with PROGNOSIS to calculate PNVs and to determine the regimes which would maximize PNV for each management intensity.

Since management options are comparatively few for existing stands, all distinct options were included in the model. Model size considerations prohibited inclusion of all management intensities developed for managed stands. Management intensities were selected based upon economic efficiency, timber volume contributions, silvicultural considerations, and operational practicalities. Tables B-6, B-7, B-8, and B-9 also display which of the following criteria were used to eliminate particular management intensities:

- No precommercial thinning (1);
- Commercial thins were not economically practicable (2);
- Ten-year commercial thinning intervals (3);
- Silvicultural considerations (4);
- Lower PNV (5).

[1] PNV not calculated since the final harvest did not pay.

Those intensities without precommercial thinning were eliminated since they were inferior both in terms of PNV and in timber volume when compared to intensities with precommercial thinning. Intensities where revenues returned from the timber volume sold were insufficient to cover expenditures were also eliminated. This occurred primarily with commercial thinnings and had the effect of forcing commercial thinnings to occur later in the rotation for the intensities retained. The third criterion was based on District experience with laying out and administering timber sale contracts for commercial thinning. The extremely large number of acres to be thinned when thinnings are scheduled every 10 years was considered to be operationally unworkable. The Forest cannot legally operate two sales in the same area at the same time. The effect of dropping intensities with 10-year thinning intervals was to have fewer thinnings with the remaining intensities. A fourth criterion, silvicultural considerations, resulted in the elimination of a few yield tables due to the scheduling of commercial thinnings after stand relative density exceeded a value of 60. Forest silviculturists felt that the DP-DFSIM model projected an unrealistic growth pattern after commercial thinning stands with relative densities greater than 60. A final criterion resulted in the elimination of management intensities with a low PNV if similar intensities were available with a higher PNV. Those management intensities without any elimination criteria listed were carried forward into the next analysis step.

Potential effects due to use of these screening criteria can be estimated by comparing two tables that are identical except for the parameter of interest. For example, to estimate the volume loss of criterion 3, ten-year thinning intervals, under a maximum timber objective, for Douglas fir/western hemlock, compare intensities 10 and 12 from Table B-6. In the MAI column under CMAI rotation the difference between 157 and 159 indicates a 2 cubic feet/acre/year potential effect.

A final set of analyses were performed examining the use of natural regeneration versus planting, the competitiveness of non-timber prescriptions with timber prescriptions in terms of PNV, and the types of timing choices to provide FORPLAN. These analyses were combinations of both FORPLAN and non-FORPLAN analysis.

Since the per acre stand level analysis in DP-DFSIM consistently showed natural regeneration to be more economically efficient than planting, intensive analysis of this question was done. To achieve the biological conditions for successful natural regeneration, a seed source is needed. This is accomplished by using a two-stage removal process on the stand to be harvested. The trees left after the first entry provide the seed source for stand establishment. The second entry removes the seed source after stand establishment occurs and completes the harvest operation.

Since there is a period of about five years between the two entries, a reduction in PNV for the existing stand occurs. The net revenues associated with the second entry are delayed and the effects of discounting make them worth less in today's dollars. In the analysis displayed in Table B-10, the reduction in PNV on the existing stand more than offset the PNV gain on the managed stand for the natural regeneration prescription. These results indicate that if natural regeneration is selected when either method would accomplish the reforestation objective, a loss in total PNV would result.

Table B-10. Analysis Results

Rx/Stand	Existing Stand	Future Managed Stand	Total
Plant	11,210	-284	10,926
Natural Regeneration	10,251	-132	10,119
Difference	959	-152	807

Additional analysis of this issue was also conducted with FORPLAN. Two runs that used the maximize PNV objective function were compared. The only difference between the two runs was that one allowed natural regeneration prescriptions to be considered in addition to planting, and one did not. Only 393 acres of natural regeneration came into solution on the run where this option was available. This result could be due to the factors described in the previous paragraphs, or to the ability of FORPLAN to harvest more high valued existing timber by bringing into solution planting intensities with higher future volumes.

A preliminary analysis of other resource prescriptions was conducted outside of FORPLAN to determine if they could compete with timber on a per acre basis. Dispersed recreation and scenic resource prescriptions were analyzed and compared to timber prescriptions. This analysis showed that when an existing stand of mature timber is present, other resource prescriptions with their higher costs, could not compete despite higher recreation values. If an existing stand could not be harvested immediately, the higher recreation values enabled a number of these other resource prescriptions to be economically competitive. To determine if this would still hold true on a Forest-wide basis when future stand growth considerations enter into the analysis, a FORPLAN run was made which included the most competitive of the other resource prescriptions. Approximately 920 acres went to a scenic prescription in this run. Since this represented less than 0.1 percent of the suitable timber acres, non-timber prescriptions were dropped from further consideration when PNV was the sole objective.

Finally a *Stage II* (discounted present net value per acre) financial analysis was completed. The results showed that values per acre were dependent upon timber type, volumes per acre, logging cost class (average logging cost in a watershed), and projected growth rates. Present net values range from over $11,000 per acre for Douglas-fir stands on flat ground, to almost zero for many mountain hemlock/ Lodgepole stands on steep ground. Timber harvests in areas where positive financial returns are questionable will be carefully reviewed.

Development of Yield Coefficients

Timber Yield Coefficients

Timber yield tables for the Willamette were developed for three separate components; i.e., empirical yield tables for existing mature stands, managed yield tables for plantations and future stands, and merchantable material available but not regulated, such as salvage. Each of these three components will be discussed in this section. Processes for constructing empirical yield tables and for building tables for the unregulated volume were relatively simple. More intensive effort was expended on development of the managed tables. The "Timber Yield Tables" process record contains further details (1920 12/31/84).

The empirical yield tables were generated from information obtained from the Willamette National Forest Timber Inventory by the Regional Office. The timber inventory information was compiled by

timber type and size class stratum. The existing stand volume per acre was determined. The rate of growth on the growing stock was also determined. Curves were constructed for both the projected stand volume and the projected growth. These curves were then combined to create a controlled volume curve that predicts future volume for each stratum. Empirical yield tables were then tabulated from this curve (USDA Forest Service, R-6).

Between the DEIS and FEIS, new defect and breakage (D&B) values were calculated for the empirical yield tables, to more accurately reflect the variation by species and size class. Cruise data from a sample of timber sales across all Ranger Districts was used to determine the percent D&B for poles, small sawtimber, large sawtimber and old growth for each of the model components. A reduction in breakage was applied to large sawtimber and old growth stands, based on uphill falling studies on slopes of 30% or greater. The yield tables have also been updated for growth to 1994.

The Douglas fir Simulator (DFSIM), a growth and yield model, was used to simulate a wide variety of growth and harvest patterns over time for the Douglas fir and Douglas fir/true fir managed yield tables (Curtis, 1981). With DFSIM the user can simulate yield regimes for Douglas fir under different regeneration options (planted or natural) with or without precommercial thinning (PCT) and with or without fertilization. For a given set of investments, the goal was to find the combination of intermediate harvest and final harvest that best met the objective of maximizing volume or present net value (PNV). To search for the combination of thinnings and final harvest over different rotation ages that best met the objective and constraint set would require a great number of DFSIM runs.

Dynamic programming in conjunction with DFSIM (DP-DFSIM) is a computer program that automates the search for yield regimes in DFSIM that optimizes either volume or PNVs, and does so in a computationally efficient manner (Johnson 1984).

Yield tables were developed to represent each objective for a range of management intensities from "natural regeneration with no intermediate treatments" to "planting genetically improved stock with full stocking level control plus fertilization."

Three major operational constraints affecting commercial thinning entries were placed in the DP-DFSIM program for the yield tables eventually selected for use in FORPLAN. Commercial thinning entries had to be spaced at least 20 years apart, had to break even economically, and had to be scheduled before the relative density reached 61 when called for after PCT. Relative density (RD) expresses the average level of competition in a given stand, relative to a stand of maximum density. Numerical values range from 0 to 100. Relative density was constrained because DP-DFSIM ignores the effect of high initial RDs on the growth of trees after thinning. Some of the optimal regimes allowed the RD to exceed 60 and still showed normal response to thinning. To avoid this, any regime which showed a RD of 61 or greater prior to a commercial thin (if PCT'd) was dropped from consideration (2410 Plans, May 22, 1984). Without PCT, the stand exceeds 60 RD before reaching commercial thinning size.

The above constraints generally resulted in commercial thinning regimes that were similar to what empirical appraisals had indicated were necessary. The average stand diameter at the first commercial thin is about 12 inches, and the per acre volume removed is 4,000+ board feet depending on the logging system. A ground-based system with lower logging costs requires less volume to break even than a skyline system. It must be emphasized that these figures are averages for the entire Forest, and individual stand prescriptions by certified silviculturists will vary depending on site-specific conditions.

The different logging system costs produced some minor differences in yield tables due to the amount of commercial thin volume needed to break even. If the objective is to maximize volume, an unconstrained DP-DFSIM run shows numerous light thins starting at age 27 with as little as 200 board feet per acre removed to be best. With operational constraints, the lower costs for ground logging means lighter

thins are possible and produced slightly higher volumes over the rotation than skyline systems. Aerial logging costs were too high to allow commercial thinning to break even.

Separate yield tables were developed for ground and skyline logging systems. However, the differences were minor, the greatest being 3 cubic feet mean annual increment (MAI). The Forest area designated suitable for ground logging includes high-lead cable systems which cannot be used for commercial thinning. These areas (90% of the ground logging area) will have to be skyline thinned, and, therefore, would fit the skyline yield tables. Because of these considerations, only the skyline yield tables were used.

For the objective of maximizing PNV, the best regime is to thin heavy as soon as possible to generate revenue and offset the earlier investments. In this case, skyline and ground logging systems thinned the same amounts. Only the PNV was different due to the different logging costs. Again, only one yield table was necessary. FORPLAN applied the appropriate costs for each logging system at the time of final harvest.

A major consideration was the precommercial thinning level and the effect it would have if commercial thinning was delayed until the stand averaged about 12 inches d.b.h. (Reukema 1979). The precommercial thinning level was set at 300 trees per acre in the Douglas fir/hemlock, Douglas fir/true fir, and true fir types and 400 trees per acre in the mountain hemlock stratum. Three hundred trees were picked in the DFSIM model because this was the bottom limit of data, and the model operation is such that it never reaches a point where growth does not respond to lower stocking and taper off. Bob Curtis, the Douglas fir simulator model developer (DFSIM), does not recommend modeling precommercial thinnings below 300 trees per acre. Thinning below 400 trees per acre in the PROGNOSIS model caused volume losses. However, when 400 trees per acre was used in the true fir stratum, a large jump in mortality was observed before commercial thinning, and the RD approached 65. This indicated undesirable overstocking. Reducing stocking to 300 trees solved the problem with little loss in MAI. The mountain hemlock stratum did not show the large jump in mortality when age 30 stocking was set at 400 trees per acre.

The optimum precommercial thinning age is 12 years for the Douglas fir/hemlock stratum and 15 years for the other strata. Actual precommercial thinning within that range is not very sensitive. For natural regeneration, PCT was not scheduled until stand age is 14. This additional time to PCT is due to the difference in height growth between planting a 2-0 seedling and a natural germinant. Calculation of the net MAI is based on the age of the stand plus the time between harvest and planting (regeneration lag). Using Forest-wide information stored in the TRI systems, the average time between sale closure and planting was found to be 1.9 years for the period 1978 to 1980. This was considered the most recent data available for normal operations. The actual period of bare land condition would be somewhat longer depending on the amount of time between harvest and sale closure. Based on this, a 3-year regeneration lag between the time trees are severed from the stump and the unit is adequately restocked was considered most accurate. For natural regeneration, 2 years was added for a total regeneration lag of 5 years. This is due to the inconsistency of seed production from year to year.

The DFSIM model is based on data from actual stands. However, very little information was included on stands over 80 years old. Growth and yield outputs for ages 80 to 100 are considered plausible extrapolations. The program contains a warning that stand statistics beyond 100 years are gross extrapolations of the model.

Yield information was also needed for longer rotations beyond age 100, for wildlife, visuals, riparian management, and dispersed recreation.

It was decided to use the empirical yield tables growth for longer rotations and to gradually change from managed to empirical tables over a five-decade period. This provides a smooth transition between tables and a gradual slowdown of growth.

The time at which the shift begins is age 100 or the age at CMAI on the DP-DFSIM run, whichever is greater. A few regimes culminated a little beyond age 100. DP-DFSIM often shows a different regime is better for longer rotations, so no information would be available beyond CMAI. For these situations, DFSIM runs were matched to the DP-DFSIM regime and the rotation extended five decades beyond age 100 or CMAI, in order to provide the necessary information for the shift to the empirical tables. The point at which the empirical table is entered is where the basal area most closely matches the managed basal area at age 100 or CMAI.

The DFSIM model was generally believed to be inappropriate for the true fir and mountain hemlock strata. The data base does not include stands growing under these ecological conditions. By their classification, Douglas fir can only be a minor component. Observations and plot data show that although height growth may not be as good as that of trees growing in lower elevations, the sites can support good diameter growth, and that growth can be maintained for long periods of time (Hegyi 1981). In the DFSIM model, stands with low site index appear to be concentrated on warmer sites with low productivity.

The PROGNOSIS model, developed in Northern Idaho by Stage (Wykoff 1982), was examined and then chosen as the model to develop yield tables in these upper elevation strata. The model was chosen because:

- The ecological types of the silver fir zone closely resemble conditions in Northern Idaho where the model was developed,
- The model was developed for mixed true fir stands,
- There is a strong white pine data base and white pine is becoming a more important tree in these elevations,
- The model can handle a mixture of age classes,
- The model provided great flexibility for local calibration. Therefore, of all outside models, it looked like the most adaptable,
- It had excellent support in Region 1, and they were willing to help adapt it to Willamette National Forest conditions.

The PROGNOSIS model was adapted and calibrated as follows:

- Species were grouped to conform to species in the model. Noble fir, white fir and grand fir were grouped under grand fir. All cedars were grouped under western redcedar. Silver fir and subalpine fir were grouped under subalpine fir.

- Instead of using site index to calibrate growth, the model uses habitat type. After consultation with Miles Hemstrom, the Area Ecologist, the subalpine fir/beargrass habitat type was chosen as a broad representative habitat type for model building.

- The model requires that a Forest aspect and slope be input (Wykoff, 1982). Parameters chosen were the Clearwater Forest, an aspect of northwest and a slope of 5%. Most of the true fir zone lies in the New Cascades where the slopes are fairly level and the aspects west facing.

- The model has a diameter growth calibration feature in which actual plot growth is used to modify the internal growth equations. All inventory plots in the true fir and mountain hemlock strata were run for one 10-year cycle in the model to find the calibration factors for each species. Multiple linear regression analyses were then run to determine if there were trends that could be found to recalibrate the diameter growth functions.

- Most relationships were weakly correlated, although the regression line was significant. Data for Douglas-fir in both the true fir and mountain hemlock strata were combined to increase accuracy. Noble fir had to be similarly combined.

- Height growth had to be modified to fit Willamette National Forest conditions. The shape of the curves generated by the model was compared with growth curves developed for ecology plots and published curves for west coast conditions and species (Herman 1978). Height growth modifiers were then applied to force the model to follow the shape of the local curves.

  Model projections started at stand age 30, the estimated time it would take the stand to reach approximately 5 inches d.b.h. Five inches was chosen because this is the point the PROGNOSIS model switches from the small tree to the large tree growth model. Individual species diameters at age 30 for the mountain hemlock and true fir strata were calculated from increment cores taken on ecology plots in the silver fir zone. Only cores were used that showed little or no signs of early suppression. Not enough white pine was sampled in mountain hemlock types for a good diameter estimate for that stratum. The diameter was estimated by using the difference in diameter for noble fir between the mountain hemlock and the true fir stratum, and Englemann spruce had too small a base in the mountain hemlock stratum. Therefore, the same approximate starting diameters were used for these species in both strata.

- Mortality estimates are the weakest part of most models. The embedded mortality estimates in the model are from northern Idaho. The estimates appear too high when compared to local conditions. Two checks were made of the mortality rates. First, rates in the model were compared with rates experienced for Douglas-fir at Wind River in the 50-year old stocking study (Reukema 1979). Mortality rates for similar stocking densities were only 54% as large as the model rates. At first, an adjustment was made to the model to reduce the mortality to Wind River rates until age 50. Then an adjustment was made to use the model rates after that. Two problems developed: (1) for runs made with no commercial thinning, a too rapid buildup of the basal area (BA) was experienced; (2) when commercial thinning was done, recovery of the BA appeared too slow.

  The top end of the BA is limited by the BA function of the model. The model limits the BA by increasing mortality rates to reduce stocking. For the true fir stratum, maximum basal area was set at 367 square feet. This is one standard deviation above the average BA for the stratum. For the mountain hemlock stratum, the average inventory BA of 243 square feet was set as the maximum. The average was used for the mountain hemlock stratum because it was felt that the environmental conditions are such that sustaining basal areas much over our in-place average will not be possible.

  The maximum BA function did not entirely solve the problem of a too rapid rise of BA in the 50 to 120-year age range. BA projections from sample model runs were compared with published normal yield tables. The model was reprogrammed so that the maximum BA for each age class was then limited to those published values. Grand fir tables developed by Cochran (1979) were used for the first 100 years, and tables developed for white pine by Haig (1932) were used for older stands. Site index 60, age 50 base, was used for the true fir stratum; and site index 50 was used for the mountain hemlock stratum. This was based on curves developed from site index data on inventory plots.

The problem still remained of the model mortality rates reducing stocking faster than growth could recover. In order for the model to be able to grow trees approximately along the normal curve, mortality rates were reduced to 0.75 of model estimates for the true fir stratum and 0.8 for the mountain hemlock stratum.

- An economic analysis was used to determine the diameter of the first commercial thinning. This occurred at the start of decade seven after harvest for both true fir and mountain hemlock strata. The residual commercial thinning level was first estimated using the default values in the model. The model residual thinning basal area was 45% of normal tree numbers as determined from Haig's normal yield tables for second growth white pine.

  This was rounded down to the nearest 10 square feet. This produced residual basal areas of between 190 and 200 square feet. That appeared too high. Mortality rates continued at high levels. Other smaller residual basal areas were tried and 170 square feet was settled upon. This produced a residual relative density of about 42 after thinning.

- Precommercial thinning levels were chosen so that relative density would not be over 63 at the time of the first commercial thinning. The rationale for this upper limit was the same as in the Douglas fir/hemlock and Douglas fir/true fir strata, except a higher limit was set because of the greater tolerance of the trees. For the true fir strata, trees were precommercially thinned to 300 trees per acre; while the mountain hemlock strata was thinned to 400 trees per acre.

For all the yield tables developed from both DFSIM and PROGNOSIS it was necessary to develop adjustments to convert from gross volume per acre to net volume and to allow for volume falldown resulting from natural and manmade conditions. There are two types of adjustments: 1) an acreage adjustment which reflects land areas too small to be deleted from the suitable timbered land base, but which are unsuited for timber management (understocked plantations, nonstockable areas in plantations due to poor site, soil compaction, root rot, etc.); or 2) a yield adjustment which reflects changes due to defect and breakage, fertilization, and genetics.

The adjustments:

- A percentage reduction for plantations with stocking that meets legal minimum, but is low enough to reduce full yield.

- A reduction for unstocked areas within plantations resulting from poor site conditions, disease, soil compaction or loss, competing vegetation, and future catastrophic losses due to fire, wind, insects, etc.

- A reduction for defect and breakage which shows up at time of harvest. This would vary with age and size.

- An increase for genetics.

- An increase for fertilization.

- Wildlife trees.

- Future road construction.

The rationale behind the adjustment percentages is described in the following paragraphs:

- *Understocked Plantations* - A total of 5,244 plantations on the Willamette National Forest were analyzed for stocking. It was found that a significant number of these plantations were poorly stocked. Poor stocking will have an effect on the final harvest production.

  The percentage of understocked acres was determined for each species stratification. These percentage relationships are 2% for Douglas fir/ hemlock, 6% for Douglas fir/true fir, 6% for true fir, and 3% for mountain hemlock. It was assumed that the main falldown in volume will be uncaptured commercial thinning volume. The amount of commercial thinning volume was adjusted by the poor stocking percentages to obtain a factor to be applied to the yield tables. These factors are 0.5% for Douglas fir/hemlock, 1.0% for Douglas fir/true fir, 1.0% for true fir, and 0.5% for mountain hemlock.

- *Unstocked Holes in Plantations and Future Catastrophic Losses* - The above factors account for entire plantations that are understocked. Many other plantations contain localized unstocked areas due to unsuited soils, soil compaction or loss (landings, skid roads, etc.), competing vegetation, disease (primarily root rot pockets), etc. Information on holes in the plantations was obtained from the Districts. Each District submitted a list of plantations (representing a 10% sample of previous 3 years data) showing an estimate of unstocked and nonstockable areas within each plantation. These estimates were weighted by acreage sampled per District for each strata to obtain Forest averages. This resulted in an adjustment of 7% to the Douglas-fir/ hemlock and Douglas-fir/true fir strata and 8% to the true fir stratum. There were no samples of the mountain hemlock stratum. It was decided to use 8% in the mountain hemlock stratum also.

  There is little information on the effect on this Forest of insects and wind in managed stands. Future losses are assumed to be negligible. Past fire history was used to determine what losses could be expected in the future. The amount of land burned has decreased from 1,000 acres/year over the last 30 years to 300 acres/year over the last 10 years. Volume loss due to fire will probably continue to decline as detection and preventive methods improve and access increases. This loss should be well below 0.5%. Overall, the Forest should not experience major losses, and any volume reduction will be assumed to be included in the above deductions. Actual catastrophic losses would be dealt with by a plan revision.

- *Defect and Breakage* - The defect and breakage figures for managed stands are the same ones used in the current Land Use Plan. These figures were obtained from a 2470 memo to the files dated December 22, 1975. The deductions in the memo were broken down into more age groups than the present strata. Deductions were picked as close to the median as possible for each timber size grouping.

- *Genetics* - Theisen (1980) summarized expected gains from genetic tree improvement programs. The Forest's adjustments were based upon those recommendations.

  The Forest is just getting into seed orchard management. At the present time, it is difficult to predict when seed orchards will become available in significant amounts. Therefore, only the gain attributed to seed collected from select trees was included in the yield tables.

  A blanket gain of 10% for planting stock grown from select tree seed was added to all the yield tables that apply to plantations planted from the beginning of the new Forest Plan and beyond. No genetic gains will be assumed for plantations established before the beginning of the new plan. Select trees have been identified in all strata.

- *Fertilization* - In order to gain some consistency in the absence of statistically significant data for individual Forests, the Regional Office directed the westside Forests to use the DP-DFSIM model to determine response to fertilizer (2410, April 12, 1984). The Region also directed that fertilizer could be applied once to all stands containing at least 60% Douglas fir. These stands make up the Douglas fir/hemlock model component. An application rate of 200 pounds/acre is generally the most cost effective and was used in DP-DFSIM. The DP-DFSIM model was used to determine the optimal stand age for application without resulting in a relative density of 60 or more before the first commercial thinning. The application of fertilizer resulted in a 15% increase in mean annual increment after 7 years and an overall increase in CMAI of 8% for full stocking level control (FSLC) with genetics.

- *Wildlife Trees* - To meet wildlife tree requirements over time, it is necessary to leave green replacement trees that can be used when the existing trees no longer provide habitat. Wildlife trees were cruised on a number of timber sales across the Forest to determine volume reductions for the yield tables. Each of the green trees represents about 2% of the net volume per acre. Depending on the existing condition of a watershed, the FORPLAN model will leave enough trees to maintain at least 0.8 wildlife trees per acre and make the appropriate reduction in the yield tables. There is also a factor to account for the effect of the trees on the growth of the understory.

In addition to the empirical and managed timber yield components a third timber yield component includes volume not reflected in the empirical and managed yield tables. This volume includes "salvable dead" (salvage from harvest units), "chargeable dead salvage" (salvage found throughout the Forest), "nonchargeable cull" (unsound material used as chips, etc.), "unregulated" (nonscheduled volume such as from the Experimental Forest), and "nonchargeable miscellaneous convertible products" (shakes, posts, firewood, etc.). These components were all separately calculated and included in the total "Timber Sale Program Quantity."

An analysis of sell and harvest records was done to obtain an assumed average percentage increase to the decade timber harvest for chargeable dead salvage, nonchargeable cull volume, unregulated volume, and miscellaneous convertible products.

The Cut and Sold Reports were used to obtain the average annual sold volume (both sound and cull) from 1977 to 1982. The average sound volume was then used as the base green volume to be used in calculation of percentage increases for cull, salvage, and other miscellaneous volumes.

The Cut and Sold Reports provided the nonchargeable cull volume and the other convertible products, such as posts, shake bolts, etc.

The Timber Inventory Adjustment Record for fiscal years 1980 through 1982 provided the sound, salvable dead, and the unregulated volume from land not allocated for timber production.

The volume adjustments thus calculated are shown below:

Type of Volume	Percent Increase
Chargeable Dead Salvage	3.6
Nonchargeable Cull	20.6
Unregulated	0.1
Nonchargeable Miscellaneous Convertible	0.2
Total Percent Volume Increase	24.5

This volume is available only in the existing, unmanaged stands, and will decrease as these stands disappear. For future managed stands, volume adjustments will remain the same for unregulated and nonchargeable miscellaneous convertible products but will drop to zero for chargeable dead salvage and nonchargeable cull material. The total future adjustment will be 0.3%.

The salvable dead volumes per acre are obtained from the 1981 inventory statistics. This volume is not included in the empirical yield tables, but represents additional sound volume available at final harvest, and has been added to the ASQ figures from FORPLAN. These values ranged from about 2.4 to 2.6% depending on species and size class. The amount reflects a deduction to show the preservation of large snags for wildlife. To model this, two trees per acre of about 20 inches d.b.h., were deducted from the small saw diameter classes; and two trees of about 21 inches d.b.h. per acre were deducted from the large saw/old-growth diameter classes. The "no thinning" tree volumes were calculated from the managed yield tables by dividing the volume per acre by the number of trees for the desired diameter class. The managed yield tables give the volume down to a 7-inch d.b.h. with a 4-inch top. The inventory calculates merchantable volume using a 9-inch d.b.h. and a 6-inch top. At these large diameters, however, it is felt that the difference in merchantable tree size would have very little effect. There were no adjustments made for the difference in merchantable tree standards.

These yield tables apply only to the natural stands. The mortality in the managed stands will not be captured in the model, but instead it will be available for wildlife needs.

Wildlife Coefficients

Wildlife effects and outputs were estimated for Threatened and Endangered species, Management Indicator species, big game, and wildlife and fish user days. Effects on Bald Eagles, spotted owls, pileated woodpeckers, and martens is based upon allocations. Information on the amount of land needed to provide for these species can be found in FEIS, Chapter III, *Wildlife* and no additional information will be displayed here. The effects on primary cavity excavators are based on habitat estimates generated from FORPLAN. FORPLAN outputs for big game cover and forage were used to calibrate another big game model (based on the A Model to Evaluate Elk Habitat in Western Oregon) which was eventually used to generate cover constraints for some FORPLAN alternatives and to estimate effects for all alternatives. User days were estimated based on data from the Oregon Department of Fish and Wildlife in conjunction with the big game model.

Spotted Owls - Habitat capability for the Forest was calculated using the same formulas used in the Final Suppliment to the Environemntal Impact Statement for an Amendment to the Pacific Northwest Regional Guide. Acres of habitat and timber harvest levels were calculated using FORPLAN. It was assumed that harvest was evenly distributed across the available habitat. Habitat fragmentation was calculated using Forest Mature and Overmature Inventory data in the GIS system (Douglas fir and Douglas fir/true fir stands greater than 21 inches in diameter) to generate maps and randomly selected 2.1 mile circles to determine the proportion of the forest that maintained 1500 acres of habitat with a

minimum 300 contiguous acres of core to meet the habitat requirements of spotted owls. Details of the process are on file.

Pileated Woodpeckers - Forplan was used to generate the acres of suitable habitat and rate of timber harvest over time for pileated woodpeckers. Habitat was defined as Douglas fir, Douglas fir/true fir and true fir stands greater than 19 inches in diameter. The percentage of the Forest capable of supporting pileated woodpecker individuals was calculated as the number of 1 mile circles with 1000 acres of suitable habitat, including a 300 acre core.

Martens - FORPLAN was used to generate the acres of suitable habitat and rate of timber harvest over time for martens. Habitat was defined as all timber type stands greater than 19 inches in diameter. An additional forage component was added for stands between 12 and 18 inches in diameter. The percentage of the Forest capable of supporting marten individuals was calculated as the number of 1 mile circles with 600 acres of suitable habitat, including a 160 acre core.

Primary Cavity Excavators (PCEs) - Dead trees (snags) per acre greater than 18" in diameter provide estimates of the Forest's ability to provide habitat for cavity-dependent wildlife through the planning horizon. The 18" requirement is based on the needs of species known to exist on the Forest (Schreiber, 1987, Nelson, 1988). Snag coefficients for both existing and replacement timber stands are based on snags being produced by suppressed trees which are generally one inch smaller in diameter than the average tree.

If the trees are less than 18" in diameter they will not provide habitat for all primary cavity excavator's. Conversely, if more than 3.8 dead trees per acre (or 4.2 for high elevation areas) are available they may not be fully utilized because of minimum home range sizes. Therefore, the yield of snags per acre does not follow the actual number of dead trees but measures the usable dead trees only. Snags less than 18" in diameter are not reported and snags that exceed 4.2 trees per acre are not reported.

Specifically, yield simulators project that 2 snags of up to 18" in diameter will die each year for every 100 acres of 19" trees. This relationship holds for all timber types on the Forest. Based on this data, each timber yield table that is less than 19" in diameter does not produce 18" snags, yield tables between 19" and 20" contain 2 snags per acre greater than 18", and yield tables greater than 20" in diameter contain 3.8 (or 4.2) snags per acre.

Existing dead trees and live replacement trees will ensure that objectives for snags will be met in all replacement stands throughout the rotation. The number of snags in timber stands regenerated during the planning period will match the desired level (usually between 0.8 and 1.6 snags per acre).

Existing data on the longevity of any individual snag indicates that a dead tree that is about 18" in diameter will provide suitable nesting habitat for PCEs for about 50 years (Cline, S.P., 1980). In order to provide snags throughout the rotation of the replacement stand, some green trees which will eventually be killed need to be left on each harvest unit. The combination of existing snags and green replacement trees needs to be enough to maintain snag levels until the regenerated timber stand reaches at least 18" in diameter. From 1 to 3 replacement trees (depending on diameter) are required for every snag that is needed.

Big Game - Estimates of big game populations or population trends depend upon our ability to provide food (forage), various types of shelter (cover), and freedom from harassment (low road densities). In addition, size and spacing of the forage and cover need to be distributed for maximum utilization, as elk demonstrate a preference for areas that are close to both forage and cover.

Forage estimates are generated based on existing meadows, timber stand openings, and management techniques like burning and fertilization. Forage production in timber stands ends as crown closure

occurs. Optimal cover in mature and old-growth stands provide forage as the canopy opens up and allows growth of forage species. Lichens, typical to this habitat, are another important forage component.

Hiding cover is provided by any timber stand that creates short viewing distances (generally stands with trees greater than 2" in diameter). Usable thermal cover requires timber stand canopy closure and some amount of pruning of the lower branches (tree diameters greater than 8" and canopy closure greater than 50%). Optimal thermal cover provides both forage and cover in the same timber stand. This combination requires some openings in the timber canopy and multi-layered stand structures that begin to occur in stands over 170 years old.

The size and spacing variable in the Westside Model measures the distribution of forage and cover areas over the landscape, Optimally, units would be 60 acres or less and evenly distributed to allow maximum utilization of all forage areas. Cover areas should be larger, but be close to forage units.

Road density is the final variable that affects elk habitat. Low densities (less than 1.5 miles of road/square mile of habitat) limit poaching and harrassment of elk, lowering their energy needs.

The Westside Model combines all four of these variables to measure the habitat effectiveness. In addition, each variable has minimum thresholds for quality. Thus (for example) an area that has a high overall Habitat Effectiveness value due to few roads, excellent cover and high forage values would be less effective if all the forage was concentrated in one site, causing a low value for size and spacing.

Fish Coefficients - Estimates of Smolt Habitat Capability (SHC) outputs follow direction in the 1920 Memo of May, 1, 1987 on Anadromous Fish Planning Coefficients. These coefficients were developed by a Regional Anadromous Fishery Task Force.

The memo recommended that for Steelhead smolt densities be from 4 to 20 smolt/100 square meters (M^2), and spring chinook densities should be between 5 and 40 smolt/100 M^2.

The FEIS information is presented in terms of Smolt Habitat Capability (SHC) of existing habitat with adequate escapement and rehabilitation, and SHC of potential habitat with adequate escapement and rehabilitation.

The initial estimates of total SHC under existing conditions and escapement were developed in cooperation with ODFW during development of the DEIS. These estimates projected smolt densities of 2 to 4.2/100 M^2 for steelhead, and 34.5/100 M^2 for spring chinook in the McKenzie River. However the densities for steelhead were lower than suggested in the memo, and reflected current habitat conditions in the Fall Creek and Santiam River systems. The densities for chinook were at the high end of the range, but again, reflected the high quality habitat of the McKenzie River.

Smolt densities for 70 miles of additional chinook habitat was estimated as lower than the densities found in the McKenzie River. This estimate was based on field knowlege of the stream conditions available in the potential habitat.

The increase in smolts attributed to stream rehabilitation and enhancement projects was estimated to be 30 steelhead/structure, and 75 steelhead/structure, with 50 structures placed per mile. It was estimated that 60 miles of existing habitat would be rehabilitated and 30 miles of the potential habitat would be rehabilitated. When these increases were calculated they were within the range recommended in the memo.

The SHC estimated with this method was considered to be maximum under Alternatives L and W.

Estimates of the differences between alternatives were made based on a side model which accounted for erosion, riparian condition, and hydrological recovery. This side model was used in the DEIS. From the DEIS information, a regression was identified between acres harvested and decreases in smolts, and this regression was applied to the FEIS calculations.

Hydrological Recovery

Hydrological Recovery is calculated to estimate the capability of timber stands to intercept snow, rain and wind during rain on-snow events. Hydrological Recovery is used to assess the potential risk of adverse effects to stream channels and water quality from increases in peak flows during rain on snow events.

Hydrological recovery is calculated with the Aggregate Recovery Percent method. This method was first described by Forest Hydrologist J. Christner in a May 11, 1982 memo to District Rangers, with a curve describing the relationship of tree diameter and tree age to percent recovery, based on an average Forest Site Index of 91. A memo dated August 2, 1984 updated the recovery curve when it was determined that the average Site Index was 96. These recovery curves were based on studies of windspeeds in clearcuts and forested areas on the Oakridge Ranger District. (Christner 1982)

During development of the DEIS, the coefficients shown in the recovery curve of 1984 were used to develop intermediate values for each increase in tree diameter of 0.1 inches as shown in Table B-11. The recovery coefficients shown in the table were used as needed to assess the hydrological recovery in subdrainages and watersheds for the FEIS, Chapter IV. They were also combined into 6 categories for use in FORPLAN, to distribute the harvest according to the sensitivity of the watershed.

Table B-11. Hydrology Condition Recovery Coefficients

0-2 inches		2-4 inches		4-6 inches		6-8 inches	
DBH	% Recovery	DBH	% Recovery	DBH	% Recovery	DBH	% Recovery
0	0	2.0	14.0	4.0	45.0	6.0	90.0
0.1	0.4	2.1	15.2	4.1	45.0	6.1	93.3
0.2	0.8	2.2	16.4	4.2	49.4	6.2	96.3
0.3	1.2	2.3	17.6	4.3	51.6	6.3	97.0
0.4	1.6	2.4	18.8	4.4	53.8	6.4	97.1

Watershed Cumulative Effects Risk Rating

The watershed cumulative effects analysis in Chapter IV included a rating of relative risk between alternatives. Information on future riparian conditions, levels of sediment, and hydrological recovery was combined to assign a rating of High, Moderate, or Low. Information from the direct and indirect effects section for each watershed was assessed by assigning points to each of the three parameters as follows:

			POINTS
1.	RIPARIAN	Less than 4% reduction in LWD/decade	0
		4% or more reduction in LWD/ decade	1
2	INCREASE IN DEBRIS SLIDES	0% to 25% above natural	0
		26% to 40% above natural	1
		Over 40% above natural	2
3	HYDROLOGICAL RECOVERY	Meets Midpoint ARP in all subdrainages	0
		Within 1% to 5% of Midpoint ARP	1
		Exceed Midpoint ARP by over 5%	2

Watershed Risks were then assigned based on the total points.

LOW	0-1 TOTAL POINTS
MODERATE	2 TOTAL POINTS
HIGH	3+ TOTAL POINTS

Erosion Coefficients

Two different methods for developing erosion rates were evaluated: (1) Use of theoretical techniques or yield simulators, and (2) Use of empirical data. Due to the lack of an appropriate simulator for Forest erosion production and lack of time and data necessary to calibrate such a model, the decision was made to use available empirical data from the Forest and from other applicable studies. Use of actual local data was considered superior to estimates derived from models developed under different conditions.

A contract with the Pacific Northwest Forest and Range Experiment Station (PNW) in Corvallis was issued to develop the rates for the Forest. (Swanson and Grant 1982). There were several reasons why this decision was made:

- The original data were readily accessible to PNW researchers.
- Many of the people involved in the studies on the Forest were located at PNW and OSU.
- If the work was done on Forest, a review by Research would have been desirable anyway.
- PNW researchers were more familiar with current methods of analyzing erosion and erosion data than Forest personnel.

The final report is available in the Forest Planning Records and will be summarized in this section. Erosion was modeled from two sources - surface erosion and debris slides.

Surface erosion - Data were collected from nine studies - eight located in the H.J. Andrews Experimental Forest and one located near Ryder Creek, South Fork McKenzie River. Inorganic material from collection boxes were totaled for each year sampled. Sampling frequency and length varied. The studies occurred between the years 1967 through 1982. Length of sampling ranged between approximately one year to five years. Sampling frequency ranged between four collections per year to twelve collections per year. When data was missing for a period, the two adjacent periods were averaged. In some cases where it was felt that rates from individual boxes were high and not characteristic of the site, the boxes were not averaged in with the others. In addition, the report points out that the variety of measurement techniques used on different sites makes comparison between values somewhat questionable (PNW Final Report, p. 3). However the values were assumed to be comparable when data from different sites were combined to calculate the rates.

Annual yield rates per acre were calculated by dividing the weight by the estimated contributing area in both bounded and unbounded study areas. Two studies used unbounded plots which increases the uncertainty when expressing rates on an area basis since the contributing area could only be assumed. Weights were transformed into volumes by assuming the specific weight of inorganic erosion was 1.5 grams/cubic centimeter (1 gram equals 8.47×10^{-7} yd^3).

Table B-12 summarizes the surface erosion rates. Data were available for only eight Soil Resource Inventory (SRI) units so it was not possible to derive rates for the different classes of SRI surface erosion potential. Surface erosion rates are given by slope class for the background Forest condition and after clearcutting, with and without burning.

Erosion production is a dynamic process; however, it is difficult to represent temporal variations because the data are limited. In one study that sampled twelve years after treatment, observed rates were similar to the background Forest condition. The report concludes that in many sites surface erosion rates following management activity may decline to rates typical of Forested areas within ten years (PNW Final Report, P.8). None of the studies sampled for a full ten years, so some assumptions were made to derive decade averages. In the case where the site was re-sampled after twelve years, the decade value represents the average between the first and twelfth years. In all other cases, a gradual decline to the background Forest rate was assumed after the observed first and second years. Therefore,

the background rates and the rates two years after treatment were averaged to derive the first decade values.

A limited number of studies have looked at the rates of surface erosion from Forest roads. Two studies on the Forest evaluated different seeding treatments for reducing erosion of bare cut and fill slopes. Based on these studies, the report concludes that road erosion rates are an order of magnitude greater than rates for clearcut and burned sites (PNW Final Report, p.11). It also states that soil erosion rates on roads approach the clearcut, burned rate after five to seven years. Based on this information the following steps were taken by the Forest to calculate surface erosion rates for roads:

- The clearcut, burned rate was multiplied by ten to represent the rate after road construction. This rate was assumed to last for the first six years.
- The clearcut, burned rate was assumed to represent the remaining four years of the first decade.
- The higher six year rate was averaged with the four year rate to derive the first decade rate.

Table B-12. Summary of Surface Erosion Rates

	Surface Erosion Rate yd³/acre/year		
Slope Class Percent	**Background Forest Rate**	**Clearcut, Unburned 1st Decade**	**Clearcut, Burned 1st Decade**
0-30	4.7x10	0.0006	0.034
31-60	0.023	0.072	0.22
61+	0.13	0.615 [1]	1.1

Taken from PNW Final Report, Table 3 (p.33).

[1] The report did not provide a value, so it was estimated by the Forest to be the average between the Background Forest rate and the Clearcut, burned rate.

$$\frac{0.13 + 1.1}{2} = 0.615$$

Debris Slides - Debris slides have been inventoried in six studies on the Forest using a combination of aerial photos and field investigation. However, only three were done with comparable methods and standards. These three--H.J. Andrews Experimental Forest, Alder Creek, and Blue River--were used as a basis to calculate erosion production from debris slides. Landslide events were inventoried from the years 1950 through 1981. Only those greater than 100 cubic yards were recorded. Slide areas and volumes were determined from estimates of scar width, length, and depth measured in the field. Slides were assigned to an SRI unit based on their position and classed by whether they occurred in natural, managed (clearcut), or roaded areas.

In order to determine rates per acre, the Forest provided PNW with total acres in the three conditions (natural, managed, and roaded) by SRI unit. Natural areas were defined as:

- Pole stands equal to or greater than 64 acres
- Small sawtimber
- Large sawtimber and old-growth
- Noncommercial and rock
- Permanent grass

Managed areas were defined as:

- Pole stands less than 64 acres
- Nonstocked and seedling/saplings
- Treated areas as of October 1981

Road miles as of 1981 were also provided by the Forest. For each study area, miles by SRI unit were determined with a map wheel. Road acreage was calculated by assuming eight acres per mile. This area was then subtracted from the acres in the natural condition by each SRI unit.

The slide rate for a SRI unit was calculated by dividing the number of events in each management class by thirty years (the period of inventory) and then by the acres in each class. Rates were also given in terms of area and volume disturbed by multiplying an average area disturbed and volume per event as reported in the original studies.

Annual slide rates were calculated, based on 3 major SRI groups. SRI units were ranked in terms of slope and bedrock conditions with some minor modifications. SRI complexes were assigned the class of the major unit, except when the classes were unstable and stable, in which case the moderately stable class was assigned. Table B-13 summarizes the debris slide rates. The three groups were defined as:

- *Stable* with gentle slope (less than 40 percent) of any rock type, moderate slopes (40-60 percent) with hard rocks (basalt and andesite flows), and rock outcrops with little or no soil.

- *Moderately stable* with steep slopes (60 percent), hard rocks; and moderate slopes, soft rocks (tuff, brecias).

- Potentially *Unstable* with steep slopes, soft rocks.

Temporal variations are also important in predicting slides, but again the data available is less than optimal. Of 26 debris slides that were inventoried in clearcuts, 88 percent took place within ten years after harvest. The report concludes that 90 percent of the slides in clearcut areas occur in the first decade after cutting (PNW Final Report, p.16). In addition, based on the sample of road-related slides, they believe that 80 percent of the slides from roads built to current Forest Service standards occur in the first decade and 20 percent in the second decade after construction. These temporal variations were represented in the calculations.

Effectiveness of Mitigations - All work from this point forward was done by planning personnel on the Forest. The next step in the process was to estimate the effectiveness of mitigation measures used in harvest units and road construction.

The index rates from the erosion study were adjusted to reflect mitigations described by the alternative being assessed. These practices include site specific prescriptions for potentially highly unstable areas, particularly adjacent to Class IV streams, elimination of sidecast practices in road construction, and improved road drainage practices. Estimated acres of "unstable," and "moderately stable" occurring on steep upslope areas and adjacent to Class IV streams are accounted for in FORPLAN modeling in Alternative W. In this alternative, the index rates for debris slides are reduced to reflect the mitigation.

Adjustments to the index rates to reflect mitigations were based on the available research, and on discussion with watershed specialists on the Forest. The consensus was that these practices substantially reduce the potential for debris slides, but cannot entirely erase the risk, because of the unpredictability of natural conditions, and the current understanding of the mechanisms of debris slides.

Research on the reduction of debris slides has been conducted primarily in the Oregon Coast Range. The effectiveness of measures to reduce mass debris slides in harvest units was based on monitoring of headwall leave areas in Mapleton District of the Siuslaw NF, and on estimates of professional watershed specialists on the Willamette NF. The Mapleton study showed that leaving 2 to 5 acre "headwall leave areas" reduced mass debris slides approximately 63% compared to clearcuts. (Swanson & Roach p.90) The proposed mitigation measure to retain trees on Class IV streams to provide streambank stability is estimated to reduce debris slides into streams by 17%, for a total of an 80% reduction in volume failed when compared with practices as assessed in the PNW Final Report.

The magnitude of reduction of debris slides from roads was based on "Road Location and Construction Practices: Effects on Landslide Frequency and Size in the Oregon Coast Range." This paper showed that in 3 landtypes in the Coast Range the volumes of landslides were reduced from 117 cubic yards per slide on roads constructed with sidecast in the 1960s to 6 cubic yards on steeper roads, where waste material was end-hauled. On another landtype the reduction was from 265 to 111 cubic yards with the same type of improvement in practices. For the FEIS it was estimated that improved road practices would reduce debris slides to one-quarter of the 1945-1975 rates, with no average watershed rate higher than 5 cubic yards/road acre occurring.

Further adjustments were made in the erosion rates to more accurately model watershed conditions. For each erosion process influenced by management activities (road construction and timber harvest) included in the analysis, weighted average rates were calculated for each watershed. Acres were summed by different characteristics depending upon the erosion process being modeled. Factors used as a basis for weighting the rates within watersheds for individual processes included:

- Stability Class
- Slope Class
- Soil Suitability
- Availability for timber harvest
- Merchantable Timber (Pole size and larger)
- Timber Type

Table B-13 displays the rates used as a basis for calculating the weighted average rates for each process. For more information on erosion rate and volume calculations, see the Soil Erosion Process Paper.

Table B-13. Erosion Rate Summary

Erosion Type	Stability Group	Background Forest Rate	TP1 Managed Without Enhanced Protection[1]	TP2 Managed Without Enhanced Protection[1]	TP1 Managed With Enhanced Protection[1]	TP2 Managed With Enhanced Protection[1]
Surface[2] (Harvest)	0-30% slope	$4.7x10-^{7}$	0.206	0	N/A	N/A
	31-60% slope	0.023	0.161	0	N/A	N/A
	61% + slope	0.13	0.906	0	N/A	N/A
Surface[2] (Roads)	0-30% slope	$4.7x10-^{7}$	0.218	0	N/A	N/A
	31-60% slope	0.023	1.408	0	N/A	N/A
	61% + slope	0.13	7.040	0	N/A	N/A
Slide (Harvest)	Stable	0	0	0	0	0
	Moderately Stable	0.220	0.550	0.061	0.330	0.030
	Potentially Unstable	0.270	1.500	0.167	0.600	0.060
Slide (Roads)	Stable	0	4.600	1.150	1.150	0.287
	Moderately Stable	0.220	8.000	2.000	2.000	0.500
	Potentially Unstable	0.270	68.00	17.0	17.0	4.250

[1] Assumes harvest units include protection of potentially unstable stream Class IV and headwall areas, and assumes roads are constructed with compacted fills.
[2] Rates shown assume 60% of areas are burned, 40% unburned. Enhanced protections are not projected to have any effect on surface erosion rates.

Recreation Coefficients

Recreation capacity and use coefficients were developed for each of the various Recreation Opportunity Spectrum (ROS) classes. Development of these coefficients involved developing projected demand and capacity estimates for each of the categories tracked. In cases where capacity was always greater than projected demand for any Alternative, demand estimates were utilized for projected use coefficients. In cases where capacity was less than projected demand, capacity estimates were utilized for projected use coefficients. The following paragraphs describe the process used for generating these demand and capacity estimates. Detailed documentation can be found in the planning records.

In order to determine the most likely rate of change in future recreation use it was necessary to examine trends in historical data. The primary source of visitor use data for the Forest is the Recreation Information Management (RIM) System. RIM files contain use data for specific activities and sites on the Forest which can be combined into appropriate categories for analysis and display. All use and capacity data in this Appendix are expressed in terms of recreation visitor days (RVDs). One recreation visitor day equates to twelve hours of use.

A survey of the literature revealed a number of studies which developed indices or growth rates for future recreation use for various activities or groups of activities on a National, Regional, State, and local area basis. Since RIM activities are fairly specific and projections are generally only available for broader categories, some aggregation was necessary. Thus, similar RIM activities were grouped into classes for which projections were available from a number of sources. RIM data for 1980-89 were analyzed in these activity groupings. Table B-14 contains the 1980 through 1989 use by activity grouping and the percent change over this time period.

This Table shows some fluctuation in the data extracted from the RIM system. These may be the result of inconsistencies in estimating or reporting use from public and private sector sites and areas.

Despite these vagaries, relatively clear trends are evident in the data from the past decade and RIM contains the best recreation use estimates available for Forest planning analyses.

During the 1980-89 period, participation in most recreation activities increased at varying rates with some noticeable peaks, valleys, and plateaus in the trend lines. It seems evident from the figures that recreation use is affected by such variables as weather and travel costs. Although use in most activities showed some decline during the 1980-89 period total use has increased steadily. Total recreation use did not change from 1981 to 1982. This may be due in part to the economic recession that the region was going through.

Two activity groupings show a decrease in participation over the 10-year period: Organized camping and Resort use. Hiking and picnicing use dropped dramatically in 1975 in 1982 and have only recently regained their 1982 participation levels. Swimming use follows a similar pattern. Between 1982 and 1985, Swimming use decreased significantly. Since then, it has risen to approximately the 1982 level and shown increases over the last four years.

The most popular recreational activities on the Willamette National Forest are camping, driving for pleasure, fishing, and boating-related activities. In 1982, participation in these activities represented approximately two-thirds of the total recreational use on the Forest. Next in popularity were swimming, picnicking, hiking, and resort use. These activities occur at a variety of sites located throughout the Forest.

Table B-14. Recreation Use for Selected Activities[1] [2](Thousands RVDs)

Activity	1980	1981	1982	1983	1984	1985	1986	1987	1988[3]	1989[3]	Average Annual % Change 1980-89
