IMPLAN, a computer-based system for developing non-survey input-output models, is discussed. The contents and procedures used to develop the extensive national-wide data base are identified and the analytical capabilities of the system described in the context of Forest Service planning efforts. Finally, possible extensions of the system are noted.

**DATA BASE**

The IMPLAN data base consists of two major parts: (1) a national-level technology matrix and (2) estimates of sectoral activity for final demand, final payments, gross output and employment for each county. The data represent 1977 county level economic activity for four hundred and sixty-six sectors.

The national technology matrix denotes sectoral production functions and is utilized to estimate local purchases and sales. This 466-sector, gross domestic based model was derived from the Commerce Department's 1972 national input-output model (U.S. Department of Commerce, 1979(a)). The "use" and "make" table was restricted to an industry by industry basis and updated to 1977 using relative price changes and the RAS procedure (Stone and Fromm, 1969) with the 1977 National Income and Product Accounts (U.S. Department of Commerce, 1977(b)). Information was used as control totals. Aggregation of some agriculture, construction and manufacturing sectors, and disaggregation of the mining sectors resulted in the reduction in the number of sectors from 466 in the Department of Commerce tables to 386 in IMPLAN. The matrix is a highly disaggregated representation of national average sectoral input and output technology and it is on the basis of these production functions that regional purchase patterns are estimated.

3/ Approximately 124 forest plans, 9 regional plans and a national program.

4/ This was developed by Engineering Economics Associates of Berkeley, California. This use of the company name is for the benefit of the reader, such use does not constitute an official endorsement or approval of any service or product by the U.S. Department of Agriculture to the exclusion of others that may be suitable.
Estimates of economic activity and production employment for each of the 466 sectors for all states and every county within each state were made for the components of an input-output table listed in Table 1. The estimates of economic activity for states and counties were made through a downward movement approach beginning with total national activity and disaggregating to states and ultimately to counties with control totals employed at each level. As previously noted, the updated 1977 national table was benchmarked with the 1977 National Income and Product Accounts. Since comparable accounts are not available for states or counties, the most suitable regional measures of economic activity were used to disaggregate the national production and demand activity, first among states and then among counties within each state.

Gross output and employment estimates utilized several sources, principally censuses. For example, agriculture sector activity used the Census of Agriculture (U.S. Department of Commerce, 1977(b)) and the Agricultural Statistics (U.S. Department of Agriculture, 1979). Gross output measures for most other sectors utilized proxy measures derived from employment and payroll data, principally the national summaries of the County Business Patterns (U.S. Department of Commerce, 1977(a)) and employment data from the Dun and Bradstreet Corporation (1977). Some sectors could be related to specialized data sources, such as the Census of Housing (U.S. Department of Commerce, 1970) for owner-occupied dwellings and the Census of Governments (U.S. Department of Commerce, 1977(c)) for government-related sectors. All data was adjusted to the 1977 base year and unreported data was estimated utilizing the RAS procedure.

Final demands were estimated consistent with control totals from the National Income and Product Accounts, by updating the 1963 Multi-Regional Input-Output data (Polenske, 1970) using the RAS procedure as suggested by Hickman and Harring (1974). The three components of value added were allocated on the basis of gross outputs. Both final demand and final payment estimates were disaggregated using the 'downward movement approach'.

In its entirety, the IMPLAN data base provides a comprehensive, nation-wide set of input-output information which can be used to construct non-survey based regional tables. The national technology matrix is maintained at the highly disaggregated 466-sector level of detail which greatly reduces aggregation errors caused by using 1- or 2-digit SIC (Standard Industrial Classification) industry groupings. Consequently, the industry-commodity relationship is much more consistent than in highly aggregated models. The hierarchical nature of the data base, achieved by the use of published control totals at each level of disaggregation, results in a data base that permits the construction of models that are consistent both in terms of definition and activity. These principal aspects result in significant improvements over that used in many previous non-survey input-output studies.

DATA REDUCTION

The IMPLAN software system was designed to serve three functions: (1) data retrieval, (2) data reduction and model development and (3) impact analysis. The first two functions are discussed in this section and the third in the following section.

5/ Bureau of Economic Analysis input-output sectors 3 00 through 77 05, excluding sectors 11 00, 12 00, 65 01 and 71 01 (U.S. Department of Commerce, 1979(b)).
The data retrieval system was designed so that the user could have access to input-output data for any U.S. state or county combination thereof. The study area data is referenced via a standard set of state and county codes with the extracted data treated as control totals for the region being analyzed. Modification of data, if desired by the user, is permitted.

Utilizing the national technology matrix and the regional control totals, a data reduction method is employed to develop a regional input-output table. The method exploits the property of "openness" displayed by regional economies compared with the national economy (Richardson, 1972). Regional economies exhibit much greater propensities to import and export than is observed at the national level. Based on the assumption that trade patterns are the principal difference between national and regional purchase patterns (that is, industry production functions are identical but import and export make local interindustry transactions different), the supply-demand pool technique (Schaffer and Chu, 1968) for data reduction is adopted.

This method for constructing a regional table begins with the national technology matrix and regional data for gross outputs, final demands, and final payments. Regional data for all 466 sectors is sorted with respect to gross outputs. If the sectoral gross output is greater than zero (farms producing the commodity exist within the region), the corresponding column of direct coefficients is extracted from the national matrix. Using regional gross outputs and the abbreviated matrix of national direct coefficients, regional purchase transactions are computed. This transactions matrix is then scanned row by row. If the industry represented by any row has zero regional gross output (the industry does not occur within the region), the estimated purchases of that commodity are assumed to be non-competitive domestic imports and are shifted from the regional transactions matrix to final payments. If the gross output is positive and the commodity balance shows a surplus, the domestic import purchases are assumed to be zero, the regional transactions estimated with national direct coefficients are left unchanged, and the surplus assumed to be domestic exports. If the commodity balance indicates a deficit, the regional final demands and transactions estimated with the national direct coefficients are proportionately reduced across the row to obtain a balance, and the differences assumed to be competitive domestic imports. The result of this process is a matrix of local transactions between regional industries plus estimates of both competitive and non-competitive imports as well as exports.

The data reduction procedure used in INPLAN produces a complete table of regional input-output accounts including a transactions table, the final demand and final payments quadrants, and the fourth quadrant.

Regional gross output is greater than regional final demand plus intermediate demand estimated with national direct coefficients.

In addition to this typical table of accounts, detailed reports of sectoral competitive and non-competitive import purchases are given. Based upon the regional accounts, the predictive input-output model can be derived by computing the standard Leontief-type inverse and calculating various income and employment multipliers. If appropriate, the number of sectors in the model can be reduced through aggregation prior to inverting the matrix.

Several limitations to non-survey data reduction techniques have been noted (Richardson, 1972, Fisch and Gordon, 1978) and the supply-demand pool procedure likewise has limitations. One principal limitation of the supply-demand pool technique is that cross-haul conditions are ignored while evidence suggests that this may be a common occurrence in regional economies. This arises from the technique's method of allocating local production to meet local requirements before imports or exports are estimated. Through the use of a highly disaggregated technology matrix and a consistent data base, the INPLAN system has mitigated though not eliminated many limitations noted by others. For example, Richardson (1972) comments that the use of the national technology matrix may overestimate the interdependence of a regional economy. Similarly, Hieary (1976) criticizes the supply-demand pool technique assumption of proportionate impacts by all purchasing industries. Continued improvements are being sought to enhance the system.

The analytical capabilities of the INPLAN system can be classified into two broad categories (1) the estimation of impacts originating from changes in final demands, and (2) the evaluation of constraints upon sectoral gross outputs. Estimating the regional economic impacts of disturbances in the final demand vector caused by resource management activities is the most frequently used form of input-output analysis employed in Forest Service planning studies. These demand disturbances arise from such activities as timber harvesting, grazing and recreation, as well as direct budgetary expenditures for goods and services. Economic impacts are expressed by the changes in regional income and earnings, employment, gross output and various other parameters.

Input-output models are typically used in Forest Service planning studies to estimate the regional economic effects of implementing management objectives in a National Forest with the expected external effects, resource uses and budgetary expenditures. Economic impacts are characterized as changes (increases or decreases) from current conditions. Planning teams frequently employ input-output models in other ways. The models provide excellent descriptions of regional economic structure, giving planning teams valuable information for formulating agency policies regarding economic growth or stabilization. Opportunities for developing markets for forest products can often be identified through the use of input-output models.
accounts. Major structural changes in an economy, caused by such
events like mine construction or sl area development can be
investigated by generating hypothetical models that characterize the
introduction of new industries. Input-output models have become
integral components of the formal planning models employed by the
Forest Service

The linkages between Forest Service management actions and
and corresponding estimates of net changes in regional final demands are
critical components in the use of input-output analysis for impact
estimation. These disturbances in final demand arise from two
principal sources: public expenditure effects and private sector
output effects (Cartwright, 1979). Public expenditure effects arise
from demand disturbances caused by government purchases of goods and
services. For example, timber stand improvement projects or the
construction of recreational facilities involve purchases for labor,
materials and so forth which can directly be transformed into a demand
disturbance vector. Private sector output effects are somewhat more
complex. These effects stem from the use of forest resources and
indirectly (from the viewpoint of the Forest Service) result in demand
disturbances. For example, the Forest Service's provision of various
factors of production such as stumpage for wood producers water for
municipal and domestic uses, and forage for red meat production must be
traced to its final regional economic use, either directly to
exports or via forward linkages and "spilling-from" effects (see,
for example, Koester, et al, 1968). The effects of the use of forest
resources for recreation can be directly transformed into demand
disturbances by deriving a typical "bill of goods" purchased locally
by the recreationalist during the pursuit of such activities. In all
cases the demand disturbances represent regional market transactions
expressed in purchaser's prices with appropriate transportation and
trade margins

Traditional applications of input-output models utilizing demand
disturbances as the source of interindustry effects, contain an
implicit assumption of sufficient resource supply to permit attainment
of an equilibrium economy. As is often the case with forest
resources, some of the primary resource supplies may be restricted
within a regional economy (for example, the amount of water may be
restricted). If the change in forest output is used under these
circumstances, to derive a disturbance in demand and the model used to
estimate the resultant multiplier effects, the backward linkages would
usually indicate a total demand for the resource exceeding the
original change. The IMPLAN system has been designed to perform
analyses under these conditions by permitting the user to link the
change in resource output directly to a change in sectoral gross
output rather than a change in final demand. The input-output model
is then used to estimate the maximum level of delivery to regional
final demands attainable given the constrained level of gross output.
This kind of analysis is often applicable to economies that are highly
dependent upon primary resources

The economic effects estimated with IMPLAN are described by parameters
typical of input-output studies. They are structural in nature
permitting multiplier effects to be traced throughout the various
regional sectors. Direct, indirect and induced changes in gross
outputs and final demands, employment and import requirements, income
and earnings are the most representative parameters used to describe
impacts. The availability of a complete table also permits
calculation of gross regional product. Induced effects are computed
using a modified "Type III" multiplier procedure (Kieryk, 1965),
iteratively solving the open model to capture the effects of induced
consumptive spending. Detailed employment analysis is possible by
tracking employment requirements among various occupations and
accounting for the effects of either in-migration of workers or
re-employment of unemployed local labor. In combination, this
information provides a comprehensive, detailed account of potential
regional economic impacts

IMPLICATIONS AND EXTENSIONS

The IMPLAN system provides the user ready access to detailed
non-survey based input-output models of regional economies. The
availability of an extensive data base permits construction of
detailed models that portray the structure of the regional economy
under study. The data reduction technique takes explicit account of the
"open" nature of these economies, tracing both intra-regional
flows as well as imports and exports. The models also permit analysis
of Forest Service activities, either individually or in combinations
such as a management program. The construction and use of these
models are relatively rapid and inexpensive, and the system is
available throughout the Agency via distributed computer network. A
major advantage of the system is to permit resources to be devoted to
the utilization of input-output models in planning rather than to
model construction.

Possible extensions in the use of IMPLAN data and models involve more
extensive uses of impact models in Forest Service planning. To date,
most impact analyses have focused upon local area studies. In the
context of a multi-level planning system (see the article by Hof in
this volume), the usefulness of input-output models will certainly
become apparent. State and regional models will likely become closely
linked to the planning model to estimate the economic implications of
various Forest Service policies. Similarly, structural analyses of
timber policies investigated by the Timber Assessment Market Model
(Haines and Adams, 1980) may also be possible. It appears that the
availability of input-output models on a regional basis will permit a
wide breadth of innovative uses in natural resource management

Sectral Output Multipliers for Rural Counties

Lessons from Oregon's Input-Output Studies

People interested in economic development in rural communities often face the need to assess impacts of economic changes (such as plant openings or closings or expansions) or to forecast population, employment, business activity, or public service demands. An economic tool that is often used to assist in this task is the multiplier. This circular is designed both as an introduction to multipliers for the practitioner (planners, public officials, business people, etc.) and as a guide to help them affect the appropriate multiplier for a given application.

The circular is divided into four sections. The first explores what a multiplier is and how multipliers are estimated. The second section (page 3) identifies two principal uses of multipliers. The third section (page 4) summarizes what we have learned about multipliers for local economies, including agricultural and nonfarm sectors of Oregon and University of Oregon counties during the last two decades. Average sector multipliers and measures of variation in multipliers across counties are then presented to give practitioners a feel for the size and nature of multipliers for different sectors.

The fourth section (page 7) is a guide for practitioners who wish to use sectoral multipliers with existing I-O models in areas where no input-output model has been constructed or where the existing I-O model may be inappropriate because of the structure of the economy. The final section (page 8) contains a list of references.

In this circular, multipliers are measures of the degree to which the various firms and industries in an economy are interrelated. They measure the impact of a given external change (for example, a change in the economy's total output) on the output of all the other sectors in the economy. Multipliers are calculated by dividing the change in total output by the change in total input. MULTIPLIERS ARE USED TO ESTIMATE THE IMPACT OF CHANGES IN OUTPUT ON THE ECONOMY.

Aggregate versus sectoral multipliers

Two types of multipliers are commonly used by economists: aggregate and sectoral. Aggregate multipliers reflect the interdependence of all economic activities in an economy. They are calculated by dividing the change in total output by the change in total input. Sectoral multipliers, on the other hand, are calculated by dividing the change in output in a specific sector by the change in total input. They provide a more detailed analysis of how changes in one sector of the economy affect other sectors.

The process begins when a dollar enters the local economy. In this case, the result of an export sale (column A). The dollar will be respended by the exporting firm in order to purchase inputs to meet the increased export demand (column B).

Do you wonder how this additional $600 of business activity generated figure 1 demonstrates how local respending of the export payment by businesses and households creates this multiplier effect.

EC 1166 / February 1984

OREGON STATE UNIVERSITY EXTENSION SERVICE
Using multipliers

Impact analysis

The most straightforward application of the multipliers is to use estimating economic impact of small changes in existing industries. For example, if the Morrow County sawmill increases its exports by $1,000, this year, the Morrow County lumber and wood products sector multiplier of 1.323 indicates that total business sales in the county should increase by approximately $1,400 ($1,000 x 1.323) more or less as a result of the annual change in export sales. This assumes that the county’s economic structure has not significantly changed since 1975, the year for which the Morrow County input-output model was constructed. An entirely new industry or other major change in the economy may significantly alter the county’s economic structure to necessitate modification of the multiplier values.

It is important to note that the multiplier merely indicates the impact per dollar of change, not the total amount of impact that will take place. For example, a $500 increase may have a multiple larger than a $2,000 increase. The sawmill would have a greater economic impact due to its greater volume of sales.

These sectors with the highest multipliers are not necessarily those that have the greatest potential economic impact on a community. Remember that sales is not just the most important measure of community well being. Sectors with the greatest impact on sales may not have the greatest impact on income or employment.

Forecasting

Another important use of multipliers is in making forecasts of business activity, employment, or income. If you have an estimate of export sales, or employment or income for a given future year, or series of years, you can use multipliers to estimate total business sales for employment or income in the county for these years. You must make some adjust

Output, income, and employment multipliers

The multipliers presented in this circular are business output-linked multipliers measuring the total change in local sales generated by a one dollar increase in export sales. Economists sometimes compute other kinds of multipliers in order to measure changes of other types. The most common types of multipliers other than the business output multiplier are the employment and the income multipliers.

Employment multipliers measure the total change in employment generated in the local area for each unit change in employment in a local export sector. An income multiplier indicates the total change in local household income from a one dollar change in household income payments by an export sector. For many forecasting and impact analysis applications, total employment and income are more important indicators of community well being than total sales. With additional and additional information, output input models can be used to divide income and employment multipliers. This circular however reports only business output multipliers.

Sectoral output multipliers for nine rural Oregon counties with I-O models

During the period 1963 to 1992, agricultural and resource economists at Oregon State University constructed 11 input output models for nine Oregon counties based on surveys of firms, local government, and in some cases households in each county. Two counties, Grant and Union, were surveyed twice, with several years between the surveys in each case. Figure 2 shows the location of the counties with survey based input output models. These counties (called “I-O counties” in this report) are located in all parts of the state except for the Willamette Valley, Tillamook, Lincoln (Mazama Bay region), and Clatsop counties in the northwest coastal region. Douglas and Tillamook counties in southwest Oregon and Grant, Morrow, Union and Baker counties in northeast Oregon.

More detailed information on the construction, interpretation, and use of the I-O models in this report is based on the public reports listed on the end of this report. The models are used in order for which the input output model was completed, with the oldest models listed first.

Accuracy of the multipliers

Multipliers are estimates. The primary data upon which the O models and multipliers are based are obtained through interviews with a sample of the firms in each sector, leading to possible sources of error.

The first of these errors usually relates to the accounting records providing sales and services information. Incomplete records sometimes mean that estimates must be made.

Second, because not all firms in every sector were interviewed, the possibility exists that the sample was not truly representative of the entire sector. For a more complete description of the accuracy of the results see Harris and Vanoumm ("Survey Methods," section 1, page 10).

Each O model reflects the structure of the county economy in the year of the model. To the extent that the buying and selling patterns in any county have been changed since that time, a model and the multipliers derived from it will not accurately represent current economic structure.

You can observe the average amount of change that has taken place in multipliers in four Oregon counties by comparing the values of the multipliers in the model developed for 1973. Multipliers were completed several years apart Clatsop and Grant.

Carroll has offered the opinion based on his research in Clatsop County that regional O models become outdated quickly. "Although some variations would be expected among regions, present results indicate that a regional model may not be good for more than ten years and more likely for less than five years. See References, page 10 section 1, Carroll 1980, page 80."
Factors affecting multiplier size

The most important of these factors is the degree of leakage. Sectors that import a large share of their first round purchases (that is, have large leakages) generally have smaller multipliers than those that import a smaller share of inputs locally. Other things being equal, the greater the leakages at any round of responding, the smaller the multiplier. The extent of leakages, however, is very difficult to determine without a survey.

In the absence of information about the extent of leakage in a given sector or economy, you must look for characteristics of sectors or economies that tend to be related to the degree of leakage—and hence the size of the multiplier.

Figure 3: Sectoral output multipliers for each sector, the dot represents the mean, and the lines extending in both directions represent the standard deviation.

Guidelines for using existing sectoral multipliers

Survey-based multipliers exist in a number of industries and sectors. What you want to estimate is the economic impact of a given type of output or input in a particular location.

There are several ways to approach this problem. One is to use an input-output model, which allows you to estimate the economic impact of a given type of output or input in a particular location.

Another approach is to use existing sectoral multipliers, but this approach requires careful consideration of the characteristics of the sector or economy in question.

Using existing sectoral multipliers

Generally, the more closely a county resembles a given type of output or input, the more accurate the multiplier. However, this approach requires careful consideration of the characteristics of the sector or economy in question.

*Data from the Bureau of the Census and the Oregon Department of Revenue.*

Thus, multipliers based on older models probably underestimate today’s multiplier effects in many counties. The older the model, the more the multiplier understates the current multiplier effect.

In the absence of information about the characteristics of a given sector or economy, you must look for characteristics that are related to the degree of leakage—and hence the size of the multiplier. When using an economic model, you should identify several sectors that help explain the differences in multipliers between Oregon counties. Reference section 3 page 8.

Four factors that influence multiplier size along with the nature of their influence are identified in Table 5.

- The three characteristics are county population, income per capita, and geographic location. Since more populous counties have larger leakages and tend to develop more diversified economies, with more opportunities for local businesses, dollar multipliers in more populous counties tend to be larger. Income per capita is inversely related to leakage size, so the income per capita relationship may reflect the tendency of household income in high-income counties to be more outside the county, perhaps for luxury items and recreational activities.
- Greater geographic isolation that is a longer distance to the nearest major trade center leads to no local purchasing as a means of avoiding travel costs—hence larger leakage.
- The age of an input-output model also affects the appropriateness of using its multiplier estimates in a current analysis. In the post-25 years, the 10-year sector in the United States has grown relative to the rest of the US economy, providing opportunities for greater local spending and responding.

Using existing sectoral multipliers

Generally, the more closely a county resembles a given type of output or input, the more accurate the multiplier. However, this approach requires careful consideration of the characteristics of the sector or economy in question.

In the absence of information about the characteristics of a given sector or economy, you must look for characteristics that are related to the degree of leakage—and hence the size of the multiplier. Summary

Multiplicase can be used (1) to estimate the total economic impact on a region of a proposed or current economic change, such as a plant expansion, plant closure, or government investment, and (2) to make forecasts. Business output multipliers, as outlined in this circular, measure the total change in sales resulting from a one-dollar increase in exogenous sectoral multipliers for non-Oregon counties.

In any case, the information about the average sectoral multiplier and the variation in sectoral multipliers among surveyed Oregon counties should be of help to practitioners in putting bounds on multiplier estimates.

b. Input-output multipliers
Mr. Earl Layser  
Ochoco National Forest  
Box 490  
Prineville, Oregon  

Dear Mr. Layser,

Thank you for your appearance before the Grant County Resource Council last month. At our meeting the other night we agreed on comments in response to the proposed forest plan. We grouped these a little differently from your response sheet, so please bear with us.

1. The proposed plan and supporting documents are too big and much too complicated. We realize you are trying to cover all your bases, but the product we have now discourages people from trying to wade through it. Perhaps alternatives could be worked out in general terms rather than fine detail, pending a decision on direction to work.

2. We proposed that anyone who has the opportunity to participate in this planning process, and does not, should not then have the option to come in on appeal and hold up the implementation of the plan. To allow this is to essentially say that the planning process is not sufficient, and negates the purpose of having a plan in the first place.

3. Are the numbers accurate? One comment concerned an error in a grazing fee (sorry, I can't find page number now).

4. Related to #3—we believe the value of wilderness use is greatly exaggerated.

5. Related to #3—variation in big game use days ref B-72, B-64, 65.

6. In the interest of good timber management, with the interest of the sustained forest the primary goal, we think thinning and other management practices are not sufficiently emphasized. We would urge a total resource management objective, including soil, water, and air as well as products such as grass and timber.

7. The effects of various alternatives on school and county budgets needs to be followed.

8. Costs of various alternatives was laid out, but the practical question of whether the funding was available was not addressed. It seems there is a good possibility that an alternative could be chosen and then not followed if funding were cut off.

9. We have a real concern for timber harvest. Are we overcutting on the short term and will find a sustained yield impossible? Have the cumulative effects on the regions timber supply of this plan and other forest plans been considered? Certainly we need to be aware of the capacity of the local mills, but we also need to think 20, 50 and 100 years into the future. Here on the Malheur we are getting the effect of a reduced cut on the Wallowa-Whitman—mills in NE Oregon are coming in here for sales. The regional timber supply should be sustained with the entire region in mind, considering haul time, reforestation potential, and all the other factors that go into meshing a timber harvest with a sustained yield.

Thank you for the opportunity to comment.

Sincerely,

Lorene Allen  
County Judge
Forest Supervisor
Ochoco National Forest
Box 450
Prineville, OR 97754

December 17, 1986

Dear Forest Supervisor:

The Crook County Soil and Water Conservation District would like to comment on the proposed Forest Plan.

1. Protect the land economy.
2. Protect natural resources but use them in a wise manner. Grass and timber are both renewable resources and are in better condition when they are in an active growing state than in a dormant stagnant one.
3. Cut down on permanent road building. Use temporary roads and see them over. Paved hard surface roads contribute a lot to run off during storm. This can contribute to an undue amount of erosion.
4. Provide for 32,000 acres of old growth, and preserve the core of Lookout Mountain and Silver Creek as roadless areas.
5. Provide more tree thinning in stands that will respond.
6. Use the present level of firewood availability.
7. Use a combination of B Plus and E Departure. Round off the edges and make it work.

We emphasize the need for proper soil and water stewardship. We also emphasize the need for man to utilize these and not just sit on them.

Thank you for your consideration, and Good Luck!

CROOK COUNTY
Soil and Water Conservation District
889 North Main Street
Prineville, Oregon 97754

HARNEY COUNTY COURTHOUSE
425 N BUENA VISTA - BURNS OREGON 97720

December 17, 1986

Forest Supervisor
Ochoco National Forest
P.O. Box 450
Prineville, OR 97754

Dear Forest Supervisor:

The Harney County Juvenile Department wishes to convey our concerns to you regarding the forthcoming decision for the Ochoco National Forest Management Plan.

We are concerned about possible cutbacks in the lumber industry and the effects this would have on families and youth in Harney County. Our recent past experience has proven that high unemployment rates cause family disintegration and increased Juvenile delinquency. Only recently has Harney County begun to climb out of the economic depression we have endured since early 1980. We believe the forest is big enough for all users without negatively impacting any of them if it is managed properly.

We urge you to carefully consider the impact a decrease in lumber production would have on Harney County families. We further recommend that present firewood availability remain at the present level.

Thank you for your consideration in this matter.

Sincerely,

Mary Hanneman, Court Director

LIVESTOCK -- RECREATION WILDLIFE LUMBERING

1-4-97
Dear Forest Supervisor

Please consider these comments to the Ochoco Forest Plan:

First and primarily it must be recognized you are a National Forest. As such you are not designated as a park. Your responsibility should not be preservation as in wilderness, but rather preservation as in production. Production takes many forms including, but not limited to, recreation opportunities of all kinds; wildlife habitat, firewood, Christmas trees, grazing AUMS and commercial timber sales. Of these the last two probably have the most impact on the economy of the area.

Jobs are the key to judging the successful management of the Ochoco. Other benefits will continue regardless, if the highest possible production is obtained. By this means erosion and other man caused activities must be managed. Only through such careful measures can production be perpetuated. Allowed harvest must not exceed the capacity of the land to reproduce.

However, no creature can look far enough into the future to determine what limits of timber cutting or grazing will be desired to maintain a perpetuating production. There are absolutely too many variables that cannot be accurately predicted. Weather, fire, disease and insects all will have their effect.

Therefore, it makes no sense to establish a timber cutting program that is not flexible, that is not new in production and at or near the prime harvest stage. Due to economics, timber that is ripe for harvest may not always be saleable; witness the very recent past.

It makes no sense to overgraze forage and it makes no sense not to graze available feed. Under-harvest does nothing to improve the grass or the economy, also true of rotting trees. True, an attempt to average should be made, but in the case of grazing, an annual evaluation is critical which is somewhat different than a timber crop that takes many years to produce.

Studies now appear to indicate riparian areas should be stocked with livestock or game to maintain their natural condition as has gone on for eons. Nature should be allowed to take its course along streams although upstream impoundments do appear to be highly beneficial from all aspects.

Firewood is a desirable side product of the forest and there is no reason all local need cannot continue to be met. We would estimate ten times as much wood rots or burns in the forest every year than is ever used domestically.

To summarize:

1. AUMs should be increased to utilize all forage to a degree that perpetuates its production and be under constant review to avoid erosion.
2. Timber harvest can be more easily determined on long range projections and should not be increased even temporarily unless such increase can be sustained over a long period of time.
3. Upstream impoundments should be constructed to improve water quality, improve game habitats, improve riparian areas and improve recreation with little if any effect on production of timber or game.
4. Domestic uses should receive highest priority for accommodating the needs of surrounding residents.
5. No management plan should adversely affect the economy or lifestyle of communities nearby.

Sincerely,

Herb Davis, President
Donna Hurtibs, Secretary
December 19, 1986

To Forest Supervisor
Ochoco National Forest

From Crook-Wheeler County Farm Bureau

Subject Proposed Plan Ochoco National Forest

The Board of Directors of the Crook-Wheeler County Farm Bureau on behalf of its 336 members in Crook and Wheeler Counties wishes to respond to the proposed Forest Plan for the Ochoco National Forest.

The Farm Bureau at the county, state and national level solidly supports the multiple use concept of federal land management. We do not support the addition of any lands for wilderness designation. Furthermore, we do not support the set-a-side of any lands for wildlife habitat.

We believe that a plan can, and should be selected that would maximize the utilization of the renewable resources without endangering any one phase of the multiple use concept. We feel at this time, none of the proposed alternatives meet this criteria. The final plan should blend certain elements of the several proposals to achieve the multiple use concept.

Signed Greg Merritt, President
CROOK-WHEELER COUNTY FARM BUREAU
left whole, for all useable purposes, rather than having set aside areas for specific purposes. Proper management of the whole will provide for all uses, rather than inferior management by property lockup.

We feel that there should be greater emphasis on reforestation, on bug control and on salvage, none of which appeared to be well addressed, if addressed at all in any of the plans.

The two areas which would be most manageable would be to plant more trees and develop a creditable system for salvage of timber from bug kill, blow down, lightning strike, fire and other types of disease.

In the past thirty years I have failed to hear the charge that from "30 to 50 million board feet of lumber is lost annually in our forest", disputed by members of industry or Forest Service personnel.

Appropriate provisions for a consistent salvage program could have a profound effect on maintenance of sustained yield and at the same time reduce that element of our wastefulness and lack of stewardship.

We do feel that a few reasonable corridors should be protected, such as, Highway 26, the road to Walton Lake and possibly two or three more, where travel is or probably will become significant.

Finally, we would submit that we have three wilderness areas in the Ochocos, none of which met the federal criteria for wilderness designation, however, they are set aside and we believe the future will prove the wisdom of the designations in spite of the political motivations.

In this context, however, it is the unanimous opinion of the County Court that we can ill afford any further roadless areas, or large areas set aside for single purpose situations.

There does not appear to be any unchallengeable, factual evidence that the existence of the pileated woodpecker or continued existence of other forms of wildlife or the management of game animals cannot be dealt with in harmony and compatibility with the harvest of timber throughout the entire Ochoco range.

We would encourage the re-opening of the road to the top of Lookout Mountain even if on a controlled basis for the enjoyment of the view for the elderly and handicapped.

We would encourage a selective cut harvest of the forest, rather than even or clear cut.

In spite of periods of controversy over the years, it is our opinion that the Ochoco National Forest has been competently managed. We feel that drastic changes as proposed by the E departure plan are wrong, unnecessary, detrimental to the economy and would not serve the best long range interests of any of the various factions.

It is our belief that those involved in the forest products industry, the cattle rancher, environmentalist, hunter, game biologist and those for recreation can co-exist, utilizing the entire forest. We believe that the U.S. Forest Service has both a policy and a moral obligation to continually seek procedures which will protect the long term economic stability of our Community.

Respectfully submitted,

Crook County Court

by Dick Nopper, Judge

Df/cm

Ochoco National Forest Plan
Page 3
Dear Mr. Rittersbacher,

After studying the Economic Impact Analysis, submitted by Brian Long, and attending the December 12, 1986 C.O.C. meeting and hearing testimony regarding this analysis we, the Jefferson County Court, would like to go on record that we oppose the Ochoco National Forest, E - Departure, plan.

It is our opinion that if 50,000 acres must be set aside, then this should be for the use of selective logging and not for any other purposes.

In conclusion, the economic impacts that this plan would have would adversely affect Central Oregon industry.

Sincerely,

HERSCHEL READ
Jefferson County Judge

The following endorsement was adopted by the City Council on December 17, 1986.

The City Council of the City of Prineville hereby endorses any modifications to the Ochoco Management Plan which would maintain or increase timber related employment through:

A. Intensively managing a balanced timber base suitable for all uses of the forest.

B. Increasing salvage programs to maximize timber production.

C. Stewardship of land be included in grazing application.

We feel that a major factor to be considered in managing the forest is economic stability of the local community and our quality of life.

Henry Hartley
City Administrator
December 18, 1986

Mr. James Torrence
Regional Forester
Pacific Northwest Region
319 S.W. Pine
P.O. Box 3623
Portland, OR 97208

Dear Mr. Torrence,

The Columbia River Inter-Tribal Fish Commission appreciates this opportunity to comment on the Draft Environmental Impact Statement (DEIS) and the proposed Ochoco National Forest Plan. The commission is composed of the Fish and Wildlife Committees of the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes and Bands of the Yakima Indian Nation, the Confederated Tribes of the Warm Springs Reservation of Oregon, and the Nez Perce Tribe. These four tribes have rights reserved by treaty to take fish that pass their usual and accustomed fishing places. Among these fish are the anadromous species that originate in the Ochoco National Forest.

The Nature of the Treaty Right

The tribes' right to take fish that pass their usual and accustomed places is a right confirmed by numerous court decisions. See e.g., Schappy v. Smith, 302 F.Supp. 899 (D. Or. 1969), aff'd, United States v. Oregon, 529 F.2d. 570 (9th Cir. 1976); Washington v. Washington State Commercial Passenger Fishing Vessel Ass'n, 443 U.S. 658 (1979) (Passenger Fishing Vessel). In addition to binding state governments, See Passenger Fishing Vessel 443 U.S. at 682 and n.25, the treaties are also binding on private citizens, See e.g., United States v. Hanaw, 198 U.S. 371 (1905), and, of course, the federal government. Passenger Fishing Vessel, 443 U.S. at 682; See also Confederated Tribes of the Umatilla Reservation v. Alexander, 440 F. Supp. 555 (D. Or. 1977). Absent specific authorization by Congress, Indian treaty rights cannot be abrogated. Id., citing Nez Perce Tribe v. United States, 391 U.S. 404, 413 (1968).
In *Passenger Fishing Vessel*, the Court painstakingly examined the circumstances surrounding the negotiation of the treaties in an attempt to define the parties' long-term intentions. The Supreme Court emphasized that Governor Stevens invited the tribes to rely on the United States' good faith efforts to protect their right to a fisheries livelihood. Stevens specifically told the tribes: "If you sign the treaty it secures your fish." Id. at 667 n.11. During the treaty negotiations, "the Governor's promises that the treaties would protect the source of food and enhance the utility of the Indians' assent." Id. at 676 (emphasis added). As the Supreme Court stressed:

"It is absolutely clear, as Governor Stevens himself said, that neither he nor the Indians intended that the latter "should be excluded from their ancient fisheries," . . . and it is accordingly inconceivable that either party deliberately agreed to authorize future activity to crowd the Indians out of any meaningful use of their accustomed places to fish.

Id. The Supreme Court also mentioned that the treaty guaranty of "the right of taking fish" was meaningful only if fish were available for the taking. Id. at 678 (emphasis added).

The 130 years since the treaties were signed have witnessed a truly startling number of methods by which the quantity of fish available for the taking could be reduced -- if not eliminated. The courts have responded to these threats to the treaty right by declaring a policy that the treaty right cannot be defeated by technology or other methods not anticipated by the treaty signatories. For example, in *United States v. Winans*, 198 U.S. 371 (1905), the defendant constructed a fish wheel (a device capable of trapping an entire run of fish) in common with the Indians from one of their usual and accustomed fishing places. Commenting on the effects of improved fishing devices, the Court noted that:

wheel fishing is one of the civilized man's methods, as legitimate as the substitution of the modern harvester for the ancient sickle and flail . . . It needs no argument to show that the superiority of a combined harvester over the ancient sickle neither increased nor decreased rights to the use of land held in common.

Id. at 382. Thus, although improved technology may be brought to bear on the fishery, that technology cannot be allowed to imperil the rights secured to the parties to the treaty.

This result was reaffirmed by the Supreme Court in *Passenger Fishing Vessel*. There the Court declared that "[n]on-treaty fishermen may not rely on property law concepts, devices such as the fish wheel, license fees, or general regulations to deprive the Indians of a fair share of the relevant runs of anadromous fish in the case area." *Passenger Fishing Vessel*, 443 U.S. at 684. The Court's intent is clear: absent specific treaty guarantees and legislative acts from Congress. (Nez Perce Tribe v. United States, 391 U.S. 404, 413 (1968)), no one may use any method to deprive treaty fishermen of their fair share of the anadromous fish.

**Federal Duty to Protect Subject Matter of Treaties**

In addition to their obligation to not destroy Indian treaty rights without specific Congressional action, federal agencies must use their authority to safeguard that which is the subject matter of federal treaties. In *Kittitas Reclamation District v. Sunnyvale Valley Irrigation District*, 703 F.2d 1035 (9th Cir. 1983), the Ninth Circuit affirmed a district court order to operate a Yakima water project in a manner that would preserve spring chinook salmon redds. Federal project operators had originally sought to reduce water releases in order to store water for the next irrigation season. The proposed flow reductions would have left the redds high and dry. Testimony at the district court hearing indicated that the proposed water storage would be possible if twelve redds were transplanted or if beaks were constructed. Id. at 1035. However, the district court judge was "unaware of the effect of these measures, so he continued the watermaster's authority to release water as necessary." Id. Expressly declining to decide the scope of the Yakima Indian Nation's treaty fishing rights, Id. at n.5, the Ninth Circuit found that the district court judge had fashioned a reasonable remedy. Id.

The message in Kittitas is clear. Federal agencies are obligated to exercise their authorities in a manner that will protect -- not degrade -- the habitat needed to support anadromous fish. In addition, when addressing anadromous fish habitat needs, various measures may be utilized, but the choice turns not on traditional notions of agency expertise, but on the biological needs of the fish.

**Magnitude of Fisheries Reserved by Treaty**

The Forest Service's duty to protect and enhance anadromous fish habitat does not cease once a fish run becomes viable. The tribes did not reserve a right to take a few fish from a near run struggling for survival. Some might argue that the Columbia River treaty tribes reserved the right to continue harvesting that number of fish that they had traditionally harvested.
Obviously, that harvest level is not yet possible given the contemporary depleted fisheries. The Supreme Court has held that both Indian and non-Indian fishermen possess a right, "secured by treaty to take a fair share of the available fish." Passenger Fishing Vessel, 443 U.S. at 684-85. The Court determined that Indian harvest allocation should not exceed 50% of the harvestable fish. Id. at 695-96. The Court then declared:

It bears repeating, however, that the 50% figure imposes a maximum but not a minimum allocation... The central principle here must be that Indian treaty rights... are a natural resource, that one cannot be exclusively exploited by the Indians, secures as much, if no more than, is necessary to provide the Indians with a livelihood... that is to say, a moderate living. Accordingly, while the maximum possible allocation to the Indians is fixed at 50%, the minimum is not, the latter will, upon proper submissions to the district court, be modified in response to changing circumstances. Id. at 686-87.

Perhaps the reason why this "moderate living standard" remains anachronistic by the Supreme Court has not proven to be a thorny problem in Pacific Northwest fisheries management is because no one can reasonably contend that the Indians' harvest presently yields a moderate living. This fact was implicitly acknowledged by the Supreme Court in Passenger Fishing Vessel when it stated that the 50% ceiling on the Indians' harvest allocation was necessary "to prevent their needs from exhausting the entire resource and thereby frustrating the treaty right of 'all other citizens of the territory.'" Id. at 686.

Regardless of what the term "moderate living standard" means, it will eventually be defined by the judiciary -- not a federal agency. See id. at 687. As discussed earlier, the Ninth Circuit has already determined that federal agencies must refrain from taxing actions that will reduce the number of fish in a depleted run. See Kittitas, 763 F.2d at 685. Nor does this duty cease when an anadromous fish run manages to increase its numbers beyond the dangerous level of minimum viability. In United States v. Adair, 723 F.2d 1394 (9th Cir. 1984), the Ninth Circuit stated:

Implicit in this "moderate living standard" is the conclusion that Indian tribes are not generally entitled to the same level of exclusive use and exploitation of a natural resource that they enjoyed at the time that they entered into the treaty reserving their interest in the resource, unless, of course, no lesser level will supply them with a moderate living. Id. at 1415 (emphasis added).

Here the Ninth Circuit has indicated that the Klamaths must be allowed to achieve their "moderate living." No one knows what that is. The Court explicitly stated the possibility that the

"moderate living standard" may only be achieved by allowing the tribe to enjoy the "same level of exclusive use and exploitation" it had at the time the treaty was concluded. Id. The purport of this holding is clear. Federal agencies owe a duty to refrain from activities that will interfere with the fulfillment of treaty rights. Moreover, this duty cannot be performed by engaging in an "accommodation" or "balancing" process between Indian treaty rights and a competing economic interest such as timber harvest. Any such "accommodation" reached by the Forest Service would amount to a de facto abrogation of Indian treaty rights. In the context of forest management, unless the Forest Service can demonstrate that the tribes' treaty rights are presently being fulfilled, it cannot justify approving activities in the forests that will cause further degradation of anadromous fish habitat.

The National Forest Management Act Mandated Coordination

The Forest Service is only one of the many entities involved in the complex interactions that have caused the diminution of anadromous fish runs to their present state. Columbia River hydroelectric development and other downstream problems have done considerable harm to the nation's fisheries, but blame for much of the harm inflicted on anadromous fish, such blame does not obviate the Forest Service's responsibility to protect anadromous fish and the need for all parties with management authority that affects these fish to work together to improve the fishery resource.

In dealing with anadromous fish, the Forest Service must look beyond the boundaries of a given national forest. Columbia River stocks of anadromous fish migrate as far inland as theitterer's National Forest and as far north as Alaska. As the Pacific Northwest has come to realize, the anadromous fish runs can only be restored if state, federal, and tribal land, water, and wildlife managers adopt a coordinated "gravel-to-gravel" management approach to this valuable and mobile renewable resource.

This approach is reflected by the Northwest Power Planning Council's Columbia River Basin Fish and Wildlife Program. The Fish and Wildlife Program, mandated by the Northwest Electric Power Planning and Conservation Act, 16 U.S.C. Section 839b (1982), encompasses the Columbia River and its tributaries and will be financed by Pacific Northwest ratepayers. This comprehensive protection, mitigation, and enhancement effort does not appear to be integrated into the DEIS or proposed plan. Nor were the increased fish returns made possible by the recently concluded United States/Canada Salmon Interception Treaty, 16 U.S.C. Section 839d (1985 Supp.), mentioned in either document.
These efforts, along with the Salmon and Steelhead Enhancement Act, have changed the complexion of fisheries management in the Columbia Basin. The success of both the Salmon Interception Treaty and the Fish and Wildlife Program turn upon maximizing utilization of the anadromous fish habitat in Columbia River tributaries. A large percentage of these tributaries run through national forests. The Forest Service must acknowledge its responsibilities to act in concert with these policies. The Forest Service cannot make a reasoned decision with respect to anadromous fish habitat if it does not factor these activities into its decision-making process. The Pacific Northwest cannot afford to spend money enhancing fisheries that are simultaneously being degraded by timber harvest, road-building, and grazing.

Forest Service coordination with Pacific Northwest fisheries enhancement activities is not only sound policy; it is also required by law. Forest Service regulations declare that a review of state, federal, and tribal planning and land use activities shall be included in the forest plan EIS. 36 C.F.R. Section 219.7 (a)-(c) (1984). In addition, the regulations provide that this review shall consider the objectives of federal, state, local, and tribal governments, inter-related impacts of these plans, and a decision by the Forest Service on how each forest plan shall address these inter-related impacts. Id. at (c)(1)-(4). Among the objectives of federal, state, and tribal governments are the fish production plans currently being formulated under the auspices of United States v. Oregon, the Fish and Wildlife Program, and the Salmon Interception Treaty. The Ochoco National Forest DEIS and proposed plan do not reflect the consideration of these processes required by the NEPA.

Anadromous Fish Assessment

As a consequence of its federal mandate to protect, mitigate, and enhance fish and wildlife while assuring the Pacific Northwest an adequate and economical power supply, the Northwest Power Planning Council is currently estimating the location and extent of anadromous fish in the Columbia Basin. This assessment will:

- estimate the resource value by characterizing the productivity of each stream reach. Productivity is defined to be comprised of three factors: smolt production, migration use and upstream geography which may, through sedimentation, affect downstream anadromous fish areas. This study will quantify the actual productivity of each stream reach. Migration will be accounted for by including in any estimate of smolt production for an individual stream reach an upstream productivity as well. i.e., the productivity will accumulate as one moves down a stream. Stream reaches upstream of anadromous fish areas which have the potential to adversely affect downstream use will be identified quantitatively.

See Northwest Power Planning Council, Proposed Work Plan Pacific Northwest Hydro Assessment Study (August 1, 1984) at 3. The results of this study will provide the most current and comprehensive examination of Columbia Basin anadromous fish production capability available. This study will be used to identify areas and stream reaches that, due to their value to fish, should be protected from hydroelectric development. It would be wasteful and expensive indeed to invest money in habitat enhancement and protection only to have those efforts smothered by sediment generated by logging and roadbuilding. The Forest Service and anadromous fish managers from federal, state, and tribal governments should coordinate to make sure that the information generated by this study will foster the most judicious resource utilization possible.

Cumulative Impacts

There are 17 national forests in the Columbia basin that produce anadromous fish. These are the Clearwater, Nezperce, Bitterroot, Boise, Challis, Payette, Salmon, Sawtooth, Umatilla, Wallowa-Whitman, Mount Hood, Malheur, Ochoco, Gifford Pinchot, Okanogan, Willamette, and Wenatchee. All of them are going through the forest planning process. Approximately 50 to 70% of all remaining anadromous fish habitat is contained in these forests. Events on these forests will have a profound impact on the anadromous fish resource that is vital to the welfare and existence of the four treaty tribes.

Unfortunately, the Forest Service does not see to realize that each forest is an important cog in the machine that will either revive the fish runs or slowly log, road, graze, or mine them into oblivion. To adequately assess the environmental impacts of land on fish as required by NEPA, the Forest Service must study and disclose the cumulative impacts of all 17 forest plans listed above on the Columbia River anadromous fish runs and the four Columbia River treaty tribes. It is simply not adequate for each forest to merely look at the impacts of its activities within the borders of the forest or in the surrounding communities and counties. Nor is it adequate for the Forest Service to boldly assert that it has assessed cumulative impacts while offering absolutely no evidence that it has made any such consideration. Fish production precluded by activities within each forest and in conjunction with other forests affects not only surrounding communities, but also downstream Indian tribes and other fishers both inriver and in the ocean.

Adequate assessment of cumulative impacts requires a certain management worldview. It requires that managers of land, water, or fish realize that even though they may only have management
authority over a relatively small aspect of the anadromous fish lifecycle, their management decisions may have a decisive impact on other fishery management decisions or the fishery resource itself. This is by no means a revolutionary concept. In fact, the Forest Service avails itself of this management approach every time it asserts that the reason that fish production is not any higher is because of downstream passage mortality and harvest management. The Forest Service is correct when it states that harvest and passage considerations are important to the overall health of the Columbia basin anadromous fishery. However, fish production, both natural and hatchery, is also equally important. The Forest Service is directly responsible for natural fish production occurring on national forest lands. Pointing accusatory fingers at other entities does not relieve the Forest Service of its duty to ensure that its management will not adversely affect already depleted naturally producing stocks.

The idea that proper fishery management requires coordination of harvest, passage, and production needs has been around for a number of years. It is embodied in the Pacific Northwest Electric Power Planning and Conservation Act enacted in 1980. See 16 U.S.C. Section 839(h) (1982). It is also an integral aspect of the Northwest Power Planning Council's efforts to coordinate restoration of Columbia basin fisheries to the extent affected by hydroelectric power production. See e.g. Northwest Power Planning Council, Salmon And Steelhead Planning, Staff Issue Paper (June 3, 1986);

A gamut of potential problems may result from uncoordinated actions. Fish production investments may be in conflict. Power system operations may diminish production or offset increases in production. Harvest practices could prevent escapement in adequate numbers to ensure sustained increases in yield. The mixed-stock harvest could undermine passage actions designed to protect or enhance certain stocks of fish. Harvest and power needs may not be sufficiently defined to guide production efforts. Production decisions may be made without full regard to harvest needs and to power system constraints with respect to passage. Land and water management actions may undermine fish production investments.

When actions are taken in the absence of a system perspective, there also may be too little recognition of the spectrum of choices among production, passage and harvest actions. Actions may be taken without consideration of the full range of alternative means to achieve objectives. Actions may be taken with inadequate analysis of trade-offs. Any effectiveness analysis is only partially compensated for by potential losses from unmitigation. There is no history of fisheries budgets sufficient to mitigate substantial losses of quality habitat. Recent and projected budget trends indicate a status quo situation.

Moreover, in the absence of a system perspective, monitoring and evaluation of actions may be uncoordinated, lacking, short-term, sporadic, or narrow in focus. Id. at 8.

There are many who consider the need to provide for increased natural fish production to be a major constraint on anadromous fish harvest regimes. The tribes have foregone harvest of fish, to which they are legally entitled, for the purpose of providing increased escapement of naturally spawning adults. Despite these efforts, and despite the increasing numbers of returning adults (many of which are hatchery fish), the tribes are under pressure to further forego harvest opportunities. Forest management that will cause reduction in natural fish production will further exacerbate this situation. Reductions in natural fish production directly conflict with the tribes' treaty rights.

The Forest Service has often informed CITF and tribal staff that the Forest Service is only responsible for supplying smolt habitat capability and that there is far more capable habitat than there are smolts. The Forest Service's responsibilities include more than merely furnishing a given amount of habitat. The Forest Service must identify that which is being utilized by fish and, to the extent it can, that which will be utilized through either United States v. Oregon or Fish and Wildlife Program enhancement. Part of the concern behind protection of naturally spawning stocks is the desire to protect unique gene pools that will be needed to restore the basin's fisheries. For a recent discussion of the role of genetics in Columbia basin fisheries management, see Northwest Power Planning Council, Salmon And Steelhead Research, Staff Issue Paper (June 3, 1986).

Mitigation

The Forest Service has often relied upon mitigation in the hope that mitigation will compensate for the damage inflicted on fish habitat by timber harvest. However:

Mitigation of fish habitat losses is often presented as a panacea and substitute for maintenance of habitat quality. The concept of "fisheries mitigation" is more myth than substance. It seldom materializes and when it does, it only partially compensates for substantive losses. There is no history of fisheries budgets sufficient to mitigate substantial losses of quality habitat. Recent and projected budget trends indicate a status quo situation.
See Espinosa, Background Paper Fisheries Resources Analysis of the Management Situation Clearwater National Forest (undated) at 56-57 (emphasis in text). The Commission is unfortunately acutely aware of the vagaries and inadequacy of fisheries mitigation. Thus, we are extremely skeptical of vague promises of best management practices, implementation of standards and guidelines, and reliance on enhancement to mitigate management impacts on fish habitat.

Given the importance of the anadromous fish resource, very little reliance should be placed on mitigation measures that do not have a proven record of effectiveness. The Forest Service must be careful to not ask more of a mitigation technique than it can give. New or untested mitigation techniques should be thoroughly evaluated before being widely used and relied on. Monitoring should be vigilant, stringent, and should include all entities that are involved in the management of anadromous fish. Finally, mitigation methods should be chosen on the basis of the protection they will provide the fishery resource, not how much they will affect the cost/benefit analysis of commodity resources such as timber, range, and mineral extraction. See e.g., Pacific Power & Light Co., Opinion No. 361-A, 20 F.R.C. 495 (1963), aff'd in part, rev'd in part on other grounds, 333 F. 2d 689 (9th Cir. 1964), cert. denied, 379 U.S. 969 (1965) (where it is declared that it is the policy of other federal agencies to require complete recompense for fisheries damage.) The DEIS should be revised to include analyses of known mitigation techniques. These analyses should include evaluations of effectiveness, standards for application, and any other information that might be of aid in deciding whether a given mitigation technique is appropriate. In reliance on habitat enhancement as mitigation appropriate in the face of the current federal budget crunch? The Commission will be happy to contribute its expertise towards evaluating the use of various mitigation methods on a case-by-case basis.

Trust Responsibility

The trust responsibility is that special relationship between the United States and Indian tribes that originated in Cherokee Nation v. Georgia, 30 U.S. (5 Pet.) 1 (1831) where the Supreme Court described Indian tribes as "domestic dependent nations" and declared that "their relation to the United States resembles that of a ward to his guardian." Id. at 17. This relationship is part of the very fabric of federal Indian law and it imposes stringent fiduciary standards of conduct on federal agencies in their dealings with Indian tribes. See United States v. Creek Nation, 295 U.S. 103 (1935). See also Northern Cheyenne Tribe v. Nodel, Civ. No. B-116-BLG (D. Mont. May 28, 1985) at 23.

In Northern Cheyenne Tribe, the court declared that "a federal agency's trust obligation to a tribe extends to actions it takes off a reservation that uniquely impact tribal members or property on a reservation." Id. at 27. In an attempt to save its coal leasing EIS from invalidation, the Secretary of the Interior alleged that there was no specific statute or treaty that required the Department to consider the impacts of coal leasing on the tribe as an entity. Id. The Secretary also alleged that his decision to lease the coal was in the "national interest" and "vital to the nation's energy future." Id. at 29. The court declared that:

The Secretary's conflicting responsibilities and federal actions taken in the "national interest," however, do not relieve him of his trust obligations. To the contrary, identifying and fulfilling the trust responsibility is even more important in situations such as the present case where an agency's conflicting goals and responsibilities combined with political pressure asserted by non-Indians can lead federal agencies to compromise or ignore Indian rights.

Id. at 29-30 (citations omitted). Similarly, the Forest Service must not allow its obligations to the Columbia River treaty tribes to become lost in its concern for the local citizenship. It must accord the treaty right special consideration and scrupulous safeguards. Unfortunately, the DEIS did not devote this consideration to the tribes' interests.

The Forest Service owes a duty to not only discuss the effects of forest management activities on the tribes, but also a duty to safeguard resources of crucial importance to the tribes. This duty is not fulfilled by actions which sanction degradation of fish habitat needed to rehabilitate the Columbia River runs.

Sales Below Cost

Over the years, fish and wildlife concerns have often been subordinated to the needs of allegedly more economically valuable, but environmentally damaging commodities such as timber harvest, irrigated agriculture, grazing, and hydroelectric power production. Thus, it is not without some ironic assessment that the Commission observes the current controversy over unprofitable timber sales. Those who have advocated resource decision-making primarily on the basis of short-term economic gain suddenly find themselves "heirated on their own petard." Perhaps this role reversal will convince all those involved in natural resource decision-making that cost/benefit analysis is at best an "unfaithful lover" and that resource decisions are best grounded on other bases.
The Commission is not automatically opposed to "sales below cost" per se. What concerns us is that the DEIS contains no assurance that any of the timber sales proposed for the next 50 years will actually recover its real costs. The NFMA regulations require that the Forest Service shall compare the direct costs of growing and harvesting trees, including capital expenditures required for timber production, to the anticipated receipts to mitigate costs attributable to timber production activities, including "direct costs" of investments, maintenance, operating, management, and planning costs attributable to timber production activities, including mitigation measures necessitated by the impacts of timber production. Id. at Section 219.14(b)(2) (emphasis added).

The Commission is concerned that the Forest Service will respond to the "sales below cost" controversy by artificially "improving" its timber sale balance sheet by shortchanging mitigation needs. The DEIS should disclose the manner in which mitigation measures and levels of mitigation funding are chosen and applied. This information may demonstrate that the timber production envisioned by the proposed alternative fails to include all mitigation costs and is therefore even more cost ineffective than it presently appears. Bland assurances that the Forest Service will implement mitigation measures which it alone determines are necessary frustrates the policies behind both NFMA and NEPA. Both of these statutes demand disclosure, public scrutiny, and public input.

In attempting to justify "sales below cost," the Forest Service should explain where it intends to find the funds to pay for mitigating the effects of timber management on fish and wildlife. It is our understanding that Knutzen-Vandenberg funds for fish and wildlife are not generated by "sales below cost" whereas a sale that covers its costs also yields mitigation money. In other words, fish and wildlife are much more adversely affected by a below cost sale than by a sale that is financially sound.

Community Stability

Despite the utter dearth of statutory authority, the Forest Service appears to believe that the "maintenance of community stability" is the primary constraint on forest management. In addition, "maintenance of community stability" also appears to mean perpetuation or increase in commodity outputs to the detriment of non-commodity outputs and an attempt to artificially maintain lifestyles which would not otherwise be economically feasible. In essence, the Forest Service seems to perceive its mission as being the guarantor of the local timber and range industries.

The Ochoco National Forest is a national forest and should not be managed as a private woodlot for a handful of local mills. If the trends for sustainable flow from surrounding lands are on a declining trend in the local area, the intentions of the Forest to match past levels of harvest may in the long run fail to support local mills. The Forest Service is not charged with the obligation to insure community stability. Its true mission is to ensure that the resources it controls will be productive into perpetuity. It fails that standard if it allows timber harvest that reduces the productive capacity of forest fish habitat.

Budget

Given the present domestic spending trends, it is extremely unlikely that the Forest Service will be able to count on receiving budgets of equal or greater amount than what it currently gets. The DEIS should include a complete explanation of how the Ochoco National Forest will respond to budget cuts, which programs will be cut and the amount of the cuts. Region IV national forests in Idaho have a 25% constrained budget alternative in their DEISs. The Ochoco would be wise to initiate planning that would anticipate substantial budget cutbacks.

Water Quality

The NFMA and its implementing regulations explicitly require the Forest Service to ensure protection of streams and fish habitat. NFMA must "insure that timber will be harvested from National Forest System lands only where . . . protection is provided for streams, streamsbeds, shorelines, wetlands, and other bodies of water from detrimental changes in water temperatures, blockages of water courses, and deposits of sediment, where harvests are likely to seriously and adversely affect water conditions or fish habitat..." NFMA at Section 6(c)(2)(E)(iii). The NFMA regulations parrot this language. See 36 C.F.R. Section 219.27(e).

The Forest Service is also obligated to abide by state water quality standards adopted pursuant to the Clean Water Act. Unfortunately, the Ochoco National Forest appears to have adopted a rather lackadaisical attitude towards these provisions. For example, the Forest spends one and a half pages (DEIS at 172-174) discussing Oregon State Forestry Program Projections for the Forest. In stark contrast, the Forest spends one and a half pages (DEIS at 175) discussing how well the Plan meets Oregon's water quality standards. One would never know that Oregon's water quality standards, not Oregon State Forestry Program Projections, are binding on the Forest Service. In addition, the Forest does not appear to be able to comply with state standards for temperature and turbidity. TD. Does the Forest anticipate...
continuing management activities on those drainages where standards are being violated? And if so, on what legal basis does the Forest Service justify activities that will either increase or perpetuate violations of the law?

The purpose of the Clean Water Act is to protect and maintain the beneficial uses of water. Fisheries are one of these beneficial uses. The Forest states that it is using a habitat capability index ranging from 1-100 to measure fish habitat. The Forest states that habitat capability ranging from 15-60 is "fair to good." (DEIS at 69). In every other national forest plan that we have examined (2 in Washington, 5 in Idaho, and 1 in Oregon), habitat capability ranging from 15-60 is considered to be poor. For example, the South Fork of the Salmon River has an existing habitat capability of approximately 55%. This river is often cited as a prime example of a drainage that has been severely impacted by past logging. The DEIS does not contain enough information to determine whether these habitat standards are in compliance with state water quality standards. However, from what we see, it appears that in no way can beneficial uses be fully protected even by the Forest's "excellent" standard (which claims that achieving a rating of 41 out of a possible 100 is "excellent").

Hydroelectric Applications

The Secretary of Agriculture has an important role to play in the licensing of hydropower projects that will be located in national forests. Section 4(e) of the Federal Power Act, 16 U.S.C. Section 797(e) (1982) declares that the Federal Energy Regulatory Commission is authorized:

To issue licenses...for the purpose of constructing dams...or other project works...upon any part of the public lands and reservations in the United States...provided that licenses shall be issued within any reservation only after a finding by the Commission that the license will not interfere or be inconsistent with the purpose for which such reservation was created or acquired, and shall be subject to and contain such conditions as the Secretary of the department under whose jurisdiction such reservation falls shall deem necessary for the adequate protection and utilization of such reservations...

It is the Forest Service's duty to impose terms and conditions that will assure adequate protection for national forest lands from the hazards resulting from hydroelectric development. See Escondido Mutual Water Company v. La Jolla and Rincon Band of Mission Indians, 104 S. Ct. 2195, 2195-15 (1984). It is also part of the Forest Service's trust responsibility to the tribes to ensure that it exercises its duty to impose terms and conditions so that the tribes' treaty rights are protected. The tribes possess considerable expertise in this area and would welcome further consultation with the Forest Service to ensure adequate protection.

The Northwest Power Planning Council is in the process of developing a list of potential hydro sites with the least potential for adverse impacts on other resources. Forest Service activities related to hydroelectric power should be coordinated with these efforts.

Forest-Wide Standards and Guidelines

Mining

Management plans for mineral developments include reclamation requirements but there is no indication of monitoring requirements by the mining company (Plan p.49). Is monitoring of mining the sole responsibility of the ONF? What is the forest-wide goal for reclamation; does it imply restoration to natural appearance?

Range

Transitory range management will be coordinated with timber management (Plan, p.58). What factors are considered in the tradeoff between range and timber management? It often seems that the ONF will go to extreme efforts to extend grazing systems even to the detriment of timber production. The most productive bottom lands bordering streams are generally already clearcut and after becoming incorporated into grazing allotments, these lands are never returned to productive forest management. Why are the most productive lands allocated solely to range, a commodity output which costs the ONF far more to administer than it generates in receipts?

When other management strategies will not protect the integrity of riparian communities in active allotments, fencing will be used to control utilization (Plan, p.50). It seems that the predominant lesson from grazing studies near riparian areas is that salt blocks and watering structures are inadequate in.luring cattle away from riparian areas. What is the record of compliance of cattlemen with requests to frequently move their herds out of riparian zones? In which instances will fencing be required and how many miles of fencing would be needed per year? Would anadromous fish streams be fenced when found in allotments? What is the condition of particular anadromous fish streams?

Riparian Management

For projects which could impact water quality, objectives for management of riparian areas will be developed under the NEPA process through the project's environmental analysis (5A). Will
riparian zone treatments only be considered after EAs are done for timber management projects? That is, will any riparian evaluations and treatments be done independently of timber projects? What part does range evaluation play in inventory and improvement of associated riparian areas?

How was it established that 40 to 60% ground cover is sufficient to prevent significant water quality degradation? What level of evapotranspiration is considered significant? On which streams flowing through allotments does ground cover exceed 60%?

---Water Quality

Management activities "may involve some temperature increases, provided the standards for class I and II streams continue to be met." (Plan, p.52) What are the standards for the different classes? How much temperature increase is allowed? Considering the extreme temperature problems downstream of the ONP, how can any more temperature increase be considered not to have adverse effects?

State water quality standards will be met by limiting timber harvest to "no more than 25 to 35 percent of suitable land base at any point in time". What factors were considered in sediment modeling? Did sediment modeling include timber harvest, road construction, grazing, and mining (including all the methods for conducting each activity)? Relative watershed sensitivities correspond to 25, 30 and 35% limitations (Plan, p.52). There seems to be very little difference in limitation between stable and unstable watersheds. In calculating equivalent harvest what age stand is considered to be a closed stand and what is the minimum size watershed to which the standards apply?

Bank stability is generally provided by tree roots for a distance of 5 to 10 times the diameter of the trunk (Plan, p.52). Merchantable trees may be removed if sufficient trees remain to provide root strength. If bank stability and sufficient shade can be provided by the trees within 5 to 10 trunk diameters, will riparian zones be essentially cleared outside this near-stream area?

Enough trees "should be" left to meet shade requirements and supply sufficient amounts of large woody debris (Plan, p.52). Is this statement made by assumption or calculation? What is considered a sufficient amount of large woody debris? Fuzzy language such as "should not" and "if possible" needs to be reworded to will.

---Wetlands

Riparian areas "should be" managed to maintain upper streambanks in stable condition along at least 80% of the stream's length (Plan, p.53). In addition, in riparian areas normally dominated by trees, 60% of potential tree crown cover "should be" retained. Will the ONF provide a map of the potential tree covers assigned to all riparian zones so that the public can determine whether the standards (80% of potential) are being met?

If 20% of a stream length can be unstable, 20% can have no tree cover, and 40 to 60% could have no ground cover, how can this be considered to be adequate to provide excellent riparian zone conditions?

---Transportation

Road crossings will not alter stream characteristics (Plan, p.53). How frequently will roads cross streams--every 100 ft., every 1000 ft?

---Soils

No more than 20% of an activity area can be compacted to a degree which degrades vegetative productivity (Plan, p.55). Cable logging is estimated to increase soil bulk density on 10% activity areas and tractor logging on 30% (DEIS, p.177). Since the forest plan calls for predominant tractor logging, how can a maximum of 20% compaction be assured? How much reduction in vegetative productivity from soil compaction is required before it is considered a significant? Are the miles of permanent road network included in calculations of compaction? Is this surface area subtracted from the productive forest land base when calculating future production? Is the reduction in productivity from all sources factored into future timber production calculations and the estimated TSU? What length of time is required for various degrees of compaction to be reversed naturally? What percentage of soils will be ripped to reduce compaction? How much will this increase soil erosion? Are sediment output rates calculated on the basis of watersheds (if so, which size watersheds) or on a forest-wide basis? Much more drainage specific information should be provided on sediment output and erosion as well as on other characteristics of the watershed systems.

---Timber Management

Clearcut units should be prepared for planting within 2 years after harvest. Planting occurs within 1 year of site preparation and the stand is hopefully certified 3 years after planting (Plan, p.57). The process appears to take 6 years although sites are supposed to be certified within 5 years. What happens if a site cannot be certified as reestablished? Will it be replanted and are funds available for the usual frequency of second efforts at revegetation? What is the success rate of revegetation on different site types on the ONF?

---Reforestation

Stocking standards are based on trees 4.5 ft tall (5 to 10 years old). If 30% of a watershed can be in a harvested
condition at a time, then it appears that 65% could be less than
4.5 ft tall by the second decade. Would this rate of harvest in
a watershed be allowed and would it automatically be assumed to
meet water quality standards if the watershed sensitivity rating
indicated the watershed should be stable? Could wildlife demands
for thermal and hiding cover be provided under these
circumstances? What average stocking density has been achieved
in the past on the various site types on the ODFP? If only the
minimum stocking level is achieved, this apparently will be
considered sufficient. If minimum levels become common how would
future allowable harvests be adjusted? What percentage of
recommendaed stocking levels are assumed when projecting forest
productivity?

--Precommercial Thinning

Precommercial thinning will only be performed when expected
return exceeds the cost of the action (Plan, p.56). How much does
the projected timber yield depend on precommercial thinning.

--Harvest Schedule

Total timber sold (ASG plus salvage) for the decade will not
exceed the planned level by more than 5% although it is also
stated that in case of a catastrophic event this may be increased
to 13%. What is the distinction between normal operations and
catastrophic conditions? Is it commendable to require reductions
in the ASG above this level but what keeps the planned ASG plus
salvage level from being exceeded by 13% each decade. Are
adjustments anticipated from decade to decade to compensate for
ever harvest in any decade?

--Low Productivity Lands

Why is timber harvest contemplated on sites with less than
20 cu. ft/ac/year production? Other forests forbid harvest of
trees on low productivity sites.

Wildlife

--Pileated Woodpecker

How many pairs of pileated woodpeckers can be supported on
the remaining old growth outside of wilderness areas? What
percentage of maximum densities can be sustained with 2 snags per
acre? The minimum tree diameter (10 inch) allowable is far too
small to support the pileated woodpecker which depends on trees
of greater than 30 inch DBH. In addition, they prefer ponderosa
pine. What are the realistic chances that the preferred species
of snag with the necessary DBH will be provided? If old growth
areas will be harvested at 200 year rotation is it possible that the
preferred tree diameter can be achieved on these sites?

--Primary Cavity Excavators

Snag habitat will be provided by clumping acres of timber
managed for snag retention within managed stands (plan, p.81).
Will this uneven distribution of snags really counteract losses of
snag density in managed stands? Have the spatial requirements
of snag dependent species been considered relative to all the
species which use the snags? True, some species may benefit from
clumping (Thoma 1979) but this does not imply that all would.
How does the species territory size requirements match the
distribution of preferred snag trees. Given the large number of
wildlife species which depend on large diameter standing or down
dead trees, how can the requirement of 2 snags/acre and 10 inch
DBH satisfy their needs? Thomas (1979)(Appendix 28) lists many
birds and mammals that depend on tree cavities in trees larger
than 15 inch DBH. In addition, wildlife use of downed logs is
given in his Appendix 24. Numerous species, including many rare
species and big game, have various life history requirements
centered on use of downed logs. It is doubtful that 10 inch DBH
material would satisfy the needs of many of these species.

It is stated that "large snags; greater than 28 inches DBH
no longer a requirement because only the pileated woodpecker
requires the large snags and their MRR's will be met with the
benchmark old growth allocations" (Plan, Appendix M1). What is
the MRR for the pileated woodpecker? Will its populations remain
viable with the dispersed nature of the proposed old growth
areas? For reasons discussed more fully below, calculations of
forest-wide habitat potential for this woodpecker are erroneous.
As noted previously, Thomas lists many species which depend on
large snags. Among these are the barred owl which is listed in
the "Oregon Non-Game Wildlife Management Plan" (ODFW, 1985) as
being in danger of extinction in Oregon. The ODFW Plan also
lists Lewis' Woodpecker as being vulnerable and it requires
snags greater than 12 inches DBH. The fisher requires large
snags and is also listed by ODFW as vulnerable. The status of
the Canada lynx is questionable and the wolverine is vulnerable;
both species require large downed logs for cover. The tendency
to minimize the quality of fish and wildlife might be expedient
for logging companies but shortchanges the entire forest
ecosystem.

Have population trends been estimated for any of the species
listed in Thomas (1979) taking into consideration the size of
downed logs? Large snags become large downed logs. If large
snag management is inadequate, no too will be management of
downed logs. Large snags also create the most favorable in-stream
habitat upon entering a stream channel. Rotation ages of 200
years in riparian zones with removal of snags during harvest
would not provide the most effective habitat formation and will
necessitate continuing investment in artificial structures.
Winter cover? --Rocky Mountain Elk and Mule Deer

The ONF will maintain at least 10% of all winter range in thermal cover [Plan, p.61]. What standards are there for hiding cover? What plans are there for increasing thermal cover on winter range where it is deficient?

--Dead and Downed Logs

"Wherever possible", 2 uncharred logs/acre should be left for wildlife habitat. Where is it not possible to leave 2 logs/acre after logging? The minimum size log identified is 12 inches and 20 ft long. What is the value of even 2 ponderosa pine logs of good quality of these dimensions compared to the value of the wildlife species which depend on this material? What percentage of maximum densities of all dependent species could be supported by such levels of dead and downed logs if these guidelines were employed forest-wide? What are the densities of this kind of material in various old-grown forest types on the ONF? Have snag inventories ever been done?

Management Area Prescriptions

General Forest

On 58% of the ONF the largest trees will be 16 to 18 inches DBH. The only snags present will be those needed to meet the cavity nesters requirements [Plan, p.65]. Does this mean that any of these 38% is not dead and downed? The minimum requirements will be eliminated? The General Forest prescription commits a very large percentage of the forest to small maximum size. As the old overstory is removed and the understory is thinned, the forested range lands will be found more frequently in fair and good forage condition class [Plan, p.65]. This is a rather sad commentary on range management if it is necessary to convert the remaining old timber stands to thinned tree farms to provide new transitory range that does not suffer from over a century of overgrazing so that the forest-wide average range condition can be shown to be improving.

Range utilization standards will not exceed an average of 50% on meadows and on slopes less than 30%. Is this a new standard or has it been used before? If this standard has been used for some time why are the ranges predominantly in poor to fair condition still? What is new about management or enforcement that will assure a departure from the declining range conditions that the ONF has experienced until now? What grazing seasons are allowed for meadows?

Big Game Winter Range

50% of big game winter range will be managed in thermal cover [Plan, p.68]. Is the ONF distinguishing thermal and hiding cover? It appears that much of the vegetation termed thermal cover is shrubs. What proportion is dense forest cover?

The Green Dot System will be used to regulate temporary road closure. It has been our experience in reviewing success of road closure policies that a system of signs does not work. We suggest that the ONF is not a public roads agency and does not need to keep a large number of roads open after logging has ceased. Wildlife would benefit from lower road densities and less sedimentation of streams from road travel would occur. The Nezperce Forest has been successful in instituting permanent closures with concrete barricades in cooperation with timber companies and the Idaho Department of Fish and Game.

Forage utilization standards on winter range are the same as for General Forest. Since winter range has largely been incorporated by private cattle ranch operations, wouldn't it be wiser to give big game a break on habitat critical to their survival. If there is such resentment by cattlemen to wildlife use of their hay, maybe the ONF should consider much greater reductions in the heavily subsidized use of forage on national forest land. Virtually the only place where grazing is not permitted is on administrative areas.

Big Game Summer Range

Optimum summer range will be created by timber harvest to reach a 46/54 ratio of thermal cover to open range. What is the present ratio on summer range? What is the average distance from forage areas to thermal cover?

Old Growth

Only 3% of the ONF will be retained as old growth [Plan, p.74]. Why is it that when the ONF is already one of the most heavily treated forests and has lost more old growth than other forests that it cannot plan to leave the remaining old growth? It seems that present degraded conditions always set a framework for the future and the future will be the present minus 50% regardless of what the starting point was. It is difficult to see how the ONF can meet requirements for dispersion of sexual vegetative stages and ecosystem diversity by limiting old growth to 3%.

Why is the minimum snag size given as 16 inches DBH when much larger sizes are required? If the old growth area is capable of producing trees of 21 inches DBH or more, why is it too much to require larger size snags? Are 2 snags per acre expected to provide 100% of potential population sizes for pilated woodpecker?

Retention Foreground

Is it legitimate to assume that cavity nesting species can be found at 100% of potential in the linear patches created by retention foregrounds when these are found near roads, trails,
and campgrounds? It seems that the viability of many species is resting on shaky biological assumptions which are based more on multiplying total areas by assumed wildlife densities than by considering the spatial relations among management units.

Wilderness

Only 4% of the ONF is planned to be retained as wilderness. Forage utilization standards in wilderness are why some animals are found on General Forest areas emphasizing grazing. Why is grazing intensity just as high in wilderness as in intensive allotments? What seasonal restrictions apply to wilderness areas? Do these restrictions prevent the kind of soil compaction found on allotments?

Riparian in Acceptable Condition

On streams where the desired condition is not met the stream will be improved to an acceptable condition (Plan, p.93). What is the time frame for improvement from poor to acceptable condition? Which classes of streams are placed into the management category for attainment of acceptable condition?

The minimum requirement for shade is 75%. What is the average percentage shade on this class of stream (riparian in acceptable condition) presently and on specific streams of this class? If 75% shade is unattainable, the standard will be 100%. What does this standard mean? If 75% is truly unattainable, then 100% would be also.

On the John Day River, temperatures at or below 66°F may be raised a maximum of 2°F (Plan, p.93). Since high stream temperatures are such a severe problem in the John Day system, how can any further increase in temperature be allowed? If temperatures are raised on one tributary, will they be reduced on another? Is the standard equal to or greater amounts, or does the percentage reduction should be the rule if all tributaries are improved? If 75°F is chosen as the maximum allowable? Is this considered to be an optimum for fish? Why is 58°F the maximum in the Deschutes River if both the John Day and Deschutes are steelhead streams? How would the potential temperature increase be determined before harvest? For how long will harvest affect downstream species? How can be monitored to determine whether temperatures are within acceptable limits and which flow conditions do the standards apply to? What are maximum temperatures currently on the streams in this class?

If the goal for riparian shade in this management unit is 75%, why are cayce no trees to be regulated at any percent of potential?

Timber management in the riparian zone features a 200 year rotation. The Wenatchee National Forest uses a more conservative value of 260 years. Harris (1964) recommended 320 years rotation in riparian zones for Region 6 Forests, in Oregon it requires 268 years to produce trees of 30 inch DBH. How would old-growth dependent species fare in riparian stands of 268 years old?

Maintenance of older age riparian cover would reduce disturbance to streams and also provide more effective habitat for old growth dependent species and integration of the entire forest.

It is obvious that in the ONF a greater proportion of timber production occurs in riparian zones compared to other management areas than one finds west of the Cascades. This fact implies that proper riparian zone management for multiple-use would be more restrictive to the timber industry in the ONF. Thus, however, should not dictate what is environmentally acceptable. Control of water temperatures by conservation of riparian cover in eastern Oregon is even more critical than in western Oregon.

What is the planned width of riparian zones? If a riparian zone is nothing more than a picket fence it cannot assume a role as a real functional unit.

Riparian in Excellent Condition

No activities that degrade water quality in perennial and fish-bearing streams will be allowed (plan, p.95). Wild streams which were formerly fish-bearing be rehabilitated to fish-bearing status? In which anadromous fish streams have activities occurred which have degraded water quality? The statement that no activities which cause degradation will be allowed is good but what kind of commitment will the ONF make to realize this standard? If grazing is causing degradation in streams and riparian zones will it be discontinued or will out-of-riparian zone watering devices simply be installed?

How much of the riparian zone assigned to excellent management condition is presently in excellent condition and how much will be elevated to this condition? Drainage-specific information would be needed for public understanding of the goals for specific streams. Otherwise, no one will ever know whether he is following or meeting guidelines. How many of these streams meet the 80% shade guideline presently? If this guideline is not now met how can 5% be cut per decade? If trees reach 4.5 ft in a decade it would seem that little shade would be provided a decade after harvest. If 2 decades are required before sufficient shade is provided by riparian regrowth, the present riparian shade in these streams should be about 93% presently for 5% to be cut per decade, thereby reducing shade to a sustainable 88%. How much timber harvest has occurred in the past on anadromous streams? Has this timber regenerated?
Monitoring Plan

Wildlife

If priority stands are lost then land designations would be modified. What are priority stands? Does land designation modification mean that other mature forest land would be allowed to grow into old growth condition?

If snag habitat is not sufficient to meet objectives, output schedules would be revised and the management practice would be modified. What help would be provided by revising output schedule? If the objective is to provide various percentages of potential habitat, why is the monitoring unit simply acres (or even snag numbers)? The ONF should be inventorying wildlife populations to determine whether snag numbers meet the objectives for the populations and not just whether an index such as snag numbers is set.

For fish and wildlife improvements what does it mean to have methods of evaluation commensurate with permiittees? In fish improvement projects what would the objectives be? It appears that counting of fish is not considered as part of evaluation. To determine whether variability thresholds are exceeded, one must know what the objectives of projects are. Habitat improvements may be valuable assuming they are engineered correctly out without evaluation of projects and general evaluation of fish numbers in streams throughout the forest. The only thing that may result is "project completion" (i.e. installation of structures) as listed in the monitoring plan.

The only monitoring dealing with anadromous fish appears to be macroinvertebrate sampling. Will the ONF provide any funds for this sampling? How extensive a program would this be? How will the data be used? Why are there no thresholds of variability? Why are fish not actually counted? Macroinvertebrate sampling is worthwhile as an index of health of aquatic systems but it seems unlikely that enough sampling would be done to be effective.

Any management projects involving potential effects on anadromous fish streams (especially projects in their spawning and EA stages) should involve the Umatilla and Warm Springs Tribes as co-managers. These tribes plus the other CRITFC tribes have treaty-secured rights to a portion of the fish originating on the ONF. Any management activities enhancing or degrading this resource directly affect the success of the US government in meeting its responsibility to the tribes under the treaty.

Range

Which allotments are in poor or fair condition and what would be done on each to correct the situation? As part of the monitoring of trend in range condition, will utilization surveys be done on all allotments? The variability threshold for range condition is any change which would affect AUMS. What change would really require a reduction in AUMS? How often have AUMS been reduced from the planned allowable levels due to severe climatic conditions? Will rainfall or forage productivity measurements be made throughout the grazing season to determine when cattle should be removed?

The objective in planning range improvements is to gain a desired cattle distribution and use pattern. If this is the objective it should be seen that cattle distribution should be measured. If specific levels of forage production were the objective, then production analysis would be appropriate.

Timber

Have any measurements been made on the ONF of tree growth rates in second growth areas vs. previously uncut areas of the same site type? It would be interesting to know the likelihood of future growth variations caused by harvest.

Riparian areas will be evaluated every 5 years. Will permanent stations be established to determine a trend? What would these sites be? Can more precise data be given at this time for riparian condition—i.e., by drainage? If the threshold of 20% variance is used, what would be allowed? Does this statement mean 20% degradation from the previous measurement? What percentage of total riparian area would be sampled every 5 years?

Physical and biological sampling in riparian zones is noted for riparian areas. These data will enter STORET but no action is indicated if changes are noted. What is the value of monitoring when nothing will be done in case of a deviation? Will changes in stream bed sediment or fish habitat be periodically evaluated? Why isn't aerial photo surveying done on all riparian area instantaneously to determine every 3 years what the trend in percentage shading is rather than relying on the solar pathfinder method?

Soil

It was previously stated that a forest-wide average of 20% soil compaction would be allowed for activity areas. Does this degree of compaction constitute the predicted compaction level? If so, with a 20% threshold of variability from the predicted level, compaction would have to affect 24% of the activity area before action is taken. If an area is primarily tractor logged, the predicted compaction could involve 30% of the area activity (predicted value). With a 20% variance the critical compaction would be 36%. It would seem this area extent of compaction is extreme. For a given area compacted, what degree of increase in bulk density has been shown to reduce tree growth? What degree of increase in bulk density would be allowed? Is compaction considered to be an irretrievable loss in production? What
degree of compaction would be necessary before the loss is essentially permanent?

In water quality sampling will there be long-term stations established for determination of baseline data for cumulative effect analysis? How many streams will have thermographs? What are the state standards for water quality which will be followed? What procedure would be followed for determination of a deviation in water temperature or suspended sediment? If there are currently no baseline data forest-wide or for individual streams, what standard values would be used in the interim? Will water quality evaluations be made only in association with specific logging projects? Will evaluations also be made of grazing, mining, and road building compared with control areas?

Cultural Resources

Monitoring to determine whether cultural resources are being protected and inventoried shows no plan for consultation with the Umatilla or Warm Springs Tribes. This should be corrected. A point is definitely made about consulting ranchers regarding whether forage utilization standards are being met.

General Comments

Land Allocation

The DEIS (p.XII) states the "alternative E-departure emphasizes a combination of timber production, roadless recreation, and big game habitat." This statement seems to be quite misleading. Only 4% of the ONF is to remain in wilderness at the end of the planning period and a total of less than 4% will remain in semi-primitive condition. Although 8% of the ONF is classified as old growth winter range and 16% as summer range, these areas could just as easily be called cattle grazing altitudes. The justification for producing an optimal ratio of timbered to forage areas, however, elk are managed at far below their potential so the additional forage produced is evidently destined for the cattle.

The plan identifies the major management decisions proposed (p.1). Alternative E-departure is the preferred alternative. The basic tone of the plan is set by two major decisions. The first is to harvest 123 MMBF of green timber during the next decade and the second is to gradually increase grazing from 75,000 to 83,100 AUMS. Other management decisions seem incidental by comparison with these because the areas involved are so small. And because the time frames for change to occur are so indefinite, one might guess that the status quo would be acceptable. When guidelines call for maintaining present conditions "or" improving trends and there is no clearly identified baseline condition, one would never know if improvement were occurring. It seems to be taken for granted that things are better now than they ever will be in the future. Regardless how much habitat loss has occurred on the ONF from past management, we must be willing to accept more. Willing to accept the liquidation of the remaining old growth ponderosa pine, we apparently should be content to have parklike retention stands near campsites.

Timber

The preferred alternative (E-departure) calls for an ASO of 123 MMBF in decade 1 declining to 118 MMBF in decade 2 and 89 MMB by decade 5 (Plan, p.22). 69% of the harvest volume in the first 2 decades would be ponderosa pine (Plan, p.1). The volume of ponderosa pine harvested in decade 1 will be 97 MMBF/yr and could decline to 47 MMBF/yr by decade 3. The timber industry has apparently convinced the ONF that it can survive only if it releases the majority of the remaining old growth ponderosa pine. After this material is gone the industry will be faced with lower volume harvest, smaller diameter timber, lower quality timber, and lower volume species. Satisfying the short-term goals of mills which may close a decade from now when the prime timber is gone might look good on paper to those concerned with meeting RPA goals or those who want to sidestep criticism of the industry but the forest's other resources must absorb the brunt of this kind of management. It seems unfair that under MSY management that timber can be harvested at high levels or departures but that non-valued outputs are assigned to MSY levels.

The ONF has sold an average of 136.1 MMBF/yr for the last 20 years. It was decided that no more than 123 MMBF of green timber (19.3 mcf or approx. 115 MMBF) was to be cut during the Prime timber (19.3 mcf or approx. 115 MMBF), it was decided that harvest in excess of LTBY should continue for two more decades. There is presently 280.5 MMBF of timber which was sold but is uncut. There will be 5 MMBF of salvage logging in decade 1 and if a catastrophic event occurs an additional 12 MMBF (Plan, p.59) could be harvested as salvage. This brings the total potential harvest to 132 MMBF in decade 1 (green volume equivalent). It appears that in addition to this, total timber harvest can be within + or -3% of the planned value (Plan, p.184). Why is harvesting of salvage not counted toward satisfying the LTBY volume? The amount of timber produced in a period is irrespective of whether it is alive or dead at the end of the period.

Based on timber inventories conducted in 1973 and 1982 the ONF timber base has declined 14% in this short time period (Plan, p.59). If this trend continues can future harvest volumes be realized? What is the expected standing volume after decade 5? It also appears that ponderosa volumes have declined by 16% in this same time period? Why have subsurface fir inventories declined by up to 33%? It seems that the kind of forestry practiced on the ONF may not qualify as site conversion but could be termed total forest conversion. Radical changes in forest species composition should not be tolerated any more than
A point is always made about how the decadent stands need to be removed because of their low growth rates. Why then, does the mature ponderosa pine have a net growth rate of 23.6 CF/acre and the two-story and immature stands have lower net growth rates (Plan, p. 31)?

Old growth forest will be represented by 26,377 acres of old growth management and 23,500 acres in wilderness. The total and old growth on the ONF is 30,897 acres (Plan, p. 24). This should mean that 39,123 acres will be placed under the timber base. Compare with the Plan on p.28 where only 22,300 acres was available to the timber base. If old growth in the timber base had been cut on a 388 year rotation previously, why has this been reduced to 209 years? Considering the minute amount of old growth remaining and the importance to the ecosystems in the ONF of safeguarding genetic and species diversity, why should the 22 to 30 M acres of old growth be harvested on such a short rotation schedule. Very little time is allowed for old growth characteristics to become established before harvest.

Grazing

Grazing will be increased by 11% in the first decade (Plan, p.22). Of the 19,800 acres of riparian area on the ONF, 12,300 acres are slated for improvement. On almost all allotments there appears to be little room for increase in AUMS. Most allotments are stocked to capacity. Why are there so many allotments having obligated AUMS exceeding carrying capacity? For example, Wind Creek, Wolf Creek, Allen Creek, Silver Creek, Buck Mountain, Lower Nicoll. Will grazing be reduced on these allotments? How is carrying capacity calculated? Is this capacity the maximum capacity assuming the range is restored to healthy condition? Are the obligated AUMS the sum of AUMS for cattle and wildlife or only cattle? Is the use of forage by wildlife other than deer and elk considered? Increasing the total obligated AUMS so that it equals the estimate total carrying capacity would be a 3.8% increase (Plan, Appendix F-5). How is an 11% increase calculated?

The total range budget for 1985, including range protection and management and range improvement was $309,000. The range receipts for this year were $50,400. The amount spent to administer the range program was 6 times the receipts at a minimum. The costs to the environment in lost production of fish and wildlife, soil erosion and compaction, vegetation loss, and reduction in tree production are tradeoffs which are not accounted for when evaluating the wisdom of such extensive programs, let alone increasing the AUMS. The minimization of the importance of the ONF fishery resource in the Plan is covered below. The Forest Service is lucky that the BPA has invested in stream enhancement but if the Forest Service itself had to mitigate the losses in fish habitat caused by its grazing, roadbuilding, and forestry programs and repay the cumulative losses in fish production over the years, it might reconsider whether maintaining or increasing the grazing program made sense. The ONF plans to spend only $50,000 of FY funds in 1988 on "fish and wildlife" projects. How much does it expect BPA to spend? What fraction of these funds are destined for fish enhancement? Are wildlife enhancement funds basically range enhancement funds?

Over-obligation of range resources, over-allocation of water from streams and groundwater supplies, and over-harvesting of old-growth and favorite tree species has been a way of life for the John Day and Deschutes River Basins for a century. Lumber mills in the vicinity of the ONF have never operated at capacity but supposedly it is the responsibility of the ONF to meet their demands. Maybe they overbuilt for the available resources. Overconsumption and waste of water out-of-stream angers junior water users and affects senior uses in drought years. Provision of adequate water of high quality (low temperature, nutrients, and sediment) is essential in maintaining healthy fisheries. The ONF must do its job to ensure the rebuilding of this resource. Supposedly, allotments have been fully occupied for years and the survival of rangeland operations depends on using forage on the ONF (Deh5-64). If allotments are already filled to capacity, the demand is increasing for more, and range conditions are poor to fair on 70% of the ONF, then perhaps a reduction and not an increase would be appropriate if the Forest really hopes to meet the needs of other resources. The "demand" of the timber and grasslands interests are described as ever-increasing. The Plan does not address the Forest's obligation to the tribes for restoration of fish and wildlife resources and sufficient water of high quality to sustain these resources. If the "demand" is not apparent, the obligation of the Forest Service to do much more than just maintain a presently degraded fish and wildlife resource should be. Treaty obligations must be treated as hard constraints and not discretionary items.

Fish and Wildlife

The budget for fish and wildlife is planned to go from $102,000 in 1985 to $288,000 in 1986. If the need is identified for this amount of money to protect the fish and wildlife resource and funds are cut eventually, will all expenditures be cut equally or will fish and wildlife simply be funded at historic levels? Is the ONF committed to make funding for the necessary fish and wildlife programs as solid as road and range administration has always been?

Soils

Under the Plan, 156,000 acres will be logged between 1986 and 1995, 80% of this by tractor harvest and 20% by skidder. Tractor skidding and machine piling will result in 25,000 acres of compacted soil (Plan, p.26). This would result in 16% of the project area being compacted. The maximum compaction allowable in 20% (Plan, p.55). However, if compaction by tractor yarding with haul roads is 33% and cable yarding with haul roads is 16%
total (DEIS, p.115), the weighted average of 80% tractor/20% skyline is 30% compaction. If compaction of haul roads is eliminated, assuming that haul roads will become permanent lanes to the forest base, then weighted average compaction of future forest base soils would be 23%. This means that 36,000 acres will be impacted rather than 25,000 forest wide and the effect on all 20% of degree will be much greater than average. How can compaction be limited to 20% in an activity area when tractor yarding with haul roads can cause 30% soil compaction?

Total existing soil compaction amounts to 182,000 acres. Based on 495,395 acres of land suitable for timber production, this amounts to 21% of the forest base already being compacted. What is the rate of reversal of this effect? How are the cumulative effects of compaction being dealt with? If a minimum of 25,000 acres are being compacted each decade, the total acres compacted after decade 1 will be 127,000 (DEIS, p.117). Table 2V-11 shows a constant level of total existing compaction from decade to decade in alternative E-departure. The implication is that only 10 years are required to reverse the effects of each decade's compaction, but that the present level of compaction lasts throughout the next 5 decades.

Calculation of tons of sediment produced among alternatives seems to be only logging related (DEIS, p.117). What are the effects of different amounts of road building, cattle grazing, and mining? Tractor yarding with haul roads can result in 47% base damage. The effect seems to be to accommodate smaller sediment calculations; however, the loss in vegetation cover and root strength caused by grazing is not included. Why? The methodology for calculations of sediment production and delivery to stream channels should be made very clear, including the formulas and references.

Fisheries

A fish habitat capability index was developed by sampling various streams on the ONF ranging in condition from poor to excellent. It would seem that unless a complete inventory is accomplished one would not be able to know the mean state of streams with any certainty. What characteristics were measured in samples of stream condition? Was the biological potential of the streams evaluated with respect to physical potentials? It has been common for many forests to determine a habitat index based on a degraded channel or riparian structure as a standard. This kind of analysis would possibly calculate the fish potential given a channel type with broken down banks and a low percentage pool area. What means of determining what the stream used to be there is no way to determine how far the present condition is from its potential (see our Appendix on monitoring plans).

A habitat index of 41 to 60 is supposed to represent good conditions. This index should be associated with 1000 to 3000 2" to 9+ fish per mile (DEIS, p.108). Since steelhead juveniles spend two years in freshwater habitats, the mere presence of numerous 2" long steelhead may not indicate good habitat conditions. Conditions leading to successful smolt outmigration are essential if the ONF is to meet its production goals. How well is this index correlated with smolt output, not just spawning and emergence success?

A present habitat capability index for rainbow trout (including steelhead) is 14%. Alternative E-departure is reported to be able to raise this to 53% (DEIS, p.137). Elsewhere, it is reported that E-departure will increase the index to 49% (DEIS, p.137). Why the discrepancy? Minimum viable populations are listed as being supportable by a 9% habitat capability. If one can be comforted by calculations such as these, we should be grateful for 1.6 times minimum viable levels presently.

In an attempt to determine how the ONF Plan is coordinated with other public planning efforts under 36 CFR 219.7, the Warm Springs Indian Reservation Comprehensive Plan was studied (DEIS, p.172). It was found to contain "no references to the Forest or the Grassland. Concerns expressed included availability of access to the Forest and Grasslands, being able to gather vegetative materials, support of prescribed burning, protection of archaeological sites, and the general availability of forest and grassland resources." The ONF appears to be taking a management plan developed for use on the Reservation, which is outside the boundaries of the Forest, as an indication of the full range of constraints the Tribe might place on management of the region. Although there were meetings there were no meetings between the Tribe and representatives of the Tribe, we wonder whether most of these meetings were confined to the Culture and Heritage Committee as most of the acknowledged tribal concerns focused on these issues. It should not be considered that a lack of reference to anadromous fish on the ONF in the Reservation Comprehensive Plan means a lack of concern for this resource or indicates no need to discuss it with the Tribe on fishery issues. Although the ONF is outside Reservation boundaries, it is clearly within the tribal ceded area. If the ONF were to meet with the Tribe to discuss fish and wildlife issues, there is no doubt that the issues addressed within these forest plan comments would also be among the areas of concern discussed at that meeting. As explained earlier, the Warm Springs Tribe, along with the other Columbia River treaty tribes, have taken a Columbia basin-wide approach towards managing fisheries.

The Dechutes and John Day Rivers have 42 miles of spawning area and a total of 87 miles of perennial tributaries on the ONF (Plan, Appendix H3). Although plans are presented for riparian protection around fishable streams, it is unclear how the intermittent and ephemeral streams that are tributary to these anadromous fish drainages will be treated. These types of stream courses are important sources of high quality water for downstream reaches and also serve as sites of temporary sediment and organic matter storage. During high flow periods this accumulated material is transported downstream to spawning and
rearing areas and can be deposited. The Plan should reveal what the treatment of the stream source areas is. Can unrestricted loadings and accumulation of logging debris occur in these source areas? What level of grazing control is applied to these areas in comparison to the perennial waterways designated as spawning areas?

Our review of Plan appendix H2 (Inventory of Anadromous Fisheries Habitat) gives us cause for concern about both the qualifications and data used to generate potential spawning areas and the resulting options themselves. While the appendix appears to accurately list stream systems supporting anadromous species, data delineating extent of fish-use within those systems are frequently suspect. Conversations with ODFW staff lead us to question how Ochoco NF derived mileages of steelhead spawning habitat and adult steelhead escapement numbers cited in the appendix. Spawning habitat mileages appear understated (or are, at best, minimum) as are the numbers of spawners indicated as typically using the areas. On some of the listed creeks, ODFW's spawning index areas stop short of the Ochoco NF border. On at least one stream (Rock Creek) ODFW conducted no annual spawner surveys. What then, was the source of Ochoco's data? How were the adult escapement figures estimated?

If appearances are correct and minimum steelhead values are being used, then the end result is that the forest's importance as a steelhead producer is downplayed. The management implications of this action are that, relative to steelhead, other resource values are made to appear greater than they actually are, thus it becomes easier to justify management choices favoring those inflated values. Such deliberately introduced biases thwart any meaningful assessment of total forest resource values and serve only to denigrate both forest planners and the planning process in general. Ochoco National Forest is charged with producing a forest plan that adequately and fairly presents management options available to it given its actual resource base. So long as that resource base is inaccurately portrayed, and particularly so if the misportrayal is known to be false, the planning documents will be fatally flawed and begging for appeal. A more realistic assessment of the forest's anadromous fish resources (as well as other fish and wildlife species) is needed in the Plan.

Further, to be useful any habitat inventory must recognize the species' habitat needs at each of its life stages. Steelhead require more than just spawning habitat. Where is the inventory of juvenile rearing habitat? Where are the references to juvenile and adult migration corridors? What is being done to ensure that these important areas are maintained? Providing for less than a species' total habitat needs is a futile gesture.

Finally, if it should be found that major rearing areas or migration routes for Ochoco-produced steelhead do lie outside the forest, it is the Forest Service's responsibility to help insure that this resource, which is legally charged with maintaining in a viable condition, is not being wantonly destroyed elsewhere?

**Snag Management**

Pileated woodpeckers are reported to presently enjoy 55% of their estimated potential forest-wide (Plan p.45). Decline in logging activity and liquidation of the majority of the remaining old-growth, they are expected to have a habitat capability index of 51 by year 2030 (UNIS, p.137). Although ONF planners can easily multiply 8.5 or 9.0 estimated snag levels (DEIS, p.43) by a standard woodpecker density for excellent habitat, the formula does not necessarily obey ecological principles. Snags in the middle of young regenerating stands or clearcuts do not necessarily have the same value to wildlife as the same density of snags in pristine habitat. Figures such as 55% habitat capability probably are very deceptive when applied forest-wide. Although it is admitted that 10 inch snags are inadequate for the pileated woodpecker, these would be the rule for management area 1 (General Forest) where trees will be harvested at 92 to 98 years age. Although recommended snag levels here are reported as 40%, they are effectively 0% for pileated woodpecker. The 40% level is a level at which the ability of a species to maintain self-sustaining populations becomes tenuous (Thoma 1979, p.72). Reducing snag levels does not necessarily produce linear declines in wildlife levels and it is doubtful that these kinds of ecological effects are reflected by the seemingly precise percentages of potential habitat capability reported.

Since 55% of the ONF will be in the General Forest category having essentially no value for pileated woodpeckers, the forest-wide capability for the pileated woodpecker is an inaccurate value for the pileated woodpecker now or in the future. Use of the pileated woodpecker as a MIS and then monitoring the number of snags of 10 inch DBH is a ridiculous exercise in meeting goals on paper. Reporting erroneous habitat capabilities is merely an attempt to make the public believe that we can keep our fish and wildlife while still increasing timber and grazing programs.

It seems doubtful that with the complete clearing of the ONF, the practice of summarily dispatching all snags during logging, and the demand for firewood, that the ONF's policy of green dot systems to limit access to parts of the forest will prevent snags and down wood from being pulled from wildlife habitat, riparian corridors, and stream channels. Although all standards for snags relate to hard snags, maintenance of soft snags is not specified. Will recruitment and preservation of soft snags be assured outside of wilderness? Permanent closure of many areas must be accomplished to provide security areas for wildlife and safeguard imperiled streams. A good inventory is needed of the distribution, species composition, size frequency, and condition class of snags existing on all management units to establish a baseline for accurate estimate of present potential. This should be related to actual estimates of population densities of dependent wildlife. Such inventories are needed for all
resources, not just green timber volumes.

Cumulative Effects on Soils

The Forest was divided into 24 major watersheds and each was assigned an index of equivalent clearcut acres (ECA) "based on its soil, slope, channel stability, riparian values" (DEIS, p.133). This index supposedly represents a watershed's sensitivity to disturbance. Even though watershed stabilities are described as ranging from stable to very severe erosion hazard, thresholds of erosion are assumed not to be exceeded if ECA, as a percentage of basin area, is not greater than 25 to 35%. This narrow range of ECA values does not seem to correspond to verbal description of the range of landscape sensitivities.

It is stated that "exceeding a threshold value does not in itself limit management options on the Forest. It does, however, indicate the need to undertake other specific mitigation measures to offset potential reduction in site productivity or long-term impact of water quality" (DEIS, p.133). The Plan should clearly list all the coefficients of mitigation efforts which would be used. The idea that threshold values are set up and that they can then be exceeded if something positive is done somewhere else in the basin is unacceptable. Mitigation factors are some of the most tenuous management tools the ONF is dealing with. These coefficients work well in FORPLAN runs when a coefficient is called for to complete the analysis or to balance high sediment outputs on activity areas. The validity of mitigation factors is very site-specific. Unless extensive monitoring accompanies a large share of the mitigation efforts, mitigation is apt to be primarily an office exercise with no connection to reality. The ONF does admit that "after the fact" mitigation is often not as effective as preventing degradation on a site in the first place (DEIS, p.134). Despite this admission, there appears to be little hesitation to apply mitigation while exceeding thresholds. If thresholds of slope stability are exceeded resulting in excessive loss of topsoil, the sediment might be deposited in settling basins but it is not clear how this can counteract the loss in soil productivity on the slope.

How many factors are really considered when calculating ECA values? Does it include all management related efforts such as logging, road building, grazing, and mining?

Soil compaction from harvesting may mean "that a future stand to be regenerated in 100 years may need more time to achieve the outputs normally projected for 100 years" (DEIS, p.128). Soil compaction is "readily measurable 15 years after cutting" (DEIS, p.128). It was shown that reductions of tree growth rate by 12% over a 15 year period are possible from soil compaction. Establishment of new tree seedlings could be even more severely affected. Since it appears to be well accepted that soil compaction is a reality and that reduction in growth rate is to be expected, what average percentage reduction in growth is used in FORPLAN runs and what natural rate of recovery of compacted soils is used?

Timber

Stumpage prices received for old growth ponderosa pine commonly range from $100 to $300/MBF (DEIS, p.91). High value old growth ponderosa has done an adequate job in the ONF to keep most timber sales out of the "below cost" category. When the old growth is gone in the next decade or two, will sales tend to be below cost? Assuming that the forest will be fully roaded soon, how will timber receipts balance against timber management, administration, and soil maintenance costs?

If the stumpage prices are typically high for ponderosa pine, why do Forests sometimes virtually give away this timber. For example, the advertised rate for ponderosa pine in the Wallowa Whitman Forest on the Top-Skook sale in the Hells Canyon NRA was $12.94/MBF. Does the ONF ever provide these incentives for getting the old growth removed?

Of the 544,303 acres of forested land on the ONF outside of wilderness and NRAs, only 0.47% is classified as unsuitable due to regeneration difficulty. Is it reasonable in an arid environment that so little area is classified as having regeneration difficulty? What classes of soil and slope gradient are considered as unsuitable because of regeneration problems? What are the stocking success records which accompany these site classes?

If you would like further information regarding our interpretations of Wallowa National Forest plans, please feel free to contact any of our staff, Jim Weber (policy assistant), Dale McClough (biologist), or Alex Heidt (biologist), at (503)-238-6067.

Sincerely,
S. Timothy Wapato
Executive Director
Development of a Monitoring Plan

A good monitoring plan requires a good system of classification of land. Such a classification should be hierarchical. Land units should be defined by similar sets of variables at each level. Variables express a greater degree of heterogeneity, the higher the level in the regional hierarchy.

Selection of sites for monitoring is often done by a paired watershed approach. This is typically done without reference to any superstructure. Basins are selected which are close geographically in the hopes of being as similar as possible. Often single variables such as drainage area are the sole insurance of similarity. One watershed then becomes a representative of pristine conditions for the other "managed" watershed. Another approach is to observe one watershed over a period of years to note the series of performances in relation to management treatment. In order to allow instantaneous observation of performances of a given watershed type under different states of management requires a classification. This permits identification of a set of watersheds of similar capacity which only vary by present state of management.

Classification systems provide the theoretical grounds for planning scientific investigations in an effectively managing tracts of land. Many stream classification systems rely on single variables to identify stream types. For example, a stream supporting steelhead may be said to be different from one with coho. A stream with a riparian zone dominated by alder may be said to be different from one covered by Douglas fir. A stream on alluvial deposits may be said to be different from one on bedrock. In order to observe a given watershed over a period of years to note the series of performances in relation to management treatment. A stream type may describe conditions for a brief period of vegetative succession. A manager would want to observe the stream's performance over that period and then be able to specify a classification which would require a stream be reclassified each time vegetation changes; likewise, for changes in velocity, width, etc. Variables are selected which represent long-term potential of a stream. Daily, seasonal, or annual changes can only be understood against a backdrop of understanding of the capacity or potential of the system. Capacity of a system (e.g., a stream, watershed) is basically a theoretical concept, representing all possible performances or states. Variables can be selected to act as proxies for capacity at any level in a hierarchy of classification.

APPENDIX

Drainage Specific Monitoring

Both CRITIC and the EPA have pointed out in their comments on proposed national forest management plans that the Forest Service needs to produce more drainage-specific information and do more drainage-specific monitoring. Forest-wide averages of fish populations and watershed conditions tend to camouflage drainage-specific problems. Unique fish stocks found in single drainages do not necessarily maintain viable populations on the basis of forest-wide averages of bed sediment or fish numbers per mile.

Because of the fact that many agencies have monitoring responsibilities and that the Forest Service and BLM have responsibilities for maintenance of habitat for many critically weak fish stocks wielding great leverage on national and international economies, there is abundant reason for inter-agency planning for monitoring progress, sampling, evaluation, and review. This type of inter-agency overview has been in effect on the South Fork Salmon River for several years. In the past this committee has been effective as a board of professionals charged with insuring the survival of the summer chinook population found only in this area. Without this committee, intensive timber harvest would have resumed in the South Fork despite the precarious state of this irreplaceable stock. There could be large scale regional direction in planning of monitoring and assessment but sub-regional committees of agency, tribal, and university experts could be assembled to provide advice on drainages which are unique, sensitive, or unmanaged. Typical Forest Service monitoring plans call for reports every five years but action is not indicated until "trends" have been established. This means that an entire planning period would elapse (10 to 15 years) before enough information is available to warrant change in management. The problem is that the level of monitoring to date has been minimal both geographically and in terms of variables considered. Monitoring often includes little more than records of municipal watersheds, incidental records on a few streams and long-term (e.g., five to 10 years) on one stream. Baselines do not exist for the majority of streams. The Forest Service has a duty to address the condition and continued health of its aquatic resources. A good monitoring plan created with overview by an inter-agency monitoring committee is the best way to protect these resources which have historically been the first to be disputed in conflicts between multiple-use options.
Definition of terms used to this point:

**Capacity:** Theoretical term for a potential of any system; this represents all performances of which the system is capable.

**Performance:** Any state of a system — this is an observed event such as a current velocity at a point in time, a certain species composition in a riparian zone, etc.

Systems should be defined by capacity because if performances are used the basis for applying a given management strategy to two systems may be superficially similar. Any two systems may look alike at some point in time but this does not mean that their capacities (long-term potentials) are equal. For example, two streams may have fish communities dominated by steelhead. For one of these streams, steelhead may be the species best adapted to all states of the watershed system in which the stream is embedded. For the other stream, steelhead may be found under a limited set of watershed states. Likewise, the mere lack of fish in any stream at present does not indicate lack of capacity to support fish. In fact, the stream may have had great fish production potential which was altered by poor logging practices. Poor management on top of this may assure that fish never return to the stream system. A good classification system should recognize long-term potentials and not just present state. The difference between two systems may be shown diagrammatically below. The zone of overlap represents points in time for which the systems had similar performances. X and Y axes represent two performances of a stream such as mean annual width and depth.

Figure 1.

Bankfull width

Bankfull depth

Hierarchical land systems could be given labels such as region, zone, sub-zone, watershed, stream, reach, and habitat type. Each land system subsumes the capacities and performances of all systems within it. The class of any system (i.e., at any level in the hierarchy) is defined by the capacity of the system itself and the environment it is found in. The environment of a system is the next higher hierarchical level. That is, a stream network is classified as its environment. A watershed has a system of watersheds as its environment. Two watersheds classified by hierarchical classification would be said to be fundamentally different if found in two different zones even though they have the same drainage area and fish species. For example, they may have different rock types, climates, hydrologic characteristics, etc.

Definitions to emphasize:

**System:** A land system of any size which can be defined by its unique capacity.

**Environment:** The higher level system which subsumes the collection of lower level systems within its geographic bounds. The environment is a single geographic unit and not a collection of discontinuous spatial units. Environment is the framework in which any system evolves biologically and geologically. It is not just climate but the entire set of capacity determinants. An environment for a given system is just a system in its own right but at the next higher level.

What are the components of capacity which must be represented by sets of variables? These can be categorized as climate, substrate, biota, water, and culture. Substrate may also be decomposed into geology, soils, and topography. Some variables such as climate may be easily understood in broad geographic terms but data for specific locations are rarely available. Culture represents land use decisions; such decisions are often dependent on climatic, vegetational, geological, and other zonations, especially in primitive cultures.

Examples of variables representing each of these components of capacity are given in Table 1. Most of the variables can represent systems at any level in the hierarchy; the degree of generality becomes greater at higher levels.

Robert Bailey (USFS, Ft. Collins) has classified the entire United States into eco-regions. This system emphasizes potential natural vegetation, Koeppen's climatic classification, and physiographic regionalization. This system does not utilize some of the variables illustrated above. For example, culture or detailed descriptions of topography are not employed. At the scale at which eco-regions are drawn, the simplicity of deleting some variables may be convenient considering the fact that the remaining determinants of classification are broad capacity-type concepts.

Robert Hughes, James Omernik, and Mostafa Shicari at USEPA in Corvallis, Oregon have developed a system of land classification which starts from Bailey's eco-regions. The heterogeneity of eco-regions is then described in a regionalization which identifies frequency distributions of facets of land units using features such as potential vegetation and soil types.

The type of classification emphasized in this document was initiated by Charles Warren in Oregon State University Department of Fisheries and Wildlife. Warren's classification contains all
components of a complete classification by capacity. Frissell et al. (1986) present ideas on stream classification at the lower levels in the hierarchy described above based on Warren's concepts.

McCullough (Columbia River Inter-Tribal Fish Commission) used Warren's theoretical concepts of system classification but established eco-regions. These areas were identified using the concept of drainage area and downstream slope. This concept entailed utilizing soil series, slope, aspect, altitude, and solar radiation (calculated for winter solstice and equinox). These variables were determined for all facets of 0.014 x 0.012 mile from a regular grid laid over each watershed. All variables except soil series were determined based on altitudes read from the grid system into computer programs which calculated characteristics of land facets. Multivariate statistical programs determined similarities between watersheds using the detailed descriptions of all facets comprising the watersheds. These similarities were applied to all facets of the watershed, thus allowing clustering of basins on the basis of many variables at a time. This procedure does not require predetermination of priority of any variable although only variables considered to represent capacity were used. This type of system for classification on any scale is useful and efficient given the ready availability of digital topographic map data from USGS. More information about applications and results of computer classification of lakes is obtained from Dal~ McCullough at the Columbia River Inter-Tribal Fish Commission.

Classification of all watersheds must start with selection of a given drainage area. With every change in drainage area proceeding downstream, the character of the watershed changes. Also, the average stream bed slope changes downstream. Drainage area and mean-derived stream slope for the half mile upstream from the basin mouth set the framework for further attempts to classify watersheds. These variables set the bounds for system capacity. Change in basin capacity with change in drainage area is reflected in the "river continuum" concept of Vannote et al. (1980). Management principles vary likewise along a continuum down a drainage network (i.e., longitudinally). It must also be recognized that management should vary from region to region, zone to zone, etc. (or laterally). A classification system sets up a regionalization on theory and experience. Future experimentation and monitoring help confirm the utility of the classification and suggest possible changes. This framework establishes logical units for management. Experience will dictate whether adequate management of a national forest can occur using a given hierarchical level or a lower one.

Given any national forest, classification systems such as Bailey's, McCullough's and Frissell's in sequence could be employed to work down through larger to small spatial systems. A national forest should be broken down into eco-region and at least to zones at the next lower level. At its simplest level geology could be used to identify zones in an eco-region. The full set of capacity determinants can be referred to by the complete zonal classification that is indicated. Classification of watersheds within these zones could utilize all variables specified above.

By using the previously mentioned systems to regionalize the forest and to find stream reaches of a given class, sampling sites are selected. Within a reach (i.e., a stretch of stream within a stream segment having a homogeneous overall bed slope and geology which contains series of habitat complexes) samples for monitoring will be taken to represent a portion of the capacity of the reach, the watershed, zone, and region in relation to present state and history of management in this hierarchical framework. Fish sampling, for example, can take place by logical habitat clusters. These are repeating units containing riffles, pools, backwaters, side channels, etc. Riffles and pools act as units for species which can move sufficiently between them such as fish. The spatial organization of these habitat types can form logical sampling units for fish. Sample sites would not be simply a randomly chosen 100 ft reach but would be selected to include a habitat cluster. Replicates of these kinds of clusters could be sampled.

The stream reach is classified by the class of network in which it is embedded plus the capacity of the reach. The reach capacity (C) should be used in its classification. Proxy variables are reach variables are given below. Reach performance (P) should be established as a baseline and then periodically monitored.

Reach classification

(A) upper bank condition (above mean annual peak flow line outward horizontally 100 ft)
C: bedrock type
P: overstory vegetation type and cover density
% bare soil; evidence of erosion; classes of mass wasting

(B) lower bank condition (from mean annual peak flow line to channel edge)
C: bedrock type
P: substrate type and size composition
% bedrock exposed
% of overhanging banks by habitat type

(C) stream
C: bedrock type
P: substrate type; size composition
% bed fines by depth
% embeddedness in riffles, pools
% bedrock exposed by habitat
surface area and volume of reach in habitat types
(see Bisson's habitat clarification)

depth distribution by habitat
mean height of boulder size classes above bed

discharge--flow frequency distribution; peak flows
sediment discharge in relation to water discharge
water chemistry

% of overall drop in bed elevation over 0.5 miles due
to falls over bedrock, logs, chutes, cascades, riffles

(D) biology

C: species pool (fish, invertebrates, algae, aquatic
macrophytes, beavers, other aquatic vertebrates)
P: juvenile fish counts
small counts plus spawning ground surveys
invertebrate species composition
fish species composition

cover density, height, species;
degree of damming of reaches in network by beaver
activity or log jams
aerial photographic analysis (1:2000) of mainstem to
determine whether reach is representative of species
of reaches in mainstem; distribution of large wood

Watershed classification

C: watershed is classified by class of watershed system,
zone, region, etc. in which it is embedded

P: aerial photographic analysis (1:12000) of
vegetation cover density, height, species;
use timber stand types, stocking density available in
mapped surveys
aerial photo analysis of % bare ground; degree of
erosion hazard from watershed; evidence of mass
failure hazard and historical failures

Integration of Physical, Chemical, and Biological
Systems Provided by Classification

A good classification system is the proper basis for a good
monitoring plan. A good classification system which is
progressively validated and refined with experience will be a
good framework for future monitoring and land management as
system performances change through the years. Such a framework
provides the means for effective management at minimal costs.
Other types of monitoring schemes could reduce costs even more
but at a loss of understanding of the systems and a loss of
predictive ability.

Use of a classification system would allow a cost savings
through its broad geographic scope. That is, some watersheds or
streams in one national forest could represent behavior of a
class of system found predominantly in an adjoining national
forest. Duplication in monitoring efforts is then reduced.

The type of general classification system proposed also
lends itself to adoption by many different agencies with interest
in environmental monitoring. For example, one primary capability
determinant used in classification is geology. The mixture of
rock types of a watershed set the general chemical regime for
surface and groundwater on the watershed. This is a partial
determinant of aquatic productivity, sensitivity to acid rain,
and to nutrient enrichment. Therefore, a classification system
in an appropriate framework for monitoring of acid rain by EPA,
nutrient problems by a State Environmental Quality agency, and
management of watersheds and their resources by the USFS.

The combinations of rock types found in watersheds above a
given reach plus overall bed slope of the reach are determinants
of system capacity for aquatic macrophyte distribution.
Scientific studies by aquatic botanists become more significant
ecologically by enabling linkage of the physical and biological
systems on small as well as large geographic scales. Ability to
use a general classification system as a monitoring framework on a large regional basis would be considerably aided by geographic computer analysis. These methods allow overlaying maps of many resources and production of integrated maps. Such capabilities have been explored by many agencies such as Forest Service, USGS, and EPA.

**Provision for Adequate Monitoring**

If a regionalization or classification system were developed to adequately represent watershed/stream types, an important benchmark for monitoring would be established. The Forest Service's point of origin in discussions of monitoring is what it chooses to budget for monitoring and not what is adequate. It is our position that we must first determine what is necessary for proper management of resources and then determine how this can be achieved. Monitoring funds should be linked to the receipts from major land disturbing activities -- timber, grazing and mining. Unfortunately, grazing, which is a major cause of non-point source stream degradation, is a money-losing venture of the Forest Service which cannot provide funds from receipts for use in stream protection and monitoring. The US Government, if it considers it in the interest of the few ranchers to subsidize grazing, should also consider the interests of other users of public rangeland who enjoy streams and range in good condition. This necessitates adequate funding for protection, rehabilitation, and monitoring.

**Some Investigations which can be Facilitated by a Good Monitoring Framework**

A good monitoring framework provides the basis for a refined understanding of many biological and physical relationships of importance to land managers. Among the questions which can be explored are:

**Biological**

What is the carrying capacity of streams of different classes and stations within a class (zonal or sub-zonal level study)?

What is the relationship between carrying capacity and stream flow and temperature regime (regional level study)?

What is the relationship of carrying capacity to extent of watershed and riparian zone management (i.e., spatial organization of timber stand history and erosion sources in relation to the downstream study reach)?

What is the threshold of biological response for try emergence from gravel in relation to percentage of bed fines?

**Physical**

What is the average natural erosion rate from watersheds of a given class?

What percentage over natural erosion rate is due to different degrees of management in watersheds of a given class?

What are the rates of recovery of stream reaches of different classes in terms of reduction in bed fines, depth distribution, % surface area by habitat type, surface substrate size composition, mean channel width, riparian vegetation density?

What is the effectiveness of mitigation methods?

What is the relationship between quantity of sediment delivered and increase in embeddedness or fines?

What percent over natural erosion rates can be handled by different classes of reach without changing % bed fines?

What is the extent of downstream impact (e.g., sediment, temperature increase) to the mainstem from a disturbance originating at a given reach. This type of study is necessary to establish the appropriate scale for measurement of cumulative effects throughout a large basin?

**Implementing the Monitoring Plan**

In the development of a network of monitoring stations, consideration must be given to the kinds of variables and intensity of sampling given to each station. Because some types of monitoring are more labor intensive, it may be better to do a good job sampling in a few carefully chosen stations than to dilute the effort by extensive sampling without a real plan formulated. For example, stream hydograph stations are expensive to run and maintain. The USGS may or may not have adequate coverage to represent watershed classes. Usually their stations do not well represent small drainages. Hydrographic regimes can often be correlated to other systems with similar climate, geology, and soils. Most invertebrate sampling programs are labor intensive but provide a good biological index of year-round environmental conditions not as clearly afforded by migratory fish, which are subject to downstream and oceanic effects. Meaningful studies on anadromous fish can be performed, but the best of these may require careful monitoring of red counts associated with smolt output. Smolt output measurement requires investment in weirs. Juvenile fish counts may suffice for general monitoring on most streams. However, a certain stream class may be represented by an index stream for which more intensive studies such as smolt output can be done. Such streams may be those important in the US/Canada Pacific Salmon Treaty negotiations because of the opportunity to track production of significant anadromous stocks and their contribution to ocean fisheries.

Some of the monitoring variables can be handled by
experienced crews of two to four covering extensive reaches on numerous streams per summer. Fred Everest and James Sedell (USFS Forest Science Lab, Corvallis, OR) have led stream survey crews covering physical and biological parameters on numerous streams for years. McCullough (CRITFC) also has extensive experience measuring physical characteristics of long stream reaches in Northwest Oregon.

There are a lot of advantages in having some degree of monitoring on a large percentage of streams. This would enable confirmation of the utility of the classification and would provide an extensive baseline from which to assess further change. Adequate monitoring also requires long-term sampling of streams which are key indicators because of their fish stocks or representative bio-physical conditions. Both intensive and extensive monitoring should be based on a good watershed/stream classification and an inter-agency monitoring committee should be established to guide planning and review of monitoring in the Northwest.

Newspaper Articles Chronicling Publication of the Draft Documents and Supplement to the DEIS
Forest Service prepares 15-year resource plan

A guide to the management of resources on the Ochoco National Forest and Crooked River National Grassland is now available for public review. The Ochoco National Forest and Crooked River National Grassland is on the Ochoco, planning documents are available for review which display alternative choices for integrated management of all the natural resources on the Forest and Grassland," he said. The forest plan is being prepared at Congress's request as part of the National Forest Management Act of 1976. A reviewer's guide, draft proposed forest plan, the draft environmental impact statement which includes information on a wilderness proposal, alternative maps and appendices are available at all offices of the Ochoco National Forest. Additionally, copies will be available for loan from the Crook, Jefferson, Umatilla and Deschutes County Libraries.

"We will be hosting open house public meetings to help show folks how to find what they may be interested in and send them in understanding the planning documents," Rittersbacher explained. "We plan to meet with interested groups and individuals and will arrange such meetings at their request. Each person's thoughts, ideas, concerns along with their reasons, will be invaluable they will be used to help shape the final forest plan for the Ochocos," he added.

Public meetings are scheduled in Prineville for Tuesday, Oct. 9, at the Prineville Fire Hall from 7 p.m. to 9 p.m. A public meeting will be scheduled in Paulina with the date and location to be announced later.

Forest officers and planning team members will be available at the open house to answer questions. Displays will be used to give an overview of the plan and each of the 11 alternatives. No formal presentations are planned.

"The meetings will be informal and relaxed," Rittersbacher said. "They are designed to provide an opportunity for individuals to get an overview of the issues and alternatives and discuss how they might best prepare any comments." The Ochoco National Forest has been working on the development of this plan for the past four years. The intent of preparing a comprehensive land and resource management plan is to consider all resources under one plan. "Forest planning is not new. However, in the past, resource planning has generally looked at one resource at a time, not considering integrated interrelationships," Rittersbacher explained.

The life of the plan is 10 to 15 years, but it projects the effects of management for up to 156 years.

The documents under review (See FOREST, page 2)...
ised in the first meeting set for 7 p.m. Oct. 14 in the Prineville Fire Hall.

An Oct. 15 meeting is scheduled from 4 to 7 p.m. in the commons room at Ochoco Junior High School in Redmond, and a meeting during the same hours will be held at Madras High School Oct. 20.

An open house also will be held from 6:30 to 7:30 p.m. Nov. 19 at the Pro Rapi Club in Prineville. A discussion for those holding permits to graze cattle on the forest will follow.

Earl Layser, Ochoco forest planning staff officer, said forest officials will also be available to give presentations on the plan to groups in the area.

He said people planning the road should read the newsletter's guide, which outlines where specific information can be found in the document.

For more information or to arrange a presentation on the proposed plan, call Meade or Layser at 541-702-1667.
Debate on Ochoco plan heats up

By Stephanie Mcensen

Bull. Staff Writer

PRINEVILLE — A proposal to cut more timber on the Ochoco National Forest in the next 10 years than in each of the four decades after that has drawn opposition from some of those studying the plan.

"We are concerned about the departure aspect," said Don Morgan, logging manager at Ochoco Lumber Co in Prineville. "In the past, the concentration was on improving the condition of the forest for future harvest, not on maximizing the harvest.

The proposed plan outlines how forest officials would implement the preferred alternative, which is similar to one released last winter on the Dechutes National Forest in response to the National Forest Management Act of 1976 requiring each national forest to develop a land management plan.

The plan, which will be open for public comment until Dec. 29 to comment on the contents, outlines steps the Forest Service will take to answer questions about the documents at an open house from 4 to 7 p.m. Tuesday in the Prineville Fire Hall, 500 N Belle St.

Another open house has been scheduled for 4 to 7 p.m. Wednesday in the community room at Ochoco Junior High School in Redmond.

The environmental impact statement contains 11 alternatives or managing the forest over the next 10 to 16 years. One of them is preferred by the Forest Service.

The plan would allow a harvest of 100 million board feet of timber over the next 10 years. A total of 132 million board feet of timber would be included in the allowable sale quantity, defined as green timber suitable for sawing and the total allowable sale quantity would decrease to 69 million board feet after 25 years.

If the Forest Service implements the preferred alternative, a drop in the sale quantity over time is necessary to provide the forest with enough timber to sustain healthy forest ecosystems.

Ochoco forest officials are on hand to answer questions about the documents at an open house.

Central Oregonian 10/9/86

Mill stays in local hands

---

After nearly a month of negotiations, the Louisiana Pacific mill in town is now Prineville Sawmill Company. The mill, which was recently purchased by local businessman Craig Woodward, now produces about 100,000 board feet of lumber daily, an increase from the 80,000 board feet produced by the previous mill.

Woodward said the increased production is due to improvements made to the mill, including new machinery and better management practices.

The company currently has about 120 employees, with plans to hire more in the near future.

---

BEM Proposes land exchange

A new proposal that would allow the Bureau of Land Management to exchange a piece of private land for public land in the Mount Shasta and Phillips area has been submitted for review.

The proposal, which is being considered by the BLM, would exchange a 100-acre piece of private land near Mount Shasta for a 200-acre piece of public land near Phillips.

The land would include habitat for wildlife and recreational areas.

Issues considered in forest plan affect Prineville

Information on the future of the Ochoco National Forest and Crooked River National Grassland will be presented to the public at a series of open house meetings held by the U.S. Forest Service.

The Forest Service is in the process of preparing a Draft Proposed Plan and Draft Environmental Impact Statement for the Ochoco National Forest and Crooked River National Grassland. The Draft Proposed Plan will be presented Oct 14 at the Prineville Fire Hall and Oct 15 in Bend at Oregon State University.

"Forest personnel will be available at each in person meeting to discuss the Draft Proposed Plan and answer any questions you may have. Dave Miller and I will be available to meet with small groups of individuals or groups of 10 or more to discuss the Draft Proposed Plan and answer any questions you may have," said Ed Selby.

The meetings are scheduled to provide an overview of the Draft Proposed Plan and include a discussion of the impacts of the Draft Proposed Plan on the social, economic and environmental values of the Forest and Grassland.

Prineville Fire Hall, Prineville
Oct 14, 4-7pm

Oregon State University, Corvallis
Oct 15, 4-7pm

In order to help the public better understand the Draft Proposed Plan and Draft Environmental Impact Statement, we have scheduled a meeting in Prineville to provide an overview of the Draft Proposed Plan and discuss the potential impacts on the social, economic and environmental values of the Forest and Grassland.

For additional information, contact Earle Layser at 447-6247.
Forest plan comments asked

A public information meeting on the Ochoco plan will be held in Burns on Nov 8 at the Museum Clubroom from 4 to 7 p.m.

"Forest personnel will be available to discuss the forest planning documents and we encourage everyone who has interested in the Ochoco forest and grasslands to attend one of the meetings," said Ochoco forest supervisor Ron Alger. "We will have displays to help provide a simplistic overview of the forest planning process and highlight the key issues which the plan is designed to address. Maps and information will be posted illustrating 11 alternative ways the forest and grandstand could be managed," he said.

When finalized, the planning documents will guide management of the Ochoco National Forest and Crooked River National Grasslands for the next 10 to 15 years.

Interested persons are invited to submit written comments on how they feel about the draft documents.

"As people respond to our planning documents it will be very helpful for them to include supportive reasons for their thoughts," said Alger. "We will work to help us in corporate the public comments into the final plan." Alger added that he will try to respond to the suggestions and comments.

Copies of the draft plan will be obtained from the Snow Mountain District office in Burns and will be seen at the Harney County Library.

---

Abandoned mine marks trailhead

The U.S. Forest Service plans to recommend that it declare a trail trailhead at an abandoned mine that was long ago a mining operation.

The mine, which is located near a popular hiking area, has been closed by the Forest Service since the early 1970s. The agency is preparing a draft environmental impact statement on the proposed action.

"We're looking into whether it would be feasible to reopen the mine," said Alger. "If it were to be reopened, it would be a trailhead for a hiking area."
Forest Service to hold information meeting

The U.S. Forest Service will hold an open house in Madras on Nov. 11 to discuss the public input on the proposed plan for the Ochoco National Forest. The open house will be held from 4:30 to 7 p.m. at the Harney County Museum in Madras. Public information officer Joe Meade encourages those who want to attend to call or stop by the meeting site.

The Forest Service has developed 11 alternatives that reflect a wide range of options on the 12 issues addressed by the alternatives. The timber harvest ranges from 34 percent greater than current levels under one alternative to 17 percent more than current levels. The number of AUM’s (annual use months) allotted varies from 23 percent more than current levels to 12 percent less. Big game habitat will support increased populations under all the alternatives, ranging from 76 percent to 91 percent more than current levels. Acreage specifically dedicated to old growth habitat will range from twice the minimum level to only the minimum level itself, 17,000 acres. There are currently about 80,000 acres of old growth habitat on the forest. The alternatives offer a range of choices for the amount of roadless area ranging from only that now in wilderness to several additional roadless areas and more wilderness.

The people of the Ochoco have a lot at stake in the forest's plan. Written comments will be received until Dec. 20. Send them to Forest Supervisor, Ochoco National Forest, P.O. Box 490, Prineville, OR 97754. All documents are available at the Prineville office.

Paulina to hear grazing plans

Ochoco National Forest officials will be in Paulina Wednesday to discuss the US Forest Service’s Draft Forest Plan and Draft Environmental Impact Statement. The meeting, open to the public, will be held in the Paulina High School auditorium at 7 p.m. Dues to be addressed after 7 p.m. Joe Meade, Ochoco National Forest Public Information Officer, said that public comment is encouraged.
Land plan review slated

PRINEVILLE — The proposed open house on the proposed land management plan for the Ochoco National Forest and Crooked River National Grassland will begin on Tuesday.

The open house begins at 6:30 p.m. in the Prineville Club and will be held on site at the Prineville office. The meeting is expected to last until 8 p.m.

The U.S. Forest Service will provide an overview of the proposed land management plan and seek input from the public on the draft plan.

The public is encouraged to attend and provide feedback on the proposed land management plan for the Ochoco National Forest and Crooked River National Grassland.

Pro-economy forest plan support asked

Central Oregon's core community groups have been asked to support any economic plan for the Ochoco National Forest that would cut off the economic revenue from timber sales.

The request is for the Oregon Forest Service to meet with the community groups to discuss the economic impact of the proposed plan.

The Oregon Forest Service is scheduled to meet with the community groups on Thursday, May 20th, to discuss the proposed plan.

Mill manager prefers alternative B

By Terril Lowry

John Shelk, general manager of Ochoco Lumber Co., spoke to the members and guests of the Crook County Chamber of Commerce Legislative Committee Tuesday morning on behalf of the mill industry and the potential economic impact of the proposed land management plan.

"The issue at hand is a local issue, and it is not an issue that affects the forest service plan," Shelk said.

He stressed the importance of community members getting as much information about the plan as possible and then making known their opinions by writing to the forest supervisor by Dec. 20.

The future service plan, which is concentrating on what it refers to as an Alternative E3 Departure, is a preferred alternative by the forest service for managing the national forest for the next 10 years.

The state has decided to cut timber from the forest in an effort to reduce the availability of forestwood, which is one of the most important importations on the community. Shelk said.

Conservative estimates by the state show the personal income of county residents will drop by at least $50 million dollars, Shelk said.

The Oregon Forest Service is scheduled to meet with the community groups on Thursday, May 20th, to discuss the proposed plan.

Under the plan, there will be less emphasis on old-growth timber, more emphasis on reducing fire risk and overall forest management.

Furthermore, McClaran stated, the Alternative B plan will mean the current system of planed timber sale.

Forest Service accused of overcutting

By Steering Wheels

The U.S. Forest Service is accused of overcutting timber and allowing the public to cut more trees now than they did 50 years ago, according to the Oregonian National Forest Management Plan released recently.

A new survey and mapping of the public timber management plan for the Oregon National Forest by the Forest Service shows that overcutting is occurring.

The Forest Service should have more a market based model and not reduce the number of harvests in the forest, said the Lakeview timber consultant.

Oregonians have a right to expect the Forest Service to manage the forest in a sustainable manner and to provide for the public's interest in the forest.

The plan calls for reducing the number of harvests and increasing the number of years between harvests, which would allow for the forest to recover from past cutting.

The plan calls for a 10-year cycle for harvesting timber and a 20-year cycle for recovering the forest.

The plan also calls for reducing the number of harvests to one every 10 years and the number of acres harvested to 200 acres per year.

The Forest Service has been accused of overcutting timber in the past, according to the resulting report.

"We are not opposing the idea of overcutting timber, but we are concerned with the number of acres harvested and the number of years between harvests," Shelk said.

"There is not an economic benefit for the community to cut more timber, but rather a benefit for the management of the forest."
Get facts about the forest plan

To the Editor

Alternative B—Unfashionable and short-lived

The proposed land and resource management plan of the Ochoco National Forest and Crooked River National Grassland contains eight (8) options plus three (3) departures from Plans B, E, and H. In addition, Northwestern Resources, a business entity hired by local wood-products companies has proposed a "forest plan" that would contain a grand total of twelve (12) plans to select from. Information regarding the contents of these plans is contained in three volumes and eight maps and that would require months of study to understand well. We have until December 31, 1976, to make our opinions regarding these plans known to the Forest Supervisor and I urge all readers to do so.

The USSFS will then make a decision that may well affect all of us for the next 50-60 years, so let's hope that they make a good one. I wonder if Alternative B came from and why I am against it? The Resource Planning Act requires that a spectrum of plans be developed ranging from maximum commodity (timber and cattle) production to maximum amenity management of the forest considering all users including the animal and plant communities residing there. Alternative B is the minimum management maximum commodity production alternative. There would be no scenic corridor left along Highway 26 or anywhere else. The Riparian (stream bank) management in acres is the lowest of all the plans. Roads will be constructed into roadless areas. Indeed, there will be no roadless protection area outside wilderness areas. There are no provisions for waterfowl and their habitat. There is no emphasis on deer and elk. Snags left standing are not a part of the potential population of cavity nesting animals. In addition to the above, Alternative B endangers the future and guarantees economic disaster for Crook County in 50 years due to increased current cut and the B poster plan selectively logs old growth everywhere in the forest through low value Douglas and White Fir to predominate in the future. The sustained yield in the Ochoco National Forest is 17 million board feet per year. Cutting more than that will lead to a drop in production in the future. The average annual cut from 1973 through 1984 is 11 million board feet. Plan B proposes to increase this production by 10 percent now. At this rate, if we have been told, the old growth forests of the country will be gone from the Ochocos in 18 years.

In summary, Alternative B is never meant to be a "poster plan." It is a planning tool, not a "poster plan," a "worst possible" case. If B is selected, when the timber is gone from the Ochoco, then we will be left holding a very empty log. Those who have profited at the expense of the forest and future generations will probably be long gone. Alternative B is the only one of the forest management plans that is not a "poster plan," but instead it is a "worst possible" case. I am against it and I urge you to express your views to the Forest Supervisor and the Forest Service.

Prineville

Mills' spokesman rips Ochoco plan

By David Braly
Bulletin Correspondent
PRINEVILLE – Prineville lumber mill operators oppose the U.S. Forest Service's favored plan for future management of the Ochoco National Forest. They have been active in the fight to save the forest, and their opposition to the proposed plan is quite strong.

Jim McClan, speaking for the Crooked County lumber industry and wood manufacturing firms, told the council that the proposed management plan would adversely affect the forest, farms, and the entire community.

McClan said 58 percent of Prineville's jobs were dependent upon the lumber industry and that 22 other jobs were dependent on each lumber job, although the Forest Service has asserted that only one-third of a job results from each lumber job.

"If the Forest Service's proposal for the Ochoco is enacted McClan said lumber merchants, professional people, as well as the lumber and manufacturing industries. He noted that schools alone drew 11 million dollars a year from taxes on timber firms.

'The lumber industries that would be lost. McClan said, would be better paying than the 50 related jobs the Forest Service claims will result from its preferred alternative.
Supervisor speaks on forest plan

By TERRI LOWBY

Ochoco Forest Supervisor Dave Rittersbacher said he has two concerns about the proposed Ochoco Forest plan. "One is the lack of community understanding of the complex issue, and two is the realism that there is to manage the national forest," he said. "The issues at hand are very emotional and very real issues, and we must address those issues in an open, factual and forthright manner."

Those were the opening remarks of Rittersbacher during the Tuesday breakfast meeting of the Crook County Chamber of Commerce Legislative Committee as he briefly addressed members and guests.

Rittersbacher went on to explain some of the issues in the plan.

"Under the forest service plan the number of acres planned for actual timber harvest would be 400,000," he said, continuing to detail the plan by outlining an editorial from the Bend Oregonian of Burns, which Rittersbacher said he agreed with.

The editorial stated the timber harvest rates from 34 percent less current levels under one alternative and 48 percent more under another alternative.

"Big game habitat will support increased populations under all proposed alternatives, ranging from 56 percent more than current levels, he said. "Acreage specifically designated for old growth habitat will range from the minimum level of 17 percent to twice that amount," Rittersbacher said.

"Firewood taken from the forest is tied closely to timber harvest at most firewood is provided by logging residuals, he said. "It may vary from high to low levels depending on the plan."

"Other issues addressed by the plan alternatives are social and economic effects, riparian management, the transportation system, scenic qualities, snag management and water sports."

Rittersbacher pointed out that if "by law, the forest service must name a preferred alternative, but that does not mean the current Ochoco Forest Plan will become the chosen plan."

"There are choices, he said, "We are not locked into any plan at this point. This is just the beginning of a process of analysis."

Stand on forest plan stalled

By Mike Freeman
Bulletin Staff Writer

The Bend City Commission has subverted — at least temporarily — a controversial request to put itself on record against any changes in the Ochoco National Forest management plan that might hurt local industry.

The commissioners postponed taking action on the request brought forward by the Central Oregon Economic Development Council until they read a summary of the U.S. Forest Service's plan for Ochoco.

"I'd rather give no opinion than give an uninformed one," said Commissioner Ruth Burchel.

The Forest Service has come up with 11 different options for negotiating roadless area timber harvesting, wildlife habitat and other matters in the Ochoco. One of these plans is the preferred alternative recommended by the Forest Service.

City commissioners received a letter from Bill Hemingway, executive director of COEDC, asking them to pass a resolution opposing any "modifications to the Forest Service plan which would reduce timber-related employment, income or local government revenues, derived from timber sales."

COEDC has hired an consultant to study the economic effects of the plan and the consultant's report should be finished sometime this month, Hemingway said.

Laws? LeGate of the Sierra Club testified Wednesday that the Forest Service's plans stray from the principle of "sustained yield" timber harvesting.

According to LeGate, the Forest Service is recommending a 6 percent reduction in the allowable timber cut in Ochoco this year for the next five years. The staggered reduction, LeGate said, is designed to give the timber industry time to prepare for reduced harvests in the future.

The Sierra Club and the timber industry disagree about how much timber should be cut at the Ochoco to ensure that the forest can provide a steady flow of logs for several decades, LeGate said.

"History is a overcutting," LeGate said. "You manage for sustained yield. You don't cut more than the forest can reproduce now and then make up for it sometime in the future by making drastic reductions in the harvest."

The commissioners plan to continue the discussion again before the end of the year.

Forest Service officials said they hope to have a new plan for the Ochoco adopted by 1988.

In other business, the commissioners approved a proposal to ask the state for $150,000 to build sewer strategies and water lines in the west end of town.

But John Hassack, city planing director said the city's chances of getting the grant are poor. The last time the city applied for state funds for the neighbor hood — bordered by W 13th and 17th streets and Elgin and Galvez ton avenues — the application came in 12th out of a list of 30.

The city is competing with other cities and counties throughout the state for the funds.

The city also will ask the state for $55,000 in lottery money to develop some recreational property.

Devon Blank can improve Nef Road from NE 27th Street to Tucma Way. Blake proposes to build a recreation center at the corner of 27th and Nef.

W接地 said the chances of winning that grant also are poor. Have you bought any lottery tickets lately? he quipped.

Forum nears on Ochoco plan

PRINEVILLE A public forum to discuss the proposed land management plan and draft environmental impact statement for the Ochoco National Forest will be held Wednesday in Prineville.

The forum will begin at 6 p.m. in Our Saviour Lutheran Church, on the corner of Third Street and Harvard Avenue.

Jim McGirl, a representative of the timber industry, will give a presentation on the plan. Officials from the Forest Service state departments of Fish and Wildlife and Forestry also will be at the forum.

Representatives of the Ochoco Elk Hunters Association and possibly the Sierra Club also will attend.

Dave Rittersbacher, Ochoco forest supervisor, will be on hand to answer questions about the document until 7 p.m. Thursday and Friday at forest headquarters 239 Sixth St. in Prineville.

The public comment period on the plan ends Dec. 20.

E Departure is mismanagement

To the Editor

The proposed Forest Service Plan "E Departure" A Departure from Sanity

As we close out last week, there is a smorgasbord of 12 possible Ochoco National Forest Land Management plans (E through P) for us to comment on, by December 15. The Ochoco National Forest Service will then select one plan and use it to continue managing the forest and grasslands for the next ten years. Or, they will modify some of the forest plans and decide on a "consensus" plan and so on.

More on that later. Right now, let's evaluate the Forest Service preferred plan "E Departure". Timber harvest would increase by 1 percent in the first decade then slowly drop to 29 percent below the current level after 12 years. The sustained yield of the Ochoco National Forest is 72 million board foot per year. A 72 million board foot system would be 123 million board feet per year. The sustainably managed system would yield -20 percent would still be 1 1/2 times the sustainable goal. Ok, we're eating our seed potatoes. Bon appetite.

Lackluster grazing would increase by 11 percent. Now this is really preposterous to anyone who understands the need for riparian recovery and the fact that cattle grazing is by far and away the overwhelming cause of riparian devastation on our forests.

The Riparian Management goal is listed in page 19 of the environmental impact statement as "Excellent conditions in all areas, including riparian conditions, channel and anadromous fish (salmon, steelhead) or high valued trout fishing." These are 100 of stream sides on the forest and grasslands. The 100 points support the southwestern Oregon and 100 support no trout now, but they once did. (We're going to keep those 100 points, apparently, as late as 1959 prior to construction.) However, there are almost no funds to support this goal by conventional means. Ok, they want $2,500 per mile, as well as planing rip-rap, dams, dikes, potlows at several thousand more dollars per mile. So, this is a hollow plan. The timber harvest plan E Departure, the 1979 Land Management Plan (LMP) called for "Excellent" conditions in all areas, including riparian conditions, channel and anadromous fish. The 1979 LMP, a reduction in animal use and management of the goals were not met. So, historically, the Forest Service has not implemented measures pertaining to Riparian habitat recovery in its land plans. The riparian gap begins to reveal itself.

Speaking of history, the U.S.F. & W. was summed in 1877 by the Organic Act which established two purposes 1. Watershed protection 2. Timber management. The U.S. Supreme Court has said that there were two purposes for the reserves, favorable conditions of water flows, and to furnish a continuous supply of timber. Is the 1960 LMP beginning to sound like parts of it may be illegal?

Nowhere there take notes - the top of Lookout Mt. would be closed to you. Only us noncomposers, the area north of Lookout is closed, no mountain biking of Lookout - logging access roads, no hunting, no smoking in a continuous roadless area.

Picking at parts of the plan, however, saves little purpose. The Forest Service, as a large governmental regulatory bureaucracy, will continue to study, test, and abet those specific interest groups (timber and cat) that it was supposed to regulate, because that is the side their bread is buttered on.

Luke Willy Sutton, who robbed banks, was quoted "that's where the money's at". The Forest Service is dependent upon their large offices, remote and minimally grazing receipts to measure their value and justify their existence. Historically, they haven't enforced the law of the land and it will take major constraints to change, why else would they have large offices with provisions which are predictably illegal and others which are minimal? They do spend hundreds of thousands of dollars on their huge staff of employees after all, and we allow our rangelands to be destroyed when simply keeping the expense from the forest would allow nearly complete recovery in 10 years. And calisthenics not suffer - we could afford pay them many times their current salaries, the 1979 LMP beginning to sound like parts of it may be illegal?

Where are the plans for the Forest Service input to end?

To the Editor

The Ochoco National Forest Land and Resource Management Plan proposal has been available to the public since June 15. The time to comment on the proposal was extended to December 15. I would like to urge all forest users groups and individuals to please take time to review the plan and respond. Your thoughts are needed.

Applauds letter on forest plan

To the Editor

It was indeed refreshing to read Dr. Runehart's letter in the May 27, 1986 edition of the Central Oregonian. It's hearing to know that there are some within the communities who have the ability to let their concerns be known on the issue of the Ochoco National Forest. As Dr. Runehart points out, the opinions may go against the commodity interests within the area. Thank you for the opportunity provided Runehart for being so forthright about this.

December Official's dispute forest industry job claims

The timber industry preliminary plan adds that 100 million board feet of ponderosa pine be sold annually less than the amount of 100 million board feet that has been sold each year for the past decade. The timber industry claims that 100 million board feet would not meet sustained yield goals. The principle of sustained yield says that the number of board feet that can be grown back annually must be equal to or less than the volume sold. The additional harvest plan described in the proposed plan means that the timber industry would have to sell 132 million board feet per year.

More miles would mean more miles. The proposed plan would result in the sale of 100 million board feet of ponderosa pine to the forest industry each year. This would be far more than the harvest goal set by the U.S. Forest Service. The Federal Forest Service has already threatened to add the Forest Service to the list of federal agencies if the proposed plan goes through.

Lassen and the industry also noted that there would be a loss in the volume of potential which that each lumber mill could be realistically sell.

BLM land swap opens elk range

To the Editor

There is a proposed land exchange in Wheeler County that has the potential of providing 60,000 acres of public hunting, fishing, and recreation. This proposed exchange would not only provide prime habitat for big game but also roughly 60 miles of the John Day River access for fishermen. I would like to urge everyone to contact the local BLM office, the Prineville BLM office for information on how to attend the public open house meeting at the Prineville Fire Hall on December 11, 1986 (1:30 p.m.).

Wants Lookout road open again

To the Editor:

Last night I spent about an hour and a half talking to Dave Butternbacher, "Real man for our Forest Service." And I do think it is "true."

Dave assured me that there is no plan yet. Only their ideas and they need us to tell them what we want. Boy! I am glad they suggest not for real — any of it.

I have had hundreds of people talk to me about the forest plan, as I have been involved in this from the start.

I know nothing about logging except there are some very rich, selfish timber owners around here. Also, out-of-work loggers are mean and hungry ones are worse.

I do know of a lot of trees in what is now closed areas that could be logged to the better of everyone.

As for grazing, cows are stupid, stupid leave a mess and taste good when cooked right. They are owned by rich selfish land owners too. From the grass left where there was no grazing, there could have been quite a bit of it.

Since these selfish land owners have taken away the recreation from hundreds of thousands of acres from ordinary people then we have to count on public land.

Now recreation I know about I like to play. I worked with the Forest Service and agreed on the three wilderness areas we have I worked with the original skiers laying out the ski area by Bandit Springs. Then I thought the rest of the public land should be for the rest of the public not excluding but including those who use the four set aside areas. "Three wilderness and Bandit Springs." I hike, fish hunt, four wheel, horseback motorcycle snowshoe, and just camp out a lot. I do not x-country ski because I do not know how and am probably too clumsy and old to learn. But more power to those who do.

The moral of this story is: Let's not be like those mention ed before. Let's share what we have."

For 48 years I know of there was a primitive road going across a few miles of the most beautiful part of the Ochoco National Forest. It was passable to all types of vehicles as long as you used a little caution. Thousands of people traveled this road because of its scenic beauty. Nowadays in our forest there were you as likely to see big game. You could drink from several springs and see all the rest of the Ochoco's from there. In 1979 this road was paved out and the mountain was as stone as a stone before. It was taken away from 65 percent of those who used it. The people who used this road were not told this was going to happen. After it did happen, about 2,000 people said they wanted the road put back like it was. "That is 2,000 local people who used to hike, backpack or cross country ski up there can't choose to keep it from the rest of us. For everyone who goes there now a hard surface would be "if you're not managing the forest yield" be said. "You're using up our management."

But Let's change that and the new plan addresses many other areas of forest management, and District Ranger Fred Harmsz, encourages the public to attend comments.

"This plan shares some people's land and the Forest plan would reduce harvest by 30 percent over what is now closed area that could be used for the better of everyone."

For information call Woodward at 389-9216. If people have comments we want to hear them and the comment period ends Dec 20 and comments to Forest Supervisor Ochoco National Forest Box 490 Prineville Or 97754.

Consultant says wrong plan will jeopardize economy

Jim McCann

The U.S. Forest Service has rejected a proposed alternative plan for the Ochoco National Forest that would have allowed timber sales to continue throughout the area, according to a report released by the Central Oregon Economic Development Council (COEDC).

The Forest Service’s decision follows a series of public meetings held in the Central Oregon region, during which residents expressed concern about the potential impact of the 16-year forest management plan on local economies.

In a statement, the Forest Service said the proposed alternative plan did not meet the criteria for consideration.

The decision comes as the region is facing economic challenges, with many local businesses relying on the timber industry for employment.

Opposition forms to forest plan

By David Enz

The Oregon Department of Environmental Quality (DEQ) has issued a draft environmental impact statement (EIS) for the Ochoco National Forest’s proposed 16-year forest management plan.

The EIS outlines the potential impacts of the plan, including changes to timber harvest and the use of natural resources.

The draft EIS is open for public comment until January 10, 2018.

In its report, the DEQ said the plan would have minimal environmental impacts, but called for additional monitoring of wildlife and fish populations.

The report also highlights the importance of maintaining a healthy forest ecosystem, which is crucial for the region’s economy.

Study finds ‘E-Departure’ flaws

The Forest Service has found several issues with the current 16-year forest management plan for the Ochoco National Forest.

The problems identified include issues with timber harvest levels and the impacts on water quality.

The report recommends changes to the plan to address these issues, including reducing the timber harvest and improving water quality management.

The Forest Service is expected to release a final EIS in the coming months, which will provide a more detailed analysis of the potential impacts of the proposed changes.

In the meantime, residents and businesses in the region are encouraged to participate in the public comment process to ensure their concerns are addressed.

Charges forest plan creates defacto wilderness areas

By James S. Smith

Local timber operators have sought a Commission decision on the Forest Service's 2,000-page draft plan on the Oregon National Forest. John L. Chisholm, general manager of解除

The plan would have created defacto wilderness areas, according to the plan's proponents. The proposal was similar to the Oregon rule that would have created a wilderness area in the Northwest. The Forest Service's plan would have included 150,000 acres of land in the eastern Oregon region, including

John Shelton, State Sierra Club head, has been critical of the Forest Service's plan, arguing that it would create a wilderness area in the eastern Oregon region. He has said that the plan would have created a wilderness area that would have been infeasible under existing regulations. Shelton has said that the plan would have created a wilderness area that would have been infeasible under existing regulations.

On the other hand, the Forest Service has defended the plan, saying that it would have created a wilderness area that would have been feasible under existing regulations. The Forest Service has said that the plan would have created a wilderness area that would have been feasible under existing regulations.

Major changes may not be needed to fix forest

In the opinion of John Blank, general manager of Ochoco Lumber Company, the Ochoco National Forest is a national treasure to the local residents and the community. It provides jobs for many people in the area, and it is a primary source of income for a significant number of families who are employed by the Ochoco National Forest Supervisor's Office.

Their wages spent locally and taxes paid provide revenues for many local businesses and rural residents.

The Ochoco base is the source of irrigation water that folks both Ochoco and Prineville reservoirs providing water to most of the agricultural enterprises in the valley. ranchers graze their livestock on the forest during the summer.

The Ochoco National Forest also provides recreational opportunities for local residents and throngs of tourists who come here to dig for gold and hunt for game and just generally enjoy the beauty of the trees for whateversonal reasons they have.

Treasure harvesting-agriculture is tying into those basic industries that bring money into the local economy. This revenue adds up to a huge amount of money that could probably stagnate if we were not so dependent on dollars around here among ourselves.

We ought to be pretty satisfied that three houses or Prineville who show the forest in one way or another. They ought to be pretty unanimous in their support of the establishment as a national forest.

We ought to be pretty careful to use the forest in one way or another. They ought to be pretty unanimous in their support of the establishment as a national forest.

A lot of voters who are also very concerned about conservation and the Ochoco want to see a national forest established in the area. We ought to be very careful to use the forest in a way that they feel it's being used to the benefit of the government.

I'm sure I will tell you that this is the best of all of the alternatives offered by the Ochoco National Forest Supervisor's Office and the Ochoco National Forest Supervisor's Office and the Ochoco National Forest Supervisor's Office and the Ochoco National Forest Supervisor's Office.

By Stephanie Monson

Ochoco plan claims disputed

Paul Cuddy, forest manager, defended his proposed 177 million board foot plan for forest harvest at a Thursday press conference.

"We're working very closely with the state of Oregon and the U.S. Forest Service to make sure that the plan is in line with the state's own plans for forest harvest," Cuddy said.

However, Long said in the timber industry is still down by about 950 positions in 1990, and he expects the Oigo plan to create another 177 million board feet of timber annually.

The establishment of a new federal forest plan may lead to less forest harvest, but it will also have a significant impact on the forest industry.

The Forest Service is in the process of developing a new federal forest plan, and the Oigo plan is one of the options being considered.

The Oigo plan is designed to provide a stable supply of timber to the forest industry, while also protecting the environment.

The Oigo plan was developed in response to a series of legal challenges to the Ochoco National Forest's timber harvest plan.

The Oigo plan was proposed in 1994, and it was initially approved in 1996. However, the plan was challenged in court, and it was ultimately revised in 2000.

The Oigo plan calls for a reduction in timber harvest, and it also sets aside a portion of the forest for conservation purposes.

Forest Management plan may take year to prepare

By Pam Anderson

Some have pressed for more timber zone for more 'cutting' zones and others want to preserve old-growth trees. Public opinion has varied, with some groups favoring the idea of more timber harvesting, while others have argued for maintaining existing forests. A group has been formed to address the conflict, and discussions have been held to find a solution. The Forest Management plan may take a year to prepare.

Dave Ritterbach

With the controversy over the Forest Management plan still ongoing, the issue of old-growth timber preservation remains a concern. The plan is being reviewed by the public and will be addressed collectively in the next long-term management plan.

Ochoco plan review set

PRINEVILLE — The Prineville City Council Wednesday will hold a public meeting to discuss the Ochoco National Forest plan. The meeting will be held at 7 p.m. at Prineville City Hall. The public is welcome to attend and provide input on the plan. The Ochoco plan is being reviewed by the public and will be discussed at the meeting.

Please send comments to the editor:

We are interested in hearing from you. Please send your comments to the editor, Pam Anderson, at pam@prineville-oregon.com. We welcome your input and feedback on the Ochoco plan review set.
COUNCIL BACKS OCHOCO PLAN RESOLUTION

By David Bixley
Staff Writer
PRINEVILLE — Members of the Prineville City Council are backing a revised land management plan for the Ochoco National Forest.

The Ochoco National Forest is currently divided into two areas: the Ochoco 2000 and the Ochoco 500. The Ochoco 2000 is located in the western part of the forest, while the Ochoco 500 is in the eastern part.

The revised plan, known as the Ochoco 2000 Plan, includes changes to the existing land management plan that were proposed by the U.S. Forest Service.

According to the plan, the Ochoco National Forest would be managed to protect natural resources, such as water quality, wildlife habitat, and scenic beauty, while also providing recreation opportunities for the public.

The revised plan also includes provisions for the sustainable management of natural resources, including timber, wildlife, and water.

Council member Steve Ufford said that the new plan would provide a long-term solution to the management of the Ochoco National Forest.

The revised plan was approved by the U.S. Forest Service in 2010 and was implemented in 2011.

The new plan is expected to provide benefits to the local community, including increased recreation opportunities and more sustainable management of natural resources.

Keep lookout roadless area

The Editor

Lookout Roadless Area is the subject of much discussion and debate. The issue involves a provision of the Oregon National Forest Plan that sets aside about one million acres of land for roadless area management, which means that logging and road building are prohibited. This provision was intended to protect the area's unique ecological, cultural, and recreational values. However, it has also sparked controversy among different stakeholders, including environmentalists, timber industry representatives, and local communities.

Off-road vehicles

Another aspect of the issue concerns off-road vehicles. The national forest management plan includes provisions for off-road vehicle use, but many residents and environmental groups are concerned about the impact of these vehicles on the area's sensitive ecosystem. The plan outlines guidelines for off-road use, including the establishment of designated trails and areas for recreational activities.

Impacts on the area

The roadless area is home to a diverse array of wildlife, including species like the western lowland gorilla, mountain lion, black bear, and various bird species. The area is also important for cultural reasons, as it is home to native tribes who have a long history of interaction with the land.

The proposed plan

Many people are concerned about the proposed plan's impact on the environment and the local community. They fear that the restrictions on logging and road building will lead to economic hardship, while others worry that the area will become overgrown and unsafe for wildlife. The plan is expected to be finalized soon, and stakeholders are urging the public to stay informed and provide feedback on the proposal.
The Ochoco National Forest Plan, whatever shape it takes when it becomes final, will have profound effects on Harney County. For that reason, and because public comment has been slow in getting started, we believe that the comment period, which expires Dec. 20, should be extended.

Some timber industry spokesmen claim that the proposed plan, E-phase, will reduce by 40 percent the acreage designated for full timber harvest.

A Seattle economist claims that the plan would cost 317 jobs in Grant, Wheeler, Crook, and Harney counties, the four that contain parts of the Ochoco.

Conversely, a recent timber inventory on the Dechutes National Forest reveals that the amount of ponderosa pine growing there is 20 percent below what was previously thought. It is one of the leading concerns in the Ochoco forest and I believe that this area is the future of the timber industry.

The Ochoco timber industry believes it is not doing for increased harvests, just a continuation of those already in operation. The Sierra Club claims that the past levels have resulted in "rampant overcutting". Whether a reduction is justified or not, it seems certain that adoption of Forest Service's E-phase alternative would result in decreased timber harvests.

To request an extension of the comment period, write Dave Ritterbush, Ochoco National Forest Supervisor, Box 490, Prineville, Ore., 97754.
Comments deluge Ochoco planners

BY JIM DONOVAN
The Prine Herald

The response to the Ochoco National Forest's proposed plan has been overwhelming, according to Earl Layser, a planner for the Ochoco.

"We have had three or four people working full time on these comments, and two part time," Layser said in a telephone interview Dec. 29. "And we're going to get some more."

The Forest Service has received more than 2,000 comments—one day it got more than 600 letters.

Layser said, "The mail room has just been swamped." "I think we can say there's been an excellent response," he said, adding that the Deschutes National Forest received about 1,600 responses during the comment period for its proposed plan.

Layser said that more than half of the comments received have been form letters—some from the timber industry, some from snowmobile groups, and others. He expressed disappointment that these letters offered little substantive information to Forest Service planners.

"We know that 1,000 people voted for the timber industry's B plus alternative but that doesn't really tell us much. It's just counting voices," Layser said. "And though the Forest Service is not interested in vote counting, the fact that many people in the affected area feel strongly one way or another will be taken into consideration by planners."

But he said that there were also many comments from people asking for more roadless areas and greatly reduced timber harvest. "It's very polarized," he said.

Layser also said that he had received the letter from Harney County Judge Dale White.

Forest plans may change

By Stephanie Madison
Bulletin Staff Writer

Proposed plans that chart the future of the Deschutes and Ochoco national forests may have to be subjected to public scrutiny again because of timber industry objections.

That means people will have another 60-day period—tentative—yet to begin in a month—to comment on draft plans that were released last year for the Central Oregon forests and are about for those in Oregon and Washington.

However, this time the plans will contain supplemental information requested by the Northwest Forest Resources Council and John Buttrull, deputy regional forest supervisor for the Northwest region.

Layser, chief of planning for the Deschutes forest, this morning said officials at the Deschutes forest will ask to be exempted from the new order. Layser said the draft plan for the Deschutes still contains information similar to what the timber industry requested.

Officials with the Ochoco forest could not be reached for comment this morning.

The last time, in the almost 11-year-old forest planning process which is mandated by the National Forest Management Act of 1976, the public turned out en masse to protest the current forest plans, said the forest service.

Buttrull added that comments in the next 30 days will not be restricted to the supplement. All of the 1,000-plus pages in the documents will be open for comment.

Continued from Page 1

the county court concerning the Ochoco plan. He said the letter would carry exactly the same weight with planners as a letter from an individual. He added that the Forest Service has received letters from the county courts of three of the five counties affected by the proposed plan.

The Harney County Court expressed the desire for multiple aged management, and a continuation of current timber harvest levels, among other things.

The plan supported by the timber industry, which calls for a timber harvest of 125 million board feet for 10 years, and greatly reduced harvest thereafter, in order to achieve a sustained yield. Current annual timber harvest levels are about 153 million board feet.

Layser said that the forest is capable of producing 125 million board feet per year to perpetuity.

"The timber industry will either have to forfeit the budget now or bite it later," he said. "And if anything, they will be asked to provide data for an analysis."

The supplement will contain figures showing logging levels for the past several years and predict what harvest levels would be if current land management plans were followed.

Buttrull added that the alternative that was supposed to show current harvest levels did not.

The alternative states that a higher level of current land management plans that were rewritten to incorporate public input were not revised, said Layser.

Buttrull added that comments in the next 30 days will not be restricted to the supplement. All of the 1,000-plus pages in the documents will be open for comment.

Industry representatives such as Don Wimmer of Snowpine Co. in Hines cite the Forest Service's own benchmark figure of 144 million board feet. The benchmark refers to the maximum amount of timber the Ochoco could produce if all its available acres were devoted primarily to timber harvest. This would mean harvesting wilderness areas or other current exempt areas.

Layser said that the Forest Service is required by federal law to manage the forest for multiple use and to incorporate the state's goals for wildlife habitat. Managing for sustained yield (cutting timber at the rate the forest is growing), is also a statutory requirement.

In fact he said the Ochoco National Forest has been working for years on its plan because such a plan is required by the 1976 National Forest Management Act.

He said that the final plan should be completed in about a year. "We will try to keep the public informed about our progress," he said. "It's a not a process that just terminates with the end of the public comment period (Dec. 29)."

He said that the planners will try to reconcile competing interests before the plan is issued. "We would much rather publish the final agreement on issues than to issue it with controversies unresolved."

He said that the controversies may be resolved through conferences between groups, public and private meetings, and informal communications among interested groups and the Forest Service.

One issue Layser said may not be difficult to resolve is that of uneven aged management as a majority of writers were opposed to it. As we said...
Could mean longer review period
Supplemental forest info a possibility

A long review period is hanging over the Ochoco National Forest and it will be at least two more weeks before the question is answered.

That's because regional Forest Service officials are awaiting an evaluation to determine if the Northwest forest should need to provide supplemental information to staff environmental impact statements and the Ochoco National Forest Supervisor Dave Rittershacker.

Should the evaluation determine that supplements are needed, public comment periods will be extended for another 30 days or so, Rittershacker said.

The evaluation stems from two appeals filed with the forest service by the Northwest Forest Resource Council in April and August of this year. The NFRC, an association of timber industry groups, did not approve of the way the current management plans were displayed and characterized in the Draft Environmental Impact Statements and extended the forest service's deadline for the Forest Management Act Revisions.

The NFRC provides an opportunity to comment on the proposed Ochoco National Forest plan because of slowly building public interest in the kind of information asked for in the suit.

Today That decision will be made by a panel of Forest Service planners in Seattle. They will decide whether all seven forests need to publish supplements, or whether each may be considered individually.

If a new public comment period is opened for the Ochoco, it will provide an opportunity for people to give the kind of responses that the Forest Service is looking for—thoughtful and well-reasoned.

During the initial comment period, most of the comments received were form letters, according to Ochoco Forest Planner Earl Lysier. Many of them supported the timber industry's proposal for continued high timber harvests. Others were from snowmobile groups, and from environmentalist organizations.

This new period would give people the chance to more fully outline their concerns and to give the reasons for their views.

The plans for our local forests will, in large measure determine the mix of economic value, aesthetic qualities, and recreational opportunities that provides the economic stability and the beautiful quality of life that we find in eastern Oregon. That concerns every citizen in Harney County. We encourage every citizen to take an interest in the matter.

Group reacts to forest issues

To the Editor

The long-range plans for the 19 national forests in Oregon and Washington now being issued for public comment by the U.S. Forest Service are extremely important to the people of these states, especially those who live and work in the scores of small, timber-dependent communities. These plans can be blueprints for economic stability by providing high levels of timber output while protecting wildlife and recreational values. However, there is a growing fear spreading through these communities that our way of life is threatened by major reductions in the wood harvests from these forests—55 percent or more—that sustain logging and mills and jobs in the local businesses they support.

We've heard a lot lately about setting aside huge acres of forest for the spotted owl; a bird that isn't even on the federal threatened or endangered species list. We're going to hear even more about new management requirements that were adopted without any input from local communities. The planning process is tied up, or whether each may be considered individually.

If a new public comment period is opened for the Ochoco, it will provide an opportunity for people to give the kind of responses that the Forest Service is looking for—thoughtful and well-reasoned.

That concerns every citizen in Harney County. We encourage every citizen to take an interest in the matter.

Page 4 TIMES HERALD Burns Oregon

---Editorial

About a month ago, a Times-Herald editorial called for an extension of the public comment period for the proposed Ochoco National Forest plan because of slowly building public interest.

It now appears that the comment period may be re-opened, but for different reasons.

A forest industry group, in an appeal to the regional forester, said that the public should be given certain information about current management practices and about minimum management requirements.

The appeals were rejected, but the regional forester has ordered all future plans to include a statement that it will provide an opportunity for people to give the kind of responses that the Forest Service is looking for—thoughtful and well-reasoned.

During the initial comment period, most of the comments received were form letters, according to Ochoco Forest Planner Earl Lysier. Many of them supported the timber industry's proposal for continued high timber harvests. Others were from snowmobile groups, and from environmentalist organizations.

This new period would give people the chance to more fully outline their concerns and to give the reasons for their views.

We're going to hear even more about new management requirements that were adopted without any input from local communities. The planning process is tied up...
Analysis of public comment on forest plans continues

Locals groups needed

To the Editor:

The long range plans for the 19 national forests in Oregon and Washington now being sought for public comment by the US Forest Service are extremely important to the people of these two states, especially to those who live and work in the scores of small timber-dependent communities.

Getting these plans right is vital for economic stability by providing high levels of timber output, while protecting wildlife, water, and recreation.

It’s important for all of us to make our voices heard in the Forest Service planning process before it’s too late. We need to organize at the community level and do this. A few such communities have already started, and we’re trying to get together on an umbrella group called CPR, or the Congressional Planning Roundtable. Your community needs to be a part of this effort and will benefit from the ideas you share. We can connect you with KPRT, 19 Florence, Oreg 97439. Bond Phillips, President.

Citizen input aids legislator

To the Editor:

The nuts and bolts of what happens in the legislature is important to the voter. It is here that the final form of legislation is hammered out, and in order for this process to run smoothly, the citizens of Oregon must be given an opportunity to be heard. Your comments and suggestions are welcomed and will be considered.

The Joint Committee on Trade and Economic Development enjoyed an interesting and enlightening meeting Wed., Jan. 30. John Stadtler, President of Ochoa Lumber Company in Minnesota and Walker Lumber Company in California, gave testimony before the committee on the forest industry’s past and future.

Stadtler addressed the Forest Service’s Ochoa Plan which includes a 25 percent projected decrease in the allowable cut. Aspects of this plan are controversial and John did a great job of discussing its merits and problems.

Our forests, in large part are the economic base of Oregon. The only way we can make in accurate decisions is by those involved in the industry. The only way we can make those decisions is by those involved in the industry and communicating with their representatives in the legislature.
Ochoco Forest may issue supplement to forest plan

By Walter Y. Sillian

The Oregonian

The Ochoco National Forest may issue a supplement to its current forest plan.

The proposed supplement would add new alternatives to the current forest plan, including changes to timber harvests and management practices.

The supplement would also address changes to the minimum requirements for timber harvests and management practices.

The supplement would be available for public review and comment until July 15.

To show current direction

Forests to work up new alternatives

The Ochoco National Forest plans are working on a supplement and a mockup display to provide information on the proposed supplement.

The display will be available for public review at the Forest Service office in Burns.

Comments received on the Ochoco National Forest Plan

The Ochoco National Forest will accept public comments on the proposed supplement until July 15.

The comments will be considered in the development of the final plan.

A public comment period will be open for the supplement, and comments will be accepted on elements of the plan that have already come under public comment.

---

The Ochoco National Forest is considering changes to its current forest plan.

The proposed changes would include new alternatives to the current forest plan, including changes to timber harvests and management practices.

The changes would be available for public review and comment until July 15.

The comments will be considered in the development of the final plan.

A public comment period will be open for the supplement, and comments will be accepted on elements of the plan that have already come under public comment.
Public needs voice in management

It's Don NEIL GOLDBERG

Oregonians can and must have a decisive voice in determining how federal timber lands are managed. Those timber resources are too important to the state's economic future to be left to the federal government alone.

In the upper隅 the top lumber producer in the United States, we produce 24 percent of all softwood lumber in the country. We are first in plywood production and 28 percent of the nation's wood sawtimber is cut here. More importantly to Oregonians about 27 percent of all our manufacturing jobs are in the wood and paper industries. That doesn't account for the fact that each timber industry job supports about two others.

Now, these jobs are in the small towns and rural areas that have not yet benefited from the economic recovery of Oregon's economy.

Moreover, more than half of Oregon is federally owned and more than half the logs produced in Oregon come from federally owned lands.

That's the reason we are becoming more involved in Forest Service and BLM forest planning.

And that's why some of you may have seen Norm Johnson and other environmentalists in my office in John Day, Granta Pass, Gold Beach and other towns and communities around the state.

We are in the process of reviewing the federal forest management plans that are due out for each National Forest and many of the BLM lands in the state. And we want to know what local people think of these trails.

My goal is to present a clear, direct state response to each Forest Service and BLM plan.

The campaign I said that it is deeply regretful and it is to try to ensure that our federal forests and many of the BLM lands in the state are managed in ways that will maintain a healthy forest products industry, while at the same time maintaining our high environmental standards. That's all the case and that's why we're working hard to ensure that the places that are both economically and environmentally sound.

It bears repeating that Oregonians care passionately about their federal forests and the way those forests affect our future and not just over the short run.

Oregonians care about a steady supply of jobs to our mills and sawmills, well managed fisheries and high quality wilderness recreation areas. And we care about long term stability in our timber based communities. That's why we're finally taking ourselves heard in the federal timber management process.

Five Central Oregon rivers included in Hatfield proposal

Shelf and wire supports

PORTLAND - Five Central Oregon rivers are included in logssubmitted by Sen. Mark Hatfield to designate or study more than two dozen Oregon rivers that would be included under the Willamette and Snake River Act.

Hatfield, D., in Wash. D.C., by letter, intends to introduce legislation in January to designate or designate for study at least 27 rivers in Oregon as wild, scenic or recreational under the Wild and Scenic River Act.

The legislation, which will include sections of the Deschutes, Metolius, John Day, Willamette and North Fork Crooked rivers, will be the "largest river protection act in the history of the lower 48 states," and Bob Doppelfeld of the Oregon Rivers Council.

Oregon Democratic Rep Peter DeFazio and Sen. Pat Conroy announced Friday they plan to introduce similar legislation in the House.

The Senate bill will include these rivers the U.S. Forest Service has recommended as minimum criteria for wild, scenic or recreational designation, after a program released for the 15 national forests in Oregon, Hatfield said.

One of Oregon's rivers runs as long and deep as the rivers themselves, Hatfield said.

Nine of Oregon's rivers run as long and deep as the rivers themselves, Hatfield said.

Boise Idaho (UP) - Most Idaho timber jobs lost in the 1980s were replaced by machines and are gone forever an article in Boise State University's student newspaper.

The article cited statistics showing that while production has largely bounced back from the recession employment levels have not.

When lumber production peaks in 1987, the industry likely will employ about 18,000 workers, the newspaper said that's about 2,500 less than in 1979.

The Journal said the popular perception has been that the whole lumber industry is not in a recession.

But the cause of job loss in the industry is not in a recession by long-term factors such as the demand for lumber and the recession's effect on the economy. The fact is that the process of modernization has changed the industry and permanently reduced employment, the study said.

One of the authors, Arnold Brumble, who has a master's degree in public affairs from the University of Oregon and studied the effects of changing timber industry on the people of the Northwest, said, "The impacts of the changes held in the future will have the same productivities and impacts that will employ about 40 percent fewer workers.

Permanenit job losses in forest industry

Ochoco project tops list

A 47 million expansion of the Ochoco-Lumber Co. in Prineville topped the list of new industrial projects announced in Central Oregon during the third quarter of 1987.

Construction of a new pellet sawmill at the Ochoco Lumber Co. in Prineville began in September and is scheduled to be completed in April or May of next year, said John Shelk, managing general partner. The addition of the 500 ton per hour mill was expected to create about 25 new jobs.

Shelk said the new small wood pellets will allow the company to compete successfully with other mills in the region that process small logs.

"We felt the definite need of automating the handling of small logs," said Shelk. "This will bring us to the same size as some of the newer, more automated mills in the region, so far as processing small logs.

In addition to the Ochoco Lumber project, The Products Corp. announced a $5 million co-generation plant for Prineville, and the Prineville Forest Products Co. announced plans to build a new wood reusing plant in the region.

The three projects, with a total value of $12.5 million, were the only planned investments announced in Central Oregon from July through September, the Oregon Economic Development Department said.

More than $328 million in planned investments were reported in Oregon during the third quarter and Richard Peterson, director of the Department of Commerce, said the number is about 60 percent of the previous quarter's total.

The planned investments for this third quarter amounted to about one-third the amount logged in the third quarter of 1986.

Appendix B

Description of the Analysis Process

Introduction (Section 1)

The Planning Problem

The National Forest Management Act and the implementing regulations (USDA-Forest Service 1982) require each National Forest to develop a comprehensive multiple resource land management plan. These regulations outline a complex, systematic process aimed towards the development and evaluation of alternative Forest plans designed to resolve public issues and management concerns, and to capture management opportunities in a cost efficient manner.

The complexity of this problem for the Ochoco National Forest and Crooked River National Grassland stems from several sources. First, potential management activities must be scheduled and evaluated over a long period of time, ranging from 50 to 150 years. Second, the entire National Forest and Grassland, approximately one million acres in size, need to be assessed simultaneously. A wide variety of conditions exists within this area. For resource plans to be effective management tools, the direction provided must be specific enough to enable project level planners to readily determine if contemplated activities contribute towards and are consistent with Forest-wide goals and objectives. In addition, potential activity schedules need to be assessed relative to multiple resource criteria. These resources include many types of fish and wildlife, recreation, range, timber, water, minerals, and cultural assets.

The need to ensure that the scheduled activities are cost efficient adds an additional complexity. Related to this problem is the fact that, in many cases, a proposed management regime that appears to be best for a specific site or timber stand will not be best from a Forest-wide perspective. Constraints placed upon timber harvest, which require harvest levels to remain at a given level, can cause this condition.

The scope, complexity, and cost efficiency orientation of this planning process led the Washington Office of the USDA-Forest Service to conclude that National Forests must use linear programming (LP) as the central analysis tool. The optimization characteristic of LP ensures cost efficient allocation of land, labor, and capital resources. Additionally, LP appears to effectively deal with the complexities described above.

The Planning Process

The planning process described in the NFMA regulations (USDA-Forest Service 1982) was conceived within the framework of systems analysis. That is, the planning process was seen as a rational, analytical means of solving the complex problems associated with multiple-use forest management. The ten step planning process described below is outlined in the NFMA regulations and is intended to meet the requirements of both NEPA and NFMA.
Step 1: Identification of issues, concerns, and opportunities - In any systematic approach to problem solving, the first step is to identify the problem. In this step, the interdisciplinary team (ID Team) identifies and evaluates public issues, management concerns, and resource use and development opportunities. What does the public want? What does the Forest Service want? What needs to be done?

Step 2: Planning criteria - The issues, concerns, and opportunities (ICO's) collected and evaluated in Step 1 are used to develop decision criteria for evaluating alternatives. Planning criteria are also used to guide the collection and use of inventory data and information, analysis of the management situation, and the design and formulation of alternatives. What tests, rules, and guidelines are needed to complete the plan and select the best solution?

Step 3: Inventory data and information collection - Based on the ICO's, data is collected which will allow analysis of the problems identified. What and where are the resources available? In what amounts?

Step 4: Analysis of the management situation - In this stage, the Forest estimates the range of various goods and services it can produce, the potential to resolve public issues and management concerns, and the technical and economic feasibility of providing various levels of goods and services. The primary purpose of this step is to provide a basis for formulating a broad range of alternatives.

Step 5: Formulation of alternatives - A broad and reasonable range of Forest Plan alternatives is formulated to provide a variety of ways of responding to the ICO's. Each major problem must be addressed in at least one alternative.

Step 6: Estimated effects of alternatives - This stage estimates and displays the physical, biological, economic, and social effects of implementing each alternative. What will happen if a certain set of management prescriptions is chosen?

Step 7: Evaluation of alternatives - The significant physical, biological, economic, and social effects of each management alternative are evaluated with respect to the decision criteria established in Step 2.

Step 8: Selection of alternative - Using the decision criteria, a preferred alternative is selected.

Step 9: Plan implementation - The preferred alternative will be used to develop multi-year program proposals. These proposals will be consistent with the standards and guidelines set forth in the Plan.

Step 10: Monitoring and evaluation - A monitoring plan is established to evaluate how well objectives have been met and how closely standards and guidelines have been applied. Periodic evaluation reports are required. Based on these reports the Plan may be revised or amended if necessary.

This process can be viewed more broadly as occurring in three phases: (1) judgmental phase, (2) analytical phase, and (3) execution phase. Planning Steps 1, 2, 7, and 8 make up the judgmental or selection phase of the process. In this phase, ICO's are identified, and decision criteria are established. Then, based on the analytical phase, alternatives are evaluated and a preferred alternative is chosen.

No one alternative will satisfy all goals and objectives better than all others. The decision maker compares the trade-offs between alternatives and decides which balance of outputs, conditions, and uses represented by an alternative maximizes net public benefits.

Planning steps 3, 4, 5, and 6 represent the analytical phase of the process. Appendix B is primarily concerned with this portion of the process. In this phase, data is collected which addresses the ICO's and objectives of the Forest. Estimates of the Forest's potential to address the ICO's are developed. Alternatives which focus on producing various combination of goods and services are developed and the effects estimated. This information is then provided to the decision maker to use in choosing a preferred alternative.

The final phase is implementation and monitoring (planning Steps 9 and 10). Planned actions will not
always produce the desired results. Through monitoring and evaluation, inconsistencies between desired conditions and actual results can be identified and corrected.

Changes Between the DEIS and FEIS

As a result of responding to comments received from public and organizations following the release of the Draft EIS, the following listing is a summary of changes made for this Final EIS. These changes are the result of a concerted Forest effort to respond to comments received during the Draft review process. The changes revolved around data and data sources, processes, additions of new issues, additional analysis, and the elimination or modification of DEIS alternatives or the development of new alternatives.

New and Expanded Issues

Between the DEIS and FEIS the timber issue was broadened to include uneven-aged management and large diameter ponderosa pine; four new issues were also identified: anadromous fish, historic trail preservation, off-road vehicle use (ORV), and Round Mountain. The following sections describe the changes made since the DEIS to deal with new or updated issues or new ways of addressing the old issues.

New Prescriptions and Yield Streams Applied in FORPLAN Model

Uneven-aged timber management applied to ponderosa pine on general forest (20" target size).

Uneven-aged timber management applied to ponderosa pine in special areas with 30-inch DBH target size: Lookout Mountain, Stein's Pillar, Deep Creek, North Fork Crooked River.

Uneven-aged timber management (group selection) applied to mixed conifer in some areas.

Extended rotation ages and new thinning cycles for ponderosa pine in general forest.

More reliance on mixed conifer to produce cover for big game.

Acres and Timber Yield Tables

Acres - Condition classes (i.e. the amount of pine sawlogs, saplings, etc.) have been updated from the 1983 information used in the DEIS. This was done to more accurately assess timber harvest scheduling and its associated outputs and effects.

Timber Yield Tables - Yield tables were updated to reflect the growth that has occurred in the last five years in order to more accurately determine outputs and effects.

Other

New elk coefficients.

New Habitat Effectiveness model for elk.

New mapping systems (Mount Hood Map, LIDES, Plot 7) installed for visual and analytical capabilities.

Standard view shed procedures eliminated in favor of set width (1200 ft)

New riparian analysis and scheduling based on updated stream condition inventory.

Potential water developments for livestock and wildlife re-evaluated.

Existing old growth inventory updated.

Anadromous fisheries identified. The analysis included resource production relationships and economic parameters.

Potential for mineral exploration and leasing, economic value of mineral leases incorporated.

Potential for capital investments concerning developed and dispersed recreation, including trails, re-evaluated.

Alternatives

Alternatives B-Dep, D, E, F, G, H, H-Dep have been dropped.

Alternatives B and C have been modified to incorporate new ICO's.

Alternatives A and E-Dep have been updated.

Alternative I has been developed based on ICO during the DEIS review process and is the preferred alternative.
Inventory Data and Information Collection

(Section 2)

Overview

Following the identification of ICO's and planning criteria, the Forest made some basic decisions concerning the types of inventory data to be used and the methods of organizing this information. Two different forms of information were recognized by the ID team as essential to complete the task. The first form consists of data tied to a map base. Timber stand mapping or potential big game management areas are examples of this form. The frequent and varied needs to relate these inventories to each other, and to aggregate or disaggregate massive amounts of data at several different levels, led the Forest to develop an automated geographic data base using the R2MAP software system at the Fort Collins Computer Center (FCCC). The second general type of data needed were items not tied to a map base. For example, forage yield data or cost data apply to certain categories without reference to a specific geographic location. Each of the individual ID team members and forest specialists organized this information in the most efficient manner for the intended use. The following page briefly describes data base development and some of the major uses of the Forest's inventory data.

At the time the Forest planning process was initiated, a new timber inventory was already underway on the Forest. This inventory was completed in 1982. The stand mapping completed for this inventory provided the most recent and accurate map of the Forest's timbered vegetation. Consequently, this map was heavily relied upon throughout the planning process and was the basis for development of analysis areas (see Section 3, pages B-18 through B-20). For most other resources, the ID team felt that adequate data was already available or could be readily assembled. In some cases, better inventory data would have been very useful had time and dollars permitted major new inventories. In order to adequately address public comment to our DEIS, updates were made to our riparian, old growth, and range structural improvement data. Section 2, pages B-7 through B-9, gives a brief summary of the major data sources used and the general reliability of each.

Changes Between the DEIS and FEIS

The major changes discussed in this section are the new or updated data concerning old growth, riparian condition, water developments, and the installation of new computerized mapping systems.

Data Organization and Use

Data Base Development

The Forest considered use of several different geographic data bases before settling on R2MAP. R2MAP is a simple grid cell mapping system available to the forest through the FCCC. The system was thoroughly tested at the time this decision was made and had, in fact, been used previously on the Ochoco for a limited area in a unit planning effort. Selection of a grid cell size and map scale was neces-
sary to initiate data base construction. Three different scales were considered for use: 1" to the mile, 2" to the mile, or 2.64" to the mile. The latter scale, 2.64" to the mile, is the one used in the standard 7 1/2 minute USGS quad series which has been adopted by the Region for the primary base map series. Regional Office support and the suitability of this scale for most of the forest’s mapping needs led the ID team to select this scale. The most convenient grid cell size for this scale is approximately three acres per cell. Given that several of our inventories were mapped to a 2-3 acre resolution, and the ID team wanted to retain as much accuracy as feasible, the use of a three acre grid cell size seemed appropriate and was adopted.

Many different layers of data were identified by the ID team as necessary for calculation of outputs, conditions, costs, and effects for the Forest Plan. In most cases it was apparent that use of the R2MAP data base would be an efficient method to provide the necessary data. Existing mapped data was gathered from several sources (TRI, specialist’s maps, inventory records, etc.) Easily mapped information was prepared where none existed at the time. In most cases this information was placed on 2.64" to the mile quad maps or 4" to the mile quad maps.

Coding schemes were developed for each layer using two character codes for each attribute. An up-to-date code book containing all of these codes is maintained in the planning files. Each of the input layers was then coded, quad by quad, by placing an acetate grid over the source map and placing the appropriate attribute code on the grid. These maps were then entered onto floppy disks via a R2MAP data entry program (GRIDENT) available on TI-990 intelligent terminals, and transmitted to FCCC. The various programs of the R2MAP system were then available to format the data and perform the basic functions of a grid cell mapping system. Each of the layers input was overlaid against an ownership base layer to ensure that consistent boundaries were present on each layer. Updates, changes, or corrections to data already in the system were accomplished by either changing the codes, changing individual cells, or re-inputting affected quads.

The selection of layers to include in R2MAP followed from several criteria. The major need for forest planning was the ability to combine basic resource data and geographic locations into analysis areas and relate those acreages to potential land allocations. Therefore, basic resource data, geographic locators, and potential land allocations were selected for inclusion in the data base. Other layers were included to help provide data for the calculation of costs, yields, constraint values, or acreage adjustments. Additional criteria involved in the decision to include or exclude potential layers included: 1) time or costs to map, code and enter, 2) frequency of potential use, 3) stability of data, 4) importance of related ICO’s, 5) complete current data available, and 6) potential for development of new applications. As needs and conditions changed new layers were added and/or revisions made to existing layers. Between the DEIS and FEIS, the Forest undertook an extensive effort in updating its mapping capabilities. Computer maps were produced with Mount Hood Map, LIDES, and Plot 7.

**Major Uses of Inventory Data**

**Analysis Areas**

In current planning processes the land and resource base is described in terms of a set of delineators that define analysis areas. Analysis areas represent aggregations of many individual mapping units that are identified with identical delineators. Without reference to these individual units, sometimes called capability areas, analysis areas lose site specificity. The fact that forest planning attempts to deal comprehensively with multiple resources across an entire Forest requires that analysis area delineators reflect fairly broad conditions. The selection of these identifiers is an important step, however, since the composition of an analysis area defines the range of management activities appropriate for a given objective and the resultant costs and yields. The analysis model FORPLAN does much of the assignment of prescriptions to analysis areas based upon these costs and yields.
Analysis areas were constructed by overlaying several resource inventories (District boundaries, unroaded areas, working groups, slope classes, timber size classes, and forage productivity classes) with the R2MAP data base and aggregating small units into larger ones. Verification of the spatial feasibility of the model results also requires that analysis areas be represented on a map. In addition to these functions, use of RZMAF has allowed the Forest to efficiently determine how each analysis area relates to broader land classifications.

Costs and Yields
In order to estimate various costs and yields, data was assembled from many sources. In some cases, data representing several years experience were averaged together (e.g. precommercial thinning costs). In other situations, historical data were not representative of anticipated practices, and estimates were constructed (e.g. reforestation costs). Another example of data usage to construct production coefficients involved using Forest plantation data to drive a simulation model (e.g. timber yields from PROG-NOSIS). The Forest's R2MAP data base aided in the construction of production coefficients by providing the acreages of specific categories within other more general categories. More specific data could then be averaged together, using acreages as weights for use within the broader classifications (e.g. forage yields by fairly broad working groups). The derivation of production coefficients is discussed in more detail in Section 3, pages B-44 through B-45 (yields) and Section 4, pages B-51 through B-52 (costs). Section 2 contains a summary of major data sources used by the Forest.

Timber Suitability
The Forest followed a process to determine which timbered lands were unsuitable for timber management according to Regional and National direction. This process included a screen for regeneration difficulty. The Forest's soil resource inventory was used to locate areas with potential regeneration difficulty. Field checking focused on those sites and, when completed, resulted in a new map of verified unsuitable areas. This inventory was entered into the Forest's data base and overlaid with the timber map, resulting in an updated suitable timber map. The timber suitability process and results are presented in more detail in Chapter 3 of the FEIS (pages 3-62 through 3-65).

Alternative Development
A basic need in the development of alternatives was inventory data describing the land base (analysis areas). Section 3, pages B-18 through B-20, contains a description of the Forest's analysis areas. Analysis areas provided the basis for the scheduling of activities and estimation of outputs, costs, and effects for each alternative. As described above, data were also essential for estimation of the production coefficients used to drive the Forest's FORPLAN Model. Additionally, it was essential to relate the activities scheduled on individual analysis areas to broader land classifications suitable for implementation of management direction for each alternative (management areas). Potential management areas were inventoried for many of the management area prescriptions (big game, visual corridors, recreation areas, etc.). The Forest's R2MAP data base greatly facilitated this task.

Implementation and Monitoring
Inventory data will continue to be essential when the plan moves into the implementation and monitoring phases. Activities will be scheduled for implementation by referring the analysis areas on which they are scheduled to management areas. Changes in analysis areas, primarily due to timber harvest activities, will be reflected in an updated inventory to guide future activity scheduling. Data collected to monitor activities will be stored to facilitate mid-course corrections and future analyses. More detail can be found in the Proposed Forest Plan document, particularly in the monitoring plan.
Summary of Major Data Sources

Major data sources used in the planning process are summarized below.

Recreation Information Management (RIM) - This system consists of two major components. The first of these, a facility condition inventory, identifies maintenance and reconstruction needs for all developed facilities on the Forest. The second aspect of RIM contains recreation use estimates for each recreational activity, within each Recreation Opportunity Spectrum (ROS) class. This data provided the basis for recreational use projections by alternative (1982, updated 1988).

Recreation Opportunity Spectrum (ROS) - This inventory establishes the recreation potential on the Forest for various types of recreational opportunities (1983, revised 1985).

Trail System Inventory - This map shows existing and potential trail segments, existing trail conditions, and trail maintenance priorities. Trail systems for each alternative were developed from this information (1983, updated 1985, 1988).

RARE II and Roadless Area Inventories - These maps identify roadless area boundaries, according to Regional criteria, for use in the alternatives (1978, 1984).

Visual Quality Objectives (VQO) - The Forest was inventoried according to visual quality objectives as determined through a combination of variety class and sensitivity levels. This data guided application of management area prescriptions designed to retain or partially retain natural beauty (1983, revised 1985, 1988).

Existing Visual Condition Map (EVC) - This map depicts the existing visual condition of the Forest, in terms of the degree to which an area appears to have been altered by man's activities. By establishing a reference point, this inventory allows a determination of how the alternatives alter existing visual conditions (1983).

Big Game Winter Range and Summer Range Areas - Based on big game habitat differences and actual big game usage, this map depicts the associated summer range and winter range areas used by various subpopulations across the Forest. This inventory was used to develop big game population projections, and to help develop management areas for the alternatives (updated 1-20-87).

Crown Closure/Thermal Cover - A data set describing the relationship between timber stand crown closure and big game thermal cover values was used to evaluate and control big game habitat (updated 6-26-84).

Old Growth - Maps of stands currently in an old growth condition were used to help identify how existing old growth would be affected by the alternatives. Maps of potential old growth management areas, based largely on distribution criteria, were used to help develop alternatives (3-15-88).

Nationwide Rivers Inventory - This inventory was conducted by the National Park Service, and served to identify which rivers on the Forest have the potential to be classified as Wild or Scenic Rivers (1982).

Watershed Condition - Watersheds were classified according to soil depth, riparian condition, road concentrations, and compaction hazards to help schedule timber harvests while meeting soil and water requirements (11-84).

Soil Resource Inventory (SRI) - This inventory identifies mapping units according to soil characteristics, vegetation, slope, aspect, landform, and bedrock characteristics. It was used to identify cost differences, suitability for some types of activities, and mitigation measures (12-77).

Riparian Improvement Schedule - This inventory identifies soil, water, and riparian problem areas, and was used to help determine costs and apply prescriptions (1-15-87).

Watershed Improvement Schedule - This inventory identifies soil, water, and riparian problem areas, and was used to help determine costs and apply prescriptions (1-12-89).
Physical and Biological Stream Surveys - Physical and biological data on most of the Forest's major streams were used to help develop and apply riparian prescriptions (1972-79).

Timber Inventory - The timber inventory and associated stand mapping was recently accomplished (1980-1982) and was the primary data used to describe the Forest's timbered vegetation. The stand mapping was a major part of the analysis area stratification. Timber volume and growth by species from the inventory were used as the basis for existing stands yield tables.

Managed Timber Yield Table Data - Several sources of data were used to develop and calibrate the timber yield tables for regenerated stands. Plot data from actual Forest plantations and naturally regenerated areas formed the main data input to the PROGNOSIS model used to generate these tables. Additionally, Forest stand exam data, previous inventory statistics, and published site index tables were used to calibrate the growth and yield model (1985, updated 1987).

Timber Suitability Map - Lands unsuitable for timber production due to physical and biological conditions that prevent successful regeneration were identified based on soil mapping, district experience, and field checking (1983).

Ecoclass Inventory - The Forest was mapped into plant communities using the classification established in the "Plant Communities of the Blue Mountains" guide. This map base provided a means of stratifying analysis areas for non-timber vegetation. Forage production data from the guide for each of these ecoclasses was used to develop livestock yields.

Cultural Resource Inventory - This inventory contains site specific data for the pre-historic sites known to exist on the Forest, and provided the context for the estimation of effects for the alternatives. (1976-present)

Transportation Sheds and Road Map - Areas of the Forest were mapped into transportation sheds, thereby delineating areas of similar traffic patterns and costs. This facilitated analysis of cost efficient transportation investments, and tied directly to a map of existing road segments and conditions (1989).

Road Management Plan - This plan contains data identifying road segment categories, mileages, travel times, haul and maintenance costs, construction/reconstruction needs and costs, and existing traffic levels. This provided the basic data for the Forest network analysis for each alternative (1989).

Slope Map - The Forest and Grassland was mapped into two slope classes to help determine appropriate activities and costs, and to schedule prescriptions efficiently (1983).

Timber Sale Appraisal Records (2400-17 Forms) - This data set was used to develop stumpage values and logging costs (76-84).

ADVENT/RPA Cost Data - Actual expenditures and planned costs were used to help develop cost data (76-86)

IMPLAN National and County Data Files, 1982 - These data describe the local counties' economies and the inter-industry transactions that occur as goods are produced and sold. They formed the base data used by IMPLAN to help predict local economic impacts of the alternatives.

Output Expenditure Data - These are used in the IMPLAN model. They compute the effect upon given sectors in the local economy of changing a unit of Forest outputs. This allows IMPLAN to trace the effect of the alternatives on local jobs and income. Some expenditure data was computed from the IMPLAN model for 1982, other data was originally computed for 1977 and then updated to 1982.

Socio-Economic Overview - A contractor prepared overview described the social constitution of the local area. This was used as the basis to describe the effects of the alternatives on social patterns and trends (2-82).

Fuels inventory - Project-level site-specific fuels inventories were used to select fuels models for the Fire Analysis System (late 1970's to early 80's).
Fire History/Weather History Records - These historic records provided the baseline data for the Fire Analysis System. This system was used to determine the most cost efficient fire suppression strategies given these historic probabilities of fire behavior and weather (1970-79).

Brush Disposal (BD) Appraisals - These appraisals provided data used to develop BD costs for efficient treatment scheduling (1980-84).

Mineral Potential Reports and Maps - Two separate documents were prepared - one for the Crooked River National Grassland (6/88) and one for the Ochoco National Forest (3/89). These documents discuss locatable and leasable minerals, addressing the geology of the area, historic mine production, and mineral potential. Both documents include mineral potential maps that are reproduced in the Plans. The documents are available for review in the Supervisor’s Office.

The Forest Planning Model (FORPLAN)

(Section 3)

Overview

Forest planning is a very complex process. An enormous amount of information must be considered before an alternative management plan can be recommended as the one which best addresses the issues, concerns, and opportunities identified at the outset of the planning problem. Because of this complexity, several interrelated computer models and analytical tools have been utilized to help determine the decision space within which alternatives can be developed, and to evaluate their associated outputs and effects.

One of these models is called FORPLAN. The name is an acronym for FORest PLANning Model. FORPLAN is a computerized linear programming (LP) model which has its roots in RAM (Resource Allocation Model) and MUSYC (Multiple-Use Sustained Yield Calculations). It is composed of a matrix generator, a linear programming solution system (FMPS), and a report writer. Within the bounds of the matrix generator and the FMPS solution package, the user is allowed a great deal of latitude in formulating the mathematical representation of the forest planning problem to be analyzed. Our modeling analysis was performed with Version
The Ochoco FORPLAN Model was specifically designed to help the Interdisciplinary Planning Team analyze the economic and production tradeoffs associated with the recreation, timber, visual, range, water, and wildlife resources, and to help evaluate the extent to which various alternative management scenarios were able to address and resolve the identified planning issues. One key step in the development of the FORPLAN Model was to divide the Forest and Grassland into analysis areas. Analysis areas are tracts of land with relatively homogeneous characteristics in terms of the outputs and effects that are being analyzed in the FORPLAN Model. Their delineations were intended to capture the significant social, biological, and economic differences in the way the land responds to alternative management strategies. The focus of the delineations was upon the planning issues.

In the FORPLAN Model, analysis areas were assigned to management emphases in order to achieve the resource management objectives of a particular benchmark analysis or alternative. “Management emphasis” is a FORPLAN term and is directly related to the “management areas” described in Chapter 2. Each management area has a set of standards and guidelines concerning how the resources in that area are to be managed to meet multiple use objectives. These are termed management prescriptions (see Appendix D). Six to ten different management emphases were available to each analysis area, depending upon its resource production opportunities.

In turn, “modeling prescriptions” were developed to achieve the multiple use objectives of each management area. In FORPLAN these are referred to as combinations of management emphases and intensities. Modeling prescriptions are combinations of scheduled activities and practices, and their associated outputs and effects. The modeling prescriptions and their range of timing choices are represented as decision variables in FORPLAN. The outputs and effects associated with the prescription choices are represented as mathematical coefficients in the respective decision variables. FORPLAN had from one to twenty prescriptions to choose from for each management emphasis for each analysis area. In addition, dozens of different timing patterns and rotations were provided for most management emphases—management intensity combinations on timbered lands.

The prescriptions FORPLAN selected depended upon the objective function and the set of constraints used to represent a particular benchmark or land management plan alternative. The objective function was usually to maximize present net value or the production of timber. These were subject to first satisfying all the specified constraints. Constraints were designed to guarantee the spatial and temporal feasibility of land allocation and harvest scheduling choices. Once the model had determined that a feasible solution existed by satisfying all of the constraints, it would then search for the set of prescriptions and timing choices which permitted it to optimize the solution according to the specified objective function.

Since operation and interpretation of the Ochoco’s FORPLAN model must be consistent with the basic assumptions and limitations of LP, many analyses must be performed to fully analyze resource opportunities and trade-offs.

The next 3 segments of this section describe the concepts underlying the Forest’s model and how the model was used to fully evaluate the ICO’s. The last four segments of this section describe more completely the Ochoco’s FORPLAN model.

Changes Between the DEIS and FEIS

The changes described in this section relate to a number of facets of the use of the FORPLAN model. The incorporation of new issues, and how these issues relate to modeling characteristics, is described. The section also discusses new analysis of such issues as uneven-aged management and elk habitat. The description of the use of other modeling tools has been expanded. Finally, the updating of analysis areas and management areas, and the development of new yield tables are explained.
Analysis Process

Ochoco Model Design and Relationship to ICO'S

Modeling Assumptions
Ideally, Forests would be able to take full advantage of the optimization characteristic of LP to allow the scheduling of activities from a full set of prescriptions that completely describe production potentials for all relevant resources. Prescription selection by LP could be based on economic efficiency criteria alone, since all the relevant resources, with competing economic values, would be represented in the model. Differences in the land's ability to provide these outputs would all be reflected in the land and resource stratification, allowing the model to differentiate between production functions to find the most efficient set of prescriptions. The land stratification would also contain specific geographic boundaries, enabling control of modeling inputs, outputs, effects, or conditions within these areas to ensure feasible activity schedules. The resulting solution would represent assignment of management direction to suitable, geographically coherent management areas.

Several assumptions underlie the ideal approach described above. Relationships expressed in the LP matrix must be congruent with the fundamental mathematical assumptions of LP. Activity variables are assumed to be linear and homogeneous. All significant aspects of the production functions to be analyzed must be known and quantifiable. Data required to categorize and measure these productive interrelationships must also be available. All resource values must be known and quantifiable. If the above assumptions can be met, current technology must be available to construct and solve the LP within reasonable time frames and without undue expense.

Ochoco Planning Problems And Modeling Characteristics
Design and development of modeling and analysis processes on the Ochoco required a determination of the public issues, management concerns, and resource opportunities to be addressed in the planning effort. These ICO's defined the objectives to be represented. Delineation of analysis areas, development of prescriptions, and model design were all influenced by the content of the ICO's. Consequently, the first step to understanding the Ochoco's LP model and its capabilities and limitations is to identify the planning problems being addressed. Data gathered from public involvement processes and

TABLE B-3-1
ISSUES, CONCERNS, AND OPPORTUNITIES FOR THE OCHOCO NATIONAL FOREST AND CROOKED RIVER NATIONAL GRASSLAND
As Presented in the DEIS

1 What should be the level of timber production?
2 How can activities on the Forest and Grassland benefit social and economic wants and needs of local communities?
3 What is the appropriate level of livestock grazing and intensity of range management?
4 How should riparian areas be managed to meet various resource needs?
5 What habitat levels should be provided to meet public, commercial, and administrative access needs?
6 What road system should be provided to meet public, commercial, and administrative access needs?
7 How much roadless recreation opportunity should be provided?
8 What level of emphasis should be placed on management of scenic resources?
9 How much old growth habitat should be provided?
10 To what extent should firewood be provided to meet demand?
11 How much habitat should be provided for wildlife species dependent upon dead trees?
12 To what extent should the Forest provide for winter sports activities?
from Forest personnel were analyzed to develop a list of ICO's (Table B-3-1). Appendix A describes the evaluation of these ICO's and Chapter 1 summarizes them. The following paragraphs summarize the factors affecting production of key outputs and effects related to these ICO's, and the adaptability of these factors to LP modeling.

A few of the more important issues facing the Ochoco area are the level of timber harvest, species mix, and size of material. The scheduling of intermediate and regeneration harvests, and the timing and stocking level of reforestation methods and precommercial thinnings, are the major activities affecting timber growth. The size class and species mix of the standing timber inventory is the other major component of harvest level projections. Fortunately, use of LP is well suited to analysis of timber harvest schedules (Ware and Clutter 1971, Navon 1971, Johnson and Scheurman 1977, and Johnson and Jones 1980). Different timber types can be reflected in the analysis area stratification, and inputs related to the activities described above are reasonably linear in the production of timber. In fact, FORPLAN (Johnson et al. 1980) contains many features of the harvest scheduling model called MUSYC (Johnson and Jones 1980). Adequate analysis of the combinations of stand treatment options that best meet Forest objectives and constraints consumes a great deal of model space, however. Each of the treatment sequences for an analysis area needs to have many scheduling choices available to provide the LP with sufficient flexibility.

The issue of social and economic impacts is to some degree a composite of all the ICO’s, since the resolution of any ICO has a social and/or economic impact. Several related aspects of social and economic concerns comprise this ICO. One major focus of this issue is the provision of job opportunities and income to the local area. Forest Service planning processes employ an input-output model (IMPLAN) to trace the effects of changes in National Forest outputs through the local economy to estimate the impact on local jobs and income. Within this context, factors relating to commodity and non-commodity production, and the economics thereof, that affect local jobs and income deal directly with this issue. A second aspect of this ICO arises primarily from a national management concern for determination of the most cost efficient set of prescriptions appropriate for a given set of objectives. This concern focuses on attaining the most efficient use of capital in the national economy, thereby maximizing national wealth. A major factor affecting and limiting analysis of this concern is lack of good, specific cost data. This concern is a composite of all ICO’s but places greater emphasis on those ICO’s with larger economic implications. A third component of this ICO stems from a national concern to maintain or attain a high level of returns to the Federal treasury. All three of these components are most affected by the level and scheduling of timber harvest and timber management practices.

A third major ICO for the Ochoco concerns the number of animal unit months (AUMs) permitted for livestock. Factors affecting the level of forage available for livestock include the particular analysis area, timber stand density, application of nonstructural improvements, and the percentage of total forage production allocated to livestock. These activities can be reasonably represented as coefficients in a LP. The presence or absence of water sources also affects livestock yields, as this controls the area over which livestock graze. This spatial distribution factor is more difficult to deal with, however, since it is related to factors which are hard to measure and do not completely fit the linearity and homogeneity assumption of LP. The water improvements associated with a prescription should be modeled as a step function, not a linear function. In the context of forest planning, the steps may be small enough that this is not a significant problem. Another problem associated with water improvements is that the area served by one development usually encompasses several analysis areas with different yields, thus distorting LP coefficients developed for specific analysis areas. Additionally, an economic analysis of water development opportunities would need to account for differences in the land base which cause water improvement costs to vary widely. Measurement and categorization of those differences would involve accounting for topographical, climatic, and historical variations, and would be a difficult task at best.
The spatial distribution of livestock is a major aspect of another important ICO, i.e., riparian area conditions. Livestock concentration in riparian zones often reduces vegetative shading, which increases stream temperature and reduces channel stability. In order to attain riparian objectives, activities need to be coordinated along and adjacent to lengthy stream segments. This aspect of the issue and the highly constrained management prescribed for these areas greatly reduces the value of modeling activity optimization within riparian zones on a per acre basis. For example, timber management practices influence the shading present over streams, thereby affecting stream temperature. Achievement of specific temperature objectives requires consistent treatment over long stream reaches. Additional difficulties with modeling riparian area choices include an inability to quantify the aesthetic, vegetative diversity, and non-game wildlife values obtained, and lack of accurate in-place data within riparian influence zones.

Similar modeling problems hinder efforts to effectively analyze transportation-related questions and problems within the LP. Development of reasonable network road construction and reconstruction costs requires site-specific knowledge within the model of the activities scheduled and the associated management area objectives. Roads are built by segments that must follow a certain sequence and are not linearly related to prescriptions applied to spatially disjunct analysis areas on a per acre basis. Transportation planning models are available for use (Kirby, et al., 1980), but making an effective linkage between models requires large amounts of model space in the LP to provide a usable degree of spatial resolution. Even with fairly specific geographic boundaries, the loading of harvest volumes from analysis areas to road network nodes still requires somewhat arbitrary assumptions. This is one of the most difficult problems to deal with since road related costs are a significant portion of the total costs on the Ochoco.

Analysis of big game habitat levels is one of the more complex and interesting modeling problems. The major component of big game habitat is the amount and spatial arrangement of cover and forage over broad areas. Sufficiently large contiguous blocks of land must be represented in the model for valid assessment of habitat-population relationships. The approximate home range of elk was used as a minimum size. If these contiguous areas are modeled, then cover and forage habitat components can be manipulated with harvest scheduling constraints to control big game habitat and provide compatible harvest schedules. Provision of cover and forage varies according to the timber management practices used, which generally can be reasonably portrayed on a per acre basis. Modeling big game habitat as a function of relatively large areas, however, renders valuation of big game-related recreation in the acre-based LP ineffectual.

The roadless recreation issue also presents modeling difficulties. Management of large contiguous areas in an unroaded state is necessary to provide the desired condition. Historical patterns of use, intermingled ownerships, and expressions of public interest are all factors which are difficult to measure and affect the relative desirability of one area over another. Primitive recreation area attribute rating systems are highly subjective and not widely accepted.

The scenery issue is primarily concerned with the type of timber harvest constraints imposed to meet scenic objectives. Factors related to modeling scenic quality trade-offs include the inability to specify a dollar value for the benefits obtained, difficulty with categorizing the relative desirability of one area over another, and the fact that scenery prescriptions are logically applied to specific broad areas of land. Similar to the modeling of big game, attainment of scenic objectives can be insured by manipulating harvest scheduling constraints if appropriate areas are represented.

The winter sports issue is primarily concerned with the allocation of competing recreation uses on specific areas. Prescription assignment must be specific to the areas involved to resolve the issue. Another aspect of the issue relates to the type of timber harvest activities occurring in these areas. In some cases management objectives for these areas would require modification of timber harvest practices for scenic purposes. Harvest scheduling constraints can
ensure attainment of these objectives in the model if the appropriate areas are represented.

The two remaining wildlife issues, old growth and snags, have similar modeling characteristics. First, neither of these resources produces outputs with monetary values. Second, effects of providing different levels of old growth or snags are straightforward in that both result in direct timber harvest level reductions. Analysis of other resource interactions in the LP is not particularly useful for these issues. Additionally, in order to ensure attainment of objectives old growth needs to be provided in units of certain sizes at particular spacings, further limiting modeling flexibility.

The remaining ICO, firewood, is relatively minor from a modeling standpoint by virtue of the values involved and the magnitude of the trade-offs required. Provision of firewood would be relatively amenable to modeling in a LP if it were competitive with normal timber harvesting on the Ochoco.

Four new ICO’s were identified since the DEIS, and are incorporated in the FEIS. They are:

13. Anadromous fish
14. Historic trail preservation
15. Off-road vehicle (ORV) use
16. Round Mountain

All four new ICO’s present modeling characteristics similar to the problems described above. Anadromous fish presents modeling problems similar to riparian; historic trail and Round Mountain are similar to the scenery issue, and ORV use is similar to winter sports.

As evidenced by the foregoing discussion, much of the effort associated with constructing an LP model for the Ochoco centers around the spatial relationships inherent in the analysis of Ochoco planning problems. These relationships present modeling problems because they are not congruent with the nature of the LP activity variables. Activity variables represent the assignment of prescriptions to analysis areas and are assumed to be linear and homogeneous on a per acre basis. Stratification of the land and resource base so that costs and yields portrayed in the LP meet these assumptions results in analysis areas composed of many individual units scattered across broad sections of the Forest. The analysis necessary to explore the resolution of the ICO’s was supported by other tools (see pp. B-17 through B-18).

Figure B-3-1 illustrates this pattern on a typical section of the Forest. Many of the Ochoco’s planning problems, however, require the application of management direction to specific land areas. Riparian, roadless, scenery, winter sports, and old growth ICO’s all fall into this category. Other planning problems, such as big game habitat, necessitate analysis of broad contiguous areas for valid representation of management objectives. As a result, land areas allocated to a particular set of management directions to resolve an ICO are comprised of portions of many analysis areas. Figure B-3-2 depicts this relationship with a realistic land allocation pattern. These circumstances led to the conclusion that some sort of spatial control over the assignment of management direction to analysis areas is necessary to realistically analyze the management opportunities on the Ochoco.

Basic Model Design

The design of a valid and meaningful model for the Ochoco required the careful consideration of the factors discussed in the previous section. The assumption of linear, homogeneous activity variables and the relationships inherent in analyzing planning problems with particular spatial characteristics had to be reconciled to meet the planning mandate. Several additional criteria were used to guide model design. An evenly spaced sample of production functions adequately covering the full range of production possibilities was necessary to ensure thorough analysis of management opportunities, and to provide as much flexibility as possible to the LP. A need consistent with this objective was to include all of the relevant cost and price data in the LP, if feasible. A further model design goal was to capture as much of the significant land and resource variability in the analysis area stratification as the data would support. The inclusion of specific geographic

boundaries enabling control of the LP to ensure both accurate representation of objectives and technical feasibility was also desired. In an environment of limited budgets, a final criterion placed a high premium on the design of a relatively inexpensive model.

The planning problems described earlier fall into several categories relative to model design criteria and modeling characteristics. Analysis of timber and range ICO's requires portrayal of a wide range of potential activity schedules. These activities generally meet the assumptions of LP variables, comprise a large proportion of the total economic picture, and can be stratified in the land and resource base to reflect cost and yield variabilities. The scenery, historic trail, Round Mountain, winter sports, and big game habitat ICO's can be categorized as requiring some sort of spatial control over the assignment of management direction to analysis areas. However, provided that the objectives of areas assigned to this type of management can be ensured, a range of potential timber and range activities may be scheduled. The riparian, anadromous, old growth, and roadless area planning problems are similar in that spatial control is again needed. In this case, management objectives are obtained through imposition of strict timber harvest and/or grazing constraints. These latter two categories are similar in that both require spatial constraints over prescription assignment to ensure attainment of objectives. A wide range of land areas that could be assigned to these types of emphases needs to be examined to consider a full spectrum of production opportunities and selection of cost efficient activities. Similarities also exist between the snag ICO and a major aspect of the road system planning problem. Both snags and local road construction and reconstruction needs are directly associated with costs and yields modeled as a per acre function of timber and range activities. Due to the difficulties described earlier, a second component of the road system, major arterial and collector roads, is not analyzed within the LP. The firewood ICO is also addressed utilizing other processes.

The model structure selected as best meeting the design criteria stated earlier can be described in terms of three types of model components. The first of these, management prescriptions, provides the objectives and types of direction necessary to coordinate and schedule activities to ensure attainment of the desired condition within relatively large land areas. This type of direction is portrayed on maps of alternative forest plans and responds to the particular spatial characteristics of individual planning problems. The second and third model components are closely linked together in that one, analysis areas, represents the land and resource stratification, and the other, modeling prescriptions, contains sequences of management activities applied to specific analysis areas. The level of resolution attainable in a Forest-wide planning effort prohibits sensible mapping of activity schedules for individual analysis areas. Accordingly, activity sequences for specific analysis areas are regarded as modeling prescriptions used to calculate broader activity schedules applicable to the larger management area. These analysis area-modeling prescription combinations constitute the columns in the LP matrix. A simple example is presented (Table B-3-2) to illustrate the relationships between these components in the LP matrix.

Management prescriptions are represented in the LP matrix by selecting a particular column or subset of columns and fixing the analysis area acreage to which it is assigned for any one model run. This spatial control is necessary to ensure that appropriate areas are assigned to special area prescriptions and contiguous blocks of land are assessed when resource considerations require it. Right hand side constraints can then be applied to these subsets of columns controlling the activity scheduling to represent management prescription objectives. A simplified matrix depicts this structure in Table B-3-2. Two analysis areas and four management prescriptions are represented. Three modeling prescriptions showing the timber yield and resulting effects on big game cover are contained in the matrix for the timber/range and big game management prescriptions. The timber management activities portrayed in these columns are described in Table B-3-3. The first set of rows, the acreage control rows, constrains the acreage assigned for each management prescription to...

the constituent analysis area proportions. In the case of the timber/range and big game management prescriptions, several columns are available within the overall acreage control. In the full Ochoco model, several dozen columns containing different sets of activities and many scheduling options are generated for these management prescriptions when applied to timbered analysis areas. Only one column is displayed for the riparian and old growth prescriptions. The timber volume rows illustrate that the average periodic harvest from the riparian prescription contributes to constraints in the LP. The third set of rows, thermal cover constraints, displays the application of right hand side constraints representing big game habitat objectives to a subset of columns. The combination of the acreage control rows and the thermal cover rows ensures that habitat objectives are assessed for contiguous potential management areas.

In order to ensure that model results could be validly interpreted, some compromises in model design were required as compared to the ideal optimization model. These compromises took two major forms. The first category includes monetarily valued outputs not present in the FORPLAN LP model. Fish, wildlife, and roadless-oriented recreation are the major outputs in this category. The second form of compromise refers to the assignment of management objectives to specific management areas prior to the execution of any particular model run. Ensuring that the most efficient assignment of prescriptions occurs, given these compromises, requires thorough analysis utilizing sequences of model runs or other supplemental analyses. For example, to compensate for assigning a roadless management emphasis to a specific area prior to running the model, a series of runs were made with candidate areas successively assigned an unroaded emphasis. Opportunity costs and trade-offs were examined and decisions made in light of this information. Another example concerns the development of structures, primarily water developments, to increase livestock utilization of existing forage. Since this could not be adequately dealt with in the LP model, supplemental analysis was conducted to determine the economic prudence of these proposed investments. More detail on these types of analyses and the role of the Ochoco’s LP model in the overall analysis process can be found in the following segment.

Other Analysis

The overall analysis process followed on the Forest and Grassland was designed to ensure a wide range of reasonably distributed, cost efficient alternatives that responded to the identified issues and concerns. From an analysis standpoint the guiding direction is found in the NFMA regulations (36 CFR 219.12 (f)(8)) as stated below:

“Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in the alternative.”

The Forest met this requirement through careful design of the FORPLAN model, use of the model to select and schedule prescriptions for each alternative, use of the model in sequential analyses to help design alternatives, and by conducting supplemental analyses. The following paragraphs summarize the types of analyses performed.

The Forest performed several types of analysis in the process of designing and building the Ochoco FORPLAN model. The purpose of these analyses was to allow FORPLAN a wide range of choice to evaluate the significant aspects of cost efficient prescription assignment. The Forest developed analysis areas several times, testing different combinations of land classifications each time, finally leading to use of analysis area data that most efficiently reflected economic factors (see Planning Records, 1920, 7/7/83). Specific modeling prescriptions were developed, tested, and selected based to a large degree upon cost efficiency analysis (see Planning Records, 1920, 9/10/84). Once the model was built, scheduling options for management of two-storied stands were evaluated and refined based upon a cost efficiency analysis. This is the largest timbered stand component on the Forest. Specific modeling procedures were also analyzed for cost efficiency. The
Forest elected to manage and model old growth habitat with a dedicated stand system based in part upon economic efficiency considerations (see Planning Records, 1920, 6/21/84). Final procedures for modeling dispersion of harvest units were adopted to minimize the impacts on present net value (PNV) while meeting dispersion objectives (see Planning Records, 1920, 6/13/85). The resulting Ochoco FORPLAN model is flexible, trackable, and capable of determining cost efficient prescription assignment and scheduling for each alternative or benchmark.

The Ochoco FORPLAN model was used to select and schedule prescriptions for all alternatives. The goals and objectives of each alternative were represented by constraints and the objective function in the LP matrix. These are described in detail in Section 7 of this appendix. Other components of the LP model (analysis areas, prescriptions, and economic data) are described in Sections 3 and 4 of this appendix. Design and use of the LP model consistent with the underlying assumptions of LP, as described on pp. B11 through B-16, helps assure cost efficient prescription selection due to the optimization characteristic of LP.

Many different types of analysis were performed with FORPLAN, both to evaluate different mixes of goals and objectives and to fully evaluate choices not explicitly analyzed within FORPLAN. An analysis in the latter category examined the relative cost efficiencies of different management prescriptions and the timing of initial entry, as applied to individual roadless areas. The Ochoco FORPLAN model was not able to validly analyze these choices with a single model “run”, so sequential analyses were performed to provide economic efficiency trade-off data (see Planning Records, 1920, 10/3/85). A similar type of analysis examined relative cost efficiencies of different management area locations on the Forest and Grassland (see Planning Records, 1920, 10/2/85). The Analysis of the Management Situation (AMS) (see Planning Records, 11/24/84) documented a series of analyses performed to provide a framework for alternative development. Economic relationships were examined relative to the maximum PNV obtainable, to competition between market and assigned values, and to current management direction. The opportunity costs of economic assumptions, minimum management requirements, and timber harvest policies were also displayed in the AMS.

For various reasons the Ochoco FORPLAN model was not able to effectively deal with some types of choices. Significant choices of this nature were analyzed “outside the model” with supplemental analyses. Early in the planning process the Forest ID team recognized an opportunity to increase domestic livestock utilization of forage by constructing additional water developments. An economic analysis of these proposed investments was conducted and the results used in the various benchmarks and alternatives (see Planning Records, Range Structural Improvement Analysis, 2/85). Similarly, the trade-offs between livestock usage and recreation users in riparian areas were examined in an economic analysis and used accordingly in benchmarks and alternatives (see Planning Records, 1920, 3/27/85).

Between the DEIS and FEIS many types of analysis were performed to update the design of the Ochoco FORPLAN model, to both evaluate different mixes of goals and objectives, and to fully evaluate choices not explicitly analyzed within FORPLAN. Model design was experimented with and changed to handle various uneven-aged management scenarios, changes in timber yield stratification, desired rotation lengths, new thinning options for low-site pine and maximizing species volume.

The model was used extensively in evaluating different mixes of goals and objectives for the three new or updated alternatives, and to evaluate choices not explicitly analyzed within FORPLAN. For example, the level of management intensity applied to certain roadless areas was varied. The effect of cover component manipulation on elk habitat was analyzed. The Forest also updated analyses that the Ochoco FORPLAN model was not able to analyze effectively. These include the opportunity to increase domestic livestock utilization of forage by constructing additional water developments, riparian and
watershed improvement analysis, and stream condition (Planning Records, 1920, 1/87). Others analyses considered acres of remaining old growth existing and over time, biological diversity, and road management. Considerable effort was also put into the updating of the elk habitat effectiveness model. Elk production potential and the effect of open roads were modified.

The question of whether forage should be in the elk habitat model was also revisited. As in a similar analysis done in 1983, it was felt that forage is generally not limiting, and at this level of planning would not have any effect in the model.

Other Tools

Due to the complexity of planning, numerous computerized and noncomputerized models and analytical tools have been used in addition to FORPLAN.

FORSUM (FORplan SUMMARY)

Due to FORPLAN Version One’s limitations, both in model formulation and report writing capabilities, the Ochoco National Forest developed a post FORPLAN processor. This processor aggregates timber harvest information in a more useful manner for the Ochoco National Forest. Some of the major summary reports listed acres by Management Intensity, rotation age, and diameter; and various treatment types by working group and management emphasis. It also uses FORPLAN outputs and additional formulas to generate information on snag levels, successional stages, big game habitat, road construction, soils, and number of AUM’s.

IMPLAN (IMpact PLANning Analysis)

IMPLAN is a computer-based input-output (I-O) model designed to assess the potential economic impacts of alternative courses of action. Economic input-output analysis is a procedure for describing the structure of inter-industry dependencies in a regional economy. The three regions in this case are Crook, Harney, and Wheeler counties. I-O analysis is based upon the interdependence of the production and consumption sectors of the economy of the area being studied. Its foundation rests on the concept that industries must purchase inputs from other industries, as well as from primary sources (i.e., natural resources), for use in the production of outputs which are then sold either to other industries or to final consumers. Thus, a set of I-O accounts can be thought of as a “picture” of an impact area’s economic structure at one point in time. See Chapter 3 of the FEIS and Section 5 of this appendix for a more complete description.

The IMPLAN system consists of:

A database of economic information from which input-output tables for the three counties were constructed,

Several computer programs designed to access the data base and construct an input-output model for any county or group of counties that the user designates; and

An analysis program that records data about land management planning alternatives and computes their economic impacts.

The IMPLAN data base has two major components:

The national level technological matrix, derived from the Department of Commerce 1977 national input-output model (updated to 1982, and in some cases to 1987); and

Estimates of sectoral activity for final demand, final payments, industrial output, primary inputs, and employment by county. These county estimates provide a detailed description of the structure of the regional economy, identifying which industries are present and their relationship to other industries.

IMPLAN estimates the changes (direct, indirect, and induced) in gross outputs, employment, income, and value added. In addition, IMPLAN provides some features that, thus far, have not been used by the Ochoco.

The availability of a complete transactions table permits the estimation of gross regional product. Detailed employment analysis is possible by tracking employment requirements among various occupations and by accounting for the effects of either
in-migration of workers or re-employment of unemployed local labor. This type of information could provide a comprehensive, detailed account of potential regional impacts.

Spreadsheets
Numerous spreadsheets were developed to process economic efficiency information (PNV, discounted benefits and costs), budget item information, and other resource related information.

Other
Most resource outputs, scheduled activities, and environmental effects were generated with the assistance of noncomputerized processes. They range from the very simplistic to more complicated, such as the elk habitat effectiveness model.

Development of Analysis Areas

Overview
In our current forest planning process, the land and resource base is described in terms of analysis areas. Analysis areas represent aggregations of many individual non-contiguous mapping units that are characterized by having identical delineators and are considered homogeneous in terms of costs and yields. Without reference to these individual units, sometimes called capability areas, analysis areas lose site specificity. The fact that forest planning attempts to deal comprehensively with multiple resources across an entire Forest requires analysis area delineators that reflect fairly broad conditions. The selection of these identifiers was an important step, however, since the composition of an analysis area defined the range of management activities appropriate for a given objective and the resulting costs and yields. Selection of analysis area delineators followed from criteria and general principles set forth in Forest Service planning handbooks and manuals, and in the relevant literature. One of the criteria used was that delineators had to be able to provide information useful for resolving issues, concerns, and opportunities (ICO's). Analysis area identifiers responding to several ICO's or higher priority ICO's were favored over those that did not. A second major criterion used was that delineators must reflect the key factors affecting the variability of cost and yield responses to potential management practices. The relevant costs and yields were those that were significant to the problem and met the linearity and homogeneity assumptions of LP. The availability, resolution, and accuracy of the data being considered was a third major criterion used to select analysis area identifiers. Another factor important to the interdisciplinary (ID) team was recognition of the need to accommodate a wide range of prescriptions and the limits of FORPLAN. In general more analysis area meant fewer prescriptions per analysis area.

Since the Forest used a large number of prescriptions for each analysis area, a goal of having a fairly low number of analysis areas effectively limited the types of information portrayed with analysis areas. Three types of data were not included in analysis areas due to this practical and technical limit. The first type desired was more specific geographical boundaries, such as watersheds or aggregations of watersheds. Not including these reduced the accuracy of some objectives modeled with FORPLAN and increased the difficulty of determining some outputs and effects. Elk winter range boundaries were also excluded from the model with similar consequences. The third type of data desired was aggregations of soil types. Soil types affect the types of practices allowed and the related costs. Not using these delineators required some averaging of costs (e.g., brush disposal costs), resulting in a less discriminating analysis and less accurate cost calculations.

Composition
The set of delineators currently in use on the Ochoco evolved through a lengthy process fully documented in the Ochoco planning records (file designation
1920, dated 7/7/83). Table B-3-4 displays these analysis area identifiers using FORPLAN terminology to identify each level of information, i.e., Level 1, Level 2, Working Group, Land Class, and Condition Class. The following paragraphs describe each level in terms of their composition, relative specificity and accuracy, use for cost and yield differentiations, and use for reporting and control purposes.

Level 1 identifiers represent our five District boundaries and provide some geographic definition to the LP. These boundaries are accurate but fairly general in that each district contains 110,000 to 240,000 acres. The only cost or yield differences tied to this level are higher timber haul and road maintenance costs on one District (Paulina), and different livestock distribution percentages on another District (Crooked River National Grassland). One of the primary functions of these boundaries is to make the multiple resource harvest scheduling constraints more specific, and therefore more accurate, than for the full Forest. The ability to report, control, and interpret outputs at the district level for implementation purposes, as well as to address administrative and community stability concerns is also a major reason for their inclusion.

Three different roading categories are recognized in the Level 2 identifiers. Small unroaded areas not requiring network road construction for access are lumped together and differentiated from the general roaded areas of the Forest. Larger unroaded areas that require collector construction for access are each uniquely identified in this level. Boundaries for these areas are accurate. The small unroaded areas category is fairly general in that most Districts contain several of these areas. The large unroaded areas are very specific since each area is uniquely identified. Local road construction cost differences for currently unroaded areas are reflected with these identifiers. The major purpose of individually identifying the larger unroaded areas is to interpret and control the scheduling of activities within each area so that road building costs can be more accurately analyzed using the Forest's transportation network model. These boundaries also enable the reporting of outputs and effects for these areas by alternative.

Major cover type differences for both timbered and non-timbered lands are represented with the Working Group level. These cover types are fairly general, reflecting major structural and productivity differences. Each of the Working Groups contain several different plant communities. Given the general nature of these Working Groups, the data are fairly accurate. The stand mapping used was the basis for the recent timber inventory (1981). Major cost differences are tracked by Working Group, including logging, brush disposal, haul costs, road mainte-
nance, reforestation, and range treatments. Stumpage values vary by Working Group, as do livestock forage yields. Working Group identifiers also enable the Forest to control and report timber outputs and practices, range practices, and big game cover provision. This latter capability is essential to meet multiple resource objectives.

The Land Class identifier distinguishes the major slope break commonly used by the Forest to determine the appropriate logging system. These two categories are fairly general since they do not reflect all of the site-specific factors that govern the actual logging system used and costs incurred. These identifiers are believed to be very accurate, however, since they were mapped to a 2 acre level of resolution from USGS topographic maps. Major cost differences are tracked by Land Class, including logging, brush disposal, road haul and maintenance, and range treatments. Range forage utilization and distribution factors also vary by Land Class. This level is not generally used for reporting and control purposes except for dispersion of timber harvest units.

Timber size classes and forage productivity classes are represented with the Condition Class level. Both of these stratifications are general in nature. The timber size classes represent an average of many different conditions found on the ground. This is particularly true of the Forest's many two-story stands, most of which have been entered several times in the past with some type of partial cut. The same stand mapping base used for the Working Group level was used for these size classes. The forage productivity classes also represent averages of many different ground conditions. They are considered to be reasonably accurate for purposes of estimating forage yields. Timber size classes affect treatment opportunities and the scheduling thereof. All associated costs and yields related to timber scheduling are therefore affected. Livestock forage yields, and to a degree utilization and treatment opportunities, are affected by the productivity classes. This level is not generally used for reporting and control purposes, except for timber harvest dispersion.

Between the DEIS and FEIS, the Forest evaluated their Analysis Area delineators and acres assigned to each. This intensive analysis was undertaken for two main reasons. The first reason was the large amount of volume that was returned to the Forest (buy back) that the model assumed had been treated. Secondly, during the five years since acres were assigned to analysis areas, the Forest had cut and sold a historically high level of timber. Based on this analysis, the acre assignment to analysis areas was updated because of significant shift in acres between the condition class levels.

Development of Prescriptions

Overview

The analysis of factors required to produce outputs and conditions related to the resolution of ICQ's described earlier (pp. B-11 through B-20) demonstrated that two levels of prescriptions were necessary. The first level applies to relatively large manageable areas and contains the types of management direction needed to coordinate activities within a management area to ensure attainment of objectives. These are called management prescriptions. As described previously, many of the factors related to broad areas do not meet the assumptions necessary to be modeled in LP columns, and, consequently, are controlled with Right Hand Side constraints. The second tier of prescriptions is called FORPLAN prescriptions, or modeling prescriptions, and represents sets of activities applied to specific analysis areas to meet management prescription objectives. This level of prescriptions constitutes the columns in the LP matrix and represents the resulting costs, yields, and conditions. Potentially, there is a set of these columns in the LP for each analysis area-management prescription combination. For any one model run, potential management areas are selected, each of which contains portions of analysis areas. Geographic control is maintained in the model by constraining the acres
assigned to each management area to those analysis area proportions. Right Hand Side constraints can then be applied to specific management areas to meet management objectives. One of the keys to the successful use of LP within this modeling framework is providing adequate choice among production possibilities for each analysis area-management prescription combination. A discussion of how these choices are structured follows the ensuing description of the Ochoco management prescriptions.

Management Prescriptions

The National Forest Management Act (NFMA) regulations define management prescriptions as "management practices selected and scheduled for application on a specific area to attain multiple use and other goals and objectives" (36 CFR 219.3). Management prescriptions consist of a goal statement which establishes the purpose of the prescription and a compatible set of management practices designed to develop and/or protect some combination of resources and to create or perpetuate a desired condition. Prescriptions were constructed within the requirements specified in 36 CFR 219.27 (see Planning Records, 1920 1/84). These requirements guide the development, analysis, approval, implementation, monitoring and evaluation of Forest Plans with regard to

(a) Resource protection
(b) Vegetative manipulation
(c) Silvicultural practices
(d) Even-aged management
(e) Riparian areas
(f) Soil and water
(g) Diversity

The process of identifying and subsequently developing management prescriptions began with an Interdisciplinary Team review of the issues, concerns, and opportunities (ICO's). Prescriptions were then identified which would help address those ICO's related to decisions regarding standards and guidelines, scheduling, or land allocations. There were other ICO's which were to be addressed through policy statements for which it was not appropriate to develop prescriptions.

To start the development of management prescriptions, the ID team identified a list of potential resource emphasis strategies. As these strategies were fleshed out, similarities and differences became apparent, allowing consolidation and further definition. The final list of management strategies responded to the ICO's and ensured a full range of choice among realistic management possibilities. These strategies provided the direction for construction of detailed management prescriptions (see Planning Records, 1920 8/10/83).

Once the need and purpose for certain types of prescriptions were identified, goal and objective statements for each management prescription were designed to respond to the ICO's. The ID team then identified the practices which would be used to meet the objectives. To accomplish this, the ID team used professional judgment, evaluation of existing policy, legislative directions and research literature. As appropriate practices were identified for each prescription, standards and guidelines for accomplishing them were developed. Essentially the standards and guidelines are intended to meet legal requirements and objectives of the prescription and to provide the guidelines for how the prescription is to be implemented on the ground. In addition, general policies, standards, and guidelines were written by the Interdisciplinary Team to cover practices common to all prescriptions and resource management situations that are Forest-wide in scope.

In addition to addressing ICO's, the process of designing management prescriptions was also guided by the following criteria: (1) prescriptions should be achievable and contain realistic practices, (2) they are to be general enough to accommodate the variable site specific conditions on the ground, (3) they should be specific enough for the Interdisciplinary Team to develop accurate resource and economic output and effects coefficients, and (4) to the extent practicable they should be the most cost effective means of achieving the intent of the prescription.
To a large degree, the particular structure used represented a consensus judgment about the type and detail of direction appropriate for management areas. Sufficient detail is necessary to resolve problem areas and provide clear direction. Enough flexibility must be preserved to allow for efficient accomplishment of objectives. Improvement of the accuracy and specificity of data and of analysis techniques may allow more specific direction in the future.

In the DEIS, prescriptions were developed for each of the fourteen management areas to which different parts of the Forest could be allocated. For each management area, a resource management goal and the general objectives to achieve a desired future condition are described. Management practices are implemented within each prescription according to the resource management goals and the standards and guidelines. A map of the land allocation to each management area is available for each alternative. This map, in conjunction with the associated prescriptions and the standards and guidelines, identifies what and where activities will take place. Table B-3-5 compares the major elements for each management area prescription. Between the DEIS and FEIS, the Forest decided to create many new management areas to address the ICO's. The Draft management areas are identified as MA-D1 through MA-D14, and have been updated and carried forward from the DEIS. The Forest management areas are identified as MA-F1 through MA-F28, while the Grassland management areas include MA-G1 through MA-G16, all of which were developed for the FEIS. There may or may not be any difference between the 14 DEIS management areas and those developed for the FEIS. Table B-3-6 lists management area groupings by resource emphasis. The fifty-eight management areas are summarized below. Appendix D describes them more completely.

### Draft Management Areas

#### MA-D1. General Forest Emphasis
The primary management objective is to produce timber and livestock.

**Desired Condition**
Timber management activities will include planting genetically improved stock, natural regeneration, precommercial thinning, commercial thinnings, and regeneration harvests generally at or near culmination of mean annual increment. Timber stands will generally be even-aged, 20 to 40 acres in size, with relatively uniform spacing. The largest trees in managed stands will be 16 to 18 inches DBH. Forage production for livestock will be enhanced by most timber harvesting activities and by range improvement activities, including the use of prescribed fire and the construction of additional water sources.

#### MA-D2. Big Game Winter Range Emphasis
The primary management objective is to produce winter range habitat of sufficient quality to ensure high big game survival potentials.

**Desired Condition**
A quality big game winter range habitat will be brought about, over time, through vegetative treatment, including timber harvests and prescribed fire. These activities will be designed to create an optimal relationship between the size and spacing of thermal cover units for maximum deer and elk use. Open road densities will be kept low to limit the amount of disturbance to big game from vehicle traffic. Livestock grazing will be monitored and controlled to ensure sufficient forage for big game.

Uneven-aged management has been added to Alternative C-Modified, and it will have an effect on a portion of this management area. It is not known at this time how close those acres managed under this silvicultural system will be to the desired future condition specified for this management area.
MA-D3. Big Game Summer Range
Emphasis
Management is directed towards ensuring big game habitat of sufficient quality for high production levels of deer and elk.

Desired Condition
A quality big game habitat will be brought about, over time, through timber harvest and other vegetative treatments. These activities will create an optimum relationship between the size and spacing of cover units and forage areas for maximum deer and elk use. Open road density will be kept low to limit the amount of disturbance to big game from vehicle traffic.

Uneven-aged management has been added to Alternative C-Modified, and it will have an effect on a portion of this management area. It is not known at this time how close those acres managed under this silvicultural system will be to the desired future condition specified for this management area.

MA-D4. Old Growth
Emphasis
The management emphasis on these lands is to provide habitat for wildlife species dependent on old growth habitat.

Desired Condition
Timbered stands of 300 acres or greater in size will contain mature and overmature trees in a multilayered canopy. Standing dead and down material will also be a significant component of the stand. Stands managed for old growth will generally be distributed throughout the Forest. To create this pattern, existing old growth stands will be utilized where possible. If no suitable old growth exists, areas capable of becoming old growth will be managed to bring the stand to an old growth habitat condition as rapidly as possible.

MA-D5. Retention Foreground
Emphasis
The primary management emphasis of these areas is to provide scenic views that retain or enhance natural beauty.

Desired Condition
Lands in this management area are comprised of the seen area immediately adjacent to areas of very high recreational use. Management activities will only repeat form, line, color, or textures frequently found in a natural landscape. Changes to the scenery will not be visually apparent to the casual Forest user. Where possible, forested areas will contain a major component of large ponderosa pine in open, parklike stands.

MA-D6. Partial Retention Foreground
Emphasis
Management in these areas is directed towards providing scenic views that partially retain natural beauty.

Desired Condition
Lands in this management area are comprised of the seen area immediately adjacent to areas of high recreational use. Management activities may change form, line, color, or texture but should remain subordinate to natural patterns and not dominate the landscape. Where possible, forested areas will contain a major component of large ponderosa pine in open, parklike stands.

MA-D7. Partial Retention Middleground
Emphasis
These areas provide scenic views that partially retain natural beauty, with man’s activities remaining visually subordinate to the natural landscape.

Desired Condition
Lands in this management area are located in the visual middleground adjacent to areas managed under a retention prescription (Management Area #D5). Management activities may change form, line, color, or texture but should remain subordinate to natural patterns and not dominate the landscape. When viewed from a highway, widely dispersed, small timber harvesting units will be visible, but will be shaped to the terrain.
MA-D8. Wilderness Emphasis
Protect the Wilderness ecosystems. Manage to maintain a natural setting and preserve solitude.
(This management area has changed from the Draft and presently applies to the Deschutes Canyon-Steelhead Falls area for Alternatives C-Modified and E-Departure only.)

Desired Condition
These areas are to be managed in a manner "...where the earth and its community of life are untrammeled by man..." and where "...natural processes operate without interference by man..." Opportunities for solitude and challenge are offered away from the sights and sounds of motorized mechanical vehicles or equipment. Scientific information may be sought without the intrusion of permanent improvements or motorized equipment. Special exceptions provided in the Oregon Wilderness Act will be allowed.

MA-D9. Semiprimitive Nonmotorized Emphasis
The management goal for these areas is to administratively provide near-natural, unroaded, and undeveloped recreational opportunities.

Desired Condition
Motorized vehicles are excluded except for over-snow vehicles, allowing for a semiprimitive nonmotorized recreational experience. Generally, interaction between users is low, but there is often evidence of other users. Natural processes will generally be operating without human interference, but management may occur to protect or enhance roadless qualities.

Motorized equipment such as chainsaws may be used in the management and maintenance of these areas. Nonmotorized mechanized equipment, such as "mountain bikes" and wheelbarrows, is acceptable. River corridors that are eligible for designation as Scenic Rivers under the Wild and Scenic Rivers Act are included in this management area.

MA-D10. Semiprimitive Motorized Emphasis
The management emphasis on these lands is to provide challenging motorized recreational opportunities in a natural appearing environment free from developed roads, highway vehicles, and concentrations of people.

Desired Condition
This Management Area contains selected roadless areas that meet these goals. Management is directed towards maintaining a natural appearing setting for off-road vehicle use while maintaining other resource values.

MA-D11. Developed Recreation Emphasis
The management goal at these sites is to provide and maintain safe, healthful, and aesthetically pleasing recreational facilities.

Desired Condition
This applies to sites currently developed or planned for parking, camping, picnicking, boating, and other recreational activities.

MA-D12. Research Natural Areas Emphasis
The management goal of these areas is to preserve Research Natural Areas (RNA's) as scientific benchmarks.

Desired Condition
This management area contains natural or nearly undisturbed areas which are representative of important forest and range land ecosystems. These areas fulfill identified needs for completion of the Regional RNA system. The RNA's will preserve natural ecosystems for research, education, and comparison with those affected by human activities.

MA-D13. Riparian in Acceptable Condition Emphasis
The primary management emphasis of these areas is to improve poor riparian areas to a fair condition,
and to maintain existing conditions in other riparian areas.

Desired Condition
Streambank vegetation will be managed to maintain or improve streambank stability and fish habitat as needed to meet this objective. Water temperatures will generally not be increased in major streams. Temperatures in other streams will not deteriorate downstream fish habitat. Natural, large, woody material will be provided. Range allotment plans will reflect forage utilization levels necessary to meet brush and hardwood protection needs.

MA-D14. Riparian in Excellent Condition

Emphasis
Management in these areas will ensure that riparian areas are maintained or improved to provide excellent streambank stability and fish habitat in 15 years.

Desired Condition
Streambank vegetation will be managed to provide the amount of cover and shade needed to meet this objective. Water temperatures will not be increased in major streams, and may need to be decreased in some areas. Temperatures in other streams will contribute to improved downstream fish habitat. Natural, large, woody material will be provided to help achieve high quality fish habitat. Range allotment plans will reflect forage utilization levels necessary to meet brush and hardwood protection needs.

Forest Management Areas

The land and resource management emphasis and goals for the management areas for Alternative I are summarized on the following pages. The 28 management areas for the Forest and the 14 management areas for the Grassland are presented in narrative form to provide a picture of the physical description, management emphasis, and desired future condition of each area. The standards and guidelines that apply to each of the Management Areas and the Forest-wide Standards and Guidelines are presented in Chapters 4 of the Forest and Grassland Plans.

MA-F1. Black Canyon Wilderness

Emphasis
Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

Desired Condition
The Black Canyon Wilderness will be as natural as is possible, with little evidence of human activity. The area will be a place of natural settings with opportunities for solitude. Present road access and hunter caches and camps will be rehabilitated so that their presence is no longer a dominant land feature. Recreational improvements, such as trailheads and access trails, will be evident where they are necessary to control use in order to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident.

Old growth stands will be evident within the Management Area, along with those wildlife species in the Ochoco National Forest which are dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, will be evident, along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where lightning starts occur.

MA-F2. Bridge Creek Wilderness

Emphasis
Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude. The area will be managed as a trailless wilderness where people can use their orientation skills.

Desired Condition
The Bridge Creek Wilderness will be as natural as possible, with little evidence of human activity. The area will be a place of natural settings where solitude may be sought. Present road access will be rehabilitated so that its presence is no longer a dominant land feature. Recreational improvements, such as trailheads and access trails, will not be evident, but entry points will be signed where necessary to control use and to preserve wilderness qualities.
Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures.

Old growth stands will be evident within the Management Area, along with those wildlife species in the Ochoco National Forest dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

Tree mortality, resulting from past Mountain Pine Beetle infestations and other endemic insects and pathogens will be evident, along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where lightning starts occur.

MA-F3. Mill Creek Wilderness
Emphasis
Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

Desired Condition
The Mill Creek Wilderness area will be as natural as possible, with little evidence of human activity. The area will be a place of natural settings where solitude may be sought. Present road access will be rehabilitated so that its presence is no longer a dominant land feature. Recreational improvements, such as trail heads and access trails, will be evident where necessary to control use to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. The stock driveway in the northeast portion of the Wilderness will be evident due to its routine use in association with the Mill Creek Allotment.

Old growth stands will be evident within the Management Area, along with those wildlife species dependent in old growth habitat on the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

MA-F4. North Fork Crooked River Wilderness Study Area
Emphasis
Management will maintain the existing conditions of the area pending a decision by Congress on wilderness designation.

Desired Condition
The wilderness study area will be as natural as possible with reduced evidence of human activity. The area will be a place of natural settings where solitude may be sought. Present road access, and hunter caches and camps, will be rehabilitated. Recreation improvements, such as trail heads and access trails, will be evident where necessary to control use in order to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures.

Old growth stands will be evident within the management area, along with those wildlife species in the Ochoco National Forest dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

The Final Environmental Impact Statement for Wilderness by the BLM has not been published, but a decision on the status of this area along with the adjoining BLM lands is pending. If these areas are not designated wilderness, they will be managed...
under old growth, riparian, and general forest standards and guidelines.

**MA-F5. Research Natural Areas Emphasis**

These tracts of land are areas where natural processes are maintained for research and education purposes. They will provide baselines against which other activities may be measured, sites for study of natural processes in undisturbed ecosystems, and gene pool preserves for both plant and animal species.

**Desired Condition**

Natural conditions will be maintained. Any management activities within the RNA's will be directed at maintaining the natural conditions of the area, and these human-caused changes to the ecosystem will not be readily evident. Continuing, nondestructive baseline studies may be occasionally visible in terms of equipment, instruments, and related activities. Fire occurrence will be evident where natural lightning and human-caused fire starts occur.

**MA-F6. Old Growth Emphasis**

Provide habitat for wildlife species dependent on old growth stands.

**Desired Condition**

Stands of old growth are not expected to change significantly over the next ten to fifty years, barring natural catastrophe. They will continue to provide habitat for a number of wildlife species, such as the pileated woodpecker and Rocky Mountain elk, and may become more extensively used by these species as the majority of the Forest moves towards a "managed condition." High levels of snag habitat will continue as individual trees within the stands die of old age, as well as from periodic infestations by insect and disease populations. Management activities and roads will generally not be evident. Fire occurrence will be evident where lightning and human-caused starts occur. Prescribed fire may be evident if natural fuels accumulate to dangerous levels, threatening the existence of the old growth stand, or where vegetation manipulation is needed to maintain stand structure and species composition. Grazing by livestock, as well as by big game wildlife species may be evident.

**MA-F7. Summit Historic Trail Emphasis**

Protect the existing integrity of the Summit Trail. Enhance and interpret significant segments for public enjoyment and education. Pristine segments will be managed to protect, interpret, and preserve their historic qualities.

**Desired Condition**

The Summit Trail will be a place where Forest visitors can enjoy the cultural and recreational resources offered in a visually pleasing environment. The majority of the trail route is along developed roads and will provide travel by highway vehicle, as well as by mountain bike and horseback. Vegetation may appear manipulated in widely dispersed areas in order to enhance cultural and recreational resources, but will generally not dominate the landscape. Interpretive facilities such as signs and landmarks may be visible in special, culturally significant areas. The outer boundary of the management area will generally not exceed 600 feet on either side of the trail.

**MA-F8. Rock Creek/Cottonwood Creek Roadless Area Emphasis**

Provide for protection of soil, water, and fisheries, and for opportunities for nonmotorized recreational use and enjoyment. Maintain vegetation on steep slopes to prevent erosion and to protect water quality and the anadromous fishery.

**Desired Condition**

Recreationists will see natural appearing areas free from motorized vehicle use. Recreational use, livestock grazing, prescribed fire and wildfire will occur, but the area will appear natural. These activities, along with any desired recreational improvements, will be the only visible impacts of direct human activities.
Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the Management Area, along with those wildlife species in the Ochoco National Forest which are dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Structures may be constructed, or other work may be done to maintain or improve habitat for the anadromous fishery. The area will remain one where there are above average numbers of trophy-sized elk and deer. Tree mortality, resulting from past spruce budworm infestations and other endemic insects and pathogens, will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning and human-caused starts occur.

MA-F9. Rock Creek/Cottonwood Creek Unroaded-Helicopter Area

Emphasis
Allow timber harvest while protecting the anadromous fishery, sensitive soils on steep slopes, and big game habitat.

Desired Condition
The area will be unroaded. Timber harvest and associated activities will use helicopter systems. The area will remain unroaded with landings located outside the management area. Prescribed fire use will also be evident in some areas where its use is desirable to attain management objectives. Visible harvest impacts will generally be limited to vegetation modification with little soil or other surface disturbance.

Recreation improvements, such as trailheads and access trails, will be evident where necessary to enhance access. Livestock use may be evident, but the successful application of allotment management requirements will show acceptable grazing practices. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the Management Area, along with those wildlife species dependent on old growth habitat in the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resulting from spruce budworm and other endemic insects and pathogens, will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning and human-caused starts occur.

MA-F10. Silver Creek Roadless Area

Emphasis
Protect and enhance the roadless qualities and provide nonmotorized recreational use.

Desired Condition
Recreationists will see natural appearing areas free from motorized vehicle use. Recreational use, livestock grazing, prescribed fire and wildfire will be evident over time. These activities, along with any desired recreational improvements, will be the only visible impacts of human activities within the Management Area.

MA-F11. Lookout Mountain Recreation Area

Emphasis
Maintain a natural setting, providing continued opportunities for high quality, semiprimitive recreational activities and wildlife habitat, while maintaining healthy forests.
Desired Condition

General
The Lookout Mountain Management Area will become a well-known area for year-round recreational activities and will provide excellent habitat for big game.

Prescription Area A:
This area will comprise approximately 7,550 acres of Forest land in a semiprimitive state with no vegetation manipulation planned. The recreational user will experience a highly diverse, natural landscape with interspersed stands of trees, openings, rock outcrops, and talus. A tree species mix including early successional species such as ponderosa pine, western larch and lodgepole pine will be seen across the lower elevations of the landscape. Lodgepole pine, sub-alpine fir, white fir and Douglas-fir will dominate at the higher elevations. Pockets of mixed conifer old growth will be an integral part of the vegetation mosaic. Natural tree mortality will be evident.

Big game habitat will be excellent due to the secluded nature of the area, high elevation moist meadows, and good year-round springs with heavy dense cover. Elk wallows will be numerous and big game use will be evident.

The area will be roadless, with currently existing roadbeds exhibiting evidence of rehabilitation activities and revegetation. Man-made improvements will be subordinate to the natural landscape and will be present to enhance recreational use of the area. Typical improvements apparent to the recreational user may include trails, trailheads, signing, trail shelters, livestock fencing, and possible wildlife habitat enhancement projects.

Prescription Area B:
This area will comprise about 8,110 acres in a relatively natural appearing condition.

A variety of trails, roads, trail shelters, signs and other improvements for the benefit of recreational users may exist, but will be designed and managed to be subordinate to the natural landscape. Several existing roads into the Management Area will remain open for motorized travel to dispersed campsites and mining activities.

Vegetation may appear manipulated in widely dispersed places in order to enhance recreational opportunities and wildlife habitat resources; vegetation manipulation will not dominate the landscape or generally be evident to the casual Forest visitor. Various vegetation manipulation techniques will be used to promote healthy forests which are more resistant to catastrophic events that may detract from big game habitat or a recreational experience. As a result of these limited entries, ponderosa pine and western larch, which are tree species valued for their appearance, will become more abundant over time. These species will be interspersed in a mosaic of other mixed conifer species of various size and age classes, including stands of old growth mixed conifer and ponderosa pine.

Minimum standard roads designed for specific projects will exist in low densities on the more gentle ground. Road use will be restricted to project activities and roads will be closed upon completion of each project. Roadbeds and banks will be seeded with mixtures of legumes and grasses to improve wildlife habitat. The amount of activity occurring at any one time will be limited.

MA-F12. Eagle Roosting Areas

Emphasis
Provide winter roosting habitat for migrating bald eagles from December through April.

Desired Condition
An uneven-aged stand will contain large trees which are at least 22 inches DBH, and a few trees which are 36-40 inches at DBH. Roost trees generally are at least 22 inches DBH and have an open structure which allows eagles to land easily. Those trees actively being used will be preserved along with replacement trees in the same vicinity.

The area will be free of potentially disturbing human activity during the period from December 1 to May 1. When actual or potential roosting areas overlap with areas which have more restrictive prescriptions, the area will be managed under the most restrictive prescription as long as roost trees are maintained.
MA-F13. Developed Recreation

Emphasis
Provide safe, healthful, and aesthetic facilities for people to utilize, within a relatively natural outdoor setting, while pursuing a variety of recreational experiences.

Desired Condition
This Management Area will consist of natural-appearing areas with obvious man-made controls and structures to direct users, provide for comfort and sanitation, and protect the natural resources. Developed sites will be provided for a broad range of recreational opportunities.

New and upgraded sites will incorporate a barrier-free design.

Management activities will not be visually evident. Scenic views may be enhanced through harvest or thinning but will appear natural.

Facilities, roads, and trails will have a well maintained appearance and provide a safe recreational environment. When vandalism is a problem, public use may be prohibited on a seasonal basis.

MA-F14. Dispersed Recreation

Emphasis
Provide a near-natural setting for people to utilize while pursuing outdoor recreation experiences.

Desired Condition
Within the immediate dispersed site, management activities will not be evident to the casual observer. Activities may be evident in areas adjacent to the site, depending on the management prescription applied to them. Primitive, user-constructed structures or facilities, consistent with a site’s use, will be seen. Sites will be managed so that users tend to feel relatively isolated. A strategy will be developed that encourages individuals or groups to “find their own place.”

Livestock grazing may be evident, but the successful application of allotment management requirements will also be evident.

MA-F15. Riparian

Emphasis
Manage streamside vegetation and habitat in order to maintain or improve water quality and meet temperature and turbidity levels as required by state standards under the Clean Water Act (See Forest-wide Standards and Guidelines, Water; and Best Management Practices (BMP’S), Appendix G).

Desired Condition
Riparian areas will exhibit a low but apparent level of management. Vegetation may or may not appear manipulated, depending on the condition of the stream. An abundance of wildlife species should be evident. Due to management restrictions and the low risk associated with these areas, the signs of natural or man-caused fire will be infrequent.

For management purposes, a special protection area (100 feet from the edges of perennial bodies of water) will be apparent. In addition, the streams listed below will receive extra protection to 200 feet from the stream edge, in order to provide “connective habitat” for a variety of wildlife species on the Forest:

- Trout Creek, Bear Creek, Drake Creek, Pine Creek, Allen Creek, Indian Creek, West Fork Bridge Creek, Porter Creek, Howard Creek, Fox Creek, Cottonwood Creek, Baldy Creek, Little Windy and Windy Creek, and Nicoll Creek

Roads not planned for future use will be obliterated and revegetated to a natural or near natural condition.

Within the limits of ecological potential, a shady, brushy condition with a canopy of alder, willow, aspen, or other deciduous vegetation will exist.

Where coniferous evergreens are a natural component of the ecosystem, a variety of size classes will exist to perpetuate the supply of shade and woody debris over time. Sites unable to support a canopy of deciduous or evergreen species will be characterized by vigorous stands of forbs, grasses, and grass-like riparian species.

Bank slopes containing high plant densities, thick root masses, embedded angular boulders, and old
logs will also characterize these areas. Extensive scouring of streambanks will be an uncommon occurrence, as will soil deposition outside the norm for the individual stream system. Streambeds will be commonly covered by native aquatic growth on assorted sizes of rocks and boulders.

Where cobble and gravel bars are prominent, they will become covered by sandy loam soils as riparian vegetation filters and traps stream sediments. As stream banks are re-built and cutbanks stabilized, a narrower, deeper channel will gradually develop.

Springs and wet meadows are not specifically included in this management area prescription, but should receive appropriate protection as stated in Forest-wide Standards and Guidelines for Water, Chapters 4, Forest and Grassland Plans.

MA-F16. Bandit Springs Recreation Area

Emphasis
Provide dispersed, nonmotorized recreational opportunities, within a setting where management activities are generally not evident to the casual observer. Expand the recreational activities and opportunities beyond winter recreation to year-round activities.

Desired Condition
The Bandit Springs Recreation Area is expected to become an important winter sports use area on the Forest, as well as for other year-round recreational activities, including environmental education, mountain bike riding, day hiking, hunting, and horseback riding. Developments to accommodate a broad spectrum of nonmotorized recreationists’ needs will be built. Emphasis will be on enjoying the natural scenery, with interpretation aiding the casual visitor. Developments may include trail shelters, maintained trails, horse unloading ramps, toilets, information areas, parking, picnic areas, and signs.

Periodic manipulation of vegetation to meet recreation and visual objectives for the area will be apparent to the user. Timber stands will be managed to develop and maintain resistance to catastrophic events that would detract from the recreational experience. Both uneven- and even-aged silvicultural practices will be used. A road system will be visible, but secondary to the natural setting. Livestock use will also be evident.

MA-F17. Stein’s Pillar Recreation Area

Emphasis
Maintain a scenic, natural or natural-appearing setting associated with unique geologic formations, particularly Stein’s Pillar. Provide roadless nonmotorized recreation with opportunities to enjoy nature.

Desired Condition
The area will be a natural or natural-appearing place with a variety of volcanic plugs, topography, plant communities, and wildlife, where recreationists can enjoy nonmotorized recreation.

Ponderosa pine stands will have large, yellow-bark trees, particularly along the Stein’s Pillar Trail. There will be a mosaic of these large-tree, open pine stands interspersed with juniper scab flats and fir stands. Created openings will blend with the natural appearance of the area. Scenic views will be created but management activities will not be evident to the casual observer.

The area will offer scenic views of Stein’s Pillar and other volcanic plugs, as well as the Ochoco and Cascade Mountains. Recreationists will enjoy nonmotorized activities, including hiking, picnicking, rock climbing, sightseeing, horseback riding, and group activities. These activities will mostly be day use.

Nonmotorized recreational opportunities and facilities will be provided. A rustic trail, designed and maintained for family day walks, will access Stein’s Pillar. There will be an associated trailhead and access route. The trail system may be extended to the north to tie to the Benefield road. Also, a safe way to the base of the pillars will be constructed to allow easier access for climbers and others. Interpretive facilities will highlight geological, recreational, historical, old-growth, and wildlife features, and the nearby wilderness.
Streamsides will be extremely shady and brushy with an abundance of tall overstory conifer trees and/or shorter hardwoods of alder, willow, and aspen. Streamsides will meet the Riparian Management Area objectives.

Deer and elk may use the area for winter cover, feed, and security. Deer and elk may summer throughout the area. A 300-acre Old Growth Management Area will be available for wildlife, such as the goshawk and pileated woodpecker. Snags will occur naturally, providing habitat for woodpeckers, nuthatches, owls, and other cavity nesters.

Livestock use will be evident, but the successful application of allotment management requirements will also be evident.

MA-F18. Hammer Creek Wildlife/Recreation Area

Emphasis
Provide and maintain habitat diversity for a variety of wildlife species where open road density is minimal. Provide a scenic, semi-natural or natural-appearing setting for nonmotorized recreational opportunities.

Desired Condition
Forested areas of ponderosa pine will be seen as a wide variety of size/age classes with a major component of large, yellow-barked pine. Mixed conifer areas will be a mosaic of open and closed canopy stands of various size classes to provide an optimum forage and cover mix for big game. Nonforested areas will generally appear natural in character, but with periodic evidence of livestock grazing. Riparian areas will be shady and consist of a mixture of trees and shrubs. Management activities will remain visually subordinate to the characteristic landscape.

Developed facilities such as trailheads, picnic/camp areas, and associated access routes will be evident on the periphery of the unit. Interpretive facilities will be available to highlight historical, recreational, and wildlife features.

Access roads to trailheads will be open. All other roads will be closed to motorized use and rehabilitated after management projects are completed.

MA-F19. Deep Creek Recreation Area

Emphasis
Provide a near natural setting for recreational pursuits within the area.

Desired Condition
Forested areas will contain large larch and ponderosa pine. Nonforested areas will generally appear natural in character with little immediate evidence of management activities. The riparian area will contain abundant alder and other riparian hardwood species.

Dispersed recreational areas will be protected. Opportunities for camping in developed sites will be provided at Deep Creek Campground.

Trails may be developed that provide day hiking or interpretive recreational opportunities.

Management activities, including timber harvest and prescribed burning, will not be evident to the casual observer. Livestock use will be evident, but the successful application of allotment management requirements will also be evident.

MA-F20. Winter Range

Emphasis
Manage for big game winter range habitat.

Desired Condition
Big game use on winter range will be the primary activity, with other management activities and human intervention restricted from December 1 to May 1. Habitat effectiveness for big game will improve over time, due to increases in both quality and quantity of thermal cover, and to reductions in open road density. Road and trail use will be limited to one mile of open access per section, from December 1 to May 1, but up to three miles per section will be available during the remainder of the year.

Vegetation cover types, key species condition, big game use, and domestic livestock grazing will be inventoried and mapped. Treatment units will be identified and treatments prescribed on a scheduled basis to maintain key forage and browse species. Treatments will be monitored to assure appropriate forage and browse allocations for big game.
Management, including vegetation manipulation, structures, and prescribed fire to maintain or improve winter range, may be apparent. Livestock use of forage will be conducted in harmony with big game winter range habitat needs.

Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, may be evident along with associated changes in fuel loadings and plant succession, in areas reserved for big game cover.

MA-F21. General Forest Winter Range Emphasis

Manage for timber production, with measures taken to maintain habitat effectiveness for big game. Design and implement management activities to recognize big game habitat needs.

Desired Condition

Big game use on winter range will be the primary activity, with other management activities and human intervention restricted from December 1 to May 1. Habitat effectiveness will slowly decrease in this area, mainly due to future reductions in quality and quantity of thermal cover. This decrease will not be as rapid as in MA-22 General Forest, due to specified road closures and other incidental wildlife improvements. Road and trail use will be limited to one mile of open access per section during December 1 to May 1, but up to three miles per section will be available during the remainder of the year.

Fire occurrence will be visible where lightning and human-caused starts occur and where prescribed fire is applied.

Management activities will take into account vegetation types and successional responses in order to apply prescriptions which have beneficial results for habitat. Areas of particular importance as big game habitat will be identified and management activities modified to complement, protect, or improve habitat. Livestock use of forage will be conducted in harmony with big game winter range habitat needs.

Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, may be evident along with associated changes in fuel loadings and plant succession, in areas reserved for big game cover.

MA-F22. General Forest Emphasis

Produce timber and forage while meeting the Forest-wide standards and guidelines for all resources. In ponderosa pine stands, management will emphasize production of high-value (quality) timber.

Desired Condition

Most ponderosa pine stands and some mixed conifer stands on slopes less than 30 percent will exhibit the application of uneven-aged management. Trees up to 20 inches DBH will be seen in these stands, and the evidence of trees managed for high quality lumber (where the first log is relatively free of limbs) will be noted.

Most mixed conifer timber stands, most stands on slopes greater than 30 percent, and some pine stands not suitable for uneven-aged management will be seen as even-aged, with trees uniformly spaced and fully occupying the site, except in seedling and sapling stages. Regenerated stands will generally be 20 to 40 acres in size. A mix of species, with emphasis on the seral species such as pine and larch, will be evident where conditions permit. The largest trees will generally be 18 to 22 inches DBH, but larger ones may be found where left for snag replacements or other resource reasons. Snags will be apparent over the area with potential snag habitat managed at the 20 percent level for Alternative B-M, and at the 40 percent level for Alternative I.

A variety of native grasses, sedges and forbs will be available for grazing animals. Competition from nonforage species such as sagebrush and juniper will not be a major problem. Most of the forested range lands will be in fair and good forage condition class. Forage use will be apparent, and improvements installed to facilitate stock distribution and effective
use of available forage will be evident.

Following use for timber haul, local access routes with planned future use will generally be open to high clearance access (maintenance level 2) for Forest visitor and administrative use, unless there are significant reasons to do otherwise. Access routes/trails will be developed to offer a variety of terrain and experience levels for ATV’s, and users will be restricted to these areas. Recreational off-road motorized use will be allowed, but users will be encouraged to use designated routes in order to protect Forest resources such as soils and water quality.

Dispersed sites will be scattered throughout the area. These sites will be maintained in as natural a condition as possible.

Fire occurrence will be visible where natural lightning or human-caused starts occur, and where prescribed fire was applied.

MA-F23. North Fork Crooked River Recreation Corridor
Emphasis
Maintain the appearance of a natural landscape in the foreground view from Road 42. Protect and enhance public use and enjoyment of the river segment.

Desired Condition
This segment of the North Fork of the Crooked River will be a free-flowing river whose shorelines may be accessible by roads. The immediate river environment (up to one-quarter mile from the river) will appear natural, though there may be evidence of past and ongoing timber harvest and grazing. Developed and dispersed campsites and interpretive signing will be seen throughout the area. The use of prescribed fire may be evident where used to enhance the retention of featured tree species such as old growth ponderosa pine or western larch.

MA-F24. North Fork Crooked River Scenic Corridor
Emphasis
Maintain and enhance a natural appearing landscape to protect the “scenic river” designation.

Desired Condition
This segment of the North Fork of the Crooked River will be seen as a free-flowing river whose shoreline is accessed by a road. The immediate river environment (up to one-quarter mile from the river) will have an overall natural appearance, though there may be evidence of past timber harvest. Other management activities will be evident, including dispersed campsites and interpretive signing. A low standard trail will be developed that will require wading or rock-to-rock natural crossings. Prescribed burning will be apparent where used to enhance the retention of featured tree species such as large old growth ponderosa pine and western larch.

Several stands have been designated for old growth within the scenic river corridor. Where old growth restrictions are more restrictive than scenic river restrictions, the old growth prescriptions will apply.

Emphasis
Maintain and enhance the scenery along U.S. Highway 26.

Desired Condition
The U.S. Highway 26 Corridor will be managed to maintain the big tree appearance; activities will not be evident to the casual Forest visitor. Vegetation will be manipulated in order to provide a variety of size and age classes of timbered stands, including open parklike stands of old growth ponderosa pine, dense shaded stands of mixed conifer, and small openings with planted and natural tree seedlings. Both uneven- and even-aged stand conditions will exist.
An established road system will be in place but will have been designed to minimize the visual effect on the landscape. Prescribed livestock grazing is planned. Pastoral scenes will add to visual variety. Prescriptive grazing will be designed to be in concert with the visual quality objectives of the area.

Wildlife may be viewed in the corridor. This might include big game and a variety of bird species. The effects of fire will be periodically evident, as a result of natural and prescribed burning.

Dispersed recreation sites will be abundant throughout the corridor. Camping will be encouraged, except where restricted for other resource reasons, such as streamside management areas along Mark’s Creek. Snowparks for winter recreation will be constructed to blend into the surroundings.

**MA-F26. Visual Management Corridors**
(This includes all visual management areas outside of other special management areas, e.g. Highway 26, Summit Trail, etc.)

**Emphasis**
Maintain the natural-appearing character of the Forest along major travel routes, where management activities are not evident, or are visually subordinate to the surrounding landscape.

**Desired Condition**

**Prescription Area A**
This area will encompass about 86 miles of Forest roads and include approximately 9,300 acres of associated landscape. The outer boundary of the Management Area will generally not exceed 600 feet on each side the road. Retention will be the visual quality objective. Long-term management activities will not be visually evident to the casual observer.

Forest visitors will encounter a diverse landscape which reflects ecosystems where management activities appear as a natural condition.

Vegetation will be manipulated, but will reflect a natural forest setting. Stands of trees will exist in multiple age classes, from young seedlings to mature old growth in both uneven- and even-aged conditions. Unique characteristics of the landscape, such as rock bluffs and aspen clones, will be highlighted, where they are currently hidden from view due to existing vegetation.

**Prescription Area B**
This area will encompass about 174 miles of Forest roads and include approximately 23,960 acres of associated landscape. The outer boundary of the management area will generally not exceed 600 feet on each side the road. Partial retention will be the visual quality objective. Long-term management activities may be evident but will be visually subordinant to the characteristic landscape. Forest visitors will encounter a near-natural scenic view, with a diverse ecosystem reflecting a low level of management.

Vegetation will appear manipulated. Stands of trees, in multiple age classes in both uneven- and even-aged conditions, will occur in a background of rock outcrops, aspen clones and native grass communities.

**Prescription Areas A and B**
An established road system will be in place, but will have been designed to minimize the visual effect on the landscape. Grazing by livestock may or may not be visible immediately adjacent to these roads.

As a consequence of visual management, an abundance of wildlife may be viewed in the corridor. This might include big game, a variety of bird species, and fish. The affects of fire will be periodically evident as a result of natural and prescribed burning.

**MA-F27. Round Mountain National Recreation Trail**

**Emphasis**
Protect and manage for scenic qualities which make the trail corridor an attractive recreational setting. Rehabilitate trail sites where management activities conflict with National Recreation Trail objectives.

**Desired Condition**
The visitor will note a naturally appearing forest along the majority of the trail route (visual quality objective of retention). The outer boundary of the management area will generally not exceed 600 feet.
on either side of the trail. The Round Mountain National Recreation Trail will be linked to trails on Lookout Mountain and the access road to the Summit of Round Mountain, as well as to Walton Lake Campground, through appropriate signing. Recreational improvements will be evident in those locations where necessary to protect the land, for public safety, and to enhance the public’s enjoyment of the area.

Old growth stands will be seen within the management area. Fire occurrence will be evident where natural lightning and human-caused starts occur. Rehabilitation will be done in areas visually impacted by past management activity.

MA-F28. Facilities
Emphasis
Provide a safe, efficient, and healthful working environment where structure design and layout of the site blend with the surroundings.

Desired Condition
Sites will be efficiently designed work areas consistent with type and intensity of use. Employee wellness and public safety will be the primary design criteria. Color and design of structures and facilities will blend with the surrounding environment.

Traffic controls and signing will be designed to provide a safe driving environment. Roads and trails will be planned, designed, operated and maintained to levels sufficient to provide safe use for the intended traveler.

The historical significance of buildings and structures will be considered during any modifications to the site.

Employee residential areas will be designed to meet employee needs.

Management activities, such as timber harvest, thinning, and fuel treatments for the protection of facilities from wildfire, may be apparent on a short-term basis.

Grassland Management Areas

MA-G1. Antelope Winter Range
Emphasis
Manage for optimum winter range conditions for antelope.

Desired Condition
This Management Area will consist of generally open grassland with shrub heights at or below 24 inches, but not over 30 inches in height. Range improvements that facilitate antelope migration will be constructed. Harassment and stress on wildlife caused by motorized vehicle traffic will be reduced.

Fall greenup will be reserved for use by antelope during winter.

MA-G2. Metolius Deer Winter
Emphasis
Manage for big game winter range habitat.

Desired Condition
Management in this area will support the Oregon Department of Fish and Wildlife management objectives for the wintering deer population. A 60/40 forage/cover ratio, and a vigorous shrub overstory will be maintained. Private land will be acquired when possible. The implementation of seasonal road closures will reduce harassment and stress on wildlife from motorized traffic. Early season livestock grazing will be used as a vegetative management tool to maintain forage in a palatable condition. Fall greenup will be reserved for deer forage. A management plan for the entire winter range area will be developed in coordination with Oregon Department of Fish and Wildlife.

MA-G3. General Forage
Emphasis
Manage for forage production and utilization in a manner consistent with general standards and guidelines for other resources.
Desired Condition
Structural and nonstructural range improvements, prescribed fire to increase the palatability of desirable species, and livestock management will be used to maintain or increase forage production. The natural composition and cover values of native grasses, sedges, forbs and palatable shrubs will be retained. Competition from undesirable forage plants, such as sagebrush and juniper, that decrease range productivity will be reduced. Proper stocking levels and distribution will be employed to effectively utilize forage production without adversely affecting plant communities. Areas planted in crested wheatgrass will proceed through natural succession to reestablish native plant species, unless specific resource management objectives can be better met by maintaining certain pastures in crested wheatgrass. Aspen clones will be allowed to regenerate. The occurrence and increase of noxious weeds will be prevented. A variety of native and introduced grasses, sedges, and forbs will be provided for grazing animals. Improvements that facilitate stock distribution and the effective use of available forage will be installed.

MA-G4. Research Natural Areas
Emphasis
These tracts of land are areas where natural processes are maintained for research purposes and education. They will provide baselines against which other activities may be measured, sites for study of natural processes in undisturbed ecosystems, and gene pool preserves for both plant and animal species.

Desired Condition
Natural conditions will be maintained. Any management activities within the RNA’s will be directed at maintaining the natural conditions of the area, and these human-caused changes to the ecosystem will not be readily evident. Continuing, nondestructive baseline studies may be occasionally visible in terms of equipment, instruments, and related activities.

Fire occurrence will be evident where natural lightning and human-caused fire starts occur.

If available, the private land on Haystack Butte RNA will be acquired.

MA-G5. Juniper Old Growth
Emphasis
Provide habitat for wildlife species dependent on old growth stands.

Desired Condition
The common flicker is the management indicator species. Stands at least 40 acres in size and not more than five miles apart will be maintained. Trees should be large with hollow centers and have broad, irregular-shaped crowns or spike tops. Most of the large trees, both live and dead, should support lichen growth. Cavities should be evident in the trees from either bole splits and/or limbs that have broken away from the tree bole. Some younger trees may be present along with various grasses, forbs, and shrubs. Management activities and roads will generally not be evident. Fire occurrence will be evident where lightning and human-caused starts occur. Grazing by livestock, as well as by big game wildlife species, may be evident.

MA-G6. Crooked River Recreation Area
Emphasis
Maintain the appearance of a natural landscape to enhance and protect recreational values.

Desired Condition
The natural and scenic qualities of the river corridor will be preserved, as required by the Wild and Scenic Rivers Act.

A trail system and dispersed campsites will be developed to assist in public enjoyment of the area.

MA-G7. Deschutes River Scenic Corridor
Emphasis
Manage for scenic quality and natural appearance of the landscape.
Desired Condition
The natural and scenic qualities of the river corridor will be preserved as required by the Wild and Scenic Rivers Act. A trail system will be developed to provide access to the area. Dispersed campsites will be designated to aid in management of the area.

MA-G8. Squaw Creek
Emphasis
Provide opportunities for semiprimitive nonmotorized recreation in a pristine canyon setting while protecting and enhancing the deer winter range habitat and fisheries. A 1,370-acre corridor along the creek will be managed for its scenic quality as a "scenic river."

Desired Condition
A travel management program will restrict vehicle access seasonally, except for administrative and special uses. Private inholdings which facilitate management of the area will be acquired when possible. Recreational use, livestock grazing, prescribed fire and wildfire will occur, but the area will appear natural. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Fire occurrence will be evident where lightning and human-caused starts occur.

A corridor along the creek from the Grassland boundary to the confluence with the Deshutes River has been determined to be suitable for designation as a scenic river under the Wild and Scenic Rivers Act. This corridor will be managed to preserve and, or enhance its natural and scenic qualities.

MA-G9. Riparian
Emphasis
Maintain riparian habitat, including streambank stability and fish habitat capability, at existing levels where the desired condition is met. On sites where the desired condition is not met, take steps necessary to bring riparian condition to its ecological potential. Allow no activities that will result in a deterioration of water quality in perennial and fish bearing streams.

Desired Condition
General: On-the-ground work and management changes are needed to improve riparian conditions on approximately 1,250 acres of the Grassland, all but 400 acres have been completed. Remaining work will be completed in the first decade. However, it will take from 20 to 60 years for some of these areas to heal and function fully as natural systems.

Rehabilitation activities include fencing, seeding, planting, and installation of physical structures such as rock structures, check dams, and log weirs. Changes in livestock management are an important part of this strategy. Range allotment plans will reflect forage utilization levels necessary to meet brush and hardwood protection or enhancement needs.

Specific projects are shown in the Riparian Improvement Schedule in Appendix A.

Work to restore riparian areas will have been completed, but not all riparian areas will have had time to recover to full biological potential. Many streams that presently flow only seasonally will flow year-round. The potential for overland flows and delivery of sediment to streams from upland areas will have been reduced by construction of improvements such as fences, the development of dispersed water sources, and adjustments in grazing systems. Water quality will be maintained or improved to meet state standards for temperature and turbidity.

Stream Channels: Establish a shady, brushy condition with a canopy of alder, willow, aspen, or other deciduous vegetation. Sites unable to support a canopy of deciduous species will be characterized by vigorous stands of forbs, grasses, and grasslike riparian species. Although cobbles and gravel are often prominent features during the development of riparian stream courses, they become covered by sandy loam soils as riparian vegetation filters and traps stream sediments. As stream banks are rebuilt and stabilized, a narrower, deeper channel will gradually develop.

Springs: Manage springs to maximize water storage and support excellent condition riparian vegetation. These ecosystems should support deciduous vegetation where such vegetation was present in the past
At spring sites not associated with deciduous vegetation manage the riparian area to support vegetation associated with excellent condition. These spring areas will not show signs of compaction, channeling, or head cuts.

Wet Meadows: Manage wet meadows to support vegetation associated with excellent conditions such as forbs, grasses, reeds, sedges, and rushes. These areas will not show signs of channeling or gully development of sufficient size to lower the seasonally saturated zone and change the plant community type. These zones should be showing no signs of invasion from nonriparian species such as rabbitbrush, sagebrush, or juniper.

MA-G10. Rimrock Springs Wildlife Area
Emphasis
Provide unique habitat (wetlands, ponds, springs) within the juniper-sagebrush steppe. Provide for nonconsumptive (viewing, photography) wildlife uses in a natural setting. Improve present habitat conditions and promote habitat diversity.

Desired Condition
Increased opportunities for wildlife viewing and photography, including a barrier-free interpretive trail and a brochure will be provided. Barrier-free toilet facilities will be available at the trailhead. Interpretation of unique cultural resources will preserve early history of the area. Prescribed fire will be used to improve habitat.

MA-G11. Haystack Reservoir
Emphasis
Provide users with a system of quality facilities that are safe and environmentally sound. Continue to emphasize camping, picnicking, boating, fishing, and swimming.

Desired Condition
The existing partnerships will be continued and new ones explored to provide for the needs of the recreational users. Bureau of Reclamation (BOR) lands around the reservoir will be acquired to simplify management of the area; BOR would retain ownership and management of the dam. New and upgraded facilities will provide for barrier-free opportunities.

MA-G12. Cove Palisades State Park
Emphasis
Manage for developed campgrounds and water related recreational activities.

Desired Condition
The landbase needed by the State to operate a high-quality developed recreational facility on the shores of Lake Billy Chinook will be provided. Other resources within the park boundary will be managed to support this goal.

MA-G13. Lake Billy Chinook View Area
Emphasis
Maintain the natural appearing character of the viewshed from Lake Billy Chinook, where management activities are not evident or are visually subordinated to the surrounding landscape.

Desired Condition
The natural and scenic qualities of the management area will be preserved.

MA-G14. Dispersed Recreation
Emphasis
Provide and maintain a near-natural setting for outdoor recreational experiences.

Desired Condition
Within the immediate dispersed site, management activities will not be evident to the casual observer. Activities may be evident in areas adjacent to the site, depending on the management prescription applied to them. Primitive, user-constructed structures or facilities, consistent with the sites' use, will be seen. Sites will be managed so that users tend to feel relatively isolated. A strategy will be developed that encourages individuals or groups to "find their own place." Livestock grazing may be evident, but the successful application of allotment management requirements will also be evident.
MA-G15. Gray Butte Electronic Site

Emphasis
Manage the site to provide low power output electronic equipment. Limit transmitters to a maximum of 150 watts.

Desired Condition
All development should meet partial retention from important viewpoints. Minimize interference potential through facility design, location, spacing, capacity and establishment of site-noise floor limits. Meet user needs, and maximize utilization of the site. Three buildings and three towers will be allowed at the site.

MA-G16. Utility Corridors

Emphasis
Accommodate energy-transmission facilities.

Desired Condition
Future development will be confined to existing corridors. No windows for future development will be designated. Identify exclusion and avoidance areas. Through design and management, the use of lands allocated to power facilities will be optimized. The proliferation of separate rights-of-way will be discouraged to reduce the cumulative environmental impact of linear facilities. The creation of corridors in addition to those currently designated will be discouraged.

Modeling Characteristics

Many new management prescriptions have been developed and included in the FEIS. In Table B-3-5, it is evident that many of the management emphases from the DEIS and FEIS are similar in their treatment of the resources. Because the Ochoco's FORPLAN model deals primarily with those activities that manipulate vegetation, it is possible for the Ochoco's FORPLAN model to group many different management areas if their vegetation treatment activities are similar. Table B-3-6 displays the FORPLAN groupings for all management area prescriptions. The following text explains some of the modeling characteristics of each.

Certain parts of the Forest and Grassland may be designated to meet wildlife, recreation, aesthetic, or scientific objectives in a particular alternative. Prescriptions applied to these areas contain moderate to completely binding constraints on timber and range management. These prescriptions include all those described above except the timber/range management area prescription (Group VII). The Group VII management prescriptions in the DEIS emphasize only timber and/or range production and allow a high degree of flexibility in the application of activities to the ground. Depending upon the analysis area to which they are applied, several dozen to several hundred columns represent these activities in the LP. In the FEIS, the Group VII management area prescription had Management Intensities, timing choices, and Right Hand Side constraints added to address resource concerns (uneven-age management, rotation ages, big game cover). As a result, other resource objectives besides timber and range may be emphasized.

The emphasis for management area prescription Groups VI and VIII are similar in that the primary objective is to produce elk habitat through control of cover and forage unit, amounts, sizes, and spacings. The key factors in regulating habitat conditions on the Ochoco are the control of cover and road use. The main factors affecting cover are the presence or absence of precommercial thinning, stocking level, and whether it is a ponderosa pine or mixed conifer working group. Relative cover values are used as coefficients in the LP based upon the concept that a stand provides differing levels of protection to an animal depending upon stand density. Use of relative cover values based upon the crown closure of the stand refines the ability of the LP to differentiate among eligible columns in order to satisfy big game cover and forage objectives. These are expressed as Right Hand Side constraints and applied to contiguous blocks of land. Considerable flexibility for response to multiple objectives or constraints is contained in the applicable columns.

Although management objectives differ, management area prescriptions in Group I are modeled in a similar manner. Each of these prohibits timber harvesting and the application of intensive range
**TABLE B-3-5**
**PRESCRIPTION STANDARDS AND GUIDELINES**

This Table Summarizes and Compares the Following Elements for Each Management Area Prescription

<table>
<thead>
<tr>
<th>Prescription</th>
<th>Timber</th>
<th>Range</th>

1/ Management area prescriptions were not developed for Grassland management areas in alternatives A, E, and NC.
practices. Consequently, they are represented in the LP as single columns. The effects of applying these prescriptions are simulated. Information about resource trade-offs and allocation efficiencies were developed through successive model runs. Objectives for the size, distribution, and stability of old growth units, and an evaluation of the trade-offs required from other resources led to the use of this dedicated stand approach for old growth (see Planning Records, 1920, 6/21/84).

Two groups of prescriptions, Groups II and III, are dealt with in a similar manner. Management activities are very constrained in these areas, although some timber harvesting is permitted. These areas are, in effect, pre-scheduled so that negligible room for optimization exists. Accordingly, these prescriptions are modeled in the LP as single columns so that the effects of their application can be simulated.

Although the management objectives differ for management area prescriptions in Group IV, V, and IX, they share modeling characteristics. Although the numbers differ for all three, extended rotation ages and restrictions on timber cutting unit rates and sizes distinguish scenic prescriptions from the rest. Spatial control achieved within our modeling framework allows the imposition of Right Hand Side rate of cut constraints on the management Areas as a unit. Several dozen columns representing alternative activities and schedules contribute to this constraint. Rotation age constraints are represented in the per acre treatment columns.

Modeling Prescriptions

In order to understand the details of how management prescriptions are structured in the LP, some knowledge of FORPLAN data structures and terminology is required. Two types of modeling prescriptions are recognized in FORPLAN. "Existing prescriptions" are specific to each analysis area and cover treatments applied from the present until the stand is regenerated. These prescriptions apply to the entire planning horizon for options not involving regeneration of timber stands. "Regenerated prescriptions" cover one full rotation from regeneration harvest and apply to specific regeneration classes. In general, there are fewer regenerated prescriptions than existing prescriptions, because there are more analysis areas than regeneration classes, and only those existing prescriptions involving timber harvest need to link with a regenerated prescription. These prescriptions are structured into the LP differently depending upon whether a Model I or Model II matrix (Johnson and Scheurman 1977) is being generated by FORPLAN. The example given earlier is a Model I formulation, as is the Ochoco model. Each column contains a set of activities over the entire planning horizon. Each set is composed of an existing prescription plus the number of cycles of the associated regenerated prescription necessary to reach the end of the planning horizon. Both existing and regenerated prescriptions are structured at three levels in FORPLAN. The broadest level is termed the "management emphasis" of a prescription, which in the Ochoco's case ties directly to management prescriptions. There may be multiple sets of activities within each management emphasis labeled as different "management intensities". Each of these management emphasis-management intensity combinations may contain a range of intermediate and regeneration harvest timings at the third level. A specific column, then, is composed of one activity schedule covering the entire planning horizon for a particular management emphasis and intensity for both existing and regenerated prescriptions.

The modeling prescriptions used in FORPLAN are best described in terms of the activities represented by each. Again, these practices are the timber and range activities affecting vegetative growth and yield. Timber practices modeled included overstory removals for existing two-story stands, uneven-aged (single tree or group selection) management, commercial thins, precommercial thins, reforestation methods, and shelterwood and clearcut regeneration harvests. In many cases stocking levels and timing patterns also differed from one management intensity to another. Within a management intensity, the timing of intermediate cuts was fixed for regenerated prescriptions to reduce model size but flexible for existing prescriptions. Uneven-aged management
entry cycles were fixed for a particular management emphasis but varied between emphasis.

Regeneration harvest can be scheduled in every eligible period of the planning horizon for existing prescriptions. There is a range of five periods in which regeneration harvest may occur for regenerated prescriptions. Rotation ages range upward from 95 percent of culmination of mean annual increment for the Group VI, VII, and VIII management emphases, with longer rotations for the other prescriptions. There is one exception to this in the FEIS. In Alternative I, the rotation age for pine stands was increased well beyond culmination in Groups VI and VII. Choice of regeneration harvest method depends upon site specific factors that could not be reasonably modeled. Recognizing that these assumptions would not apply on every case but would in aggregate balance out, all pine regeneration harvests were modeled as shelterwoods and mixed conifer harvests as clearcuts. A similar situation occurs for choice of logging method. The assumption in this case was that tractor logging would be used on slopes less than 30 percent, and cable methods for steeper analysis areas. Range practices modeled included mechanical or non-mechanical forage treatments and the associated structural improvement levels. Scheduling flexibility was built into prescriptions calling for these practices, allowing their implementation anytime during the first five decades. Once the activity is implemented, periodic treatments to maintain that production level are scheduled.

The selection of management intensities for each management emphasis was designed to ensure that either cost-efficient combinations of practices appropriate for specified objectives were represented, or to ensure the objectives would be met. For example, uneven-aged management intensity was forced into solutions in several management emphasis. A broad, evenly dispersed sample of the potential production possibilities for most management emphases was also maintained. Silvicultural options for existing stands and range practices could all be reasonably accommodated within FORPLAN. However, more potential treatment options for managed stands exist than could be included in the LP. Thus, the Ochoco undertook an economic analysis of a wide array of managed timber yield tables (see Planning Records, 1920 12/22/82 and 8/31/82). This analysis is referred to as “Stage II”.

Stage I
The Stage II analysis considered over 30 different combinations of reforestation practices (planting vs. natural regeneration, stocking level, presence or absence of precommercial thins). Timing and number of commercial thins were tested for ponderosa pine and mixed conifer, for both under and over 30 percent slope.

Each of the thirty-four timber yield tables for managed stands had a soil expectation value (SEV) calculated using the rotation age of culmination of mean annual increment, and a four percent discount rate. These are displayed in Table B-3-7 for both tractor and cable ground. Soil expectation value was judged to be the best measure for establishing a relative ranking of managed yield tables, since the sequence of practices starts from bareground. These rankings are sensitive to cost and value assumptions. In general, the less intensive management regimes ranked higher in SEV. However, these regimes also have longer rotation ages and provide considerably less volume which, if selected, would result in a lower rate of harvest of the existing high valued stands. These observations point out the need to provide the LP with the opportunity to perform this balancing act by providing a wide range of intensities and scheduling possibilities.

A set of criteria, of which SEV was only one, were developed and used to guide the process of selecting the managed yield tables to be included in the Forest’s FORPLAN (LP) model. One of the primary criteria was to provide a wide range of intensities to ensure examination of a full range of management opportunities. Related to this criterion was the need to provide a wide range of scheduling opportunities to ensure maximum flexibility for the LP. Accordingly, the timber management strategy includes yield tables with early rotation ages and/or early thinning volumes, as well as an intensity maximizing total merchantable volume. Economic criteria also weighed

1/ Rotation age used was that of culmination of mean annual increment, except for Table 32 which was 95% of culmination.
2/ This set of practices include a higher stocking level and a delayed commercial thinning.
3/ Soil Expectation Level (SEV) calculated using a 4% discount rate.

- P: Plant to increased stocking levels
- P: Plant at current stocking levels
- N: Natural regeneration
- Pct: Precalibrated thinning
- CT1: One commercial thinning
- CT2: Two commercial thinnings, 20 year interval for ponderosa pine and mixed conifer
- CT3: Three commercial thinnings, 30 year interval for ponderosa pine and mixed conifer
heavily in the selection process. A table that maximized per acre SEV, and a minimum investment yield table were included. Additionally, when other factors were nearly equal, the table with the highest SEV was selected. The resource emphasis of each strategy was also of primary importance.

The quantity and quality of big game cover was a primary criterion for big game-oriented management strategies. Range emphasis requires relatively open stands with multiple entries. Riparian standards require less intensive management, with few entries and provision for shade. The semi-primitive motorized management strategy also requires less intensive management in an attempt to provide a “natural” appearing environment. Scenery prescriptions depend mostly on longer rotation ages and provision for large, yellow-bark trees. One final criterion used was that, if every other criterion was equally satisfied, practices reflecting current management were favored. Table B-3-8 depicts the tables selected for each management strategy and the particular criteria underlying each choice. In most cases several criteria influenced the selection of a particular yield table.

Development of Yields

Timber

Timber yield tables containing both harvest and inventory volumes were constructed for all of the modeling prescriptions described in the previous section. Detailed documentation of the assumptions made and procedures followed are contained in Ochoco planning files (Existing Yield Tables, 4/13/83; Managed Yield Tables, 4/18/83). Yield tables used for the existing prescriptions were based upon empirical yield tables constructed by Regional Office personnel from data gathered in the 1981-1982 Ochoco timber inventory, and show merchantable growth into the future. These yields are specific to each of the eight inventory components modeled: 1) ponderosa pine-seedlings/saplings, 2) ponderosa pine-poles, 3) ponderosa pine-sawlogs, 4) ponderosa pine-two storied, 5) mixed conifer-seedlings/saplings/poles, 6) mixed conifer-sawlog, 7) mixed conifer-two storied, and 8) ponderosa pine-low site. Some of these categories contain acreages and averaged yields from other components merged together because of small acreages. Yield tables for existing prescriptions calling for overstory removals or intermediate harvests also relied upon information developed for managed yield tables with the Prognosis Model (Wykoff et al. 1982).

The forest silviculturist calibrated the North Idaho variant of Prognosis for use on the Ochoco. This model was used to develop managed yields for ponderosa pine and mixed conifer regenerated prescriptions. Growth and yield patterns were developed that reflected reforestation practices, stocking levels, thinning, and regeneration harvests. Ponderosa pine-low site managed yields were constructed from a local model called Growth and Yield IV (Wood 1979) and a Regional Managed Yield Tables Program (USDA-Forest Service, not dated). No additional yield differentiations were made for productivity variations or unroaded areas. Use of timber yield tables representing one forest-wide average productivity for ponderosa pine, and one for mixed conifer resulted primarily from our timber inventory being conducted at that level of resolution. Forest-wide average yields limit the degree of optimization attainable and the level of geographic specificity feasible. Yield tables for different management emphases have reductions for snag levels built into the yield stream. In many cases several yield tables have been constructed with the same set of activities but with different snag levels. We then altered the snag level of a prescription set to meet different mixtures of objectives and to evaluate associated trade-offs.

Between the DEIS and FEIS, the Forest developed uneven-aged yield tables in response to public comments. Again the PROGNOSIS model was used and tables were developed for ponderosa pine two-story and sawlog stands. It was felt that uneven-age management was biologically inappropriate, too costly, or involved too few acres to be applied to the other stand types (See Planning Record 1920). The Forest also developed new managed yield tables for ponderosa pine. These tables have a new pre-commercial thin spacing. The purpose was to provide some protection against Mountain Pine Beetle susceptibility; yet provide some cover for big game. The Forest also evaluated its managed pine tables in the context of extended rotations beyond the culmination of the mean annual increment. In this case it was felt that the yield tables were suitable and the changes were made in the FORPLAN prescriptions.

Livestock Forage

Livestock AUM (animal unit month) yields were monetarily valued in the LP using the values obtained for the Ochoco through the USDA-Economic Research Service ranch budget study (see Planning Records, 1/24/83). The process used for estimating AUM yields was based upon forage production figures obtained by averaging yields in the “Plant Communities of the Blue Mountains in Eastern Oregon and Southeastern Washington” (Hall 1973) for the productivity types modeled. Basic yield categories were established for the five major cover types, i.e. 1) ponderosa pine, 2) mixed conifer, 3) timbered lands producing less than 20 ft/ac/yr, 4)
tree shrub types, and 5) grassland types. One average yield was used for ponderosa pine, and one for mixed conifer types. Yield variation associated with differences in existing timber stand density, and changes in stand density according to the treatments prescribed were modeled as joint production functions with timber. Broad productivity distinctions were modeled for the three remaining cover types as indicated by the working group and condition class analysis area identifiers (Table B-3-4). The application of mechanical or non-mechanical range treatments to the ground results in increased forage yields. Several of the management prescriptions allow these types of activities. Tables B-3-9 through B-3-14 display the structure of these practices in the modeling prescriptions.

The translation of forage production into livestock production occurred through the use of two related factors. The first, a utilization factor, represents the amount of forage produced that is utilized by livestock. This factor is distinctly different for analysis areas with slopes less than 30 percent versus those with steeper slopes. Utilization differences are incorporated into the riparian prescriptions to allow attainment of different objectives. Other prescriptions use the same utilization factors.

The high producing grassland types (non-native wheatgrasses) are a special case requiring greater amounts of utilization to maintain plant vigor. The second factor represents the amount of area, expressed as a percentage, over which the average utilization is expected to occur. This distributional factor is tied to the level of water developments present on an allotment as well as topographical features. The modeling recognizes different distribution percentages for the National Grassland versus the National Forest based upon the types of developments in place, and the differing purposes of the two units. Major variations also occur according to the slope break. Management prescriptions state whether or not additional water developments are appropriate.

The scheduled outputs used for AUM yields incorporate all of the elements just described into a periodic livestock output. The use of scheduled outputs for mechanical and non-mechanical treatments provides the ability to control the amount of treatment allowed within a management area. This control is necessary to meet management area objectives since we are using homogeneous per acre variables. A scheduled output table is also necessary to incorporate correct costs into the matrix for range treatments. Costs are included for mechanical and non-mechanical treatments on the different cover types. Also, broad average costs are associated with the livestock distribution levels.

**Cover for Big Game**

Another major use of scheduled outputs is to track and control the provision of cover for elk. Tables showing the effects of each ponderosa pine and mixed conifer modeling prescription on cover are input to FORPLAN. Use of relative thermal cover values based upon the crown closure of the stand refines the ability of the LP to differentiate among eligible columns in order to satisfy big game habitat objectives expressed as right hand side constraints. Geographic control in the model is necessary to ensure that these constraints are applied to contiguous blocks of land. The theoretical framework for these relative values derives from several sources as documented in Ochoco planning records (“Process for Evaluating Elk Habitat”, undated). The main concept is that a stand provides more or less protection to an animal depending upon stand density. Values used are keyed to the annual energy balance of an individual elk in Central Oregon. Patterns of cover, based on timber practices, and the values used are considerably different for ponderosa pine versus mixed conifer. The main activity affecting provision of cover is the presence or absence, and stocking level of precommercial thins and the amount of uneven-aged management. Different values are used for the summer range and winter range prescriptions.

Overview of Constraints

Different types of constraints are used in the LP to represent different types of objectives. Some are incorporated directly into the columns through the yield tables. Snag levels and rotation age constraints are the primary objectives and policies treated in this manner. Another category of constraints are those applied to the selection of prescriptions. Acre-ages of management emphases by analysis area are constrained as previously described to ensure management prescription objectives are validly modeled. The remaining type of constraint is applied as a Right Hand Side constraint to some subset of columns in order to satisfy management requirements, meet harvest flow policies, attain the objectives of a management prescription or alternative, or evaluate economic implications. Section 7 describes these constraints more fully.

Management requirements modeled with right hand side constraints included timber harvest dispersion and riparian area harvest restrictions. Dispersion constraints necessary to meet water quality standards, and to meet Regional requirements, were applied on an individual analysis area basis, and reflect watershed conditions (see Appendix E). These limit the amount of area that can be regeneration harvested in one decade. Riparian area harvest limitations were also designed to meet water quality standards, by ensuring shade and limiting disturbance.

Three different types of constraints are necessary to meet harvest flow policies. The nondeclining yield policy is imposed through a series of constraints limiting the harvest of any decade to an amount greater than or equal to that of the previous decade. The policy of limiting harvests to an amount equal to or less than the long run sustained yield is also met through the nondeclining yield constraint in conjunction with constraining the last decades harvest to not exceed that quantity. The ending inventory constraint provides some assurance that the projected harvest levels can be maintained over time by requiring standing volume to equal or exceed the average inventory of the regulated forest according to the regenerated prescriptions selected. Departure policies were also allowed by adjusting the long run sustained yield constraint, and by loosening the nondeclining yield constraints to allow some downward flow variation.

Several groups of constraints are applied as right hand side constraints in order to meet the objectives of management prescriptions. Amounts of thermal cover provided, rates of harvest in visual zones, and acreage limits on range practices fall into this category. Elk cover constraints apply separately to the ponderosa pine and mixed conifer cover types at the district level. The process of determining the specific constraint values to use in the LP begins with the habitat objectives expressed in Ochoco management prescriptions. For any given run the location of big game management areas is determined and based on the total acres of these areas and the objectives of the prescription the amount of cover desired is calculated. Through map overlays accomplished with the Ochoco R2MAP data base amounts of cover provided by other management areas and non-timber cover types are subtracted from the total desired and the remainder distributed to the ponderosa pine and mixed conifer cover types. These values are then input as a range to the FORPLAN matrix generator.

Scenic area rate of cut constraints are also written separately for the ponderosa pine and mixed conifer cover types specific to the district level. These right hand side constraints limit the proportion of the area within these zones that can be regeneration harvested per decade. These proportions were developed based on the experience and judgment of landscape architects on the Forest. Acreage constraints limiting the area that can be treated by mechanical or non-mechanical methods are similar to scenic area rate of cut constraints. These limits derive from management area objectives and are applied at the district level for the timber/range and big game prescriptions. Budget constraints and output level controls were also used to meet the objectives of an alternative, or to evaluate budgetary and administrative implementation concerns.
Economic Efficiency Analysis

(Section 4)

Overview

This section describes the costs and benefits, as well as some concepts, involved in economic efficiency analysis, how they were derived, and how they were used in the Forest Planning process. Economic efficiency analysis is required by the National Forest Management Act Regulations (36 CFR 219) and played an important role in the development and evaluation of Forest Planning Benchmarks and Alternatives. Specifically, the Regulations (36 CFR 219.12(f)) state that:

"The primary goal in formulating alternatives, besides complying with NEPA procedures, is to provide an adequate basis for identifying the alternative that comes nearest to maximizing net public benefits."

They follow up in 36 CFR 219.12(F)(8) by stating that:

"Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in the alterna-

Changes Between the DEIS and FEIS

Clarification of opportunity cost and trade-offs and the updating of certain activity costs are the only major changes in this section.

Basic Concepts

Priced Benefits

Priced outputs are those that are or can be exchanged in the market place. Their quantitative values are determined by actual market transactions or by estimation methods that produce prices commensurate with those determined by market transactions. Timber, forage, and minerals are examples of commodities which are bought and sold in the market. Their values are determined through the interaction of buyers and sellers based on the supply and demand conditions in the market at the time of the transaction. RVD's, on the other hand, are not normally exchanged via market transactions. Their market values are estimated by using some market transaction data in combination with various theoretical techniques. Conceptually, these assigned values should be consistent and comparable to those values which were actually derived via market transactions (Rosenthal and Brown, 1985). Therefore, both assigned and market values for priced outputs are appropriate to use for calculating quantitative measures of efficiency such as Present Net Value.

Nonpriced Benefits

Non-priced outputs are those for which there is no available market transaction evidence and no rea-
sonable basis for estimating a dollar value commensurate with the market values associated with the priced outputs. In these cases, subjective non-dollar values must be attributed to their production. These values are qualitatively described rather than quantitatively. They may be either positive or negative. In fact, what may be considered to be a benefit to someone may represent a cost to someone else. Examples of nonpriced outputs include the maintenance of threatened and endangered species, natural and scientific areas, historical and anthropological sites, visual quality, and clean air.

Discounting

Financial analyses of alternative investment options usually involve cash flows over a fixed period of time in the future. Inherently, there is a time value associated with money. Due to man's propensity to consume now, a dollar today is worth more than a dollar ten years from now. Discounting is a process for adjusting the dollar values of costs and benefits which occur at different periods in the future to dollar values for a common time period so that they may be compared. Usually the common time period is the present. In which case, the discounted cash flow is referred to as the present value.

Present Net Value (PNV)

Present Net Value is the difference between the discounted value (benefits) of all outputs to which monetary values or established prices are assigned and the total discounted costs of managing the planning area. The maximization of Present Net Value was the criterion used to help assure that each alternative was the most economically efficient combination of outputs and activities needed to meet the objectives established for that alternative. Present Net Value calculations consider only the benefits for which market prices exist or can be assigned. On the Ochoco, the priced benefits included timber, recreation, wildlife, special uses, and range. These were compared against all Forest Service fixed and variable costs associated with managing the planning area, irregardless of whether they were incurred for the production of either priced or non-priced outputs, or as overhead expenses for general maintenance of the organization. Therefore, PNV is an estimate of the current market value of the priced forest resources after all costs of producing both priced and non-priced outputs and meeting other multiple-use objectives have been considered.

Net Public Benefits (NPB)

The maximization of net public benefits is a goal of the Forest Planning process. Net public benefits is the overall value to the nation of all outputs and positive effects (benefits) less all the associated Forest Service inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits cannot be expressed as a numeric quantity because it includes qualitatively valued nonpriced outputs.

Conceptually, net public benefits is the sum of the Present Net Value of priced outputs plus the full value of all non-priced outputs. The full value of non-priced benefits is used because the costs associated with their production is accounted for in the calculation of PNV. It is only necessary to identify the marginal values of non-priced outputs when management inputs are increased in order to provide these outputs at levels above current standards or legal requirements. In such cases, it is important to depict the physical, biological, and social dimensions of the non-priced outputs, as well as who will benefit and who will suffer from their production. Account should also be taken of any changes that may occur among the other non-priced outputs as a result of providing a particular non-priced output. In assessing the net public benefits of a particular alternative, it is necessary to judge whether the subjective value to society of its non-priced outputs exceeds the opportunity costs associated with their production.

Opportunity Costs/Trade-offs

Opportunity costs are defined as the value of a resource's foregone net benefit in its most economi-
cally efficient alternative use (FSM 1970.5). In its simplest terms it means "revenue foregone." In relation to the economic analysis performed for Forest Planning, it represents the decrease in maximized PNV of an alternative or benchmark when some alternative level of resource outputs are forced into solution. Therefore, opportunity costs measure the change in PNV for priced resource outputs, and can be used to measure the economic value traded off in order to produce other less efficient priced benefits or non-priced benefits included in net public benefits. On this forest, timber harvest is the most efficient use, therefore, the opportunity cost is associated with timber. This is not meant to imply that opportunity cost must always be tied to a loss of timber volume or that opportunity cost is the only criteria used to evaluate effects (see Trade-offs).

Trade-offs on the other hand are not consigned solely to economic parameters (revenue foregone). Trade-off is a more general term meaning forgoing of one thing in return for another.

**Income Distribution Effects**

There is another level of effects which are also a concern of National Forest Policy and Management. These are the welfare distribution effects influenced by the mix and level of outputs produced by the National Forest. They can be either positive or negative. Their impacts can also be local, regional, or national in scope. Some distributive effects such as changes in consumer prices or taxpayer costs have national level impacts. Others, such as induced jobs and income, or payments in lieu of taxes are more local or regional in nature. They are more related to questions of equity (i.e. who pays and who benefits) rather than efficiency. They are not assessed in the context of the efficiency criteria associated with the PNV and net public benefit concepts. However, these positive and negative distributive effects need to be assessed in conjunction with the net public benefit measures since equity objectives often influence efficiency objectives and vice versa. These will be discussed in more detail in Section 5.

**Parameters**

**Introduction**

In order to calculate the Present Net Value for each alternative, several assumptions had to be made regarding discount rates, demand curves, real dollar adjustments, and real price and cost trends. This section will summarize these decisions and their resulting parameters. A more detailed discussion can be found in various process records in the Supervisor's Office.

**Discount Rates**

Discounting requires the use of a discount rate which is an interest rate that represents the cost or time value of money in determining the present value of future costs and benefits. Two discount rates were used to calculate the Present Net Values for each benchmark and alternative. Both of them were real discount rates meaning that they were adjusted to exclude the effects of inflation (Real dollar adjustments will be discussed more below). According to FSM 1971.71:

> For evaluations of long-term investments and operations in land and resource management in the 1980-1985 planning period, a four percent real discount rate shall be used. Evaluations should also discount benefits and costs at the real discount rate used in the most recent RPA to determine sensitivity of alternatives to variations in the discount rate.

The four percent rate approximates the "real" return on corporate long-range investments above the rate of inflation (Row, et al., 1981). The 4 percent rate was used to solve FORPLAN and calculate the PNV for each benchmark and alternative. The 1985 RPA program used a real discount rate of 7-1/8 percent. An analysis of the sensitivity of the preferred alternative to the discount rate was performed by solving FORPLAN using both the 4 percent and the 7-1/8 percent discount rates. For all other benchmarks
and alternatives, the Present Net Values were merely recalculated using this second discount rate (FSM 1971.71). Finally, all costs and benefits were discounted from the midpoint of the decade in which they were incurred.

**Demand Curves and Real Price Trends**

As specified by the Washington Office (1920 letter to Regional Forester, “Downward Sloping Demand Curves,” 2/3/81) and in keeping with FSM 1971.65, horizontal demand curves for timber and non-timber resources were used to analyze the benchmarks and alternatives for the DEIS. Many factors can influence the demand for stumpage from any one forest (Adams and Haynes, 1985). Some of these factors include trends in (1) interest rates, (2) the species and products mix of forest products consumption, (3) use of wood for energy, (4) forest products exports, (5) the cost of wood in Canada, (6) the rate of technical improvements in wood and fiber processing, and (7) the levels of other national forests harvests. All of these contain some degree of uncertainty regarding their future states of nature. Neither the empirical nor the theoretical bases have been well enough developed to derive reasonable estimates of the demand functions for the resources offered at the Forest level. Evidence does exist, however, that suggests that the elasticity in the portion of the timber demand curve for which the Forest can influence output levels is such that prices would be relatively insensitive to some “reasonable” range of quantity offerings. In other words, it appears that the timber demand curve for the range of output levels analyzed during the development of alternatives is nearly horizontal.

As a surrogate for resource demand curves, real price trends were developed and used to represent the rate at which resource values will change over time as a result of anticipated supply and demand interactions in the market place. As specified by the Regional Office (1920 letter to Forest Supervisors, “Timber Price Trends, Values, and Costs,” 9/25/84), a 1 percent per year real price trend for stumpage was used for FORPLAN harvest scheduling analyses. These were applied for the first 50 years, and then a 0 percent price trend was assumed for the remaining 100 years of the harvest scheduling planning horizon. These imply that nominal stumpage prices (i.e., those which include the effects of inflation) will increase during the next 50 years at a rate of one percent greater than the rate of inflation, and equal to rate of inflation from there on after.

Since price trends are reflections of expected futures, there is an inherent uncertainty involved with making such projections. In recognition of this uncertainty, we performed a sensitivity analysis by re-running Run-3 of the benchmarks using alternative stumpage price trends of 0, and 3 percent. The results of these runs are quite complex and are discussed in detail in the Forest Planning Document titled “A Summary of the Analysis of the Management Situation.” Generally, higher price trends make silvicultural investments economically more attractive, but they also tend to result in the substitution of lower valued species for higher valued species in sale offerings during the early decades since it pays to hold the higher valued timber on the stump as far as maximizing PNV is concerned.

Based on Washington Office direction, a 0 percent real price trend for all other resources was used during the development of the benchmarks and the alternatives. In other words, their future nominal values will change at rates equal to inflation.

**Real Cost Trends**

As with price trends, there is an inherent uncertainty with projecting future costs. In recognition of this uncertainty we performed a sensitivity analysis by rerunning Run-3 using 20 percent reduction in forest expected costs. As with the use of higher price trends this resulted in the more intensive silvicultural investments becoming economically attractive. Based on Washington Office direction, 0 percent real cost trends were used for all future costs used in the development of the benchmarks and alternatives. In other words, the costs of labor, fuels, mate-
rials, and all other factors of production involved with managing the Forest are assumed to change at a rate equal to the rate of inflation.

**Base Year Dollars**

Future prices and costs can be expressed in both nominal and real terms. The projection of nominal values includes the effects of inflation on these values. The projection of real values does not. For example, assume that the future prices for commodity XYZ are projected to increase annually by 8 percent. Also assume that the rate of inflation is anticipated to be 5 percent. In real terms, the prices are increasing by only 3 percent per year above and beyond the rate of inflation. Real value changes are the result of the interactions of supply and demand forces in the market place. They do not include the effects of inflation.

All future values and costs used in the Forest Planning process were expressed in real 1982 dollars, consistent with the 1985 RPA program. The GNP implicit price deflator index was used to convert both historical and future nominal prices and costs to this common base (FSM 1971.32b).

**Costs**

**Introduction**

This section describes the costs used to perform economic efficiency analysis for each of the benchmarks and alternatives considered during the development of the DEIS.

All Forest Service costs were included for purposes of estimating budgets and calculating Present Net Values for each alternative. At the outset, each cost was categorized as either a fixed or a variable cost. If it was identified as a variable cost, decisions were made as to whether it would be analyzed in FORPLAN, or some form of electronic spread-sheet. Costs were determined by examining: (1) the PAMARS database, (2) Advent RPA budget files, (3) historical records and contracts, and (4) the results of time-motion studies. Professional judgement was also an important factor when it came to making assumptions regarding what bearing historical costs had on anticipated future costs. All costs were developed and reviewed by the Forest Analyst/Economist and the appropriate staff and sub-staff personnel. In the following discussion, we will summarize the cost breakdowns and how they were incorporated into the efficiency analyses for each alternative. A more detailed presentation of the specific costs and their functions in the analytical tools can be found in the process records at the Supervisor's Office. Table B-4-1 lists all costs and the categories used in estimating budgets and calculating PNV for each alternative. Costs are listed according to whether they are fixed or variable, capital investment or operation and maintenance, or in or out of FORPLAN. If the cost has changed between the DEIS and FEIS it is also included in the table.

**Fixed Costs**

Most costs that did not vary significantly by alternative are classified as fixed costs. These costs did not relate directly to specific activities within any management area prescription nor to the production of specific amounts of outputs. As a result, they did not vary by alternative and were not included in FORPLAN. They were a component of budget estimates and the PNV calculations for each alternative. Fixed costs ranged between 20 and 30 percent of the total cost for all the alternatives.

**Capital Investment Operation and Maintenance**

Capital investment costs include trails, roads, reforestation, timber stand improvement, prescribed burnings, and physical structures for range, recreation, fish and wildlife. In any alternative, capital

</table>

1/ Represents per decade cost.
investment costs pertain mostly to roads and timber stand improvements. For example, capital investment cost associated with road construction and timber management range from a minimum of 76 percent in Alternative C-Modified to a maximum of 95 percent in Alternative A.

Operation and maintenance costs are those costs associated with operating and maintaining facilities, program management and support for management of other resources. The majority of operation and maintenance costs in all alternatives are program management, followed by support funds necessary to carry out timber programs. Capital investment costs range from a high of 43 percent (Alternative A) to a low of 37 percent (Alternative C-Modified) of the total first decade cost in any alternative.

Costs within FORPLAN

In general, FORPLAN contains all the variable costs associated with implementing vegetation management activities associated with the timber and range resources. The activities included; range nonstructural improvements, site preparation, reforestation, and timber stand improvements. Costs associated with initial arterial/collector road construction and local road construction and reconstruction are also included in the model.

Costs for sale prep and administration along with non-Forest costs (logging, haul, manufacturing) were also included. These non-Forest costs are included in FORPLAN's PNV calculation but do not influence the Forest Service budget estimates.

These costs were usually expressed in terms of dollars/acre or dollars/MCF. The costs which were expressed in units of volume were also developed by diameter classes. This was true for both the marginal non-federal logging costs, and the sale preparation/administration costs. For each FORPLAN cost category, a range of costs were entered into the model based on the Management Prescriptions, and the characteristics of the analysis areas to which they applied. All in all, 136 different FORPLAN economic tables were developed to cover the different cost and value combinations to which prescriptions could be assigned in the Model.

Values other than those associated with timber, range, and roads were calculated outside of FORPLAN. This was necessary because of their unique spatial or non-linear characteristics, unknown or poorly defined joint production relationship or poor economic information.

The network model was used to calculate the cost of reconstruction of the arterial/collector system. All other costs were calculated with the use of electronic spreadsheets.

The remaining variable costs were a function of the amount of output and emphasis a particular benchmark or alternative was designed to provide for this resource, the land allocation scheme, timber management or other resource activities and outputs. Basically, the costs associated with these activities were estimated by comparing the amount of relevant land allocations under activity levels in a particular alternative to experienced costs, and projecting the cost based on these relationships.

Benefits

Introduction

This section describes both the priced and non-priced benefits which were incorporated in the economic efficiency analyses for each benchmark and alternative considered during the development of the DEIS.

Resource outputs to which dollar values were assigned constitute the priced benefits included in the Present Net Value calculations. Like all of the costs included in the analyses, only those benefits incurred during the 50 year RPA planning horizon were incorporated in the PNV calculations. The economic efficiency analysis for each alternative also considered non-priced benefits. These are outputs for which there is no available market transac-
tion evidence and no reasonable basis for estimating a dollar value commensurate with the market values associated with the priced outputs. In these cases, a subjective qualitative value must be attributed to their production. Conceptually, the addition of the non-priced benefits to PNV is used to derive the net public benefits associated with each alternative. Both priced and nonpriced outputs and their associated values will be summarized below. More detailed documentation of the specific values and the process used to develop them can be found at the Supervisor's Office.

Priced Benefits

Introduction

Priced benefits fall into one of two categories: market and nonmarket (assigned). The market values constitute the unit price of an output normally exchanged in a market after at least one stage of production, and are expressed in terms of what people are willing to pay as evidenced by market transactions. Nonmarket values constitute the unit price of a nonmarket output not normally exchanged in a market at any stage before consumption, and thus must be imputed from other economic information (FSM 1970.5). They are valued in terms of what reasonable people would be willing to-pay (above participation costs) rather than go without the output. These values were derived directly from the 1985 RPP program assignment. In either case their values are theoretically commensurate and appropriate for inclusion in PNV calculations. The resources for which dollar values were estimated on the Ochoco consisted of timber, range, special uses, and developed, dispersed, and wildlife oriented recreation.

Timber

Timber mill pond values were used in FORPLAN. These values were expressed in terms of dollars/MCF. The mill pond values were developed for both existing natural and future managed stands. The values were specific for each working group (Ponderosa Pine and Mixed Conifer) and diameter class. The process for calculating the mill pond values was quite complex. Essentially the process used the procedures directed by the Regional Office, 1920, 4/27/84 (See process record 1920; 6/84). We will summarize it here. All calculations were performed in terms of constant 1982 dollars. Also, since most of the source data was expressed in terms of dollar/MBF, it was necessary to convert these to dollars/MCF. The mill pond values were first calculated for each individual species and then converted to working group mill pond values based on the species composition of each working group modelled in FORPLAN. Also, since none of the source data was diameter specific, assumptions had to be made regarding the average diameter of trees sold for each species during the period for which the data sources covered. The diameter specific values and costs were then developed based on diameter class relative indices for stumpage values.

The first step was to use the stumpage values calculated by the Regional Office from the Ochoco National Forest's Cut and Sold Reports covering the period April 1977 through September 1983. The second step was to adjust the regionally developed price-diameter relationship to Ochoco values. This was done by placing the 100 percent value or the average DBH of that species sold between 1977-1981. Relative values for the lower DBH classes were established using the same ratios as the regional tables. DBH classes higher than the average were all assigned the 100 percent value. Shifting the diameter which received the 100 percent level to the average DBH was necessary because these values would be applied to the average stumpage value for that species.

The next step was to convert these species relative values to working group relative values. Weighted average relative values were developed for the PP and MC working groups. The PP working group percentage weights are ponderosa pine -87 percent, Douglas fir - 13 percent. The MC working group percentage weights are ponderosa pine -49 percent, Douglas fir - 24 percent, white fir - 18 percent, western larch - seven percent and lodgepole pine - two percent. These mixtures represent the major...
species harvested on the Ochoco National Forest. The percentages by working group were developed from a comparison of sell records and inventory data.

Weighted average stumpage values for the two working groups were then developed using the species stumpage rates furnished by the Regional Office and the same species percentage weightings as listed above.

Average logging cost developed from the Forest’s 2400-17 forms was added to the stumpage values, giving mill pond values for the two working groups. FORPLAN also had Analysis Area logging cost. This was done so that when management area prescriptions were applied to analysis areas the stumpage values would be adjusted to better reflect site specific differences.

Average board feet/cubic feet conversion factors for the two working groups was derived from the 1982 inventory data. These values were then applied to the millpond value based on board feet to convert this to a value per cubic feet.

The final step was to apply the adjusted price diameter index to those mill pond values to establish values by diameter groups. These values were then entered into FORPLAN.

Table B-4-2 presents the diameter specific working group mill pond values.

Range
The range outputs represent the amounts of forage permitted to be grazed and are measured in units of animal unit months (AUM’s). AUM values were calculated as the value of the marginal product of an AUM in the production of a marketable animal. The Forest Service entered into a cooperative agreement with the USDA Economic Research Service to develop livestock enterprise budgets for each National Forest. The Range Budget Approach was used for this analysis. Because Forest AUM’s are not actually priced in a free competitive market, the calculated price is an estimate of market value. First, returns from all ranch products were determined. Then, all costs of production were subtracted. The remaining returns plus the cost of the Forest Service permits became the residual value of the AUM. This residual value of an AUM to ranch livestock production is comparable to conversion surplus timber values. Based on the information provided in the RPA 1985 Program analysis for the DEIS, and a Regional Office Memo (2340, 9/30/83), the AUM value for the Ochoco National Forest in 1982 dollars is $11.75.

Although range outputs were explicitly represented in FORPLAN some adjustments were done outside the model. FORPLAN derived AUM’s were adjusted based upon the number of structural improvements and acres of riparian enhancement. Both of these factors have unique spatial characteristics not easily represented in FORPLAN. All other priced benefits were analyzed with electronic spreadsheet outside of FORPLAN.

Recreation

The non-wildlife related recreation and wilderness outputs represent the amount of use consumed on the Forest and are measured in terms of recreation visitor days (RVD's). The wildlife related recreation use is measured in terms of wildlife and fish user days (WFUD's). The values used for these priced out-puts were derived directly from the 1985 RPA program assessment. This discussion is a summary of the write-up found in Appendix F of the 1985 RPA DEIS.

The development of recreation, wilderness, and wildlife values for the 1985 RPA Program analysis consisted of two steps: (1) development of recreation and wildlife benefit values by activity per RVD or WFUD; and (2) adjustment of values to reflect standard and less-than standard levels of management.

The Resource Evaluation Group at the Rocky Mountain Forest and Range Experiment Station conducted an extensive literature search to develop the 1985 activity values for recreation. Benefit values for recreation, wilderness, and wildlife activities were developed from recent travel cost models and contingent valuation research (Loomis and Sorg, 1982). In-service and academic specialists reviewed the research and activity values and adjusted the initial values to achieve methodological consistency to apply them to regional conditions. The values represent total willingness to pay for an additional recreation site, animal unit, or wilderness area. The RVD values by recreation activity that were generated by this study can be found in Table F.4 of the 1985 RPA DEIS. For program evaluation purposes, these values were subsequently adjusted downward because:

The travel cost method represents a total willingness-to-pay. Other resource values in the RPA evaluation represent market price or value of the marginal product. Consequently, the willingness-to-pay values were adjusted in an effort to make the recreation values more compatible with values used for other resource outputs.

The travel cost method estimates values on a site-by-site basis. The method does not address the question of whether regionally or nationally a given quantity of RVD's will, in fact, be consumed if that price were changed.

It is believed that the travel cost studies are typically done at higher quality sites, do not take into account substitutes to individual sites, and do not accurately measure trip length; consequently, values from these studies may be on the high side when applied to average situations on a region-wide basis.

In response to the first concerns, the values were adjusted based on the relationship between the proportion of recreation provided by the Forest Service and estimates of an average nationwide demand elasticity for outdoor recreation. It is estimated that nationally, roughly a 5 percent increase in price will result in a 1 percent decrease in quantity demanded (Lewis, Hughes, and Lloyd, date unknown). It is also estimated that in 1982 the Forest Service provided 7.5 percent of all outdoor recreation. Consequently, it is roughly estimated that there will be a 5 percent decrease in price for each percent of the 7.5 percent Forest Service market share or a total decrease of 37.5 percent for clearing the market. Therefore, the initial willingness-to-pay values were reduced 37.5 percent for use in comparing resource allocation choices.

In response to the quality factor, the concept of standard and less-than-standard service was introduced, and the resulting impact on the value of the experience to the recreationist was estimated. If recreation facilities are not fully maintained, the quality of the experience will be lowered. Two different sets of values were developed to account for the standard and less-than-standard outputs. A special study showed that on the average the less-than-standard RVD's are valued at about 53 percent of the value of standard RVD's. Accordingly, different capital investment, and operations and maintenance costs were developed for the standard and less-than-standard recreation outputs. All alternatives except the current direction alternative manage all the recreation resources at a standard service level.

Finally, these values were expressed in terms of the recreation opportunity spectrum (ROS) activity.

LSTD - Less than standard

Soil and Water
The values used for these priced outputs were taken directly from the 1985 RPA program assessment. Values considered pertinent to increase in water yields, sediment reduction, improved water quality and maintained water quality. Increased water yields are assumed to have no additional value in the Pacific Northwest. Almost all area water meets the quality goals, as a result no additional value will be assigned. The two water related values the Forest included were increased value from sediment reduction ($6.00/M ton) and maintaining water quality ($.20/acre feet).

Minerals
The minimum bid value of $2.50 per acre leased is used. With no experience in what actual bed values may be combined with no difference in the estimate of acres leased.

Nonpriced Benefits

Introduction
The calculation of PNV enables the comparison of alternatives with regards to their output levels for priced resources, and their efficiency in producing them. However, other factors also influence the decision making process. In some cases, the importance of nonpriced benefits for which it is impossible to assign monetary values can outweigh the advantages of producing higher levels of priced outputs. The importance of the need to consider these subjectively valued benefits in Forest management decisionmaking is addressed in the NFMA Regulations which charge the Forest Service with identifying the alternative which comes nearest to maximizing net public benefits (36 CFR 219.12(F)).

Net public benefits (NPB) represent the overall value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs), whether they can be quantitatively valued or not (36 CFR 219.3). Net public benefits include both priced and nonpriced resource outputs, less all costs associated with managing the area categories in accordance with the way they were developed and tracked during the process of analyzing alternatives. The resulting values are depicted in Table B-4-3.

In addition, for anadromous fish, the RPA value of $1.05 per lb is assigned.
As stated earlier, all priced outputs and all costs associated with managing the Forest are included in the calculation of PNV. To this, the net subjective values of the nonpriced outputs must be added in order to arrive at the overall NPB of an alternative. Some of the most important nonpriced benefits addressed during the Ochoco National Forest planning process revolve around maintaining and enhancing the following:

- Lifestyles;
- Diversity and quality of recreation opportunities;
- Biological diversity;
- Old growth and snag habitat;
- Scenic quality;
- Historical and cultural resources;
- Riparian condition; and
- Air quality.

These are all outputs and effects which are influenced to a large degree by decisions regarding how to manage the Forest. They are all the topic of one or more issues and concerns which were identified at the outset of the planning process. So they are important, but it is not possible to measure their importance in dollar terms which are comparable to market values. Their values must be subjectively determined.

The nonpriced outputs considered during the development and evaluation of alternatives are discussed below. While the quantitative dollar values of each can not be determined, they can generally be evaluated by examining such quantitative indicators as acres of appropriate allocations, resource inventories, or timber production related activities and outputs.

Lifestyles
Surveys of the Central Oregon populace have shown that many people enjoy living in the area because of the outdoor lifestyles it provides. A Forest with a broad recreation base in a pleasing environment could be an asset to the Central Oregon area while still providing goods and services necessary for stable Forest-based economies.

Central to maintaining and enhancing the Central Oregon lifestyle is the provision of diverse recreation opportunities, and clean air and water to enjoy them. The freedom and ability to cut personal use firewood is also important. To the extent that an alternative results in reduced or less diverse recreation opportunities, lower quality water, smokier air, or more restrictive access to personal use firewood, the alternative will be less desirable from a lifestyle point of view. Many of these effects are directly related to land allocations and resource management goals which emphasize the production of wood at the expense of amenity values.

The stability of jobs and income in the area is also an element of the concern about lifestyles. For this purpose, each alternative was analyzed with regards to its potential impacts on jobs and income in the 3 county zone of influence (refer to Section 5). Any indications that the implementation of an alternative would result in fewer jobs and less income would be considered disruptive of the current lifestyles.

Diversity and Quality of Recreation Opportunities
The number of recreation visitor days and their associated priced values are included in the PNV calculations for each alternative. However, the assigned dollar values per RVD do not reflect the
value of providing a diversity of recreation opportunities and settings. The Forest currently provides adequate recreation diversity as indicated by the reasons many people choose to live and recreate in the area. However, some aspects of the recreation opportunity spectrum are becoming more difficult to retain. For example, as remaining roadless areas are either designated as wilderness, or roaded and developed for other uses, there are fewer opportunities for the semiprimitive and primitive recreation experiences outside of wilderness areas. Related to this is the idea that as more and more roadless areas are either developed or designated as wilderness, future generations will have fewer options regarding how to best manage them to meet changing needs. To the extent that retaining roadless areas in undeveloped conditions does not overly restrict the efficient production of priced outputs, both the recreation diversity and the future options which they offer are considered a nonpriced benefit. For each alternative, the recreation allocations and projected carrying capacities are categorized according to the recreation opportunity spectrum. This can be used to assess the recreation diversity which an alternative provides.

**Biological Diversity**
Maintaining plant and animal diversity over time is also considered as a nonpriced component of net public benefits. Benefits generally associated with biological diversity are gene pool maintenance, preservation of long-term productivity, maintenance of forest health, and insurance of viable populations of plant and animals, especially Threatened and Endangered Species. Since animal diversity is to a large extent dependent upon plant diversity, attention is focused particularly on the number of acres for each working group in each successional stage. The amount of old growth provided is especially important since this grazing component would be the most difficult to replace once it disappears. Timber harvesting and fire are the chief means of manipulating vegetative diversity. The effects of scheduled timber harvesting on vegetative diversity were evaluated through a combination of FORPLAN reports and some special software programs which were developed specifically for that purpose. To a certain extent, the more old growth and riparian areas in excellent condition and snags provided for in a particular alternative, the higher the benefits associated with this non-priced output.

**Old Growth and Snag Habitat**
Besides influencing biological diversity calculations both old growth and snags provide specific habitat for non-adaptive wildlife species. While enhancing biological diversity both the habitat and species present increase non-consumptive wildlife opportunities and visitor experiences. As a result, the more old growth and snag habitat provided in a particular alternative, the higher the benefits associated with these non-priced outputs.

**Scenic Quality**
While the value of scenic quality is not directly included in the PNV calculations, its value is indirectly represented through the consideration of recreation as a priced benefit. It is safe to assume that the provision of positive visual experiences has a direct relationship to the quantity and quality of recreation on the Forest. However, a large number of people who benefit from the visually appealing scenery are not tallied as RVD's. There are also the people who live in or around the Forest who everyday enjoy scenic qualities associated with the forested mountain environment. Again, these beneficiaries are not tallied as RVD's. These benefits are nonmeasurable.

The alternatives each vary in their emphases to satisfy scenic quality objectives. This can be measured in terms of the percentage of all sensitive retention and partial retention scenic quality objectives which are being met through the implementation of an alternative.

**Historical and Cultural Resources**
A large number of scientifically and historically valu-
able cultural resources are identified on the Forest. Over 50 new sites, mainly prehistoric Indian campsites, are found each year as a result of the Forest's cultural resource inventory program. Cultural resources are an issue in the sense that many people are concerned about how many and how adequately these cultural sites are being preserved and protected in the face of ground disturbing projects and vandalism that occurs on the Forest. The more areas that are opened up to development for road construction, timber harvesting, and minerals and energy development, the more difficult it will be to protect these resources.

Riparian Condition
The number of fish user days and their associated priced values are included in the PNV calculations for each alternative. However, the assigned dollar value per WUD do not reflect the total value of providing excellent riparian conditions. As discussed in Chapters 3 and 4 of the DEIS, riparian zones represent a small but unique opportunity on the Forest. As a result, use has been concentrated and some degradation of the resource has occurred due to road location, timber and livestock management and recreational pressure. Improving riparian conditions will have unquantified benefits to dispersed recreation users, wildlife, biological diversity, and scenic quality. The more an alternative emphasizes wood production or livestock use in riparian areas the lower the benefits associated with these non-priced outputs.

Air Quality
Air quality is another important aspect of the Central Oregon area. For the most part, air quality conditions are good. During certain times during the winter, temperature inversions create woodstove pollution problems, and during the spring and summer, prescribed burning activities reduce air quality.

Most of the firewood supply utilized in the area comes from the Forest. Different approaches for making firewood available to the public were explored in some alternatives. As a result, firewood burning and its related pollution problems will continue to exist.
Socio-Economic Impact Analysis
(Section 5)

Overview
Each of the alternatives will have economic and social effects on the surrounding areas. The ICO's which the alternatives address all represent blends of economic and social concerns. The ones which most specifically address these issues are the first two: "What should be the level of timber production?" and "How can activities on the Forest and Grassland benefit social and economic wants and needs of local communities?"

To address these ICO's, two economic and four social measures were examined. The economic measures, computed by the IMPLAN program, are:

- Employment;
- Personal Income.

The social measures were selected on the basis of Forest expertise. These measures are:

- Work related lifestyle;
- Leisure activities;
- Effects on community cohesion and community stability; and
- Effects on minorities and women.

Area Analyzed
These measures were used to analyze the alternatives' effects in Crook, Harney and Wheeler Counties. Jefferson County was examined in the DEIS, but only minor effects were found; the analysis was omitted from the FEIS. Deschutes and Grant Counties were not modeled because of the limited effects of the Ochoco National Forest on these counties. Because the economies of Crook, Harney, and Wheeler counties are not especially interrelated, each of the counties was modeled separately in the IMPLAN analysis.

Economic Model (IMPLAN)
IMPLAN is an input-output model developed by the Forest Service. Like all input-output models, it simulates an economy, and can examine the effects on the whole economy of changes made in particular sectors. This means that IMPLAN is forced to assume that the basis for the economy will remain static. This means, among other things, that there will be no technological changes, no new industries or industries that cease to exist, and no changes in the patterns in which industries purchase from one another. The industries may change in size only, not in makeup.

This assumption is assumed to be realistic for the Ochoco National Forest models for the first decade. No IMPLAN runs were made for further decades because for them the assumption was judged not to be reasonable.
IMPLAN (specifically, IMPLAN Version 2.0) is based on a 528 sector national model. This model derives its interindustry relationships from the 1977 Department of Commerce I-O model, but is updated to 1982. Individual county models are derived from the national model by examining county data to determine which sectors of the national model are present in that county. The county model is then created as a subset of the national model. This process requires the assumption that the county interindustry linkages resemble the national picture. This assumption is reasonable for the Crook, Harney and Wheeler county economies.

Data Used in the Model

The process just described creates a county model - a description of what industries are present in the county. But additional information must be provided which defines the level at which each local industry is producing. This information is also provided, in rough form, by IMPLAN. It is mostly taken from various censuses published by the Department of Commerce Bureau of the Census. The data is for the year 1982.

The 1982 economic figures were reviewed for accuracy. The fact that 1982 was a recession year with low employment does nor in itself pose a problem to the analysis. However, if there were changes in industry structure - either because of the recession, or since the recession - the data needs to be recomputed.

The Forest determined that the data for Wheeler County was adequate. For Crook and Harney counties, we judged the wood products industry data needed to be updated and the rest of the data was accurate. (For a more general discussion of changes in the wood products industry, see the “Social and Economic Setting” section in Chapter 3.) To update the data for the wood products industries, we asked the various manufacturers in the two counties for data on their operations, which they kindly gave to us. From this data, combined with published local and national data, we constructed a picture of the wood products sector as it existed in 1987.

Expenditures Associated with One Unit of Output

The final step in building the IMPLAN model was to determine the effect on the economy of varying one unit of forest output - one MMBF, one MAUM, one MRVD. This data is called expenditure data, since it measures the expenditures in the economic sectors which are associated with one unit of output.

To determine timber-related expenditures, it had to be determined how much of the timber was milled and how much was re-milled before leaving the local area. These figures were provided from Forest Service data and data gathered from local mills.

The timber harvest of the years 1980-1988 was analyzed. The results obtained are shown in Table B-5-1.

Forage expenditures were computed from USDA Economic Research Service data for the Forest and Grassland. The total value of the herd was multiplied by the percentage of the forage that came from the Forest/Grassland to obtain the value due to the Forest/Grassland; then that figure was divided by the number of AUM's to get the value per AUM. This method makes two assumptions. First, it is

B-83
assumed that all the cows and yearlings come either from calves produced by the herd or calves purchased immediately after birth. Second, it is assumed that the value of the Forest/Grassland forage is equal to the average forage value.

Expenditure data for RVD’s (recreation) were obtained from the RO, classified by RIM category. These figures were applied to the Ochoco recreation pattern.

The remaining expenditure data are related to Forest Service budgets and to 25 percent monies. The Forest Service salaries and the portion of the 25 percent monies that go to teachers’ salaries were proportioned according to the average consumer expenditure pattern for each county. Forest Service non-salary monies were proportioned according to the general federal government expenditure pattern. Twenty-five percent monies that went to roads were allocated to 75 percent road maintenance and 25 percent new road construction. Twenty-five percent monies that went to schools that were not spent on salaries were proportioned according to the education expenditure pattern for each county.

**Current Situation**

IMPLAN can compute either absolute or relative results. The Forest’s process was to define a “current situation” and then compare the alternatives to it. The current situation for timber harvest levels is the 1980-1988 average, as described above. For recreation, averages were computed for the last twenty years and values were chosen which represent the 1985 levels. For grazing, 1985 levels were also used.

**Basic Economic Cause and Effect Relationships**

Table B-5-2 shows the effect upon a county’s economy of a change in one unit of Forest output - one MMBF, one MAUM, one MRVD. The coefficients were computed independently for the three counties, but they are similar because the counties’ economies are similar.

### Description of Economic Effects

Tables B-5-3, B-5-4, and B-5-5 show the changes in employment and income for Crook, Harney, and Wheeler counties.

In Section 5 of Appendix B of the DEIS, the document displayed tables similar to the above except that results were displayed for two decades. This was done to reveal results due to the selection of a Departure for a Preferred Alternative. However, the Preferred Alternative in the FEIS is not a Departure, and results are displayed only for the first decade.

Social Effects

The social effects by alternative are listed in Chapter 4. The social measures used to describe these effects are based on the Forest Service Economic and Social Analysis Handbook (FSH 1909.17). The handbook suggests analyzing six social measures:

- Lifestyles;
- Attitudes, beliefs, and values;
- Social organization: Community institutions, community cohesion and community stability;
- Population characteristics;
- Land use patterns; and
- Civil rights (effects on minorities and women).

Of these measures, we judged that “population characteristics” and “land use patterns” would not be affected by any of the alternatives. “Attitudes, beliefs and values” was used as a measure of social effects in the DEIS. However, attitudes, beliefs and values seem to be measured well by the rest of the social measures taken together. For this reason, the separate “attitudes, beliefs and values” category was omitted. For the same reason, we omitted “community institutions” from the “social organization” category.

The “lifestyle” classification was examined extensively in the Socio-Economic Overview (pp 62-92). Six lifestyle categories were described there:

- Native American;
- Farmer;
- Loggers;
- Millworker;
- Small town merchants; and
- Government employees.

Except for the “Native American” category, these lifestyles are related to employment choices although they are not limited to these choices. See the Socio-Economic Overview for more information on “lifestyles.”

Since leisure activities are important, they were added as a separately defined social effect. Therefore, the final list of social measures is the following:

- Work-related lifestyle;
- Leisure activities;
- Community cohesion and community stability; and
- Effects on minorities and women.
Analysis Prior to Development of Alternatives

(Section 6)

Introduction

The primary analysis performed prior to the development of alternatives was the "Analysis of the Management Situation" (AMS). During this step, the conditions of the Forest, its ability to produce outputs, and society's demands for its resources were assessed. The analysis performed during this step helped to define the "decision space" within which the Forest can operate. The detailed results of this analysis step can be found in the planning documents titled "Analysis of the Management Situation."

The purpose of benchmarks is to define the range within which integrated alternatives will be developed.

Benchmark analysis will enable the Forest to:

- Comply with planning regulation direction to establish management requirements (36 CFR 219.27);
- Estimate the schedule of management activities, resource outputs, effects, costs, and PNV appropriate to achieving the purpose of the benchmarks; and
- Analyze the implications of legal and policy constraints and economic assumptions.

Benchmarks will:

- Be approximately implementable;
- Not be constrained by budget;
- Will generally use a Maximum PNV objective function to obtain a final analytical solution when FORPLAN is used, and
- Meet management requirements.

The required benchmarks are:

- Minimum level;
- Maximum PNV using market prices only,
- Maximum PNV including assigned values,
- Maximum resource levels; and
- Current Level.

For the Ochoco National Forest and Crooked River National Grassland, the following Maximum Resource Levels are displayed:

- Timber;
- Range,
- Big Game; and
- Recreation.

Changes Between DEIS and FEIS

The major changes discussed in this section are

- Dropping an MR (thermal cover),
- The effects of being characterized as having a
"surplus" inventory;
The smaller change in PNV and timber volume between the Max PNV and timber benchmarks,
The effects of different demand assumptions, timber outputs, costs, production relationships and how they relate to the production of market vs. nonmarket outputs,
The potential to maximize various resources, and
The addition of four new ICO's.

Management Requirements

Development and Efficiency Analysis

Management requirements are directed toward assuring that a viable level of resources will be provided for, both short term and over time.

These requirements stem from the National Forest Management Act as interpreted by the implementing regulations (36 CFR 219.27). The following sections of 219.27 contain the basic direction for management requirements:

- Resource Protection;
- Vegetative Manipulation,
- Silvicultural Practices,
- Even-Aged Management;
- Riparian Areas;
- Soil and Water; and
- Diversity.

Further direction for incorporating these requirements has been provided to the Forest in the form of "Regional Guidelines for Incorporating Minimum Management Requirements in Forest Planning" (1920 2/9/83). Those minimum management requirements described in the Regional Guidelines address:

- Requirements that are outside the Forest Service's authority to change;
- Requirements which impose substantive standards (as opposed to procedural),
- Requirements that can be dealt with in the analysis, and
- Requirements which are likely to have an impact on the analysis.

The Forest Interdisciplinary (ID) Team worked over a period of several years attempting to interpret and define specific management requirements applicable to the Ochoco National Forest and Crooked River National Grassland. Those requirements pertinent to the Ochoco where the Forest has discretion in the methods used to meet the requirement include old growth, riparian areas, harvest dispersion, soil and water conservation, and other wildlife habitat. In each of these cases the Forest evaluated alternative methods of meeting the requirement and, where identical effects resulted, chose the method with the least impact on PNV. Chosen methods have been incorporated into the Forest FORPLAN model.

In the fall of 1986 the Northwest Forest Resource Council filed an appeal contesting these management requirements. The appeal resulted in the Ochoco National Forest issuing a supplement to the DEIS in the fall of 1988. The supplement in part dealt with the same information discussed here. Appendix F in
the FEIS contains a more detailed discussion of this information.

In the case of old growth, the Ochoco followed Regional planning direction (1920 11/10/83) which states that this assessment can take a variety of forms, including "1) use mapping systems and logic to distribute the species in a way that minimizes the impact on the commercial forest land base but still achieves the distributional requirements of the species, 2) conduct Regional analysis to determine whether setasides or long rotations are least impactful..." The Ochoco constructed a map to the minimum level of old growth habitat following recent revision of Regional direction (1920 4/16/84).

While there was little flexibility left because of the distributional requirements, logic was applied to minimize the impact on the suitable timber land base. Examples include placing the maximum number of stands in designated Wilderness areas, the RNA, and in areas with a high probability of less intensive timber management such as visual corridors, riparian areas, and less economically viable unroaded areas. Other Forests in the region with a similar timber inventory structure to the Ochoco's have conducted some analysis of the relative efficiencies of a dedicated or managed approach. The Siuslaw found that a dedicated approach was more efficient on the order of a two to four percent difference in PNV. The Wallowa-Whitman also found a dedicated approach to be more efficient with a difference of less than one percent in PNV. Both of these Forests performed their analysis by comparing FORPLAN runs with all constraints except for old growth remaining constant between runs. Additionally, an analysis conducted on the Ochoco showed the dedicated approach to be more efficient.

The basic procedure followed was to calculate the percent of a rotation that would be in old growth, the area needed to support a given level of old growth with those rotation ages, and the resultant difference in mean annual increment (MAI). Forest-wide yield differences on a MAI basis were then calculated. Various management schemes using different rotations and different levels of old growth for both mixed conifer and ponderosa pine were examined and in every case a dedicated approach was found to be more efficient (Ochoco planning files 8/16/82).

In summary, dedicated stands were mapped in a manner to minimize the impact on the suitable timber land base. Results of FORPLAN analysis conducted by forests with a similar timber inventory structure, and an analysis conducted on the Ochoco showed the dedicated approach to be more cost-efficient. Therefore, the Forest elected to use the dedicated habitat modeling approach.

Several methods of meeting management requirements for riparian areas were considered. The more direct method involved dedicating riparian areas to non-timber harvest prescriptions. This would most directly ensure meeting management requirements but would also have the greatest impact on timber harvest and, therefore, the most impact on PNV.

The ID team thus sought to find alternative standards and guidelines that would meet riparian requirements but have less impact on PNV. The approach decided upon relies on a mix of practices and project level standards and guidelines, as well as harvest restrictions. These guidelines include the following:

- Use of designated skid trails;
- Use of non-mechanical slash disposal;
- Use of non-mechanical site preparation;
- Cable logging systems on slopes greater than 30 percent;
- Limits on road density and stream crossings;
- Extended rotations (200 years) and/or uneven-aged management;
- Limitation in the amount of riparian areas available for timber harvest in any one decade, and Manipulation of grazing utilization standards rather than structural improvements.

In addition, after ID team evaluation, the Forest decided that restrictions in riparian areas should only be placed on Class I and II streams and not the much more numerous Class III and IV streams. Thus, these requirements affect approximately 18,000 acres (less than two percent of the land area).
The DEIS contained a requirement of ten percent cover in winter range. This requirement came directly from Regional direction. Since then, Regional direction has been modified and this requirement was dropped. The Forest is explicitly modeling cover in the Ochoco FORPLAN model. This allows the linear program to select the most efficient set of management intensities and scheduling thereof to meet overall Forest objectives as well as the thermal cover constraint. Considerable effort was expended by the Forest, as documented in planning files (1920 5/16/84, 1920 9/10/84), to assure that the best set of management intensities and scheduling is available for the model to select from.

Harvest dispersion constraints are also explicitly portrayed in the Ochoco FORPLAN model. Following the two-step process in the Regional planning direction (1920 11/10/83), a theoretical dispersion factor was first calculated and then validated by extensive mapping (1920 5/31/84). This factor has been thoroughly evaluated by the IDT and tested by both Forest and District personnel. This analysis showed that a 33 percent limit on regeneration harvest by analysis area was appropriate. One distinction made in the Forest's modeling is between planting and natural regeneration. This has a direct effect on dispersion since natural regeneration takes twice as long to grow out of the opening stage. This difference is portrayed by explicitly modeling openings and allowing the linear program to select from among various management intensities with either planting or natural regeneration to most efficiently meet Forest objectives and the harvest dispersion constraint. Again, extensive analysis was conducted to assure that the best set of practices is available for the model to select from.

An option briefly considered early in the Forest's planning efforts was to use an altogether different modeling approach where alternative harvest schedules would be determined prior to running the model, averaged over time to reflect harvest dispersion, and input to the model. Since most Forest issues and concerns, as well as the major portion of the Forest's costs and values, revolve around harvest scheduling, this scheme for modeling dispersion was dropped. Far too few of the hundreds of potential schedules available for an analysis area could be represented with this approach, thus unnecessarily limiting PNV.

Analysis of benchmark runs in the AMS indicated individual watersheds had equivalent clearcut acres exceeding 45% in the first and later decades. The Forest Management Team decided this level would not meet management requirements for soil and water. The Forest's watersheds were then analyzed and assigned harvest level thresholds which they could absorb without significant impacts to the soil and water resources. Numerous FORPLAN runs were made to find the modeling techniques with the least impacts on PNV and timber volume while meeting this objective.

These final dispersion constraints include regeneration harvest limitation of between 17 and 23 percent (depending upon proportion of analysis area within low, moderate, or high sensitivity watersheds), and a 50 - 67 percent limitation on first decade overstory removals. Regeneration harvest limitations are applied to a scheduled output that tracks the difference between natural and artificial regeneration in terms of the time it takes to grow out of the opening stage. (See planning record 1920 8/13/85.)

Management requirements for the provision of snags outside of areas dedicated to old growth management relate to snags 12 inches in diameter or less. Analysis of benchmark runs showed that these levels could be provided through normal mortality and that no constraints or allocations are necessary to meet this requirement.

Opportunity Costs

Several FORPLAN runs were made with different MR constraints present so that the impacts of management requirements and National and Regional direction could be determined. All of these runs used run #3 (BM5) in Cargill's (1920, May 17, 1983) benchmark run sequence as a basis for comparison. This run maximized PNV subject to nondeclining yield and rotations restricted by CMAI. The runs used for comparison differ from run BM5 only in the presence of constraints designed to meet one or

1/ All of these runs maximize PNV subject to non-declining yield and use of GMAI rotations
2/ Volume figures do not include unregulated salvage. All runs produce at the LRSY level in decade 1 except BMC (watershed dispersion) and B7E (maximum PNV bonchead
3/ These PNV figures are taken directly from the FORPLAN reports and are not 100% comparable to PNV's given elsewhere in the DEIS. For comparison purposes, however, these figures are accurate
4/ Dropped as a management requirement in the FEIS

More MMR. Table B-6-1 shows the results of these runs. Comparisons in this narrative will be in terms of the change in PNV. Timber volume trade-offs in cubic feet can be determined from the table. The effect of not providing for these MR's is addressed in more detail in Appendix F.

When constraints to meet all management requirements are present, the total impact on PNV is a reduction of 13.2 percent (run BM5 compared to run B7E). Three other runs were made to look at the impact of individual MR constraint sets (old growth, harvest dispersion and watershed dispersion). A forth MR constraint, special riparian area prescriptions, was not examined individually due to the minor impact on PNV (one percent). PNV reductions caused by the constraints individually amounted to 3.2 percent for old growth (run BMA compared to run 607BM5), 3.4 percent for harvest dispersion (run BMD compared to run 607BM5), and nine percent for watershed dispersion (run BMC compared to run B5). The reduction in PNV for harvest dispersion while timber outputs remain unchanged is due to the difference between planting and natural regeneration in the amount of time required to grow out of the opening stage. To meet dispersion requirements, more expensive planting is frequently required.

Results of comparisons of individual management requirements would represent the maximum impact of that constraint. The linear program would not have an opportunity to consider any overlapping or interactive effects in its optimization procedures. However, these particular constraints are largely independent of one another except for harvest dispersion and watershed dispersion. In this case the watershed dispersion constraints are much more restrictive and completely overlap the harvest dispersion constraints. The independent nature of these constraints can be seen by comparing the total impact of 13.2 percent to the sum of the individual impacts, excluding harvest dispersion impacts (15.5 percent). In the context of a particular alternative, however, more overlapping of constraints, hence less of an impact on PNV, would be expected.

The preceding discussion relates directly to the DEIS. Since then changes in some of the relationships and model updates would result in minor changes. Due to the probable magnitude of the changes and the high cost and time to update, these analyses were not updated.
Timber Harvest Policy
Benchmark Analysis

In response to National and Regional direction, the Ochoco followed the benchmark run sequence (1920 8/8/83, 1920 11/10/83) in order to develop information to display the impacts of timber harvest policies (see Table B-6-2). The two types of constraints examined were nondeclining yield and rotations restricted to culmination of mean annual increment (CMAI). Using the results of the benchmark run sequence, these two policies can be examined either independently or in combination, and either with or without management requirements. As with the preceding section's management requirements, this analysis has been carried forward from the DEIS.

Looking first at rotations restricted by CMAI, the Ochoco found that the impacts on PNV are less than one percent under nondeclining yield (run #6 compared to run #7) and 1.1 percent with 25 percent sequential bounds (run #4 compared to run #5). This is not surprising since the Forest spent considerable effort constructing harvest schedules for the numerous two storied stands which most efficiently provide volume in the critical decades of the conversion period with rotations at CMAI. The small increase in PNV with a two percent increase in timber volume can be attributed to the fact that, because of the early rotation ages in the future and LRSY not being binding in BM3, more of the high volume and high valued existing stands can be harvested now. All four of these runs include constraints necessary to meet management requirements. Model updates described in Section 3, have resulted in the model characterizing the Ochoco as a surplus forest in which the LRSY is binding on the ASQ. As a result, rotation short of culmination has little to no effect on ASQ because moving rotation ages forward from their biological potential has a tendency to reduce LRSY which would further impact the ASQ.

Results of comparing runs made with and without strict nondeclining yield requirements, however, show a much more significant impact. With CMAI rotation constraints the nondeclining yield constraints reduce PNV by 1.1 percent (run #7 compared to run #5). Without the CMAI restrictions PNV is reduced by 1.4 percent (run #6 compared to run #4) with strict nondeclining yield. Timber volume on the other hand, is reduced by 15 percent in both runs under NDY (runs 6 and 7). This large decrease in timber volume with only a minor drop in PNV is a result of the departure run's additional volume coming from lower value/higher cost stands which were not

1/ Run numbers follow the convention established in Cargill's 1920 letter of 8/8/83 and use the constraints and objective function defined in that direction
2/ Volume figures do not include unreported salvage. All runs with the nondeclining yield constraint produce at the LRSY level in decade 1 except BM7.
3/ These PNV figures are those taken directly from the FORPLAN reports and are not 100% comparable to PNV's given elsewhere in the AMS. For comparison and relative purposes, however, these figures are accurate.
selected by the runs with a nondeclining yield formulation. All four of these runs include constraints necessary to meet management requirements. It is also expected that with a surplus inventory a departure schedule would have little to no effect. Even with shorter rotations, the existing inventory will still have control over the departure schedule. This is because the existing inventory will still need to be meted out until new stands (short of culmination) are available for harvest.

The effects of these two requirements (CMAI and NDY) in combination can also be extracted from the results of the benchmark run sequence. In general, since the CMAI restrictions have such a small effect, results are very similar to those obtained looking only at the nondeclining yield requirements. With all management requirements met, the effect on PNV of the nondeclining yield constraints and CMAI restrictions together is 2.2 percent (run #7 compared to run #4). Without management requirement restrictions the impact on PNV is 7.1 percent (run #3 compared to run #2). The greater difference in PNV between these four runs and that shown between runs 7 and 5 and 6 and 4, which were discussed above, indicates that it is the management requirements which prevent a departure schedule from dramatically increasing PNV while increasing harvested volume.

Because the assigned value and market value benchmarks treat the timber resource in the same way, the impacts of timber harvest policies (NDY and CMAI) will be the same for both.

The effect of removing the nondeclining even flow constraint results in elk and deer numbers remaining similar to today's level for the first two decades. A drastic reduction occurs in the fourth decade and is only slightly above viable population levels in the fifth decade.

The decline in big game populations after the third decade is due to intensive timber harvesting during the earlier decades. This results in low amounts of cover, which is poorly dispersed, and high road densities.

Removing nondeclining even flow increases sediment production between 1.4 and 1.9 times more than the other benchmark runs in the first decade. However total sediment projections are less than the total sediment for Maximum Timber, PNV, Range, and Current Situations benchmarks. Water runoff on the other hand only increases seven percent over non-departure benchmarks.

**Benchmark Descriptions**

**Minimum Level**

**Description and Purpose**

The minimum level benchmark is a determination of the minimum costs and resultant outputs necessary to retain National Forest lands in Federal ownership. Minimum environmental constraints and protection of the life, health and safety of users must be provided.

The purpose of developing the minimum level benchmark is:

- To determine the minimum costs involved with maintaining National Forest lands in the National Forest system; i.e., a cost level that is not discretionary in the Programming and Budgeting process; and
- To determine the outputs and effects related to this "minimum expenditure" level.

**Assumptions and Constraints**

In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below

Wild horse numbers are managed at today's levels according to the Big Summit Territory Management Plan.
Big game user days (WFUD's) change directly in response to changes in big game habitat capability.

Riparian based recreation use increases when riparian conditions are enhanced.

The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.

Practices and costs are only those necessary to keep the Forest in public ownership.

Some costs are necessary to protect the life, health, and safety of incidental users; to prevent environmental damage to lands or resources of adjoining ownerships, administer unavoidable special uses; and to not allow significant impairment of the productivity of the land.

Outputs associated with this benchmark include only uncontrollable outputs and uses, such as naturally occurring water runoff, wildlife and fish, and dispersed recreation.

Costs for a transition “close down” are not included, as per Regional direction (11/10/83).

**Assumptions and Constraints**

In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

- **Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Appendix for acreages).**
- **Sufficient ending timber inventory must remain at the end of the modeling horizon to sustain timber harvest at the long run sustained yield capacity.**
- **Regeneration harvests cannot be scheduled until stands have reached 95% of culmination of mean annual increment.**
- **Wild horse numbers are managed at today’s levels according to the Big Summit Territory Management Plan.**
- **Big game user days (WFUD’s) change directly in response to changes in big game habitat capability.**
- **Riparian based recreation use increases when riparian conditions are enhanced.**
- **Allocations used are those specified in current unit plans as interpreted by the IDT and Forest Management Team.**
- **Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).**
- **Timber harvest cannot exceed the long run sustained yield capacity in any decade.**
- **An objective function of maximizing timber for the first decade was used. Timber outputs were then “rolled over” to a second run which used a maximum PNV objective function for 15 periods.**

**No Action with NFMA Requirements**

**Description and Purpose**

This benchmark is also Alternative A in the FEIS.

In the DEIS the purpose behind this particular analysis is to isolate the outputs and costs that can be attributed to NFMA requirements not currently incorporated in the Current Situation Alternative, as well as to present a version of the current situation alternative updated to reflect NFMA requirements. In the FEIS, Alternative A has been modified and now incorporates all NFMA requirements. As a result, there is no difference between the No Action benchmark and Alternative A (No Action). The No Action Benchmark is displayed here for comparative purposes only.
Maximum PNV Using Market Values Only

Description and Purpose
This benchmark estimates the maximum PNV that might be attained on the Forest by valuing only those outputs that have an established market price (timber, range, and developed recreation), subject to management requirements, rotation age restrictions (CMAI), and non-declining yield.

The purpose of developing this benchmark is to estimate the level of goods and services produced by a maximum PNV objective and to permit a comparison of this PNV and associated outputs with other benchmarks and plan alternatives.

Assumptions and Constraints
In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

- Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Process Record 1920 1/84 for acreages).
- Timber harvest cannot exceed the long run sustained yield capacity in any decade.
- Sufficient ending timber inventory must remain at the end of the modeling horizon to sustain timber harvest at the long run sustained yield capacity.
- Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).
- Regeneration harvests cannot be scheduled until stands have reached 95% of culmination of mean annual increment.
- Regeneration harvests are dispersed to meet Regional Guidelines for size and separation of harvest units.
- Regeneration harvests and overstory removals are dispersed to meet management requirement for soil and water.
- Less intensive silvicultural practices are scheduled in riparian areas to meet management requirements for soil and water.
- Old growth units are dedicated according to Regional Guidelines for distribution and amount to meet management requirements for primary cavity excavators.
- Wild horse numbers are managed at today’s levels according to the Big Summit Territory Management Plan.
- Big game user days (WFUD’s) change directly in response to changes in big game habitat capability.
- Riparian based recreation use increases when riparian conditions are enhanced.
- The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.
- Objective function used is to maximize present net value for the entire modeling horizon using only market values.
- Areas of the forest not allocated to old growth, riparian, wilderness, or research natural areas are allocated to the timber/range prescription.

Maximum PNV Using Assigned Values

Description and Purpose
This benchmark estimates the maximum PNV that might be attained on the Forest by valuing outputs with either market or assigned values, subject to minimum management requirements, rotation age restrictions (CMAI), and non-declining yield.
The purpose of developing this benchmark is to estimate the level of goods and services produced by a max PNV objective and to permit a comparison of this PNV and associated outputs with the PNV and outputs of other benchmarks and plan alternatives.

Assumptions and Constraints
In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Process Record 1920 1/84 for acreages).

Timber harvest cannot exceed the long run sustained yield capacity in any decade.

Sufficient ending timber inventory must remain at the end of the modeling horizon to sustain timber harvest at the long run sustained yield capacity.

Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).

Regeneration harvests cannot be scheduled until stands have reached 95% of culmination of mean annual increment.

Regeneration harvests are dispersed to meet Regional Guidelines for size and separation of harvest units.

Regeneration harvests and overstory removals are dispersed to meet management requirement for soil and water.

Less intensive silvicultural practices are scheduled in riparian areas to meet management requirements for soil and water.

Old growth units are dedicated according to Regional Guidelines for distribution and amount to meet management requirements for primary cavity excavators.

Wild horse numbers are managed at today's levels according to the Big Summit Territory Management Plan.

Big game user days (WFUD's) change directly in response to changes in big game habitat capability.

Riparian based recreation use increases when riparian conditions are enhanced.

The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.

Objective function used is to maximize present net value for the entire modeling horizon including both market values and assigned values.

Analysis summarized below showed that the only adjustment to the FORPLAN allocation of lands for costs and benefits not included in the model that should be made according to the maximization of PNV criterion when assigned values are included was to use the enhance riparian prescription.

Areas of the forest not allocated to old growth, riparian, wilderness, or research natural areas are allocated to the timber/range prescription.

Maximum Recreation/ Unroaded

Description and Purpose
This benchmark estimates the maximum capability of the Forest and Grassland to provide semi-primitive nonmotorized, semi-primitive motorized, roaded natural, and developed recreation opportunities subject to management requirements, rotation age restrictions (CMAI), and non-declining yield.

Assumptions and Constraints
In the process of formulating benchmarks and alternatives certain assumptions must be made and con-
constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Process Record 1920 1/84 for acreages).

Timber harvest cannot exceed the long run sustained yield capacity in any decade.

Sufficient ending timber inventory must remain at the end of the modeling horizon to sustain timber harvest at the long run sustained yield capacity.

Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).

Regeneration harvests cannot be scheduled until stands have reached 95 percent of culmination of mean annual increment.

Regeneration harvests are dispersed to meet Regional Guidelines for size and separation of harvest units.

Regeneration harvests and overstory removals are dispersed to meet management requirements for soil and water.

Less intensive silvicultural practices are scheduled in riparian areas to meet management requirements for soil and water.

Old growth units are dedicated according to Regional Guidelines for distribution and amount to meet management requirements for primary cavity excavators.

Wild horse numbers are managed at today's levels according to the Big Summit Territory Management Plan.

Big game user days (WFUD's) change directly in response to changes in big game habitat capability.

Riparian based recreation use increases when riparian conditions are enhanced.

The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.

Objective function used is to maximize Present Net Value for the entire modeling horizon.

All currently inventoried semi-primitive non-motorized and semi-primitive motorized areas are allocated to prescriptions maintaining that character.

Riparian areas receive additional protection to enhance riparian conditions.

Construction of new facilities results in increased developed recreation use.

The Deschutes Canyon Further Planning Area would be recommended for wilderness in this benchmark.

Remaining areas of the Forest and Grassland are allocated to big game prescriptions with the corresponding thermal cover constraints and road closure costs.

**Maximum Timber**

**Description and Purpose**

This benchmark estimates the maximum level of timber volume that can be attained on the Forest, subject to rotation age restrictions, nondeclining yield, and management requirements.

The purpose of developing this benchmark is to determine the maximum level of timber volume that can be produced on the Forest, subject to management requirements, rotation age restrictions (CMAI), and nondeclining yield.

**Assumptions and Constraints**

In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and
effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Process Record 1920 1/84 for acreages).

Timber harvest cannot exceed the long run sustained yield capacity in any decade.

Sufficient timber inventory must remain at the end of the modeling horizon to sustain timber harvest at the long run sustained yield capacity.

Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).

Regeneration harvests cannot be scheduled until stands have reached 95 percent of culmination of mean annual increment.

Regeneration harvests are dispersed to meet Regional Guidelines for size and separation of harvest units.

Regeneration harvests and overstory removals are dispersed to meet management requirements for soil and water.

Less intensive silvicultural practices are scheduled in riparian areas to meet management requirements for soil and water.

Old growth units are dedicated according to Regional Guidelines for distribution and amount to meet management requirements for primary cavity excavators.

Wild horse numbers are managed at today's levels according to the Big Summit Territory Management Plan.

Big game user days (WFUD's) change directly in response to changes in big game habitat capability.

Riparian based recreation use increases when riparian conditions are enhanced.

The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.

Timber harvest levels are determined through the following process:

A run is made which maximizes timber for the first decade.

Using that run's results for the first decade, another run maximizes timber for all 15 decades.

Constraining in the results of the second run, a third run is made in which the objective function is to maximize Present Net Value for the entire modeling horizon.

Areas of the Forest other than old growth, riparian, wilderness, or research natural areas are allocated to the timber/range prescription.

### Maximum Range

**Description and Purpose**

This benchmark estimates the maximum capability of the Forest and Grassland to provide commercial livestock grazing, subject to management requirements, rotation age restrictions (CMAI), and non-declining yield.

The purpose of this benchmark is to show the maximum level of commercial livestock grazing.

**Assumptions and Constraints**

In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Process Record 1920 1/84 for acreages).

Timber harvest cannot exceed the long run sus-
Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).

Regeneration harvests cannot be scheduled until stands have reached 95 percent of culmination of mean annual increment.

Regeneration harvests are dispersed to meet Regional Guidelines for size and separation of harvest units.

Regeneration harvests and overstory removals are dispersed to meet management requirements for soil and water.

Less intensive silvicultural practices are scheduled in riparian areas to meet management requirements for soil and water.

Old growth units are dedicated according to Regional Guidelines for distribution and amount to meet management requirements for primary cavity excavators.

Wild horse numbers are managed at today’s levels according to the Big Summit Territory Management Plan.

Big game user days (WFUD’s) change directly in response to changes in big game habitat capability.

Riparian based recreation use increases when riparian conditions are enhanced.

The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.

Forage output levels are determined through the following process:

A run is made which maximizes forage for all 15 decades.

Constraining in the results of the first run, a second run is made in which the objective function is to maximize the PNV for the entire modeling horizon.

Areas of the Forest other than old growth, riparian, wilderness, or research natural areas are allocated to the timber/range prescription.

Acreage limitations on mechanical treatments were set so that only operable soils with range in poor to fair condition are scheduled for treatment.

Acreage limitations on non-mechanical treatments were set at operationally feasible levels to prevent extreme disruptions in grazing programs.

**Maximum Big Game**

**Description and Purpose**

This benchmark estimates the maximum capability of the Forest and Grassland to produce big game subject to management requirements, rotation age restrictions (CMAI), and non-declining yield.

The purpose of this benchmark is to show the maximum level of big game.

**Assumptions and Constraints**

In the process of formulating benchmarks and alternatives certain assumptions must be made and constraints specified in order to model or portray complex relationships and estimate costs, outputs, and effects. Those assumptions and constraints with significant bearing on cost, output, and effect estimation are listed below.

Timber harvest is scheduled only on lands classified as suitable for timber harvest through the Stage I suitability analysis (see Process Record 1920 1/84 for acreages).

Timber harvest cannot exceed the long run sustained yield capacity in any decade.

Sufficient ending timber inventory must remain at the end of the modeling horizon to sustain timber harvest at the long run sustained yield capacity in any decade.
Timber harvest cannot decrease in any decade as compared to the immediately preceding decade (NDY).

Regeneration harvests cannot be scheduled until stands have reached 95 percent of culmination of mean annual increment.

Regeneration harvests are dispersed to meet Regional Guidelines for size and separation of harvest units.

Regeneration harvests and overstory removals are dispersed to meet management requirements for soil and water.

Less intensive silvicultural practices are scheduled in riparian areas to meet management requirements for soil and water.

Old growth units are dedicated according to Regional Guidelines for distribution and amount to meet minimum management requirements for primary cavity excavators.

Wild horse numbers are managed at today’s levels according to the Big Summit Territory Management Plan.

Big game user days (WFUD’s) change directly in response to changes in big game habitat capability.

Riparian based recreation use increases when riparian conditions are enhanced.

The quantity and quality of thermal cover directly affect big game habitat capability. Hiding cover and forage are both available in abundant supply and do not limit habitat capability.

Objective function used is to maximize present net value for the entire modeling horizon.

Areas of the forest other than old growth, riparian, wilderness, or research natural areas are allocated to big game prescriptions with the corresponding thermal cover constraints and road closure costs.

Opportunity Cost of Maximum Production, Minimum Level and No Action Benchmarks

An analysis of benchmarks was conducted to ascertain opportunity costs associated with the resolution of ICO’s. These evaluations were completed using a common constraint set to localize the effect directly attributable to achieving a specific resource objective. The opportunity cost displayed here are in addition to these associated with management requirements and timber harvest policy. The following two sections treat this information in more detail.

The discussion and values in the next three sections are taken from the DEIS. Although the values would change if updated, no change in relationships is expected. When values or relationships change, the effect will be discussed. Table 3-3B contains some of the same information (updated) as Table 3-3A.

<td>PNV 441 MM$</td>
</tr>
</tbody>
</table>

Opportunity Cost: 38 MM$ (eight percent reduction)

Land assignments selected by FORPLAN to maximize timber production are identical to those selected to maximize PNV. This is primarily due to timber’s significant contribution to PNV, relative to other resource values. Opportunity costs associated with maximizing timber production occur because less efficient acres are brought into solution earlier in the planning horizon. In addition, the model selects less efficient management intensities than it would select under Max PNV. PNV declines eight percent ($38 million); average annual first decade timber production increases seven percent (1.5 MMCF). Between the DEIS and FEIS, changes in the timber yield tables and analysis area data have resulted in a smaller decline in PNV and a smaller increase in ASQ.
Max Unroaded Benchmark

Runs Compared: B7E (PNV 479 MMS)  
BR3 (PNV 453 MMS)

Opportunity Cost: 26 MMS (five percent reduction)

All presently unroaded land was placed under custodial management in this benchmark which reduced the available/suitable timber base relative to Max PNV. The remainder of the suitable acres is assigned to big game prescriptions, which limits the intensity of management and harvest scheduling flexibility. Average annual first decade timber yield is reduced 5.3 MMCF (29 percent). A reduction in PNV (five percent) occurs with the reduction in timber harvest as the increased recreational use is not sufficient to completely offset the loss in timber revenues.

Max Range Benchmark

Run Compared: B7E (PNV 479 MMS)  
BF5 (PNV 425 MMS)

Opportunity Cost: 54 MMS (11 percent reduction)

Average annual first decade timber yield increased .3 MMCF due to an increase in management intensity relative to the Max PNV. PNV was reduced 11 MMS because increased livestock use could not offset the foregone timber values (lower value, higher cost relative to the Max PNV benchmark).

Max Big Game Benchmark

Runs Compared: B7E (PNV 479 MMS)  
BE3 (PNV 422 MMS)

Opportunity Cost: 57 MMS (12 percent reduction)

Management intensities required to achieve optimum habitat for big game species reduce the harvest scheduling flexibility relative to the Max PNV. Average annual first decade timber harvest declined 4.7 MMCF. Reductions in PNV (12 percent) are primarily due to the reduction in timber harvest. The increase in wildlife user days was not enough to offset forage and timber values.

Min Level Benchmark

Runs Compared: B7A (PNV 479 MMS)  
MINLVL (PNV 176 MMS)

Opportunity Cost: 303 MMS (63 percent reduction)

The Min Level Benchmark defines the costs and benefits of operating the Forest in a custodial fashion, with no production of controllable goods and services such as timber or developed recreation. Management under this benchmark reduces PNV by 63 percent and essentially terminates all market outputs with the exception of anadromous fish for commercial harvest.

No Action Benchmark

Runs Compared: B7E (PNV 479 MMS)  
5A6 (PNV 388 MMS)

Opportunity Cost: 91 MMS (19 percent reduction)

Land assignments in this benchmark are identical to those of the “No Action” Alternative. The multiple-use orientation of this benchmark reduces average annual first decade timber harvest 2.5 MMCF (11 percent), relative to Max PNV. PNV declines 91 MMS to meet the resource objectives specified in existing management plans.

Significant Relationships in the Production of Market and Nonmarket Outputs

Comparison of outputs, costs, and effects for the Max PNV benchmark which includes assigned values shows only minor differences as compared to Max PNV with only market values. A determination of how the allocation and scheduling of lands and resources would differ if assigned values were also used requires an analysis of the relationships and
trade-offs between resource outputs with market based values and those with assigned values. Outputs with assigned values that could affect the allocation and scheduling of market valued resources include semiprimitive nonmotorized RVD's, semiprimitive motorized RVD's, big game WFUD's, fishing WFUD's, and soil and water outputs. Other outputs with assigned values do not change from one benchmark to another. Results of the analysis conducted by the Forest are summarized below.

Semiprimitive nonmotorized and motorized RVD's can only be produced on areas of the Forest in a currently unroaded or near unroaded condition. When these areas are allocated to prescriptions enabling maintenance of semiprimitive recreation opportunities there results an increase in present value of $11,551,000 due to increased SPNM and SPM RVD's (BR3), an increase in present costs of $1,978,000 due to trail and trailhead construction (BR3), and a decrease in net present value of $27,100,000 due to foregone timber harvest (BR1 compared to B7A). The total change in PNV is -$17,523,000, which leads to the conclusion that no change in the allocation and scheduling of market resources should occur according to the maximization of present net value criterion by using the assigned values for semi primitive RVD's. Between the DEIS and FEIS both the timber model component and SPNM demand estimates were updated. As a result, both discounted timber benefits and RVD's are somewhat lower.

A comparison of the contribution to the present value of big game WFUD's and timber outputs in runs BE3 and B7E shows the trade-offs involved in present value from timber harvest necessary to obtain greater value from big game WFUD's. The only difference in these two runs is the presence of thermal cover constraints in BE3 designed to improve big game habitat capability. In run B7E, $472,990,000 of present value is attributed to timber harvests and $79,733,487 of present value is attributed to big game WFUD's. In run BE3, $398,742,000 of present value is attributed to timber harvests and $89,343,507 can be attributed to big game WFUD's. A reduction in present value of $74,248,000 from the timber resource was incurred to produce an increase of $9,609,000 in present value from the big game resource. A major reason that significant differences in big game habitat capability do not show up as significant differences in present value is that these differences mostly occur after the first two decades and are heavily discounted in present dollar terms. With non-declining yield requirements, constraints necessary to produce improved habitat capability in the future translate into early decade losses in timber contributed present value. In general those areas of the Forest that require the least trade-off of timber value (predominantly mixed conifer) are the same areas that have the best habitat capability currently and show the least change in habitat capability.

Wildlife user days associated with hunting are relatively higher in the FEIS than in the DEIS. This fact, combined with slightly lower discounted timber benefits, would lower the loss in PNV due to big game habitat but will not change the relationship.

An analysis of fishing WFUD's shows the area of conflict requiring some trade-off is with livestock AUM's. Changes in timber-generated value are relatively insignificant whether a "maintain riparian conditions" prescription or an "enhance riparian prescription" is employed. However, with enhanced conditions an increase in fishing WFUD's occurs, generating an increase in present value of $12,266,100. Livestock AUM's also decrease, with an associated present value of $1,369,740. Cost decreases for livestock administration are approximately offset by increases in structural improvements necessary to obtain enhanced riparian conditions. The total change in PNV when enhancing all Class 1 and 2 streams is an increase of $11,396,360. The results of analysis in this case show that a reallocation should occur when assigned values are considered according to a maximization of PNV criterion.

Between the DEIS and FEIS the livestock/riparian interactions and fishing demand assumptions were reevaluated. This resulted in significant changes in outputs. Firstly, the amount of fishing is predicted to be higher. Also, in the FEIS anadromous fishing was valued. Capital investments needed to improve the habitat are significantly higher. Finally, the loss of
AUM's due to habitat improvement is less in the FEIS. The increase in RVD's would increase the change in the PNV while the higher cost and less reductions in AUM's would offset it. It is expected that improving riparian conditions is still more cost efficient.

Consideration of the assigned values contributed from soil and water outputs, however, shows that the magnitude of the changes in present value from soil and water is negligible as compared to the change in present value from timber that is linked to soil and water values. When comparing the resource benchmarks (excluding the minimum level) the difference in present value from the benchmark with the least soil and water value (maximum timber) to the one with the most (maximum recreation) is only $580,000. The difference in present value between benchmarks due to timber contributed value is on the order of tens of millions of dollars. Considering the minimum level benchmark where soil and water values are highest, present value attributed to soil and water increases $1,101,000 as compared to the maximum timber benchmark. The loss in present value due to foregone timber values, however, is on the order of hundreds of millions of dollars.

An additional analysis performed on the Forest was designed to ensure that the particular intensities and scheduling patterns modeled as choices in the timber-range prescription contained all of the choices used by the model to maximize Present Net Value. This analysis considered both per acre and Forest-wide scheduling aspects and is documented in planning files (1920 5/16/84 and 1920 9/10/84). Necessary changes were made as a result of this analysis, and the timber-range prescription now contains all of the flexibility in management intensity and scheduling patterns necessary to maximize PNV.

Given the conclusions of the analysis described above, it is apparent that very little difference exists in outputs, effects, and costs result due to consideration of all assigned values. The differences that do show up are attributable to use of the prescription to enhance riparian conditions.

Resource Maximization Potentials

The benchmark runs discussed earlier were made in order to explore the maximum potentials of the Forest to produce various outputs. These outputs include present net value, range, recreation, timber, and big game. In addition to helping define the maximum resource production capabilities of the Forest and the decision space within which alternatives can be developed to address the planning ICO's, some idea can be obtained about the magnitude of output tradeoffs that are incurred when various resources are emphasized.

The analysis was performed by providing FORPLAN with the land allocations and prescriptions which would lead to the maximization of a particular resource (i.e., range or PNV, or recreation, or timber, or big game). FORPLAN was then run with a maximum PNV objective function for the Max PNV, maximum recreation and maximum big game benchmarks. On the other hand, the Maximum Timber Benchmark and Maximum Range Benchmark were first run with a maximize timber objective function, and maximize forage objective function. The timber and forage outputs from these runs were then "rolled over" to a second run which was executed with a maximum PNV objective function.

The resource output's discounted benefits and costs were calculated with electronic spreadsheets outside of FORPLAN. The budget estimations and the overall present net value calculations were also performed with the use of electronic spreadsheets.

Table B-6-3A displays the outputs and effects associated with the various resource maximization benchmarks.

A comparison of the two PNV benchmarks (market values only and assigned values plus market values) has already been presented above and for this comparison benchmark #3 (B7E, market plus assigned values) will be used as the reference point. The PNV of benchmark B7E is 479 million dollars. This includes a total present value of 712 million dollars of which 215 million can be attributed to assigned

</tbody>
</table>
values and 496 million to market values. The majority of the 541 million comes from timber harvest (473 million). The basic thrust of this benchmark is to capture as much value from the existing timber stands as possible under nondeclining yield. This is accomplished by balancing the higher reforestation costs but less constraining harvest dispersion constraints associated with planting against the lower cost but more constraining dispersion constraints associated with natural regeneration. Consequently, reforestation scheduled in the first five decades is a mix of planting and natural regeneration. This results in somewhat lower timber yields as compared to the maximum timber benchmark. Range yields on transitory range are produced at levels commensurate with the timber scheduling that maximizes PNV. Range values can not compete with timber values to influence the harvest scheduling. Analysis of runs made with and without range outputs valued in the maximize PNV objective function showed no significant change in the harvest schedule (TIE and TIF). Range output increases due to non-structural improvements do not generally increase PNV except in the small number of meadows on the Forest. Additional structural improvements, on the other hand, do generate positive PNV and are included in this and other benchmarks. Analysis conducted by the Forest showed that an opportunity for construction of approximately 300 water developments exists that would increase PNV and result in an additional 22,000 AUM’s. Re-analysis between the DEIS and FEIS indicated that most developments would not support as many AUM’s (10,000 instead of 22,000) and would cost significantly more. Only 140, instead of 300, are cost effective and increase PNV. Recreation use cannot compete with timber harvest in monetary terms and is produced at background values commensurate with timber harvest in this benchmark. The fishing aspect of recreation use, however, does not compete with timber harvest but successfully competes with livestock use in monetary terms. Therefore, riparian prescriptions calling
for enhanced conditions are employed resulting in higher fishing WFUD's and lower AUM's. Soil and water outputs with assigned values cannot compete with timber harvest and are produced at levels resulting from the timber harvest schedule that maximizes PNV. More detail on these relationships is contained in Section 3.

The two benchmarks with the second highest and lowest PNV, maximum recreation (453 million) and maximum big game (422 million) are very similar. In both cases most of the Forest is allocated to big game prescriptions. However, the maximum recreation benchmark allocated currently unroaded areas to semiprimitive prescriptions and invested money into trail, trailhead, and campground development. The main reason for the differences between these two in terms of PNV is that the maximum recreation benchmark generates more present value from the higher discounted benefits and lesser cost associated with the semiprimitive RVD’s than does the additional timber and big game benefits but higher costs in the maximum big game benchmark. The presence of big game cover constraints for big game in both cases limits capturing the value in the existing stands as fast as in the maximum PNV benchmark.

The two commodity oriented benchmarks, maximum timber and maximum range, have a lower PNV than the PNV benchmark, due to the large investments required to get the last 5-20 percent of output for the maximum. In the case of maximum timber (PNV of $447 million) an increase of seven million dollars in present value from timber, as compared to the maximum PNV benchmark, occurs but the increase in reforestation and TSI costs over the first 50 years is 33 million dollars (18 million in present costs). Other costs such as roads, administration, and support are also higher. In the case of maximum range (PNV of 425 million dollars), an increase of $7 million in present value from range, as compared to the maximum PNV benchmark, occurs at an increased cost of $21 million in non-structural improvements over the first 50 years ($9.4 million in present costs). A more substantial cost is the present value from timber foregone when harvest scheduling is designed to maximize livestock on transitory range ($17 million), as well as the increased costs of timber management resulting from higher reforestation costs and TSI costs.

The benchmark with the lowest PNV is the minimum level (PNV of $175 million). This represents essentially a background value attributable to various recreation, hunting, and fishing uses. The much lower PNV of this benchmark portrays the foregone opportunity to capture the high values in our existing stands of timber.

Most of the explanation of differences in costs is contained in the above paragraphs describing the differences in PNV. All resource benchmarks show costs that decline after the first decade. Road costs and precommercial thinning costs are the items common to all benchmarks that decline after the first decade. More acres are entered in the first decade due to the opportunity to do overstory removals in existing two story stands which leads to higher road costs and precommercial thinning costs that are higher than in managed stands. In the case of the maximum range and maximum recreation benchmarks, additional dollars for structural improvements are also included in the first decade costs. Costs in all benchmarks rise between the third and fifth decades. This is largely a result of increased reforestation costs as more acres are planted.

The changes in local jobs and income are mostly a function of the total harvest level and species mix (see Chapter 4 and Section 5). As a result, those benchmarks (PNV, Timber and Range) which have a harvest level higher than today’s will have an increase in jobs. The effect of species mix is portrayed by comparing the Max Range Benchmark with the Max PNV Benchmark. Although the Max Range Benchmark has a higher timber harvest level, it creates fewer jobs because it harvests substantially less pine volume than does the Max PNV Benchmark.

The Max Recreation and Max Big Game Benchmarks both lose jobs compared to the current situation because they harvest substantially less timber volume. Their loss in timber related jobs is offset to a degree by the increase in service related jobs tied to the increase in recreational visitor days (RVD’s)
Although the increase in RVD’s offsets the loss in total jobs, it has less of an impact on income because service related jobs are not as valuable as timber generated jobs (see Section 5).

Although the Max Recreation Benchmark harvests substantially less timber than does the Max Big Game Benchmark it loses fewer jobs. This is a result of its harvesting the same amount of pine volume, providing the same amount of big game RVD’s and having a substantial increase in SPNM RVD’s. This translates into a slight decrease in timber related jobs, no change in service jobs related to big game opportunities and a substantial increase in service jobs related to SPNM opportunities. The net result is less total jobs being lost.

Potential to Resolve Issues and Concerns, and to Capture Management Opportunities

The following paragraphs summarize the ability of the Forest and Grassland to resolve the twelve issues that were identified to guide this planning process.

Timber

The Forest lacks the capability to meet the local demand for timber as indicated by the installed mill capacity. Current levels of timber harvest could be sustained, however, if reforestation and TSI investments were to be increased and some compromise in allocations to other resources were made. If management of other resources were to be reduced to the lowest level while still meeting management requirements, timber outputs could be increased 10-15 percent. The above comments pertain to timber harvest as measured in cubic feet. All analyses show declining harvests as measured in board feet. The maximum timber benchmark shows a board foot harvest in the fifth decade that is five percent lower than the current harvest level and 15 percent lower than in the first decade.

Conflicts with other resources and, to a degree, concerns about economic efficiency will impact timber harvest levels in most alternatives. Provision of old growth, roadless recreation opportunities, visual zones, riparian area management, high quality big game habitat, and snags all result in a reduced harvest level. Economic analyses show that natural regeneration competes economically with planting. Natural regeneration results in a somewhat lower harvest level.

Socio-Economic

Results of analyses show the opportunity to make progress on both the major aspects of this issue and concern; i.e., local jobs and economic efficiency. Emphasis on increased timber outputs leads to an increased number of local jobs. Emphasis on economic efficiency could lead to an increase in PNV of 63 million dollars. These two alternative directions are not identical, however, in that attainment of the highest timber output levels and local jobs leads to a lower PNV than the maximum. In general, production of resource outputs that conflict with timber outputs result in a lower number of local jobs and PNV than could otherwise be produced.

Range

Analysis of forage production on the Forest and Grassland shows that significantly higher levels of livestock outputs could be generated if substantial investments were made. Significantly higher levels of funding would have to be available for reconstruction of existing structures as well as for new construction. Existing levels of AUM’s could be maintained without additional construction but an increase in reconstruction funding is necessary to maintain this level over time. The major conflict
with livestock production is the use and condition of riparian areas. Enhancement of these areas requires some reduction in livestock production.

**Riparian Areas**

Riparian areas could be enhanced to provide higher quality water and fish habitat and higher levels of recreation use. Standards and guidelines for timber harvest, silviculture, and road management require more costly practices to enhance these zones. Continuation of current livestock practices in riparian areas would prevent improvement of riparian area conditions.

**Transportation System**

The Forest and Grassland can respond to the various aspects of this issue through the mix of prescriptions utilized in a particular alternative and through the array of alternatives considered. The portion of the issue dealing with road design standards is dealt with by the use of the most cost efficient road construction standards for local roads, and by a network analysis for each alternative which shows the most efficient schedule of investments for the arterial and collector system. Some of the considerations included in this analysis will be the timber volume flowing over the network and the degree of emphasis recreation is receiving in the assigned prescriptions. This results in a shift in traffic service levels. The road access aspect of the issue will also be analyzed through the mix of prescriptions assigned for a particular alternative. Different prescriptions call for different levels of open road density.

**Big Game**

The Forest and Grassland have the capacity to substantially increase big game numbers over time, resulting in increased numbers of hunters. Allocations resulting in increases will reduce timber harvests. Maintenance of today's levels of big game requires allocations that produce similar amounts of cover as that found in the current land allocations (big game, old growth, roadless areas).

**Roadless Recreation**

The Forest and Grassland has the ability to meet identified demands for this type of recreation over the next fifty years if allocations are made that maintain the unroaded character in some unroaded areas. If all non-wilderness unroaded areas are allocated to roaded management then first decade demands will not be met. The major conflict is with timber harvest levels.

**Scenic Resources**

Management designed to retain natural appearing landscapes in visual corridors could be either decreased or increased from today's level. The main conflict is with timber harvest levels.

**Old Growth**

Allocations of old growth could either be increased or decreased from today's level. The main conflict is with timber harvest levels.

**Firewood**

The Forest has the ability to produce more firewood through several options. Higher timber harvest levels produce more residue for firewood, salvageable material could be reserved for firewood, thinnings could be designed for firewood; lodgepole pine management could be geared for firewood; firewood use could receive higher priority than pole or chip users; and snag management policies could be altered.

**Snag Level**

Snag levels, either at today's level, or below or above that level, could be provided on the Forest. The main conflict is with timber harvest levels.
Winter Sports

Opportunities for cross-country skiing could be enhanced with a trail development and maintenance program. Conflicts between skiing and snowmobiling that occur in some specific areas, such as Lookout Mountain, may be resolved by designating separate access routes.

New Issues in FEIS

Anadromous Fish

Anadromous fisheries are a subset of the riparian issue. Due to the relative inaccessibility of these streams, they are generally in good condition.

Historic Trail Preservation

This issue encompasses two factors: the Forest could protect and manage the historic resource as it does other cultural resources, and/or manage the trail as it does other scenic corridors. The major conflict with the latter is with timber harvest levels.

Off-Road Vehicle (ORV) Use

This issue has two facets. On one hand, ORV use could be more restricted on the Forest and Grassland. On the other hand, with an expanded trail system, more acres on the Forest and Grassland could be available for ORV use.

Round Mountain

This issue is similar to other recreation issues, such as roadless areas and big game, where special management is proposed for a specific area. The main conflict is with timber harvest levels.

Ability to Meet RPA Goals

Comparisons with the 1980 RPA outputs distributed to the Forest and Grassland through the Regional Guide are difficult for two reasons. First, RPA timber harvest levels are depicted for a Forest regulated under nondeclining yield in board feet when all of the Ochoco's analyses are based on regulating the Forest in cubic feet. Since conversion ratios change with the diameter of the material harvested and the average diameter harvested changes over time, comparison of first decade board foot harvest levels can be misleading. Second, it is very difficult to interpret some RPA outputs, such as acres of habitat improvement, in terms of outputs useful for resolving an issue (e.g., numbers of elk). Given this situation, the only RPA outputs that it appears the Forest and Grassland will have trouble meeting are the timber outputs.

An annual board foot harvest level (programmed sales offered) of 150 MMBF, as depicted in the Regional Guide, does not appear to be sustainable under any foreseeable circumstance. The maximum timber benchmark harvests 147 MMBF in the first decade, 144 MMBF in the second, and declines to 125 MMBF by the fifth decade. Harvest levels that reflect current land allocations are substantially lower than the maximum timber benchmark. The amount of acres scheduled for reforestation in RPA (1100-1400 acres annually) is not coordinated with the timber harvest levels shown. For example, the maximum timber benchmark reforests between 4900 and 6800 acres annually for the first fifty years.

Need to Alter Management Direction

Several elements of the current situation continue to be areas of conflict. One area of concern is the sustainability of board foot harvests over time. All of
the Ochoco's analyses indicate declining harvests in board feet (see Section 5). Another concern is the selection of silvicultural systems. There is very little emphasis on uneven-aged management under current plans. Another area of concern is the compatibility of cover requirements for big game in the unit plans with current timber harvest levels. Again, analysis indicates incompatibilities at present (Chapter 4). A third area of concern is the compatibility of current AUM output levels with direction for riparian area management in the unit plans. Analysis of output tables in Chapter 4 shows that there is indeed some conflict. Finally, conflict among user groups continues as to the appropriate type of management for Lookout Mountain. It is evident that this issue has not been resolved.
Formulation of Alternatives

(Section 7)

Introduction

Definition of An Alternative

A Forest Plan alternative is a mix of management prescriptions and activity schedules applied in specific locations of the Forest and Grassland in order to achieve the desired management goals and objectives. Alternatives produce a unique mix of goods and services for the public, and different combinations of resource outputs, land uses and environmental effects.

Changes Between the DEIS and FEIS

The major changes discussed in this section are: the dropping of alternatives, the addition of a new alternative; the modification of certain alternatives; and the update of the cost (in terms of PNV and ASQ) of the resource objectives for each alternative.

Required Alternatives

The following were alternatives in the DEIS which were required by regulation and National and Regional direction.

No Action

This is the “No Action” alternative required by the Council on Environmental Quality (CEQ) regulations (40 CFR 1502.14). This alternative would continue the management of the Ochoco National Forest and Crooked River National Grassland as defined by existing direction in approved management plans; continuation of existing policies, standards, and guidelines; current budget updated for changing costs over time; and, to the extent possible, production of current levels and mixes of resource outputs.

Alternative A was the Current Direction Alternative (or the “No-Action” Alternative) in the DEIS.

No Change Alternative

The No Change Alternative, Alternative NC, was developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resources Council on May 19, 1986. The appeal questioned the decision by the Regional Forester to “require inclusion of minimum requirements (MR’s) in the No Action Alternative for each Forest Plan.” The substance of the appeal was that a “true no action alternative representing current management plans” was not included in the Forest Plan DEIS’s. The No Change alternative is designed to represent the existing 1979 Timber Resource Plan and unit plans and, consequently, does not comply with all provisions of NFMA and regulations promulgated to implement NFMA.

Emphasis on Market Opportunities

This alternative has an emphasis on outputs that have an established market price (timber, domestic livestock use, developed recreation opportunities, and minerals). Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on market-oriented outputs.
Alternative H was the alternative in the DEIS which emphasized market opportunities for the Forest and Grassland.

Emphasis on Nonmarket Opportunities
This alternative puts an emphasis on water, fish and wildlife, recreation and other amenity values. Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

Alternative C was the alternative in the DEIS which emphasized nonmarket opportunities.

Emphasis on the Current RPA Program
This alternative will determine how the Current (1980) RPA Program distributed to the Forests through the Regional Guide can best be implemented.

Alternatives B and B-Departure were the current RPA Program alternatives in the DEIS.

Emphasis on Nondevelopment and Intensified Management
This alternative retains all currently roadless areas in an unroaded condition while increasing commodity production on those areas already roaded. Its purpose is to analyze the economic effects of not beginning commodity production in roadless areas.

Alternative F was the alternative which best emphasized roadless management and intensified commodity management in the DEIS.

Emphasis on Economic Efficiency
This alternative emphasizes management of outputs with market or assigned values at their most economically efficient levels.

Alternative H-Departure was the alternative which met this emphasis.

The following required alternatives were brought forward into the FEIS.

Alternative A (updated to include MR's).
Alternative NC.
Alternative B, as represented by Alternative B-Modified.
Alternative C, as represented by Alternative C-Modified.

All other required DEIS alternatives were eliminated from further study in the FEIS.

Process Used to Develop Alternatives

Requirements Concerning the Development of Alternatives

Several sources of direction guided the Forest in the development of alternatives. The implementing regulations of the National Forest Management Act (36 CFR 219) prescribe a general process for formulating alternatives, particularly in parts 219.12(e) and (f). Major points from these sections require:

Alternatives shall be distributed between the minimum resource potential and the maximum resource potential to reflect to the extent practicable the full range of major commodity and environmental resource uses and values that could be produced from the forest. Alternatives shall represent a range of resource outputs and expenditure levels.

Alternatives shall be formulated to facilitate analysis of opportunity costs and of resource use and environmental tradeoffs among alternatives and between benchmarks and alternatives.

Alternatives shall be formulated to facilitate evaluation of the effects on present net value, benefits, and costs of achieving various outputs and values that are not assigned monetary values, but are provided at specified levels.
Alternatives shall provide different ways to address and respond to the major public issues, management concerns, and resource opportunities identified during the planning process.

Reasonable alternatives which may require a change in existing law or policy to implement shall be formulated if necessary to address a major public issue, management concern, or resource opportunity identified during the planning process.

Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in the alternative.

Each alternative shall state at least:

- The condition and uses that will result from the long-term application of the alternative.
- The goods and services to be produced, the timing and flow of these resource outputs together with associated costs and benefits.
- Resource management standards and guidelines.
- The purpose of the management direction proposed.

The regulations also require that alternative development processes follow the NEPA (National Environmental Policy Act) procedures contained in Title 40 CFR 1502.14.

Within the framework given by these legal requirements, the Pacific Northwest Region of the Forest Service issued further direction (1920 11/10/83) on the development of alternatives. In addition to expanding on the need for a broad range of evenly distributed alternatives, this direction required development of alternatives that:

- Meet the State of Oregon goals for timber and big game,
- Strongly emphasize unpriced amenities,
- Strongly emphasize priced commodities,
- Closely examine economic efficiency,
- Thoroughly evaluate roadless areas, and
- Analyze timber volume flows over time that depart from non-declining yield.

Formulating a broad range of reasonable management alternatives for a National Forest is an extensive and complex process. Each alternative is a combination of land uses, Forest management activities, and schedules. Alternatives must consider the resource capabilities (both the limitations and the potentials) of many different areas of the Forest. Each alternative is designed to manage the land to achieve specific goals and objectives. Some of these objectives, such as maintaining air and water quality, are common to all alternatives; other objectives, such as the mix and amount of resource outputs, vary among the alternatives.

By managing the Forest and Grassland lands and resources in different ways, varied objectives can be achieved which respond to different issues and provide different combinations of public benefits. Forest management can vary by what is done, where it is done, and when it is done. These varying combinations of management activities, management areas, and schedules will result in different resource outputs and environmental conditions, thus meeting the unique objectives of the alternatives.

Formulation of Alternatives

The Ochoco National Forest and Crooked River National Grassland used the following steps to formulate alternatives.

Public Issues and Management Concerns

The issues and concerns discussed in Chapter 1 were condensed and grouped from hundreds of comments received by the Forest from local individuals, Forest Service employees, and other governing agencies or councils. National concerns were also included. This process of sorting, screening, and condensing represented the first step in the alternative development process since alternatives attempt to resolve issues and concerns. Appendix A described this process in detail.
Analysis of the Management Situation (AMS)
The analysis conducted during the AMS produced essential information for the development of alternatives. Benchmarks, discussed more fully in Section 6 p. 71 to p. 94, and in Chapter 2 were used to:

- Define the maximum potentials of the Forest and Grassland to produce various resource output levels and economic benefits,
- Evaluate the complementary and conflicting relationships between and among major market and non-market benefits,
- Identify the range within which integrated alternatives could be developed (decision space), and
- Analyze the implications of continued management under current direction.

Maximum production potentials developed with benchmarks enabled the Forest to compare supply potentials with expected demands. Instances where the demand exceeded the potential, or where the potential greatly exceeded the demand, were noted. These, along with the issues and concerns, provided a focus for later steps in the process.

Information gathered during these steps was assimilated and analyzed to guide the formulation of alternatives. The alternatives reflect a range of future resource management options for the Forest. Each major issue, concern, and opportunity was addressed in one or more of the alternatives. The need to satisfy legal and regulatory mandates was also a factor in the development of the alternatives. Finally, cost efficiency was a consideration throughout the process. The following discussion is a summary of the planning actions involved in the formulation and analysis of the alternatives. The focus will be upon the roles which the ICO's and the benchmarks played in their development.

Development of Alternative Themes and Objectives
The Forest used a process to develop alternative themes and objectives that would help ensure a broad range of reasonably distributed alternatives. Based upon the minimum and maximum resource output levels developed in the AMS, the Forest Interdisciplinary (ID) team established a number of output levels for each issue or concern. These outputs roughly corresponded with the "quantified indicators" of issue resolution discussed in Appendix A. In some cases outputs represented production levels, such as volume of timber, and in other cases they represented conditions, such as acres of old growth habitat. The ID team began to create alternative themes and objectives by grouping compatible output levels for each issue or concern. By including each output level for each issue or concern in an alternative, the ID team ensured that a broad range of evenly distributed alternatives was considered.

The Forest next entered a second stage of alternative theme and objective evaluation. The initial set of alternatives was evaluated to make sure that every identified issue or concern was resolved in at least one alternative in an acceptable manner. The competitive and complementary relationships of the ICO's were used as a guide in this process. Alternatives were then evaluated to ensure that they were sufficiently unique to warrant full development. As a result of this review, some preliminary alternatives were consolidated, added, or refined. A previous section in Chapter 2, Alternatives Considered but Eliminated from Detailed Study (DEIS, pp. 17-18), described the preliminary alternatives not fully developed. A detailed description of alternative themes and objectives, alternative development, and how they were derived in response to the Ochoco’s ICO's is contained in Ochoco’s Planning Records, 1920 9/4/84.

In December 1984, the Forest met with the Regional Forester and his Directors to review the Ochoco AMS and proposed alternatives. The basic set of eight alternative themes and objectives was approved at that time by the Regional Forester with a few relatively minor refinements. The Forest also agreed with the Regional Forester that three of the eight should be evaluated and fully developed with timber harvest schedules that depart from non-declining yield. Thus, a set of eleven alternatives was...
then approved for full development and analysis.

In the fall of 1989, the Ochoco National Forest issued a supplement to the DEIS. In that supplement a new alternative (NC) was developed and added to the 11 other DEIS alternatives. Formulation of Alternative NC (No Change) was different than the other alternatives. As mentioned previously, it was formulated as a result of an appeal by the Northwest Forest Resource Council. Alternative NC is designed to represent the existing Timber Management Plan and, does not comply with all provisions of the National Forest Management Act (NFMA) and regulations promulgated by the Secretary of Agriculture to implement NFMA.

Alternatives Considered But Eliminated From Detailed Study Between the DEIS and FEIS

Analysis and evaluation of public comment resulted in the development of a new alternative (I), the modification of alternatives B and C, the update of alternative A to reflect the No Action benchmark and E-Departure and NC being carried forward as a reference point from the DEIS to the FEIS. Alternatives B, B-Departure, C, D, E, F, G, H, and H-Departure are eliminated from further detailed analysis in this FEIS. These alternatives were adequately addressed in the planning process and displayed in the DEIS and have contributed to the consideration of a reasonable range of alternatives in the development of the Forest and Grassland Plans. Based on a thorough review of the public comments and management concerns, it was determined that these alternatives could be eliminated at this point. The modified alternatives carried forward and the new alternative respond to planning issues considered in the DEIS and offer a reasonable and appropriate range of choice for the decision on the Forest and Grassland Plans.

See Table B-7-1 for alternatives: eliminated in the FEIS, modified, and created.

Model Formulation and Analysis in Relation to ICO's and Cost Efficiency

Alternative development and evaluation is a very complex process during which an enormous amount of information must be considered. Major factors contributing to this complexity include the following.

Potential management activities must be scheduled and evaluated over a long period of time.

1/ Alternative B-Mod represents evolution and change of Alternative B-plus proposed by timber industry. Alternative B-Mod is a new industry alternative. It is different than B-Departure in the draft, the latter of which was much the same as Alternative B.

2/ Preferred Alternative I

3/ Current Direction Benchmark with National Forest Management Act (NFMA), Alternative A in this FEIS.

B-116
The entire Forest and Grassland, nearly one million acres that are highly diverse, must be assessed simultaneously.

Potential management activities must be assessed relative to multiple resource criteria.

Scheduled management activities must be cost-efficient.

Cost effectiveness and resolution of the ICO’s has driven the entire process from data and information collection through model design, alternative formulation and the iterative analysis process. It was necessary to consider these factors in all stages of the analysis to ensure the formulation of a wide range of reasonably distributed and cost efficient alternatives that responded to the identified issues and concerns.

Many sources of data were used to incorporate the best resource information and cost and dollar value information available into the Ochoco model. Resolution of the ICO’s and cost efficiency were met through careful design of the FORPLAN model, use of the model to select and schedule prescriptions for each alternative, use of the model in sequential analyses to help design alternatives and by conducting supplemental analyses.

The following paragraphs describe how model development, alternative formulation, and the analysis performed relate to resolution of the ICO’s and cost efficiency. Sections 2,3, and 5 contain more detailed descriptions of the data collection, model design and analysis performed. See these sections for the changes between the DEIS and FEIS.

The central model in this analysis process is called FORPLAN (FORest PLANning Model). FORPLAN is a computerized linear programming model which allows a great deal of flexibility in formulating a mathematical representation of forest management interactions and activities. The major reason for using FORPLAN is to select the most efficient method of achieving a set of goals and objectives. Tens of thousands of management options can be considered simultaneously by FORPLAN. The Ochoco FORPLAN model is specifically designed by the Forest ID Team to analyze the economic and production trade-offs associated with the issues and concerns described in Chapter 1.

The first key step in the development of the FORPLAN Model was to divide the total Forest and Grassland into analysis areas. Analysis areas are tracts of land with similar characteristics in terms of the costs, outputs, and effects that are being analyzed in the FORPLAN Model. Their boundaries represented the significant physical, biological, and economic differences in the way the land responds to alternative management strategies. And, of course, the delineations focused upon the planning issues and concerns. An example of an analysis area on the Forest is all two-storied ponderosa pine stands, on steep slopes, contained in roadless areas, on the Big Summit Ranger District. The Forest developed analysis areas several times, testing different combinations of land classifications each time, finally leading to use of analysis area data that most efficiently reflected the ICO’s and economic factors (see Planning Records, 1920 7/7/83).

In the FORPLAN model, analysis areas were allocated to management strategies in order to achieve the resource management objectives of a particular benchmark analysis or alternative. These strategies are associated with management areas and contain a set of standards and guidelines describing how the resources in that area are to be managed. Management areas are delineated by applying a Management Strategy (Prescription) to a particular piece of land. The Forest ID Team developed a complete set of strategies designed to achieve a wide range of goals and objectives. The Forest’s issues and concerns guided this process. From six to ten different management strategies were available to each analysis area depending upon its resource production opportunities.

The Forest then developed several maps of potential management areas for each management prescription that could be applied to different portions of the Forest and Grassland. These maps considered resource conditions and capabilities, multi-resource and other-ownership compatibilities, economic efficiency, and non-priced benefits.
Each of these potential management areas was analyzed to develop trade-off information. The Forest’s FORPLAN model was used to assist in this process. Relative impacts on PNV, big game numbers, RVD’s, and timber outputs were assembled for each potential management area. Using this data and other information presented on the relative benefits of managing one area versus another under a given management prescription, an expanded Forest Management Team assigned priorities to management areas for each alternative. The expanded management team consisted of the Forest Supervisor and Staff Officers, the Forest ID Team, and the District Rangers and their principal staff. Using these priorities and the alternative themes and objectives, final management area maps were developed. See Planning Records, 1920 10/02/85 for a detailed description of this analysis.

Once the management strategies were designed, “modeling prescriptions” were developed to represent different methods of management to achieve the multiple use objectives of each management strategy. These specific modeling prescriptions were developed, tested, and selected based to a large degree upon cost efficiency analysis (see Planning Records, 1920 9/10/84). In FORPLAN these are referred to as combinations of management emphases and intensities. Modeling prescriptions are combinations of scheduled activities and practices, and their associated outputs and effects. The modeling prescriptions and their range of timing choices are represented as decision variables in FORPLAN. In other words, specific options concerning how to manage a particular piece of land over time serve as the basis for choice in the model. The outputs and effects associated with the prescription choices are represented as mathematical coefficients in the respective decision variables. FORPLAN had from one to twenty modeling prescriptions to choose from for each management emphasis for each analysis area. In addition, dozens of different timing patterns and rotation ages were provided for most management emphasis/management intensity combinations on timbered lands.

Cost efficient coefficients used in the model to represent management choices were developed with the aid of various processes and models (including FORPLAN). These specific modeling procedures and scheduling options were evaluated and refined based upon cost efficiency analysis. For example, the Forest elected to manage and model old growth habitat with a dedicated stand system based in part upon economic efficiency considerations (see Planning Records, 1920 6/21/84). Final procedures for modeling dispersion of harvest units were adopted to minimize the impacts on present net value (PNV) while meeting dispersion objectives (see Planning Records, 1920 6/13/85). Scheduling options for management of two-storied stands (the largest timbered stand component on the Forest) were evaluated and refined based upon a cost efficiency analysis (see Planning Records, 1920 9/10/84).

Development of potential timber volume yields from management of existing timber stands required a Forest-wide timber inventory in 1981 to 1982. Yields from future stands were developed by calibrating testing areas using the Ochoco PROGNOSIS Model. This per acre analysis was then combined with a Forest-wide prescription scheduling analysis within FORPLAN. As a result of this analysis, additional yield tables were developed with different practices and timing mixes. This iterative process culminated in the Ochoco’s Model having a wide range of management intensities to ensure examination of a full range of management opportunities and provided for maximum flexibility to the Ochoco’s FORPLAN Model for optimization.

Forage yields were adaptations of Regional averages to Ochoco conditions. Range water developments were analyzed and those which were economically efficient were included in all benchmarks and alternatives. The relationship between timber stand conditions and big game animal energetics was developed and tied to elk cover quality and represented directly in yield tables. Having this relationship directly represented in the Model allows FORPLAN to pick the most cost efficient means of meeting the big game requirements under the various benchmarks and alternatives.
The trade-offs between livestock and recreation uses in riparian areas were also examined in an economic analysis and used accordingly in all benchmarks and alternatives.

Other types of analyses were performed with FORPLAN, both to evaluate different mixes of goals and objectives, and to fully evaluate choices not explicitly analyzed within FORPLAN. An analysis in the latter category examined the relative cost efficiencies of different management prescriptions and the timing of initial entry, as applied to individual roadless areas. The Ochoco FORPLAN model was not able to validly analyze these choices with a single model run, so sequential analyses were performed to provide economic efficiency trade-off data (see Planning Records, 1920 10/03/85).

Different mixes of goals and objectives were examined to provide cost efficiency information relative to competition between market and assigned values. The opportunity costs and cost efficiency of economic assumptions, management requirements and timber harvest policies were also examined.

A final analysis concerning the ICO's revolved around a series of feasibility screens applied to the scheduling results of all alternatives. Items considered included: 1) timber volume available in the Burns-Hines timbershed over time, 2) timber species mix, 3) logging systems mix, 4) reforestation methods mix, and 5) ability to meet watershed requirements. Minor adjustments needed to produce implementable alternatives were made, and the alternatives prepared for complete analysis and evaluation. (See Planning Records, 1920 10/04/85 for a complete discussion of this analysis.)

The processes described above have provided reliable coefficients that were developed with the ICO's and cost efficiency in mind. They result in the Ochoco's FORPLAN model being capable of determining cost efficient prescription assignment and scheduling under the various goals and objectives of all benchmarks and alternatives. This guarantees valid results because these coefficients provide the bases for the model to discriminate between the various management options available.

Cost Efficiency and Scheduling of Management Activities

Having assured that the Ochoco's FORPLAN model design was valid, responsive to the ICO's, and cost efficient, and that management area assignment best fit the goals and objectives of the alternative and/or benchmark, the final step in assuring a cost efficient solution for a particular alternative or benchmark was to schedule management activities over time in a most cost efficient manner. This was accomplished using the Ochoco's FORPLAN Model.

The model was used to analyze the most economically efficient outputs and effects associated with the achievement of the multiple use objectives of an alternative. Which prescriptions FORPLAN selected depended upon the objective function and the set of constraints used to represent a particular benchmark or land management plan alternative. Usually, the objective function was to maximize PNV or the production of timber. These were subject to first satisfying all the specified constraints. The constraints were designed to guarantee the spatial and temporal feasibility of land allocation and harvest scheduling choices in order to achieve multiple use objectives. The following is a list of some of the types of constraints used:

- Constraints on timber harvest flow, rotation length, and ending inventory,
- Harvest dispersion objectives,
- Constraints on the acreages of analysis areas available to certain management strategies,
- Rate of timber harvest restrictions in riparian areas and scenic corridors, and
- Cover requirements for elk.

Once the model had determined that a feasible solution existed by satisfying all of the constraints, it would then search for the set of prescriptions and timing choices which permitted it to optimize the solution according to the specified objective function.

In the case of those benchmarks and alternatives which used a maximize PNV objective function, this
ensured a cost efficient schedule of management activities. Those alternatives or benchmarks using an objective function other than maximize PNV were then “rolled over.” This means that the outputs which were maximized became constraints and the model was run again using a maximize PNV objective function.

Several computerized models and systems were used to facilitate and supplement the use of FORPLAN in the evaluation of an alternative. Operation of the Ochoco FORPLAN model required frequent calculation of acreage data. A computerized grid cell mapping system (R2MAP) was built and used to meet this need and provide other essential information. After obtaining a feasible FORPLAN solution that met the applicable goals and objectives, several additional models were used to help analyze economic implications. These are described in more detail in Sections 3 and 4. An input-output model derived from the IMPLAN system was calibrated to local conditions and used to estimate the effects on local jobs and income by alternative or benchmark. Timber volumes scheduled by analysis area and management prescriptions were distributed onto a road network model (MINCOST) to determine the most cost efficient road investment and maintenance program. The final modeling link in the analysis process used a computerized spreadsheet program to calculate total budget costs, economic values and receipts, efficiency measures, and other intermediate results.

Common Constraints

The FORPLAN model was used to estimate the timber related management activities, economic consequences, and outputs by reflecting the multiple use resource management objectives of each alternative through a given set of constraints. Many of the constraints used to help formulate and characterize the different alternatives were the same across all alternatives. These were necessary in order to meet minimum management requirements, existing laws and policies, or the objectives of prescriptions. There were also constraints which, while serving common purposes across all of the alternatives, varied in the amounts and locations to which they were applied. In addition, there were constraints which were totally unique to a particular alternative.

In the following discussion, those constraints which were applied in common to all alternatives will be presented in terms of their purpose and rationale. The common constraints will be separated into 3 categories: 1) those needed to meet legal and management requirements; 2) those needed to ensure biological feasibility, and 3) those needed to ensure administrative/operational feasibility. The constraints which were more or less unique and those whose amounts and locations vary between the alternatives will be discussed in the next section pertaining to the development of alternatives.

Constraints Needed to Meet Legal, Policy and Management Requirements

Ending Inventory Constraints

Purpose:
The use of this constraint ensures that the total inventory volume left at the conclusion of the harvest scheduling planning horizon (150 years) will equal or exceed the volume that would occur in a regulated forest managed in accordance with the prescriptions selected for regenerated timber.

Rationale:
If this constraint were not used, the FORPLAN model would have no incentive to leave enough inventory at the end of the harvest scheduling horizon to sustain the harvest levels into perpetuity.

Tradeoff:
Since some volume which is available for harvest at the end of the harvest scheduling horizon must be reserved for future decades, timber related outputs and benefits will be reduced.
Link to Long-Term Sustained Yield Constraint

Purpose:
Assures that timber harvest in the last period of the planning horizon is equal to or less than that which can be harvested indefinitely.

Rationale:
This along with the Ending Inventory Constraint ensures that harvest equals or is close to growth in perpetuity.

Tradeoff:
As with the ending inventory constraints this constraint may result in the reduction of timber related outputs and benefits.

No Regeneration Harvest Until Stands Have Reached 95% of Culmination of Mean Annual Increment

Purpose:
Ensures a minimum tree size and full site utilization.

Rationale:
The model could potentially harvest stands before the full utilization of the site and where the average tree diameter is inappropriate.

Tradeoff:
The Ochoco’s FORPLAN model characterizes the Ochoco as a deficit forest in which the LRSY level is not binding on the ASQ. As a result, rotation short of culmination has a positive effect on the ASQ level because higher yield managed stands are brought into production earlier. An analysis determined that restricting rotation ages to CMAI results in a maximum decrease of one percent in PNV and a two percent decrease in first decade timber volume.

Model updates described in Section 3 have resulted in the model characterizing the Ochoco as a surplus Forest in which the LRSY land is binding on the ASQ. As a result, rotation short of culmination has little to no effect on ASQ because moving rotation ages forward from their biological potential has a tendency to reduce LRSY which would further impact the ASQ.

Timber Harvest Scheduled Only on Lands Classified as Suitable Through the Stage I Suitability Analysis

Purpose:
Prevent scheduled harvest from lands not meeting Stage I suitability criteria.

Rationale:
It is very likely that FORPLAN would schedule harvest from these lands if given the choice.

Tradeoff:
Because some of these lands contain merchantable timber volume, timber related outputs and benefits will be reduced.

Forty-Acre Unit Size/Logical Leave Unit Dispersion Constraints

Purpose:
This constraint is used so that the resulting FORPLAN harvest scheduling solution is in compliance with the Regulations 36 CFR 219.27(d)(2) which states that even-aged regeneration harvest units do not exceed 40 acres in size and that these openings are separated by logical harvest units.

Rationale:
If these constraints were not used, the FORPLAN model could schedule for harvest in one decade large contiguous acreages of stands in order to best meet its objective function. To prevent this, upper limit constraints are placed on the proportion of an area that can be in harvest created openings at one time. The area is specified by combining analysis area and management emphases.

Tradeoffs:
These constraints have the potential to restrict FORPLAN’s freedom in the way it schedules the harvesting of timber to meet its objectives. Analysis performed on these constraints during the AMS
indicated that a maximum of 3.4 percent reduction in PNV and no reduction in the ASQ is possible when the ASQ is set using a maximize PNV objective function. When the ASQ is set with a maximize timber objective function some reduction in ASQ is also expected. The cost of these constraints would be offset slightly due to the increase in elk they produce. Application of these constraints also eliminates the need for, or reduces the impact of, various feasibility constraints such as constraints on species mix, slope and condition class.

These constraints are completely overlapped by the watershed dispersion constraints. As a result they will have no impact within an alternative.

Watershed Dispersion Constraints
Purpose:
The upper limit of a watershed in a cutover state is limited to 25 percent to 35 percent depending on the watershed’s sensitivity level. These constraints are used so that the resulting FORPLAN harvest scheduling solution is in compliance with the regulations 36 CFR 219.27(a,d&c), (Conservation of Soil and Water Resources).

Rationale:
Without these constraints FORPLAN could schedule more harvest activities in individual watersheds than their sensitivity levels indicate they can absorb.

Trade offs:
These constraints have the potential to restrict FORPLAN’s freedom in the way it schedules the harvesting of timber to meet its objectives. Analysis performed on these constraints during the AMS indicated that a maximum of 9 percent reduction in PNV and a 4.3 reduction in the ASQ is possible.

The cost of these constraints would be offset slightly due to the increase in elk they produce. Application of these constraints also eliminates the need for or reduces the impact of various feasibility constraints such as constraints on species mix, slope and condition class.

Harvest Scheduling Constraints and Less Intensive Silvicultural Prescriptions Applied to Riparian Areas
Purpose:
To meet management requirements for riparian areas as stated in Regulations 36 CFR 219.27(e).

Rationale:
General forest scheduling and prescriptions are too intensive to ensure meeting riparian requirements.

Tradeoff:
Analysis conducted for the AMS indicated that a maximum of 1 percent in timber related outputs and benefits would be expected.

Inventory Constraints for Old Growth Dependent Wildlife Species
Purpose:
These constraints are applied to ensure that the wildlife habitat management requirements for piliated woodpeckers, pine martens, etc. are satisfied in accordance with the regulation.

Rationale:
All of these species are dependent upon mature and overmature stands of trees for their habitat. These constraints were designed to maintain at least the MR levels of habitat for these species. If they were not applied, it is very likely that FORPLAN would convert all or most of the mature and overmature suitable habitat to young managed plantations by the fifth decade.

Trade offs:
Timber related outputs and benefits will be reduced because timber harvesting is excluded on 18,000 acres of forested lands. Analysis indicates that the maximum effect would be a reduction of 2.6 percent on ASQ and 3.2 percent on PNV.

For a more detailed discussion of constraints 4 through 8 see section 6 of Appendix B and Appendix F.
Constraints needed to meet Biological Concerns

Limit Amount of Commercial Thinning Allowed on Ponderosa Pine Sapling Stands.
Purpose:
Because of the aggregation of data within the model, not all acres in this condition class are capable of being thinned. The main reasons are due to age and/or stand condition.
Rationale:
The model could possibly schedule commercial thinning on more acres of this class than is actually feasible.
Trade offs:
These constraints have the potential to restrict FORPLAN’s freedom in the way it schedules the harvesting of timber to meet its objectives. Their potential effect on ASQ and PNV is minor.

Limit Amount of Overstory Removal in Mixed Conifer Two-Storied Stands
Purpose:
Not all acres in this condition class are capable of having the understory managed due to the understory’s condition, species mix, remaining volume and/or residual fuels.
Rationale:
The model potential could schedule overstory removal on more acres than is feasible.
Trade offs:
These constraints have the potential to restrict FORPLAN’s freedom in the way it schedules the harvesting of timber to meet its objectives. Their potential effect on ASQ and PNV is minor.

Limit Amount of Acres that can be Reforested by Planting at Increased Stocking Levels
Purpose:
Planting at increased stocking levels is not feasible on all soil types.
Rationale:
The model could potentially schedule all acres to be planted at increased stocking levels regardless of soil types.
Trade offs:
Under alternatives which manage the timber resource more intensively than is economically efficient, these constraints could result in a minor reduction in ASQ and a slight increase in PNV.

Reforestation with Natural Regeneration Limited in both Pine and Mixed Conifer Stands
Purpose:
Not all areas of the forest are suited to natural regeneration. This is due either to an unacceptable time lag to become satisfactorily stocked and/or potential disease problems.
Rationale:
FORPLAN could schedule more acres than feasible with natural regeneration.
Trade offs:
Potentially, these constraints could have a minor effect on PNV (negative) and ASQ (positive).

Limitation on Acres FORPLAN can Schedule for Range Improvement
Purpose:
Treatment will be allowed only on those acres which are biologically feasible and/or cost efficient.
Rationale:
FORPLAN could potentially schedule treatment on more acres than feasible or cost efficient.

Trade offs:
This limits the amount of forage production which in turn limits the amount of AUM’s. This will increase PNV slightly.

Total Effects for all Biological Constraints
An in/out analysis, performed on all the above biological constraints, using the maximum PNV benchmark, indicates a maximum decrease of a tenth of a percent in ASQ and an increase of a tenth of a percent in PNV.

Constraints Needed to Meet Administrative/Operational Concerns
Limit Acres of Two-Story Pine on Slopes (Less than 30 Percent) Able to Receive Overstory Removal and Precommercial Thinning of the Understory
Purpose:
Due to the heavy fuel loading in these natural stands, only a percentage of these stands needing precommercial thinning could feasibly have the resulting slash treated.

Rationale:
The model could potentially schedule more acres of this stand component to receive a precommercial thinning than is feasible.

Trade offs:
Potentially, these constraints could have a minor effect on PNV (negative and ASQ (positive).

Limit Low Site Pine Regeneration Harvest to 20 Percent per Decade
Purpose:
This condition class is comprised of scattered patches around the fringes of the main pine stands. It is not feasible to harvest these as a separate component. Instead they would have to be sold mixed in with other pine sales.

Rationale:
Because these are an independent analysis areas the model could schedule the entire condition class for harvest in a single decade.

Trade offs:
These constraints have the potential to restrict FORPLAN’s freedom in the way it schedules the harvesting of timber to meet its objectives. Their potential effect on ASQ and PNV is minor.

Limit Timber Harvest Activities on Slopes Less than 30 Percent
Purpose:
These constraints are applied to ensure FORPLAN scheduled timber harvests are applied to a mix of slope classes. This is necessary to accommodate local logging capabilities and logical sale layout

Rationale:
Without this constraint FORPLAN could schedule an unacceptable mix of slope classes and fluctuation between decades.

Trade offs:
Potentially these constraints could have a minor effect on PNV (negative) and ASQ (positive).

Total Effects of All Administrative/Operational Constraints
An in/out analysis, performed on all the above administrative/operational constraints, using the Max PNV Benchmark indicates a maximum decrease of a tenth of a percent in PNV and an increase of a tenth of a percent in ASQ.
Development of Alternatives

Introduction

The following discussion pertains to the development of the twelve alternatives displayed in the DEIS, the updated DEIS alternatives brought forward, and the new FEIS alternatives. The focus will be upon describing the purpose of each alternative and identifying the constraints used to characterize them so that their multiple resource management objectives were achieved as efficiently as possible. As previously discussed, the “No Change” Alternative was developed in response to decisions made by the Chief of the Forest Service and Deputy Assistant Secretary Douglas MacCleary regarding appeal number 1588, brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by the Regional Forester to “require inclusion of (MR’s) in the current Direction Alternative for each Forest Plan”. The substance of the appeal was that a “true no-action alternative representing current management plan” was not included in Forest Plan EIS’s. The No Change Alternative is designed to represent the existing Timber Management Plan and does not comply with all provisions of the National Forest Management Act (NFMA) and regulations promulgated by the Secretary of Agriculture to implement NFMA.

Each alternative is a combination of land uses, forest management activities, and resource outputs. As such, alternatives must consider the resource production capabilities (both the high and low limitations) of the many different areas on the Forest and Grassland. Each alternative is designed to manage the land to achieve predetermined goals and objectives. Some of these objectives, such as maintaining clean air and water, are common to all of the alternatives, other objectives, such as providing a certain mix and amount of resource outputs, vary between the alternatives. Several steps were involved in the development and analysis of the alternatives. They can be summarized as follows.

National and Regional direction, the planning Issues, Concerns and Opportunities, and the benchmark analyses were all used to help define a broad range of reasonable management alternatives which needed to be developed.

Within that range, alternatives with different management philosophies, goals and objectives were developed so as to reflect a wide range of choices concerning the best way to manage the Forest in order to maximize net public benefits.

Once the management philosophies, goals and objectives for all of the alternatives were determined, a land use pattern for the Forest was developed to reflect the intent of each alternative.

Other resource management objectives for each alternative were formulated in terms of constraints on activities, resource mixes and output levels, etc. in order to fully characterize the purpose of the alternative.

FORPLAN was then used to analyze the timber and range related outputs and effects for each alternative.

The results from the original FORPLAN runs were examined with regards to how well the predetermined goals and objectives of the alternative were achieved. Biological and administrative/operational concerns were also considered at this time. Depending on how well the alternative met all these considerations, land allocations and/or constraints to protect other resource objectives were adjusted and FORPLAN run again. This process continued until all objectives and concerns for all alternatives were adequately resolved.

The Transportation Network Model, and various customized software packages and electronic spreadsheets were then used to evaluate other outputs and effects associated with each alternative. Based on the results of this analysis, additional FORPLAN runs may or may not have been necessary to finish the alternative.

In the following discussion, the purpose of each alternative, the criteria and assumptions underlying its development, and its accompanying constraints
are presented. The constraints presented are those which were used in the final FORPLAN formulation of the alternative as it appears in the DEIS.

The tradeoffs associated with the individual constraint sets within each alternative are also discussed per the requirements of the May 17th outline for Appendix B, Section 7 Part C, and Section 8 Part D. The requirements of these two sections seemed to duplicate each other, so they were combined into this one section.

"With and without" constraint analysis was performed on the Max PNV Benchmark and a multiple use issue driven alternative (see Planning Records, 1920 11/85). Table B-7-2 summarizes this information and shows the maximum and minimum cost for each constraint type developed with this process. The following paragraph described the "with and without" process.

The opportunity costs associated with the Max PNV Benchmark should represent close to the maximum possible for an individual constraint within the context of any alternative. Development of these "maximum" individual constraint costs was accomplished by applying a few acres to the constraint in question and running the Max PNV Benchmark over. The fewer acres to which the constraints are applied, the less ability the model has to minimize their impact. As a result these costs should represent the maximum in the context of any alternative. Development of the constraint cost was accomplished by comparing the change in PNV between this run and the Max PNV Benchmark and dividing by the number of acres it was applied to. This process was used for all constraint types. The opportunity cost associated with the multiple use issue driven alternative followed the same procedures. In this case, acres were removed from the constraint type and the alternative run again. Because these costs were developed with all constraint types present and applied to large acreage these costs should represent close to the minimum these constraints would cost in the context of any alternative.

“With and without” analysis was not performed for each alternative. The process would have been complex and the cost would have been prohibitive.

Alternative NC

The purpose of the “no change” alternative (Alternative NC) was in response to Appeal 1588, filed May 19, 1986, by the Northwest Forest Resource Council in which they requested that a “true no action alternative representing current management plans be included in Forest Plans and environmental impact statements.

Alternative NC is very similar to the no action alternative (Alternative A) described and analyzed in the Draft Environmental Impact Statement. Both were originally developed without National Forest Management Act (NFMA) requirements. This NC Alternative is based on the Timber Resource Plan which, in turn, is based on land allocations and other management decisions made in the three unit plans: Ochoco-Crooked River (1979), Silvies-Malheur (1978), and South Fork (1978).

Alternative NC differs from Alternative A in this FEIS in that each is based on a different computer model, timber inventory, and yield tables. Also, there are some differences in the way old growth and big game habitat would be managed, resulting in potential differences in environmental effect, and finally Alternative A has incorporated MR’s.

Criteria and assumptions underlying the development of this Alternative are:

Unit Plan direction was incorporated if it does not conflict with Timber Resource Plan direction.

It will be based on existing management direction provided by the Timber Resource Plan.

Only NFMA requirements that are part of a current direction as established in the Timber Resource Plan and unit plans are included.

The yield tables used in the 1979 Timber Resource Plan (the basis for Alternative NC) were developed in 1975 for the entire Blue Mountain area without benefit of computer models. One set of yield tables was made for each timber type (Appendix D, Timber Resource Plan, 1979).

The Timber Resource Plan was modeled using Timber RAM (Resource Allocation Method), a linear program that is less sophisticated than the FORPLAN model used to develop the other alternatives. Timber RAM cannot consider economics or other resource constraints as FORPLAN does. All calculations were based on application of shelterwood silvicultural system with planting, but the option of using other prescriptions was left open (Timber Resource Plan, pp. 15-16).

Alternative NC was based on the 1972 timber inventory. Alternative A (and all other alternatives) were based on the 1982 timber inventory.

The method for determining timber land suitability in Alternative NC was different from the NFMA-mandated methods used for Alternative A (and all other alternatives).

The suitable timber base in Alternative NC was taken from the Timber Resource Plan. Land allocations from the unit plans were deducted from the timber base in the reserved or deferred categories, or included as commercial forest land in one of four categories: standard component, special component, marginal component, or unregulated. The commercial forest land in the Timber Resource Plan (adjusted for the Oregon Wilderness Act) is 535,253 acres.

Alternative A (No Action)

The purpose of the “No Action” Alternative required by NFPA is to portray a description of the outputs and effects that could be expected to occur if the current management direction is continued. This alternative was formulated using the four Unit Plans (Ochoco-Crooked River, Silvies-Malheur, South Fork of the John Day, and the Crooked River National Grassland), and the Timber Resource Plan.
It was not specifically designed to address the identified planning Issues, Concerns and Opportunities. The interpretations the Forest made results in an alternative with a blend of resource emphasis. The timber, range, big game, roadless, scenic, riparian, old growth, snag dependent wildlife species and dispersed recreation resources are all managed at levels less than maximum but more than minimum.

Criteria and assumptions underlying the development of this Alternative are:

It will be based on existing land use patterns and management direction provided by the four Unit Plans and the Timber Resource Plan.

Timber harvest is scheduled on a nondeclining yield basis. Current direction is to intensively manage timbered stands to the degree consistent with other resource requirements identified in the Unit Plans. This involves planting harvested units with genetically superior seedlings, planting at increased stocking levels, pre-commercial thinning to control the spacing of trees, one to three commercial thinnings both to harvest trees early and concentrate growth on the remaining trees, and managing for a rotation age close to the time where average annual growth is highest. This type of management is planned for the majority of the Forest's acres. Other resource requirements for some lands may either prohibit timber harvesting (old growth and roadless recreation management), lengthen rotations (riparian areas and scenic corridors), or alter thinning practices (big game emphasis areas).

Current direction is to make forage available for livestock use at levels that do not cause conflicts with other resources. Livestock numbers will be similar to current levels.

Additional Constraints

In addition to the common constraints described in Section 6, other unique constraints were also used in order to help achieve the objectives of this Alternative. These additional constraints were incorporated into the development of the Alternative for which the results are summarized in Table B-7-3. The purpose, rationale and tradeoffs associated with each of these unique individual constraints, or constraint sets, is discussed below.

Nondeclining Yield Constraints

Purpose:
To ensure that the timber volume harvested in any decade is greater than or equal to the timber volume harvested in the preceding decade. Current management direction is based on nondeclining yield.

Rationale:
Without these constraints, FORPLAN could schedule harvest levels which rise and fall erratically. This would not be consistent with current management plans.

Tradeoffs:
Since both the Max PNV Benchmark and Alternative A schedule the harvesting of timber under nondecreasing flow, the tradeoffs of imposing these constraints on this Alternative are not measurable by comparing the two. However, by imposing the nondeclining flow constraints, the model's flexibility to harvest timber in such a way as to maximize PNV is reduced. Therefore, early decade economic returns and timber output levels are traded off in exchange for stable long term harvest levels. Comparing harvested timber harvest schedules within other alternatives indicates that it is possible that relaxing this constraint could result in a maximum increase of 16 percent in the first decade ASQ and a two percent increase in PNV.

Snag Level Constraints

Purpose:
Habitat for cavity dwelling species (snags) is managed to provide for 55 percent of maximum potential populations across the Forest. Current management direction is providing for this level. In order to meet this objective all timber yield tables for timber, range and big game emphases provided snag habitat at the 40 and 60 percent level respectively.
Rationale:
Without specifically providing for this level, FORPLAN would select timber yield tables which only provide snag habitat at the MMR level.

Trade-offs:
Because these constraints limit the volume of timber that can be harvested on a per acre basis, they reduce both the ASQ and PNV.

Limit the amount of planting at increased stocking levels in any one decade to 75 percent for any working group needing reforestation.

Purpose:
Not only is there a biological limit on the total acres for this practice (see Common Constraints), but an operational limit as well. Because the soil types amenable to this practice are intermixed with other soil types, it is practical to schedule this reforestation method on only a portion of those acres needing reforestation in any one decade.

Rationale:
Because of the intensity of timber management in this alternative, FORPLAN could schedule this practice on all acres needing reforestation in the early decade.

Trade-offs:
Since planting at increased stocking results in higher future stand volumes and or earlier rotation ages, these constraints restrict FORPLAN's harvest scheduling flexibility. Analysis indicates that imposition of these constraints has a slightly negative effect on first decade ASQ (less than one percent) and because of the high cost of this activity, a slightly positive effect on PNV (less than one percent).

Use of a maximize timber objective function to set the ASQ

Purpose:
Current management direction is to manage intensively for timber production.

Rationale:
Without the use of this objective function it would not be possible to meet both the current harvest level and other resource objectives.

Trade-offs:
Under this objective function, the Model selects more intensive management practices and schedules harvest from more costly and less valuable stands which have higher growth potential than would be selected with the use of a maximize PNV objective function. As a result, first decade ASQ is significantly higher and PNV is significantly lower.

Resource Objective Constraints

Purpose:
These constraints were applied so that the multiple resource land use pattern of the current land management plans would be correctly represented across all of the FORPLAN analysis areas.

Rationale:
Many of the wildlife, recreation, and other resources on the Forest are not represented with output and value coefficients in FORPLAN. In the absence of these constraints, the Model would only have timber and range related values available to it for making land allocation choices. These constraints indicate how many acres of each analysis area are allocated to particular multiple resource management objective. These acreage figures are in addition to those found in the Max PNV Benchmark. FORPLAN then decides which schedule of management activities, and which level of capital investment is the most efficient in order to meet the overall objectives of the Alternative. The breakdown of acres allocated to the various resource objectives for this Alternative is displayed in Table B-7-3.

</tr>
<tr>
<td>Semiprimitive Nonmotorized</td>
</tr>
</tbody>
</table>
Trade-offs:
As Table B-7-4 indicates, all resource objectives have a negative impact on both PNV and first decade ASQ. This is a result of these resource objectives limiting the percentage of an emphasis area that can be harvested in a decade, extending rotation ages or limiting the intensity of management. All resource objectives have a significant cost. This is a result of large acreage being applied to all these resource objectives.

**Alternative B-Modified**

The intent of this alternative in the DEIS (Alternative B) was to meet the 1980 RPA timber and range program targets, as identified for the Forest and Grassland in the Regional Guide, with a timber harvest schedule based on nondeclining yield. This alternative was very similar to the max timber benchmark. This alternative focuses heavily on intensive management to produce timber and range products. Special provisions were also made to provide enough firewood to meet identified local demand. Other resources were managed at minimum levels. Alternative B's basic philosophy of intensive timber management has been modified to emphasize other resource management where compatible with timber. Also, for some resources (selected roadless areas, visual corridors, etc), timber volume was given up to provide for these resources.

The criteria and assumptions underlying the development of this Alternative are:
Forage would be made available for livestock use at the current level (75,000 AUM's).

Timber harvest is scheduled on a nondeclining yield basis. Intensive timber management practices would be applied to many of the suitable acres. This involves

* Intensity of timber management increased through the use of a maximized timber objective function

1/ Only those resource objectives which have an opportunity cost are portrayed.
planting harvested units with genetically superior seedlings, planting at increased stocking levels, precommercial thinning to control the spacing of trees, up to three commercial thinnings both to harvest trees early and concentrate growth on the remaining trees, and managing for a rotation age close to the point in time where average annual growth is highest.

Approximately 120,000 acres of ponderosa pine stands would be managed under an uneven-age management system.

All riparian areas would be managed to achieve and/or maintain an “excellent” classification.

Big game habitat would receive some special management on 171,500 acres of General Forest Winter Range.

Corridors along many of the principal roadways would be managed to retain their scenic values (34,000 acres).

Old growth would receive a low emphasis (18,000 acres).

Habitat for cavity dwelling species (snags) would be managed at the 20 percent of potential populations (MR level).

Portions of Lookout Mountain and Silver Creek would be managed to retain their roadless character. A modified roadless area (Squaw Creek) would also be created.

Special protection would be provided for dispersed recreation sites (Deep Creek, Bandit Springs, Steins Pillar, and Round Mountain recreation trail management areas).

Additional campgrounds would be added and the trail system would be significantly expanded.

Additional Constraints
In addition to the common constraints described in Section 7, other unique constraints were also used in order to help achieve the objectives of this Alternative. These additional constraints were incorporated into the development of the Alternative. The results are summarized in Table B-7-5. The purpose, rationale and trade-offs associated with each of these unique individual constraints, or constraint sets, is discussed below.

Nondeclining Yield Constraint
Purpose:
To ensure that the timber volume harvested in any decade is greater than or equal to the timber volume harvested in the preceding decades to meet the requirements set in CFR 219.16(a).

Rationale:
Without this constraint FORPLAN could schedule harvest levels which rise and fall erratically. This would not meet the intent of the CFR regulations or the objective of the alternative.

Trade offs.
Since both the Max PNV Benchmark and Alternative B schedule the harvesting of timber under nondeclining flow, the tradeoffs of imposing these constraints on this alternative are not measurable by comparing the two. However, in general, by imposing the nondeclining flow constraints, the model’s flexibility to harvest timber in such a way as to maximize PNV is reduced. Therefore, early decade economic returns and timber output levels are traded off in exchange for stable long term harvest levels. Comparing departure timber harvest schedules within other alternatives, it is possible that relaxing this constraint could result in a maximum increase of 16 percent in the first decade ASQ and a 2 percent increase in PNV.

Limit the amount of planting at increased stocking levels to 75 percent for any working group needing reforestation in any one decade
Purpose:
Not only is there a biological limit on the total acres for this practice (see Common Constraints), but an operational limit as well. Because the soil types amendable to this practice are intermixed with other soil types, it is practical to schedule this reforestation method on only a portion of those acres needing reforestation in any one decade.

Rationale.
Because of the intensity of timber management in
this alternative, FORPLAN could schedule this practice on all acres needing reforestation in the early decade.

Trade offs
Since planting at increased stocking results in higher future stand volumes and or earlier rotation ages, these constraints restrict FORPLAN's harvest scheduling flexibility. Analysis indicates that imposition of these constraints has a slightly negative effect on first decade ASQ (less than one percent) and because of the high cost of this activity, a slightly positive effect on PNV (less than one percent).

Use of a Maximized Timber Objective Function to set the ASQ
Purpose.
To help meet RPA timber harvest targets.
Rationale:
Without the use of this objective function this alternative could not meet RPA timber targets.
Trade offs:
Under this objective function, the model selects more intensive management practices, and schedules timber harvests from more costly and less valuable stands with higher growth potential, than would be selected with the use of a maximize PNV objective function. As a result, first decade ASQ is significantly higher and PNV is significantly lower.

Constrain 120,000 acres of ponderosa pine to uneven-aged management
Purpose.
To ensure the Forest Plan selects a portion of the ponderosa pine stands for uneven-aged management.
Rationale:
Without it FORPLAN would not select any acres for uneven-age management in this alternative.
Trade offs
This alternative uses a maximum timber objective function to set the ASQ and LRSYC is binding. As a result, forcing the model to select acres for uneven-age management will have a negative effect on ASQ.

Resource Objective Constraints
Purpose:
These constraints were applied so that the multiple resource land use pattern needed to achieve the objectives of this Alternative would be correctly represented across all of the FORPLAN analysis areas.
Rationale:
Since many of the wildlife, recreation, and other resources on the Forest are not represented with output and value coefficients in FORPLAN, in the absence of these constraints the Model would only have timber and range related values available to it for making land allocation choices. These acreage figures are in addition to those found in the Max PNV Benchmark. These constraints indicate how many acres of each analysis area should be allocated to particular multiple resource management emphases. FORPLAN then decides which schedule of management activities, and which level of capital investment is the most efficient in order to meet the overall objectives of the Alternative. The breakdown of acres allocated to the various resource objectives for this Alternative are displayed in Table B-7-5.

</tbody>
</table>

1/ Special I is comprised of management areas that fall into FORPLAN Group IV (see Section 3) and are not visual corridors. This includes parts of MA F7 and all of MA F13, 14, 16, and 27.

2/ Special II is comprised of management areas that fall into FORPLAN Group V (see Section 3) and are not visual corridors. This includes parts of MA F7 and all of MA F18 and 23.

3/ Special III is comprised of management areas that fall into FORPLAN Group II (see Section 3) and are not visual corridors. This includes MA F17, 19, and 24.
Trade offs:
As Table B-7-6 indicates, all resource objectives have a negative impact on both PNV and first decade ASQ. This is a result of these resource objectives limiting the percentage of an emphasis area that can be harvested in a decade, extending rotation ages or limiting the intensity of management. Both the scenic and SPNM objectives have low costs associated with them because very few acres are involved. Riparian conditions, on the other hand, have a high cost because they are applied to the maximum amount of acres.

Alternative C-Modified

The purpose of this alternative is to respond to issues raised during the planning process regarding amenity resources found within the Forest and Grassland. This alternative is very similar to the Max Recreation and Big Game Benchmark.

| Increased ASQ *          | -19.7     | +13.0                 |

* Intensity of timber management increased through the use of a maximized timber objective function

1/ Only those resource objectives which have an opportunity cost are portrayed
The criteria and assumptions underlying the development of this alternative are:

Additional campground units would be added to the Delinton Lake, Antelope, and Falls campgrounds.

The trail system on the Forest and Grassland would be significantly expanded. These developments would primarily be in association with Wildernesses and roadless management areas.

Corridors adjacent to all of the principal pathways throughout the Forest and Grassland would be managed to attain or retain pleasing scenery.

The Silver Creek, Cottonwood, Rock Creek, and Lookout Mountain roadless areas would be managed to maintain the present roadless character. Green Mountain would be partially developed to provide a semi-primitive setting with primitive roads for recreational use. Deschutes Canyon would be recommended for Wilderness in this alternative.

Big game receives a special management emphasis on the majority of the Forest and Grassland (679,000 acres). In these areas, road use and thermal cover quantity, quality, and distribution would be controlled to provide high quality big game habitat.

A relatively large amount of land would be specially dedicated to old growth habitat in this alternative (45,000 acres). The Wildernesses and roadless management areas provide an additional 29,000 acres of old growth.

Habitat for cavity dwelling species (snags) would be provided for at high levels, sustaining dependent species at 80 percent of their potential population levels.

Forage would be made available at low levels, approximately 12 percent lower (65,800 AUM’s) than currently allowed. Heavy emphasis on improvement of riparian conditions, and timber management designed to maintain dense timber stands for big game cover, account for the diminished level of forage for livestock use.

Timber harvest is scheduled on a nondeclining yield basis. Timber management activities which are most economically efficient would be used while meeting other resource objectives. Resource requirements for this alternative may either prohibit timber harvesting (old growth and roadless recreation management), lengthen rotations (riparian areas and scenic corridors), or alter thinning practices (big game emphasis areas).

Approximately 170,000 acres of ponderosa pine stands would be managed under uneven-aged management systems.

Relatively low volumes of personal use firewood would be available in this alternative due to the diminished rate of timber harvest. Road closures for big game might limit access to firewood.

Management in riparian areas would be directed toward achieving and maintaining excellent streambank stability, stream temperature, and fish habitat within fifteen years. All watersheds on the Forest and Grassland would be managed to meet these goals.

Additional Constraints

In addition to the common constraints described in Section 7, other constraints were also used to help achieve the objectives of this Alternative. These additional constraints were incorporated into the development of the Alternative for which the results are summarized in Table B-7-7. The purpose, rationale, and tradeoffs associated with each of these unique individual constraints, or constraint sets, are discussed below.

Nondeclining Yield Constraints

Purpose:

To ensure that the timber volume harvested in any decade is greater than or equal to the timber volume harvested in the preceding decades. To meet the requirements set in CFR 219.16(a).

Rationale:

Without this constraint FORPLAN could schedule harvest levels which rise and fall erratically. This would not meet the intent of the CFR regulations or the objective of the alternative.

Tradeoffs:

Since both the Max PNV Benchmark and Alterna-
tive C schedule the harvesting of timber under nondeclining flow, the tradeoffs of imposing these constraints on this alternative are not measurable by comparing the two. However, in general, by imposing the nondeclining flow constraints, the model's flexibility to harvest timber in such a way as to maximize PNV is reduced. Therefore, early decade economic returns and timber output levels are traded off in exchange for stable long term harvest levels. Comparing departure timber harvest schedules within other alternatives, it is possible that relaxing this constraint could result in a maximum increase of 16 percent in the first decade ASQ and a two percent increase in PNV.

Snag Level Constraints
Purpose:
Habitat for cavity dwelling species (snags) is managed to provide for 80 percent of the maximum potential populations across the Forest. One of the main objectives of this alternative is high population levels of cavity nesters. In order to meet this objective, management emphases which do not automatically provide the 100 percent level were provided with timber yield tables which provide for the 60 percent level.

Rationale:
Without specifically providing for this level, FORPLAN would select timber yield tables which only provide snag habitat at the MMR level.

Tradeoff:
Because these constraints limit the volume of timber that can be harvested on a per acre basis, they reduce both the ASQ and PNV.

Resource Objective Constraints
Purpose:
These constraints were applied so that the multiple resource land use pattern needed to achieve the objectives of this Alternative would be correctly represented across all of the FORPLAN analysis areas.

Rationale:
Since many of the wildlife, recreation, and other resources on the Forest are not represented with output and value coefficients in FORPLAN, in the absence of these constraints the Model would only have timber and range related values available to it for making land allocation choices. These constraints indicate how many acres of each analysis area should be allocated to particular multiple resource management emphases. These acreage figures are in addition to those found in the Max PNV Benchmark. FORPLAN then decides which schedule of management activities, and which level of capital investment is the most efficient in order to meet the overall objectives of the Alternative. The breakdown of acres allocated to the various resource objectives for this Alternative is displayed in Table B-7-7.

| RESOURCE OBJECTIVES FOR ALTERNATIVE C-MODIFIED |
|-----------------------------------------------|----------------|
| Resource Objective                          | Acres          |
| Big Game                                     | 666,825        |
| Summer & Winter Range                        | 27,280         |
| Old Growth                                   | 38,961         |
| Scenic Views                                 | 67,756         |
| Retention Foreground                         | 43,960         |
| Partial Retention Foreground                 | 7,000          |
| Semiprimitive Nonmotorized & Addition to Wilderness | 2,620       |
| Research Natural Areas                       | 170,000        |

Tradeoffs:
As Table B-7-8 indicates, all resource objectives have a negative impact on both PNV and first decade ASQ. This is because these resource objectives limit the percentage of an emphasis area that can be harvested in a decade, extend rotation ages or limit the intensity of management. These resource objectives have the highest total cost in terms of PNV and first decade ASQ of all the alternatives. This is a result of the high acreage to which all the objectives are applied.
Alternative I

The purpose of this alternative is to respond to ICO’s raised since the issuance of the DEIS.

This alternative emphasizes a combination of roadless recreation, big game habitat, timber production, dispersed recreation opportunity, and uneven-aged management. A blend of resource uses provides for a high quality of life and contributes to local job stability. Almost all resources are managed at moderate levels.

The criteria and assumptions underlying the development of this alternative are:

The trail system on the Forest and Grassland would be greatly expanded. Foot and horse developments would mostly be in association with Wildernesses and roadless management areas.

A moderate number of travel corridors would be managed for scenery. These include major roads and access roads to roadless management areas.

Portions of the Rock Creek and Cottonwood Creek areas would be managed for unroaded recreation. Green Mountain would be managed under General Forest and General Forest Winter Range. The Silver Creek roadless area would be managed to retain the present roadless character. The Broadway area would be managed for General Forest. Lookout Mountain will remain roadless for the first decade. The lower portion of the Management Area would be managed for the enhancement of forest health, scenery, wildlife and recreation from the second through the fifth decades, leaving a 7,550 acre area unroaded.

A portion of the Deschutes River Canyon-Steelhead Falls Wilderness Study Area and an additional area outside the WSA Squaw Creek are combined to form a 7,840 acre management area emphasizing semiprimitive, nonmotorized recreational opportunities and wildlife habitat management.

Big game receives a special management emphasis on 230,500 acres of the Forest and Grassland. Most of this represents high priority winter range.
In these areas road use and cover quantity, quality, and distribution would be controlled to provide high quality big game habitat.

A small amount of land would be specially dedicated to old growth habitat in this alternative (19,990 acres).

Habitat for cavity dwelling species (snags) would be managed at fairly high levels, sustaining dependent species at 55 percent of their potential population levels.

Special management is proposed for dispersed recreation sites, Deep Creek, Bandit Springs, Stein's Pillar, Historic trail, and Round Mountain recreation trail.

Several areas would be proposed as new RNA's with this alternative. The Island, Stinger Creek, Silver Creek, and Dry Mountain, and a portion of Haystack Butte all fulfill research needs and would be managed in accordance with research priorities. The existing Ochoco Divide RNA would continue to be managed as such.

Forage would be made available for use at the current situation level (75,000 AUM's)

Timber harvest is scheduled on a nondeclining yield basis. Timber management activities which are most economically efficient would be used while meeting other resource objectives. Resource requirements for this alternative may either prohibit timber harvesting (old growth), lengthen rotations (riparian areas, scenic corridors, and ponderosa pine stands), or alter thinning practices (big game emphasis areas).

Approximately 100,000 acres of ponderosa pine stands would be managed under uneven-aged management strategies.

Relatively low volumes of personal use firewood would be available in this alternative, due to a lower rate of timber harvest than currently practiced.

Management in all riparian areas would be directed toward achieving and maintaining excellent streambank stability, stream temperature, and fish habitat within fifteen years.

Additional Constraints

In addition to the common constraints described in Section 7, other unique constraints were also used to help achieve the objectives of this Alternative. These additional constraints were incorporated into the development of the Alternative for which the results are summarized in Table B-7-9. The purpose, rationale, and tradeoffs associated with each of these unique individual constraints, or constraint sets, is discussed below.

Nondeclining Yield Constraint

Purpose:
To ensure that the timber volume harvested in any decade is greater than or equal to the timber volume harvested in the preceding decades. To meet the requirements set in CFR 219.16(a).

Rationale:
Without this constraint FORPLAN could schedule harvest levels which rise and fall erratically. This would not meet the intent of the CFR regulations or the objective of the alternative.

Trade-off:
Since both the Max PNV Benchmark and Alternative E schedule the harvesting of timber under nondeclining flow, the tradeoffs of imposing these constraints on this Alternative are not measurable by comparing the two. However, in general, by imposing the nondeclining flow constraints, the model's flexibility to harvest timber in such a way as to maximize PNV is reduced. Therefore, early decade economic returns and timber output levels are traded off in exchange for stable long term harvest levels.

Comparing departure timber harvest schedules within other alternatives, it is possible that relaxing this constraint could result in a maximum increase of 16 percent in ASQ and a two percent increase in PNV in the first decade.

Snag Level Constraints

Purpose:
Habitat for cavity dwelling species (snags) is managed to provide for 55 percent of maximum potential populations across the Forest. A moderate population level of cavity nesters reflects the objectives of this alternative. In order to meet this objective the timber/range management emphasis pro-
vides snags at the 40 percent level and the big game management emphasis provides snags at the 60 percent level.

**Rationale**
Without specifically providing for this level, FORPLAN could choose timber yield tables with snag habitat provided at the MMR level.

**Trade offs**
Because these constraints limit the volume of timber that can be harvested on a per acre basis, they reduce both the ASQ and PNV.

**Harvest Flow Constraints (Districts 1 and 2)**

- **Purpose:** To ensure that the harvest schedule did not fluctuate dramatically in the early decades.

- **Rationale:** These constraints were applied because the FORPLAN scheduled harvest levels which fluctuated drastically in the early decades.

- **Trade offs:** These constraints could limit the model's flexibility, thus reducing PNV and/or ASQ. In the context of Alternative I they have a minor effect on PNV and no effect on ASQ.

**Upper Limit on Ponderosa Pine Working Group Volume**

- **Purpose:** To ensure that ponderosa pine volume remains fairly stable in the early decades.

- **Rationale:** Without this constraint FORPLAN would schedule more ponderosa pine in the first decade and less in the second. The pine volume decrease between the first and second decade did not meet the intent of the Alternative.

- **Trade offs:** These constraints could limit the model's flexibility, thus reducing PNV and/or ASQ. This constraint had a slightly negative effect on PNV and no effect on ASQ.

**Resource Objective Constraints**

- **Purpose:** These constraints were applied so that the multiple resource land use pattern needed to achieve the objectives of this Alternative would be correctly represented across all of the FORPLAN analysis areas.

1/ Special I is comprised of management areas that fall into FORPLAN Group IV (see Section 3) and are not visual corridors. This includes parts of MA-F7, and all of MA-F13, 14, 16, and 27.

2/ Special II is comprised of management areas that fall into FORPLAN Group V (see Section 3) and are not visual corridors. This includes parts of MA-F7 and all of MA-F16 and 23.

3/ Special III is comprised of management areas that fall into FORPLAN Group III (see Section 3) and are not visual corridors. This includes MA-F17, 19, and 24.
Rationale.
Since many of the wildlife, recreation, and other resources on the Forest are not represented with output and value coefficients in FORPLAN, in the absence of these constraints the Model would only have timber and range related values available to it for making land allocation choices. These constraints indicate how many acres of each analysis area should be allocated to particular multiple resource management emphases. These acreage figures are in addition to those found in the Max PNV Benchmark. FORPLAN then decides which schedule of management activities and which level of capital investment is the most efficient in order to meet the overall objectives of the Alternative. The breakdown of acres allocated to the various resource objectives for this Alternative is displayed in Table B-7-9.

Trade offs:
As Table B-7-10 indicates, all resource objectives have a negative impact on both PNV and first decade ASQ. This is a result of these resource objectives limiting the percentages of an emphasis area that can be harvested in a decade, extend rotation ages or limit the intensity of management. Most resource objectives are applied to a moderate amount of acres. This results in a moderate cost which is split fairly evenly amongst the resources.

Alternative E-Departure
The purpose of this alternative is to address both amenity and commodity values. Short term community stability is also heavily emphasized. This alternative has not been modified between the DEIS and FEIS.

* Intensity of timber management increased through the use of a maximized timber objective function

1/ Only those resource objectives which have an opportunity cost are portrayed
This alternative emphasizes a combination of timber production, roadless recreation, and big game habitat. Timber is scheduled as a departure from nondeclining yield. Timber volumes are scheduled so that first decade harvests remain close to current harvest levels, and then decline gradually over the next 50 years. A blend of resource uses is attempted that both maintains local jobs in the short term, and provides for a high quality of life. Almost all resources are managed at moderate levels.

The criteria and assumptions underlying the development of this alternative are:

The trail system on the Forest and Grassland would be greatly expanded. These developments would be in association with Wildernesses and roadless management areas. Additional campground units would be added to the Delmtment Lake, Antelope and Falls campground.

A moderate number of travel corridors would managed for scenery (46,160 acres). This would apply to major roads, access roads to roadless management areas, and a recreation travel corridor on the Big Summit District.

The Rock Creek, Cottonwood, and Silver Creek roadless areas would be managed to retain the present roadless character. The Broadway area would be managed under a big game emphasis. Green Mountain and the top of Lookout Mountain would be partially developed to provide a semiprimitive setting with primitive roads for recreational use.

Big game would receive a special management emphasis on 226,400 acres of the Forest and Grassland. Most of this represents high priority winter range. In these areas road use and thermal cover quantity, quality, and distribution would be controlled to provide high quality big game habitat.

A fairly small amount of land would be specially dedicated to old growth habitat in this alternative (26,300 acres). The Wildernesses and roadless management areas provide an additional 21,000 acres of old growth.

Habitat for cavity dwelling species (snags) would be managed at fairly high levels, sustaining dependent species at 55 percent of their potential population levels.

Several areas would be proposed as new RNA's with this alternative. The Island, Stinger Creek, Silver Creek, and Dry Mountain, and a portion of Haystack Butte all fulfill research needs and would be managed in accordance with research priorities. The existing Ochoco Divide RNA would continue to be managed as such.

Forage would be made available for use at levels approximately five percent higher (79,000 AUM’s) than currently allowed.

Timber harvest is scheduled as a departure from the nondeclining yield harvest levels set in Alternative E. The objective is to maintain current harvest levels for one decade (130 million board feet annually), and then gradually decline over the following 40 years to a sustainable level. Timber management activities which are most economically efficient would be used while meeting other resource objectives. Resource requirements for this alternative may either prohibit timber harvesting (old growth and roadless areas), lengthen rotations (riparian areas and scenic corridors), or alter thinning practices (big game emphasis areas).

Moderate volumes of personal use firewood would be available in this alternative due to the increased rate of timber harvest in the first decade (13,000 cords). Future firewood availability would decline significantly.

Management in many riparian areas would be directed toward achieving and maintaining excellent streambank stability, stream temperature, and fish habitat within fifteen years. Watersheds on the Forest and Grassland which contain anadromous fish, and high-valued resident trout will be managed to meet these goals.

Additional Constraints

In addition to the common constraints described earlier in this section, other constraints were also used to help achieve the objectives of this alterna-
tive. These additional constraints were incorporated into the development of the alternative for which the results are summarized in Table B-7-11. The purpose, rationale, and tradeoffs associated with each of these unique individual constraints, or constraint sets, is discussed below.

Scheduled Output Constraint
Purpose:
First decade harvest level is constrained at the current level (132 MMBF). The objective of this Alternative is to provide high levels of amenity resources and maintain local jobs in the short term. Because most job increases and decreases are tied to timber harvest levels, maintaining current timber harvest levels will maintain the current level of forest related jobs.

Rationale:
Because of resource objectives besides the ASQ, it was impossible to meet current harvest levels without specifically constraining the Model to provide this level.

Tradeoffs:
By allowing the ASQ to depart from nondeclining yield both the first decade ASQ and PNV increase significantly.

Harvest Flow Constraints
Purpose:
Because the first decade harvest level was not sustainable, it was necessary to allow the model to schedule declining volumes in latter decades. The model was allowed to schedule up to a ten percent decrease in volume between decades one and two and again between decades two and three. Between decades three and four and four and five volume was allowed to decrease five percent. From the fifth decade on the harvest flow was controlled by nondeclining yield.

Rationale:
The rationale behind these flow constraints was to have a timber harvest level which declines as gradually as possible to minimize the negative impact on dependent communities, yet ensures a feasible solution.

Tradeoffs:
These constraints limit the rate which the ASQ can decline between decades. As a result they limit the potential increase in first decade ASQ and PNV that could have been obtained under a departure timber harvest schedule.

Snag Level Constraints
Purpose:
Habitat for cavity dwelling species (snags) is managed to provide for 55 percent of maximum potential populations across the Forest. A moderate population level of cavity nesters reflects the objectives of this alternative. In order to meet this objective the timber/range and big game management emphasis provide snags at the 40 percent and 60 percent level respectively.

Rationale:
Without specifically providing for this level, FORPLAN could choose timber yield tables which only provide snag habitat at the MMR level.

Tradeoffs:
Because these constraints limit the volume of timber that can be harvested on a per acre basis, they reduce both the ASQ and PNV.

Resource Objective Constraints
Purpose:
These constraints were applied so that the multiple resource land use pattern needed to achieve the objectives of this Alternative would be correctly represented across all of the FORPLAN analysis areas.

Rationale:
Since many of the wildlife, recreation, and other resources on the Forest are not represented with output and value coefficients in FORPLAN, in the absence of these constraints the Model would only have timber and range related values available to it for making land allocation choices. These acreage figures are in addition to those found in the Max PNV Benchmark. These constraints indicate how many acres of each analysis area should be allocated to particular multiple resource management emphases. FORPLAN then decides which schedule of management activities, and which level of capital investment is the most efficient in order to meet the...
overall objectives of the Alternative. The breakdown of acres allocated to the various resource objectives for this Alternative is displayed in Table B-7-11.

Trade offs:
As Table B-7-12 indicates, all resource objectives have a negative impact on both PNV and first decade ASQ. This is a result of these resource objectives limiting the percentages of an emphasis area that can be harvested in a decade, extending rotation ages or limiting the intensity of management. Alternative E-Departure’s resource objectives result in a moderate cost, spread fairly evenly among resources.
Effects of Benchmarks, Constraints, and Alternatives

(Section 8)

Introduction

This section provides a detailed discussion of the outputs and effects of the Alternatives. The focus is upon the tradeoffs between the Alternatives as they provide different levels and mixes of goods and services, and as they address the planning Issues, Concerns and Opportunities (ICO’s) in different ways. The purpose of presenting a discussion pertaining to the outputs and effects of each alternative, the consequences of the constraints used to help formulate them, and their relationship to the benchmarks, is to facilitate the identification of the alternative which comes closest to maximizing net public benefits. In order to accomplish this objective, there needs to be an understanding of the abilities of the Forest to produce different goods and services in response to the ICO’s, and the tradeoffs involved with the decisions to produce one mix of outputs as opposed to another. As such, this comparative analysis provides the basis for selecting a proposed action, which is Step 8 of the planning process.

Process of Evaluating Significant Constraints

The multiple resource management objectives associated with a particular benchmark or land management alternative were represented in FORPLAN as a combination of constraints, and an objective function. The final objective function used in the development of an alternative or benchmark was to maximize Present Net Value. This objective function guided the FORPLAN model in the selection of the most economically efficient combination of prescriptions, activity scheduling choices, and resource output levels which satisfied the multiple resource management objectives of a particular benchmark or alternative.

However, the maximization of Present Net Value was subject to first satisfying all of the constraints which were used to represent the other resource management objectives not provided for by the economic efficiency objective function. The imposition of the constraints often, but not always, reduced the PNV for a particular alternative. The PNV given up in response to achieving the objectives of a constraint is referred to as the “opportunity cost”. In order to isolate the opportunity cost associated with a particular constraint, or set of constraints, the resulting solutions of FORPLAN runs made with and without the constraints included in them were examined for their differences in PNV (and other outputs and effects of interest). As long as the only difference between the runs being compared was the addition of the constraints, the reduction in PNV represented the opportunity cost (at the margin) of achieving the constraint’s objective.

During the Benchmark Analyses, constraint sets which were needed in order to achieve the various multiple resource management objectives were developed and evaluated. For example, all of the different constraints which were proposed in order to achieve the MR’s were evaluated both individually and collectively, to determine the magnitude of their tradeoffs and to assess the relative efficiency of alternative constraint sets designed to achieve common objectives. If one set of constraints achieved
a particular objective with less impact on the PNV than an alternative set of constraints designed to accomplish the same purpose, it was considered more efficient and was used throughout the remainder of the process of developing and analyzing alternatives. Sometimes, alternative approaches to formulating constraints to meet a common objective were not available. In these cases, the analysis was performed solely to determine the opportunity costs associated with the constraints.

Discretionary constraints (those not legally required) were also examined in order to assess the magnitude of their opportunity costs. These constraints were often used in conjunction with special prescriptions in order to produce the desired multiple habitat management objectives (i.e., scenic quality, wildlife habitat, recreation settings, etc.) of an alternative. Land allocation constraints necessary to meet resource objectives were fully analyzed in order to assess their opportunity costs. The policy constraints associated with nondeclining flow and rotations based on CMAI were also evaluated in the context of their effects on PNV and timber output levels. Finally, sensitivity analyses were performed in order to provide information regarding the consequences involved in making assumptions about timber management costs, and future stumpage values (i.e., price trends).

The results of these analyses are provided in the “Summary of the Analysis of the Management Situation” planning document, other planning documents, Appendix E, and in Section 6 and 8 of this Appendix. Since they are discussed in detail in these documents, they will not be repeated here.

The opportunity costs associated with the individual constraints in each alternative were not evaluated individually due to the prohibitive costs of performing this type of analysis. However, many of the constraints used to formulate the alternatives were examined in the Benchmarks, land allocation process and iterative alternative development process so their approximate trade-offs can be determined from that analysis. Also, constraints with potential significant opportunity costs, were analyzed using an in/out procedure on a representative sample of Benchmarks and/or Alternatives. Finally, by comparing the alternatives in their final forms, the economic tradeoffs of their different collective multiple resource management objectives was assessed. These efficiency tradeoffs were then compared to the environmental and socio-economic consequences in order to help identify the alternative, or alternatives, which came closest to maximizing net public benefits.

Analysis of Tradeoffs Among Alternatives

In this section, the tradeoffs between the alternatives are discussed. The focus will be upon the resolution of ICO’s, resource outputs, environmental consequences, economic and social effects, and the overall tradeoffs incurred in attempting to address the ICO’s.

Response to Major ICO’s

Except for Alternative A and NC, which are designed to portray the outputs and effects associated with continuing on with current management direction, the alternatives were specifically tailored to reflect different ways of addressing the planning issues, concerns, and opportunities. The following discussion highlights some of the variation in the way the major issues were treated between them. Table B-8-1 tabularly summarizes the differences for all issues. For a more complete description of the ICO’s and the role they played in the forest planning process, refer to Appendix A, Chapter 2 of the FEIS and the following portions of this Appendix which present the detailed outputs and effects of the alternatives with regards to their responses to the ICO’s.

The factors relating to the timber issues key around how much and what kind of timber will be sold on an annual basis. This was addressed in the alternatives by varying how much of the Forest was available for timber production, by varying the objective function...
which influences the intensity of timber management by extending rotation ages in pine stands, by applying varying amounts of uneven-aged management with different diameter targets, and by exploring departure timber schedules in order to achieve higher wood outputs than could be produced under nondeclining flow. The resulting wood outputs were expressed in terms of average annual millions of cubic feet, and average annual millions of board feet. These outputs were also estimated for the three timber working groups: 1) ponderosa pine, 2) ponderosa pine low site, and 3) mixed conifer.

The factors relating to the wildlife issues key around what the population levels should be for certain key species such as mule deer, elk, trout, pileated woodpecker, and other cavity dwellers. The issues were treated by applying prescriptions to appropriate areas of the Forest in order to provide habitat which could support more or less numbers than currently exist. While population numbers were estimated for deer, trout, and elk, numbers of pairs or percent of potential populations were estimated for the other species.

The recreation issue centered around providing an opportunity for roadless recreation. Dispersed recreation was also a consideration. The alternatives varied in the amount of unroaded recreation opportunities which they offered over the long term. The output levels were expressed in terms of millions of recreation visitor days per year and acres.

New recreational issues that surfaced since the DEIS revolved around ORV use and the Round Mountain area. The ORV issue is dealt with in the FEIS by restricting use and/or developing a trail system for their use. The Round Mountain issue is measured by the number of acres protected.

Related to the recreation issues are concerns about scenic quality. This issue was addressed in the alternatives by applying prescriptions which provide for scenic quality to different areas of the Forest. The new historic trail is addressed in a similar manner. The extent to which scenic quality was provided for in each alternative was measured by the number of acres where scenic quality objectives were met in sensitive travel corridors.

The availability of personal use firewood is a key local issue. A range of options from making no special provisions for personal use firewood to fully meeting the demands for it was explored in the alternatives. The amount provided was expressed in terms of thousands of cords per year.

The factors relating to livestock grazing key around how much grazing should be allowed and how intensive management should be. The livestock use by alternative is a function of economic efficiency and the need to regulate use to meet other resource objectives.

The major factor relating to riparian areas is how they should be managed to produce the various resources they are capable of providing. The new anadromous fisheries issue is a subset of the riparian issue. All alternatives manage for excellent riparian condition where anadromous fisheries are involved. Concern is high because riparian conditions represent only a small portion of the total land base (two percent) but offer the greatest potential to meet multiple resource objectives of the Forest. Because of this, use has been concentrated, conflicts have merged and the riparian environment has been degraded. In all alternatives the present condition in these riparian areas will be maintained or improved if degraded. The extent to which the riparian issue varies by alternative is measured by the number of acres where conditions are managed to ensure meeting a condition classification of “excellent.”

The broad social and economic issue contains several factors. First, local communities are highly dependent on forest related jobs and income, and payments to Counties in lieu of taxes. As a result, economics is the major facet in measuring the effect an alternative has on social-economic makeup of affected communities. At the same time, people expect the Forest to provide jobs and protect the economic well being of the communities. They also expect and desire recreational opportunities such as hunting and fishing. The consequences of the alternatives with respect to this issue were estimated by examining a variety of outputs and effects. They are: jobs, income, payment to Counties, PNV, recreation opportunities, firewood and scenic quality.
Resource Outputs, Effects, and Environmental Consequences

The implementation of any one of the alternatives will result in the production of certain outputs and effects and their associated environmental consequences. Some of the consequences are direct while others are indirect. Some of the consequences are short term while others are cumulative or long term. Chapter 4 of the FEIS describes the associated environmental consequences. Much of the analysis performed to develop these outputs, effects, and consequences is quite complex and is described in Chapter 2 and previous sections of this Appendix. Therefore, in order to fully understand the resource outputs, effects, and environmental consequences associated with each alternative, and their derivation, it is recommended that Appendix B be read along with Chapters 2 and 4 of the FEIS.

Tables B-8-1 and B-8-2 present the direct, indirect, and cumulative resource outputs and effects associated with each alternative and certain selected benchmarks. By examining these tables, a better understanding of the relationship between issue resolution and the resulting outputs and effects for each alternative can be obtained. At the same time, it is also necessary to associate the anticipated environmental consequences that would result from the production of these outputs and effects.

The most significant environmental consequences are those associated with the manipulation of vegetation. Vegetation management in the form of timber harvesting results in changes in the appearance of the forest, changes in wildlife habitat; the short term creation of dust, smoke, and noise; and soil disturbances. The magnitude of these consequences varies between the alternatives depending on how many acres are harvested.

On areas of the Forest where producing timber is one of the primary objectives, existing old growth and mature tree stands will be converted to new and younger stands. The trees in the long term will be smaller and organized in a more uniform manner. There will be less dead and downed material except in areas where it is specifically provided. Therefore, as old and mature stands of trees are replaced with younger stands, overall plant and animal diversity shifts from species associated with old growth communities to species associated with younger communities. Also, as existing mature stands are converted to plantations, more forage is available for grazing by domestic livestock and wildlife.

Some of the alternatives require the development of roadless areas. This would introduce human activity into areas where little human activity presently occurs. This could disturb some species of wildlife, especially elk and deer. Once an area is developed, its wilderness values are diminished, if not lost, and future options for managing the area as Wilderness are forgone. Roading unroaded areas also reduces the limited opportunity for unroaded dispersed recreation on the Forest, but at the same time increases the opportunities to develop other resources such as timber or range production which, in turn, have the potential to provide economic returns to the Federal and local governments.

Ground disturbing activities will displace and compact soils, but within acceptable limits as outlined by the standards and guidelines. Some compaction will occur, however, as a result of roads, skid trails, and construction of facilities. Also, the more ground disturbing activities an alternative has, the more it risks water quality.

To different extents, the alternatives provide for livestock grazing. The higher the livestock grazing levels, the greater the chances are for competition between livestock and deer and elk. Livestock use can also cause damage to young trees in plantations and result in increased reforestation costs, and some loss of tree growth. Also, vegetation is trampled in areas where livestock tend to concentrate near water sources or salt. However, livestock use levels in riparian zones are controlled to prevent damage to the vegetation and soils and to protect water quality.

Providing for different levels and types of resources also affects other resources. Providing for undeveloped recreation and big game habitat reduces the amount of timber that could be harvested and limits
other types of development such as range improvements.

All of the alternatives have their associated socio-economic effects as well as environmental effects. For the most part, the social effects are keyed around lifestyles and expectations of Forest users. The major social concerns are related to economics (including timber and livestock use), and recreational opportunities (including hunting, fishing and nonconsumptive wildlife, scenic quality and personal use firewood). Some of the alternatives would tend to polarize people and communities. This is particularly true of both the high amenity and the high commodity alternatives since they are not well balanced regarding the development and use of the Forest. Alternatives with a commodity emphasis tend to result in fewer provisions for scenic quality, recreation opportunity, and other amenity values. On the other hand, an alternative with a commodity emphasis can result in more jobs and higher revenues. Alternatives with an amenity emphasis do more to protect the scenic quality on large areas of the Forest, and provide high recreation opportunities and other amenity values, but jobs and revenues will be less. The alternatives represented in the FEIS do not represent the extremes from the DEIS. For example, the most amenity-oriented alternative in the FEIS has a higher ASQ, and the most timber-oriented alternative has a lower ASQ and more amenity value resource objectives.

Table B-8-1 displays the average annual quantifiable resource outputs and effects by alternative. The table is quite comprehensive and will be referred to time and again throughout the remainder of this document. Most of the outputs and effects for each alternative are displayed for the decades 1, 2, and 5.

Note that the output levels for some resources during the first two time periods are similar across all of the alternatives. This makes it appear as though there are no differences between the alternatives. However, there usually are. The elk population outputs are a good example for this discussion. The output levels across all alternatives during Decade 1 vary from 3000 elk for Alternative I to 3740 for Alternative C-Modified, a relatively narrow range. However, there is quite a wide range of differences between these Alternatives in the amount and location of lands managed for elk habitat. The short term differences in elk populations between the alternatives are relatively small. The differences become greater over time as the different carrying capacities produced by different elk habitat between the alternatives begin to affect the ability of the Forest to produce and maintain elk populations. In essence, many of the consequences resulting from decisions made in the alternatives will not be apparent in the short-term, but will become more noticeable in the longrun outputs and effects. The same is true for the projections of recreation use and other wildlife population changes.

While evaluating the outputs and effects of the alternatives and assessing their ability to address the Planning ICO’s, it is sometimes useful to know how the output levels of a particular alternative compare with the total potential of the Forest to produce those outputs. Table B-8-2 presents the output levels of certain key resources for each alternative and selected benchmarks and compares them to the capabilities of the Forest to produce those outputs. The rows in the table display the benchmarks and alternatives while the columns represent various outputs and effects which vary significantly across the alternatives. Two numbers are displayed for each row and column intersection in the table. The top number is the production level associated with a particular alternative (row) and output (column). The bottom number is the percent of the potential capability represented by the alternative’s output level.

For example, the maximum PNV benchmark has a Present Net Value of $512 million (row 1 and column 1). Since this benchmark was developed to estimate the maximum Present Net Value of the priced resources (timber, range, and recreation) on the Forest, its Present Net Value represents 100 percent of the potential capability. The seventh row of the same column displays the Present Net Value of Alternative B-Modified at $455 million, or 94 percent of the potential capability. The remainder of the table may be interpreted in a similar manner.
Comparison of the Economic and Social Effects of the Alternatives

This section compares and discusses the economic consequences of the alternatives and benchmarks. The section will begin with a general discussion of PNV and the factors which influence it between the alternatives and benchmarks. The section will then cover the implications of the alternatives with regards to noncash benefits, and economic impacts on the local communities. Finally, the significant incremental changes in PNV from one alternative to another will be summarized. The focus of this discussion will be on the tradeoffs between priced and nonpriced outputs and their effects on the overall ability of the alternatives to address certain key issues, concerns, and opportunities.

PNV, Discounted Costs and Benefits, and Their General Relationships to Both Priced and Nonpriced Outputs

Present Net Value (PNV) is the primary quantitative measure of economic efficiency for each benchmark and alternative. PNV is the sum of market and nonmarket priced values less all management costs for the 50 year planning horizon discounted to present values at a four percent interest rate.

The PNV of the Max PNV Benchmark (B7F) and the six management alternatives are displayed in Table B-8-3. The alternatives are ranked in order of decreasing PNV. Table B-8-3 shows the differences in PNV between adjacent pairs of the successively ranked alternatives. These figures are estimates of the net economic values of the priced resources that would be foregone if a lower-ranked alternative is selected over the preceding one.

Before comparing the PNV's, it is first necessary to discuss some of the components of the PNV calculations in order to get a better understanding of the true differences between the alternatives. Displayed in Table B-8-3 are the present values of the costs and benefits associated with each of the alternatives. Table B-8-4 present a more detailed breakdown of the benefits and costs of major resource categories for all benchmarks and alternatives. The PNV for each alternative is the difference between discounted costs and discounted benefits.

The discounted cost is the sum of all Ochoco National Forest expenditures for 50 years, discounted to their present value using a four percent interest rate. The maximum discounted costs for management of the Forest is $260 million for Alternative B-Mod while the minimum is $213 million for Alternative C-Mod. As shown in Table B-8-4, the difference in discounted costs between alternatives is primarily accounted for in the amount of funding necessary for timber management, roads and organizational support in order to implement the alternatives.

The discounted benefits for each alternative is the sum of the present values of all market and nonmarket priced benefits over the 50 year planning horizon. As shown in Table B-8-4 and B-8-5, B7F provides the largest amount of discounted priced benefits ($720 million). Of the alternatives, Alternative B-Modified produces the most discounted priced benefits at $715 million while Alternative G Mod results in the fewest ($608 million). The differences between the alternatives can be attributed primarily to the timber related benefits and secondarily to recreation, including fish and wildlife.

Market and nonmarket resources can both be priced outputs which are or may be exchanged in the market place. Market values expressed in terms of what people are willing to pay as evidenced by actual sales transactions. Market resources on the Forest include: timber, livestock grazing, campgrounds, mineral leases, and special use permits. Nonmarket values constitute the unit price of an output not normally exchanged in a market and must be estimated. They are valued in terms of what reasonable people would be willing to pay rather than go without. Nonmarket resources include dispersed, wilderness, semi-primitive and wildlife dependent recreation. The purpose of assigning dollar values is to reflect an economic value even though none or only part of that value associated with a particular resource is actually directly collected. Thus, one can directly compare alternatives with regard to their...

3/ Forage production as displayed is the "potential" based on estimates by allotment, that could be achieved with the proposed schedule of range and riparian improvements by alternative. These potentials may not be achieved and are at the minimum, directly dependent upon the implementation of the proposed improvements in the first decade. It is reasonable to expect that some or all allotments may experience up to a 10% reduction in AUM's during the first decade to allow the accomplishment of riparian management objectives.

4/ Steelhead Habitability Capability Index, thousands of smolt.

5/ Management Indicator Species (MIS) for Old Growth on the Forest is the Ponderosa woodland. The common species is the MIS for old growth juniper on the Grassland

6/ NA - Data not available

7/ That which does not currently meet the characteristics described for "suitable", but exists on a site "capable" of producing it some time in the future

8/ This was based on managing these stands with timber harvest with long rotations

11) For the NC alternative, these lands are the regulated commercial forest lands. These lands were not classified using the suitability criteria, but were derived at using the 1972 land classification system provided for by Amendment #1 of the 1985 Timber Plan. These lands are the standard, special, and marginal components of commercial forest lands.

12) For the NC alternative, these lands are the standard component of the regulated commercial forest base.

13) Potential yield applies only to the "No Change" alternative and comes from the Timber Resource Plan. The potential yield for the next ten years is the maximum harvest that could be planned to achieve the optimum perpetual sustained yield harvesting level attainable with intensive forestry on regulated areas considering the productivity of the land, conventional logging technology, standard cultural treatments, and interrelationships with other resource uses and the environment.

14) See Appendix E, Selection of Harvest Cutting Methods.

</table>

1/ 5th Decade
priced output levels and their efficiency in producing them. Market related benefits in any alternative are attributed mostly to timber. The nonmarket benefits are primarily related to fish and wildlife, and recreation (Table B-8-4). Table B-8-4 also shows that the market resources provide most of the discounted benefits for all alternatives. For example, their contribution ranges from a high at 70 percent of the total economic benefits in Alternative B-Mod to a low of 60 percent in Alternative C-Mod.

Noncash benefits is yet another aspect of discounted benefits. Noncash benefits refer to the benefits individual resource users receive who are charged less for the resource than they are willing to pay, or current market prices indicate they should pay. They are the difference between the full economic value of the resource and the fees actually paid to use that resource. Noncash benefits are measured by the difference between total discounted benefits less the discounted receipts that are generated by each alternative. The Forest receives revenues for stumpage, grazing permits, campground fees, mineral leases, and other special use permits. Yet, the Forest generates benefits to users which are not realized in terms of cash flows. This is because dollar prices are assigned to nonmarket resources on the Forest in order to reflect their full economic value even though none or only part of that value is collected as fees under current laws and policies. Timber is the only resource for which the discounted benefits are equivalent to discounted revenues. For all of the other resources, recreation being the primary one, discounted benefits exceed revenues. Table B-8-5 displays the relationships between total receipts, net receipts, and noncash benefits for each alternative in order of decreasing net receipts. The size of the noncash benefit is directly related to the amount of recreation (primarily) and range (secondarily) benefits generated by each alternative.

### Differences in PNV between Benchmarks

The Max Recreation Benchmark (unroaded, big game) (BR3) has a PNV of $454 million. This is $58 million less than the Max PNV Benchmark (B7G). The decrease in PNV is a result of managing 61,000 acres in an unroaded condition. Although this management results in less costs associated with timber and roads and higher economic benefits associated with recreation, fish and wildlife, the foregone timber values far outweigh these advantages, causing a reduction in PNV.

1/ Direct comparisons of benefits and costs by individual resource provide broad indications of specific relationships, but they may be misleading because many costs are nonseparable under multiple-use management.
2/ These costs include general administration, cultural resources, lands and minerals, human resources, and protection.
The Max Timber Benchmark (BT7) has a PNV of $480 million which is $32 million less than B7G. The decrease in PNV is a result of the intensity of timber management. The timber benchmark manages the timber resource much more intensively than does the Max PNV benchmark. This results in higher harvest levels and, as a result, higher timber generated receipts, but the timber and road cost associated with these higher harvest levels outweigh the benefits generated. This higher intensity of timber management also results in less benefits being generated from fish and wildlife resources. The combined effect results in a lower PNV.

The Max Range Benchmark (BF5) has a PNV of $424 million, $88 million less than the Max PNV benchmark's. As with the Max timber benchmark, this benchmark manages a resource more intensively than is economically efficient. In this case it is the forage resource not the timber resource as it was with BT6. This benchmark manages both the timbered and non-forest lands for maximum forage production. This results in a minor increase in forage values and major benefits foregone from timber, fish and wildlife resources.

The Max Big Game Benchmark (BE3) has a PNV of $429 million, $83 million less than the Max PNV benchmark. This benchmark manages the timber resource to maximum big game habitat. As a result, it forgoes much of the timber value for a relatively smaller increase in value from big game. This results in a decrease in PNV.

Changes from Draft to Final
Updated timber yield tables and analysis area acres have resulted in the ASQ and PNV's of the Max PNV and timber benchmarks being much closer together in the FEIS as compared with the DEIS.

Differences in Present Net Values
Present Net Value (PNV) is the primary quantitative measure of economic efficiency used for all benchmarks and alternatives. It is also an important measure of the dollar value of the alternatives. PNV has been calculated to be the sum of all market and nonmarket priced values, less all management costs for the 50-year planning horizon, discounted to present values using a four percent interest rate. The relationship between PNV and net public benefits is discussed in Section 4.

The Max PNV benchmark and six alternatives are ranked by decreasing PNV in Table B-8-3. Table B-8-4 provides further detail on discounted costs and benefits by resource group. The Max PNV benchmark is provided as a reference point only. It is an estimate of the discounted net economic returns the Forest could receive for its priced resources if they were managed solely to maximize Present Net Value.

The main factor influencing patterns in PNV, benefits, and costs is timber management. Timber values represent from 53 percent to 65 percent of the total dollar values in the alternatives. Values produced from selling timber are, in general, far in excess of related costs. As timber harvest levels decrease across alternatives, discounted costs and benefits, and PNV usually decrease as well. This pattern is due in large part to non-timber resource objectives restricting timber practices and harvests. Although recreation related benefits (including hunting and fishing) do make up a significant portion of the total dollar benefits (28 percent to 41 percent), increases in these dollar benefits do not make up for the PNV lost from timber. Therefore, the greater the non-timber resource objectives, the lower are the timber discounted benefits and costs, and PNV.

This general pattern is modified by the intensity of the timber management activities employed. Some alternatives schedule timber practices and harvests at the most economically efficient level, given other resource objectives (Alternatives C-Modified, I, and E-Departure). Other alternatives apply more intensive timber practices to achieve the highest timber volumes possible, given other resource objectives (Alternatives A, B-Modified, and NC). This results in higher timber benefits, but also higher costs and lower PNV. In each of these two groups of alternatives the general pattern discussed above holds. The exact combination of non-timber resource objectives and timber management intensity determines the ranking in PNV of these two groups together.

The PNV of the NC Alternative is an estimate. It is
also based on a programmed harvest level of 129 MMBF. If the estimate was based on the potential yield of 136.5 MMBF, the PNV would be significantly higher.

The Forest and Grassland are considered to have potential energy resources. However, very little testing and development has taken place to date. No estimates have been made of future extractions, so energy values were not included in the economic analysis, but oil and gas leasing provides significant returns to the Treasury and to counties. The alternatives have little effect on mineral activities.

Differences in Costs
Capital investment costs include trails, roads, reforestation, timber stand improvement, prescribed burning, and physical structures for range, recreation, fish, and wildlife. Other costs include operating and maintaining facilities, program management, and support costs associated with management of other resources. Capital investment costs pertain mostly to roads and timber stand management. For example, from 76 percent (Alternative C-Modified) to 95 percent (Alternative A) of capital investment costs are associated with road construction and timber management. The majority of operation and maintenance costs are program management, followed by support funds necessary to carry out timber programs.

Because most costs are associated with timber management, the higher the timber output, the higher the costs. Generally, capital investment costs decrease significantly over time due to declining road construction and timber stand improvement practices. Operation and maintenance costs remain fairly constant over time except for Alternative E-Departure, where timber volume declines over time.

Fixed costs represent a relatively small portion of the total costs (20 percent to 30 percent). The remainder of the cost for each alternative varies with the objectives of the alternative.

Costs associated with timber practices and harvests constitute a large portion of the total costs. Alternative B-Modified has the highest cost of any alternative, and only 29 percent of the discounted cost is directly attributed to resources other than timber and roads. Road construction and reconstruction is almost entirely tied to timber harvests on this Forest. Alternative C-Modified has the lowest cost of any alternative and the highest benefits associated with amenity outputs, yet only 35 percent of the costs can be attributed to resources other than timber.

Differences in Economic Benefits and Cash Flows
The total economic benefits of the alternatives come from priced resources which include both outputs termed "market" outputs, and those with "assigned" values. Market values represent the unit price of an output that is normally exchanged in a market. On this Forest, timber is the primary market output, accounting for over 90 percent of the market outputs and 50 percent to 65 percent of the total economic benefits of the alternatives. Other market outputs include livestock grazing, campground use, special use permits, and minerals leasing. Assigned values represent the unit price of an output not normally exchanged in a market. Various analytical techniques were used to estimate values that people would be willing to pay for these benefits. Outputs with assigned values include dispersed recreation, wilderness use, hunting, fishing, and water quality improvement. Hunting and fishing are the major assigned values, comprising from 16 to 26 percent of the total economic benefits. The remaining 18 to 24 percent are split in different proportions, depending on the alternative, among livestock grazing, developed recreation use, dispersed roaded recreational use, and dispersed non-roaded recreational use.

Total market values range from 62 percent (Alternative C-Modified) to 70 percent (Alternative B-Modified) of the total economic benefits. Alternatives in the high end of this fairly narrow range have relatively high timber benefits and/or relatively lower fish, wildlife, or recreational values. The opposite is true for alternatives in the low end of the range.

Cash receipts are revenues returned to the Forest and Grassland for stumpage, grazing permits, campground fees, leasable minerals, and special use permits. However, the Forest generates economic
benefits to users which are not realized in terms of cash flows. These are referred to as “noncash benefits.” They refer to the benefits individual resource users receive when they are charged less for the resource than they would be willing to pay, or current market prices indicate they should pay. Noncash benefits are the difference between the full economic value of the resource and the fees actually paid to use that resource. Table B-8-5 displays the relationships between total receipts, total budget costs, net receipts, and noncash benefits for each alternative in order of decreasing net receipts. All alternatives receive more money than they spend (net receipts are positive). Fish and wildlife provides the most noncash benefits in all alternatives, followed by recreation, then range. Timber provides nearly all of the cash receipts.

Generally the proportion noncash benefits contribute to total economic benefits increases as net receipts decrease. The decrease in net receipts as noncash benefits increase is a result of more land and resources being allocated to producing noncash benefits, thus lessenng the resources available to produce cash receipts.

Table B-8-5 (Decade One) as compared to Table B-8-3 shows that alternatives with higher net receipts in Decade One generally have higher PNV’s. This trend holds true in all but one case.

This case involves Alternative NC. In Table B-8-3, Alternative NC has the lowest PNV but in Table B-8-5 it has the third highest net receipts. The cause of this is two-fold; first, it has the lowest non-cash benefits of all the alternatives, and second, Alternative NC is different from the other alternatives in that it does not ensure meeting all management requirements. This allows more of the higher value ponderosa pine stands to be harvested in Decade One. However, to satisfy particular harvest scheduling requirements, cash receipts drop off dramatically after the first decade. Table B-8-5 shows that the net receipts for Alternative NC drop in rank from third in the first decade, to last in the fifth decade. Alternative NC also harvests timber at levels beyond that which is efficient in order to meet current sale levels. This results in higher total receipts, but also higher costs resulting in lower PNV’s. As a result, Alternative NC has relatively high net receipts in Decade One, but a relatively low PNV.

Effect of Nonpriced Outputs on PNV between Alternatives

The differences in PNV between the alternatives can also partly be attributed to the levels of nonpriced outputs which they provide. While these outputs can not be valued in dollar terms, their output levels can often be measured in terms of other units. Table B-8-6 presents information which is useful in understanding the relationships between some of the key nonpriced outputs and Present Net Value. It is important to keep in mind that this table is intended to present only general relationships between the nonpriced benefits and PNV. The differences in the output levels and effects should not be interpreted as absolute measurable tradeoffs.

Note that the provisions of some nonpriced benefits are complementary to the production of priced outputs while the provisions of others are contradictory. The contradictory relationships generally mean that more nonpriced outputs can only be provided at the expense of producing fewer priced outputs (primarily timber) and, therefore, lower PNV’s. It is a subjective decision as to whether the foregone priced benefits are compensated for by the increased outputs of nonpriced benefits.

Maintaining and enhancing the lifestyles of Central Oregonians was identified as one of the more important nonpriced benefits. This is comprised of several components, including economic stability, the opportunity for diverse recreation experiences in a visually pleasing environment, and clean air and water. For this discussion we will cover these as separate nonpriced outputs and in no particular order of importance.

Maintaining and enhancing economic viability can mean many things to different people and can be measured in various ways. Table B-8-6 presents the change in the number of jobs in the local economy during the first decade that could result from the implementation of an alternative. To some extent, the payments to county also provide some insight.

1/ Total acreage for lands allocated to management areas with unroaded recreation emphasis (D9, F6, F10, F4, C8)

2/ Total acreage for lands allocated to management areas with visual resource emphasis (D5, D6, D7, G13, F25, F26, F27)

3/ First decade - Acres with timber harvest prescription
into the economic base from which the local Governments can provide services to residents of the area. In general, both of these have complementary relationships with the production of priced benefits. "Payments to counties" is calculated as 25 percent of total Forest Service receipts, 95 percent of which are related to harvesting timber. In turn, many jobs in the local economy are directly related to the amount of timber and recreation supplied from the Ochoco National Forest. Table B-8-6 indicates that, as the production of priced timber decreases, so do the payments to counties and potential number of jobs in the economy. The ranking of jobs and payments to counties does not necessarily fall on the ranking of PNV, because some alternatives' timber harvest levels and species mix may have a positive effect on jobs and payments to counties but a negative effect on PNV.

The ease of accessibility to personal use firewood from the Forest is also a component of the Central Oregon lifestyle. This is considered a nonpriced benefit. Different alternatives investigated various ways of supplying this material. To the extent that personal use firewood permits are priced below what this material would normally sell for on the competitive market, the rationing of personal use firewood supplies has a slight downward pressure on PNV (although the amount of decrease in PNV would be small).

The maintenance or enhancement of scenic quality in sensitive scenic areas is another nonpriced benefit. In Table B-8-6 this output is presented in terms of the amount of acres of retention and partial retention scenic quality objectives met in each alternative. While some timber harvesting is acceptable, and even necessary, in order to meet the management objectives in scenic areas, the provision of scenic quality on the Forest usually comes at some expense to the amount of timber that could be harvested. As more acres are allocated to scenic management across the alternatives, the PNV tends to be lower.

The provision and maintenance of old growth and snag habitat for pileated woodpeckers and other cavity dwellers is also considered a nonpriced benefit. Timber harvesting is excluded from old growth areas and timber volumes reduced to provide snag habitat. Table B-8-6 depicts the amount of habitat provided for these species for each alternative. Generally, as the amount of acres managed for their habitat increases, PNV decreases.

The maintenance and enhancement of clean air and water, and the protection of historical and cultural resources, are also, at least to some extent, contradictory to the harvesting of timber. While the provision of these benefits has not been a serious problem in the past, alternatives which greatly increase the amount of acres harvested will make it more difficult to protect these resources. Table B-8-6 shows that, as ASQ increases, so do the number of acres harvested.

**Economic Impacts on the Local Communities**

Changes in the levels of timber harvests, recreation use, grazing, and Forest Service expenditures on the Ochoco National Forest have the potential to impact the employment and income levels in the local economy. Many of the local communities are particularly dependent upon the Forest based timber resource as the mainstay of their economies. Therefore, the potential economic impacts on the local economy of Central Oregon resulting from the implementation of any one of the alternatives is an important element in the process of selecting a preferred alternative. It was identified as one of the ICO's at the outset of the planning process. The following paragraphs examine this issue.

The primary economic impacts resulting from changes in output levels on the Ochoco National Forest are felt in Crook and Harney Counties and small portions of Wheeler, Jefferson and Grant Counties. Crook, Harney, and Wheeler Counties will be used as a surrogate for the total area of influence. (For more detail on the economic impact analysis, refer to Section 5).

The primary economic impact resulting from changes in output levels in the Ochoco National Forest are minor when compared to the total employment base of the counties. Total employment for the three
Appendix B

counties is estimated to be approximately 9,100 jobs. Approximately 20 percent of these jobs rely on Ochoco National Forest outputs.

All alternatives have less than two percent change in jobs. In terms of payments to counties the impact is much more significant. The Forest’s contributions range from $3.5 million in Alternative C-Mod to a maximum of $5 million in Alternative E-Departure in the first decade. Looking at the wood products sector (logging, sawmill and mill works), the counties largest employer, the impact of the alternatives is slightly more significant. The change in jobs for this sector of the economy ranges from a decrease of three percent in Alternative C-Modified to an increase of four percent in Alternative B-Modified.

The timber (primary) and recreation (secondary) resources are the forest based outputs which are influencing the local economy. Since the recreation use levels will not change that dramatically in the short term from one alternative to another, it is the amount of timber that each alternative proposes to sell which most heavily influences the jobs and income levels during the first decade. Over the longer run (20 to 50 years), the differences between the alternatives in their recreation output levels increase and, therefore, become an important factor accounting for the variation in potential for long term economic opportunities.

The potential impacts on timber related jobs in the local economy are estimated as a function of the change in the amount of board feet sold by an alternative as compared to current sale levels. Timber volume is regulated in cubic feet for all alternatives. In all alternatives, diameter of harvested material will be decreasing over time. There are proportionally more board feet than cubic feet in larger material. As a result, board feet will be declining in all alternatives, even if managed under nondeclining yield. Since jobs and income are tied to board feet timber harvest, all alternatives will exert some downward pressure on local economies after the first decade. With regard to the timber related impacts, not only is the amount of wood offered for sale an important factor, but so is the species mix. Given the same amount of timber volume, pine would have more positive economic effects than mixed conifer. This is a result of pine being remilled in the local communities, thus creating more jobs and income per million board feet than does mixed conifer. Because the mix of species does not vary significantly between alternatives the effect between alternatives on local economies will be minimal.

The Ochoco National Forest is locally and regionally an important provider of recreation opportunities. Current estimates show the State’s population to be increasing at an annual rate of roughly two percent. To the extent that an alternative emphasizes the development of capacity for diverse recreation opportunities, recreation use on the Forest is likely to increase at a comparable rate. So the service industry in the local economy can be expected to grow over the long run to facilitate the recreation visitors, although the jobs will generally be lower paying than the wood processing jobs.

Another means by which the Forest Service can impact the local economy is through its payments to local governments in lieu of taxes. The Forest Service pays 25 percent of its total receipts to county governments. As was discussed above, most of the Ochoco National Forest receipts are generated by the selling of timber. To the extent that an alternative emphasizes the production of timber, the local governments will benefit financially. Stumpage receipts are not only related to the amount of volume which an alternative proposes to sell, but also the mix of species. With that in mind payments to counties by alternative will respond similarly to the change in jobs from the current situation between alternatives.

Responses to Major Issues, Concerns, and Resource Use and Development Opportunities

This section defines indicators that are used to show differences in how alternatives respond to the Issues, Concerns and Opportunities (ICO’s). It also discusses indicators that are of central concern to
the nation as a whole. Appendix A fully discusses each of these ICO's and the relevance of the response indicators. The major ICO's with the greatest influence on the alternatives, and their associated response indicators are as follows.

1. Timber Supply and Forest Management:
   - allowable sale quantity in cubic feet, first and fifth decade
   - allowable sale quantity in board feet, first decade
   - average annual salvage
   - uneven-age management acres.

2. Social and Economic Wants and Needs of Local Communities:
   - Present Net Value (PNV)
   - number of Forest-dependent jobs
   - payments to counties.

3. Livestock Grazing and Allotment Management:
   - Permitted Livestock use in AUM's, first and fifth decades.

4. Riparian Area Management:
   - acres of riparian area in excellent condition, first and fifth decades.

5. Transportation System:
   - miles of primary road, end of first decade.

6. Big Game Habitat:
   - potential deer population, fifth decade
   - potential elk population, first and fifth decades.

7. Roadless Areas and Wilderness Study Areas:
   - acres allocated to roadless recreation.

8. Scenic or Visual Resources:
   - acres allocated with scenic resource emphasis.

9. Old Growth:
   - acres allocated/dedicated to old growth emphasis.

10. Fuelwood Supply:
    - annual firewood supply in M acres, first and fifth decades.

11. Snag Dependent Wildlife:
    - average percent of potential cavity nester habitat, first and fifth decades.

12. Winter Sports:
    - areas available for winter recreation pursuits.

13. Anadromous Fish
    - production of Steelhead smolt (smolt/meter sq.), first and fifth decade.

14. Historic Trail Preservation
    - acres allocated for Summit Historic Trail.

15. Off Road Vehicle (ORV) Use
    - miles of ATV trail, first and fifth decades.

16. Round Mountain
    - area with recreation and scenic resource emphasis, planning period.

**Interalternative Comparisons and Major Trade-offs**

**Introduction**

This section summarizes relationships between economic values and the responses of the alternatives to the issues, concerns, and opportunities (ICO's). The purpose is to identify economic and noneconomic comparisons and trade-offs that can be quantified as ICO response indicators. To provide a partial framework for assessing comparisons and trade-offs, the long-term resource demands of the national, regional, and local communities have been summarized. Selected economic values and quantified indicators of responsiveness to ICO's are tabulated (Table B-8-7). Finally, differences and similarities

among individual alternatives are summarized in terms of major trade-offs among competing objectives or responses to expressed issues, management concerns, or resource use and development opportunities. A complete understanding of differences among alternatives requires reading all of Chapters 2 and 4.

National, Regional, and Local Overview

National projections predict demand will rise for all outputs from National Forests (RPA). At the same time, there is also strong demand to protect and enhance environmental quality. Demands and prices for commodity production are generally determined in national and regional markets. Demand for timber from this Forest is high. Most timber sales are competitively bid to prices significantly higher than appraised prices. When national and regional markets are strong, prices are frequently bid upwards of $200 per thousand board feet for ponderosa pine. Demand for livestock forage is also high since the Forest and Grassland are the primary sources of summer forage in this area. All allotments are currently grazed, and the desire to utilize additional forage, or take over any unused allotments, is always high.

Demands for outdoor recreation uses are essentially local or regional. Recreationists on this Forest are predominantly local. The main exceptions are the fall hunting seasons which draw hunters from more populated areas of the state. Total recreation use of the Forest is predicted to rise about 59 percent in the next 50 years (see Tables 3-14 & 3-15, FEIS, Chapter 3).

Timber Supply and Forest Management

Comparison of Past, Present and Alternative Timber Harvest Levels

The potential yield (PY) under the current timber management plan is the total harvest level that could be sustained assuming intensive forestry practices on all available acres. This includes adjustments to meet multiple resource objectives. This was calculated to be 20.86 MMCF (139.5 MMBF) and adjusted to 20.4 MMCF (136.5 MMBF) in 1984, as a result of the Oregon Wilderness Bill. A similar value was not calculated for the alternatives. It would be equivalent to a maximum timber FORPLAN run for each alternative if unsuitable acres were included in the available acreage base.

The programmed allowable harvest under the current timber management plan is that part of the potential yield scheduled for harvest in a specific year (see Table B-8-8). It was calculated for the current plan by: (1) reducing the acreage base by the acres of marginal land that we did not plan to treat, and (2) by reducing yields based on difference in acres of intensive management (planting of genetically improved stock and precommercial thinning) predicted under the potential yield and what was actually planned to be accomplished (This process was known as the “earned harvest effect” (EHE)). This could be adjusted annually if there was significant change in acres of intensive management practices or in marginal land treated from what was programmed. This was originally calculated to be 19.86 MMCF (132.7 MMBF) and was adjusted in 1984 to 19.46 MMCF (129.8 MMBF). This is equivalent to the Allowable Sale Quantity (ASQ) plus the salvage volume.

Table B-8-8 displays the past actual sold and cut volume, planned harvest level from the existing plan, and range of harvest levels for each alternative. The range of harvest levels shown shows the highest and lowest predicted harvest level in board feet for the first decade. All volumes are average annual figures for a particular decade. This table also displays the estimated volume of ponderosa pine for this same period. Additional timber resource information by alternative and benchmark is also presented in Table B-8-9.

The local industry is most interested in the ponderosa pine volume, and it has the greatest impact on the local economy, since much of the pine lumber is remanufactured to molding and other products locally.

The current plan did not have a category called "unsuitable" so there was no reduction in the available land base for lands that could not be reforested. It did have a category called "marginal" which included steep slopes and critical soils, and stagnated submerchantable lodgepole ponderosa pine was programmed from these lands but it was a separate slope component and could not be substituted for "standard" volume or vice versa.

</tbody>
</table>

1/ Note that due to different bases for calculation, these figures may not be directly comparable. However, they may be used to show changes in specific components for calculations, over time. All calculations were done in cubic feet. The volumes in this table are estimates based on board foot/cubic foot ratio.

2/ Yield of timber projected for the period of 1980 to 1989, as calculated for the 1980 Timber Management Plan and adjusted for 1984 Oregon Wilderness Bill. The Programmed Allowable Harvest (P A H) is the sawtimber from green and salvage sales scheduled for harvest.

3/ Allowable sale quantity calculated for the current land and resource management plan direction, projected into the future using new scientific information, such as yield tables and suitability for timber harvest, and using FORPLAN analysis model.

4/ Estimated volume of ponderosa pine that is included in green sale volume.

5/ Average volume sold was not adjusted for "buy-back" volume.

6/ Reduction in all but E DEP is due to change in BF/CF ratio and estimated reduction in salvage volume as more stands become managed. Change in E DEP is mostly due to the planned departure from even flow.

7/ Actual firewood volume is based on years 1985 to 1988. Essentially all of this was sold as personal use. Planned volume is the estimated amount if firewood available. Typically less than half of this will be utilized.

</table>

1/ Tentatively suitable land for all alternatives is 533 M Acres

2/ This is based on 1972 land classification system and adjusted for Amendment #1 of the Timber Plan
It is estimated that the sell volume has included 90 to 100 MMBF of pine in recent years. The current inventory shows 67 percent of the total volume is in ponderosa pine (see Appendix E). So the pine harvest in all alternatives will be 67 plus or minus five percent of the total harvest volume. However, the actual pine volume scheduled for harvest will vary considerably by alternative during the next five decades.

Effects of the Alternatives on the Ponderosa Pine Harvest
The range of ponderosa pine volume by alternative is displayed in Figure B-8-1

Alternative A has the highest volume of pine during the first decade due to the large proportion of harvesting in the first decade in two-story pine types. The volume decreases by about 30 MMBF after the first decade and remains at a relatively low level for the next four decades.

Alternative B-Modified would provide about 85 MMBF of pine during the first decade. Alternative B-Modified would maintain the highest level of pine during the first five decades of all the alternatives.

Alternative E-Departure has a first decade volume of 87 MMBF and declines to an estimated 52 MMBF in the fourth decade.

Alternative C-Modified would provide about 63 MMBF in the first decade, remaining constant through the fifth decade.

The pine volume in the long term (decades six and beyond) depends on harvest level and intensity of management. Alternative I provides for a stabilization of the ponderosa pine harvest over time, as do the other alternatives.

Uneven-aged Management
Uneven-aged management has been included in Alternatives B-Modified, C-Modified and I. This silvicultural system was included in these alternatives in response to public interest in its application as an alternative to clearcutting. Expectations would be increased size of ponderosa pine crop trees (20 inch DBH), improved conditions of forested habitat for wildlife and more desirable scenic qualities.

The range of acreage of ponderosa pine which would be managed with uneven-aged silvicultural systems is shown in Table B-8-7 and Figure B-8-2.

Social and Economic Wants and Needs of Local Communities
This section compares and discusses the economic consequences of the alternatives. The comparisons focus on present net value (PNV), market and nonmarket values, costs, net receipts, returns to treasury, and non-cash benefits. Each alternative has non-quantifiable benefits and costs which should also be considered when attempting to rank the alternatives in terms of net public benefits. This section also discusses the social effects of the alternatives.

Differences in Present Net Values
Present net value (PNV) is the primary quantitative measure of economic efficiency used for all benchmarks and alternatives. It is also an important measure of the dollar value of the alternatives. PNV has
been calculated to be the sum of all market and nonmarket priced values, less all management costs for the 50-year planning horizon, discounted to present values using a four percent interest rate. The relationship between PNV and net public benefits is discussed in Section 4 of this appendix.

The Max PNV benchmark and six alternatives are ranked by decreasing PNV in Table B-8-10. Table B-8-10 provides further detail on discounted costs and benefits by resource group. The Max PNV benchmark is provided as a reference point only. It is an estimate of the discounted net economic returns the Forest could receive for its priced resources if they were managed solely to maximize present net value.

The main factor influencing patterns in PNV, benefits, and costs is timber management. Timber values represent from 53 percent to 65 percent of the total dollar values in the alternatives. Values produced from selling timber are, in general, far in excess of related costs. As timber harvest levels decrease across alternatives, discounted costs and benefits, PNV usually decrease as well. This pattern is due mainly to non-timber resource objectives restricting timber practices and harvests. Although recreation related benefits (including hunting and fishing) do make up a significant portion of the total dollar benefits (28% to 41%), increases in these dollar benefits do not make up for the PNV lost from timber. Therefore, the greater the non-timber resource objectives, the lower the timber discounted benefits and costs, and PNV.

This general pattern is modified by the intensity of the timber management activities employed. Some alternatives schedule timber practices and harvests at the most economically efficient level, given other resource objectives (Alternatives C-Modified, I, and E-Departure). Other alternatives apply more intensive timber practices to achieve the highest timber volumes possible, given other resource objectives (Alternatives A, B-Modified, and NC). This results in higher timber benefits, but also higher costs and lowered PNV. In each of these two groups of alternatives the general pattern discussed above holds. The exact combination of non-timber resource objectives and timber management intensity determines the ranking in PNV of these two groups together.

The PNV of the NC Alternative is an estimate. It is also based on a programmed harvest level of 129 MMBF. If the estimate was based on the potential yield of 136.5 MMBF, the PNV would be significantly higher.

The Forest and Grassland are considered to have potential energy resources. However, very little testing and development has taken place to date. No estimates have been made of future extractions, so energy values were not included in the economic analysis. However, oil and gas leasing provides significant returns to the Treasury and to counties. The alternatives have little effect on mineral activities.

Differences in Costs

Capital investment costs include trails, roads, reforestation, timber stand improvement, prescribed burning, and physical structures for range, recreation, fish, and wildlife. Other costs include operating and maintaining facilities, program management, and support costs associated with management of other resources. Capital investment costs pertain mostly to roads and timber stand management. For example, 76 percent (Alternative C-Mod) to 95 percent (Alternative A) of capital investment costs are associated with road construction and timber management. The majority of operation and maintenance costs are program management, followed by support funds necessary to carry out timber programs.

Because most costs are associated with timber management, the higher the timber output, the higher the costs. Generally, capital investment costs decrease significantly over time due to declining road construction and timber stand improvement practices. Operation and maintenance costs remain fairly constant over time except for alternative E-departure's where timber volume declines over time.

Fixed costs represent a relatively small portion of the total costs (20% to 30%). The remainder of the cost for each alternative varies with the objectives of the alternative.
Costs associated with timber practices and harvests constitute a large portion of the total costs. Alternative B-Modified has the highest cost of any alternative and only 29 percent of the discounted cost is directly attributed to resources other than timber and roads. Road construction and reconstruction is almost entirely tied to timber harvests on this Forest. Alternative C-Modified has the lowest cost of any alternative and the highest benefits associated with amenity outputs, yet only 35 percent of the costs can be attributed to resources other than timber.

Differences in Economic Benefits and Cash Flows

The total economic benefits of the alternatives come from priced resources which include both “market” outputs, and those with “assigned” values. Market values represent the unit price of an output that is normally exchanged in a market. On this Forest, timber is the primary market output, accounting for over 90 percent of the market outputs and 50 percent to 65 percent of the total economic benefits of the alternatives. Other market outputs include livestock grazing, campground use, special use permits, and minerals leasing. Assigned values represent the unit price of an output not normally exchanged in a market. Various analytical techniques were used to estimate values that people would be willing to pay for these benefits. Outputs with assigned values include dispersed recreation, wilderness use, hunting, fishing, and water quality improvement. Hunting and fishing are the major assigned values, comprising from 16 to 26 percent of the total economic benefits. The remaining 18 to 24 percent is split in different proportions, depending on the alternative, among livestock grazing, developed recreational use, dispersed roaded recreational use, and dispersed non-roaded recreational use.

Total market values range from 62 percent (Alternative C-Modified) to 70 percent (Alternative B-Modified) of the total economic benefits. Alternatives in the high end of this fairly narrow range have relatively high timber benefits and/or relatively lower fish, wildlife, or recreational values. The opposite is true for alternatives in the low end of the range.

Cash receipts are revenues returned to the Forest and Grassland for stumpage, grazing permits, campground fees, leasable minerals, and special use permits. However, the Forest generates economic benefits to users which are not realized in terms of cash flows. These are referred to as “noncash benefits.” They refer to the benefits individual resource users receive when they are charged less for the resource than they would be willing to pay, or current market prices indicate they should pay. Noncash benefits are the difference between the full economic value of the resource and the fees actually paid to use that resource. Table B-8-11 displays the relationships between total receipts, total budget costs, net receipts, and noncash benefits for each alternative in order of decreasing net receipts. All alternatives receive more money than they spend (net receipts are positive). Fish and wildlife provide the most noncash benefits in all alternatives, followed by recreation, then range. Timber provides nearly all of the cash receipts.

Generally the proportion noncash benefits contribute to total economic benefits increases as net receipts decrease. The decrease in net receipts as noncash benefits increase is a result of more land and resources being allocated to producing noncash benefits, thus lessening the resources available to produce cash receipts.

Table B-8-11 (decade one) as compared to Table B-8-10 shows that alternatives with higher net receipts in decade one generally have higher PNV’s. This trend holds true in all but one case.

This case involves Alternative NC. In Table B-8-10, Alternative NC has the lowest PNV, but in Table B-8-11, it has the third highest net receipts. The cause of this is two-fold: first, it has the lowest noncash benefits of all the alternatives, and secondly, Alternative NC is different from the other alternatives in that it does not ensure meeting all management requirements. This allows more of the higher value ponderosa pine stands to be harvested in decade one. However, to satisfy particular harvest scheduling requirements, cash receipts drop off dramatically after the first decade. Table B-8-11 shows that the net receipts for Alternative NC drop in rank.

1/ Direct comparisons of benefits and costs by individual resource provide broad indications of specific relationships, but they may be misleading because many costs are nonseparable under multiple-use management.
2/ These costs include general administration, cultural resources, lands and minerals, human resources, and protection.
Appendix B

from third in the first decade, to last in the fifth decade. Alternative NC also harvests timber at levels beyond that which is efficient in order to meet current sale levels. This results in higher total receipts, but also higher costs resulting in lower PNV’s. As a result, Alternative NC has relatively high net receipts in decade one, but a relatively low PNV.

When decade five from Table B-8-11 is compared with Table B-8-10, the relationship between net receipts and PNV’s is not as strong as it was for the first decade. The ranking of alternatives from highest net receipts to lowest net receipts shows the same changes from decade one to decade five. Alternatives E-Departure and NC have higher net receipts in the first decade than in later decades, while Alternative B is ranked higher by net receipts in decade five than in decade one. Because of the PNV discounting computations, high returns in early decades will affect the PNV more than high returns in later decades. The exception is NC, because the drop in net receipts is so sharp the net receipts in decades two to five outweigh the high first decade receipts, thus lowering the PNV.

Comparing the first and the fifth decades in Table B-8-11, all alternatives show an increase in net receipts. The major factor is a decrease in costs because much less road building is necessary in the fifth decade. Also, real stumpage prices increase over time.

Noncash benefits for all alternatives increase from decade one to decade five. Part of this increase is a result of a projected increase in recreation demand. The rest of the increase can be attributed to habitat management for big game and fish. The time lag between habitat improvement and an increase in hunting and fishing causes benefits to show up most dramatically in future decades. The percent increase between decades one and five in noncash benefits ranges from 13 percent in the high commodity alternatives, to 28 percent in Alternative C, an amenity oriented alternative.

**Social Effects**

**Direct Effects**

The direct effects of the alternatives include the following:

- Employment levels produced by the alternative’s mix of outputs (see Table B-8-13);
- The amount of the Forest budget;
- The amount of 25 percent monies paid to the counties.

B-180
Indirect Effects
The previously mentioned effects of the various alternatives would produce effects on the social fabric of the area as follows.

Effects on Occupational Lifestyles
For loggers and sawmill workers, Alternative B-Modified would increase employment by 44 jobs, which is around four percent of total logging and sawmill employment. Alternatives A, I, and E-Destination would produce increases of 14, 15, and 28 jobs respectively.

For workers in remanufacturing operations, the changes range from a three percent employment gain (Alternative B-Modified) to a three percent loss (Alternative C-Modified). None of these changes is considered to be significant. However, the remanufacturing industry will be affected by the Forest Plans of several Forests. This matter is discussed in the Cumulative Effects section in Chapter 4 of this FEIS.

Merchants benefit from any alternative. The smallest gain, 21 jobs, is in Alternative A; the largest gain, 65 jobs, occurs in Alternative E-Destination. Small town merchants hire a smaller proportion of employees than do other business. Therefore, these figures are considered to underestimate the gains to the merchants. When these merchants do hire employees, they often work part time and for low wages. These jobs are often taken by women. Often these jobs provide a secondary income for a family.

Effects on Leisure Lifestyles
Alternative C-Modified would provide for the most recreational activities. Elk and fish are at the highest levels of any of the alternatives, as are opportunities for roadless recreation. Landscapes appear most natural to the driver or hiker. Fuelwood gathering is the one activity which is at its lowest.

At the other end of the scale, Alternative A provides, in general, the least recreational opportunities. Roadless areas and fish are at the lowest levels. Unlike the other alternatives, there is no construction of trails for hiking, ATV's, cross-country skiing, or snowmobiling.

Generally speaking, Alternative B-Modified provides the next lowest level of recreational opportunities. Roadless areas and elk are low. The scenery is the lowest of all the alternatives. However, fuelwood is at its highest; and trail construction and increased numbers of fish improve the picture.

Alternatives E-Destination and I provide an intermediate situation. Alternative I provides more roadless areas, trails, and fish; while Alternative E-Destination offers slightly more elk plus a provision for a semiprimitive motorized area.

Effects on Social Structure: Community Cohesion and Stability
"Community Cohesion" is an estimation of whether a given alternative will tend to unify or polarize a community. While a diversity of opinions in a community is generally desirable, it is assumed that polarization of the community is harmful and that cohesion is beneficial. It is further assumed that polarization will be caused by the adoption of an alternative which greatly favors one point of view over others. In contrast, the selection of an alternative that meets to some extent the desires of diverse participants is assumed to produce cohesion.

Judging by this criterion, Alternatives B-Modified and C-Modified would produce polarization. The public response to E-Destination, the Draft Preferred Alternative, included many negative comments about its "departure" harvest schedule. Under Alternative A, existing polarization would not diminish. Alternative I is the one alternative judged likely to promote some degree of community cohesion.

Livestock Grazing and Allotment Management
Alternatives E-Destination, I and B-Modified all seek to increase the forage available over time. Alternative B-Modified is the most aggressive of the three in its emphasis on forage production. Alternative C-Modified emphasizes amenities over commodity resource use and accordingly shows the lowest forage
production for livestock. Alternatives NC and A maintain about the current level of forage production over time.

**Riparian Area Management**

All alternatives show some progress toward meeting the public and management concerns over livestock impacts to riparian areas. Alternatives NC and A would improve the least amount of riparian area over time, generally limiting the rehabilitation and enhancement to anadromous fisheries. Alternative E-Departure would improve more acreage by adding additional enhancement work on key trout fisheries, as well as to anadromous fisheries. Alternatives B-Modified, I and C-Modified would include rehabilitation and enhancement to bring 17,500 acres to “excellent” condition by the fifth decade. The desired future condition for these three alternatives would be “excellent” for all of the 20,240 acres of riparian area on the Forest and Grassland.

**Transportation System**

The primary difference between the alternatives is in the management strategy for the miles of road maintained open for public travel. All alternatives close and or restrict use on some roads to protect the investment, to provide for public safety, to reduce soil erosion and degradation of water quality, and to increase the wildlife habitat effective in key areas on the Forest and Grassland.

**Big Game Habitat**

A number of the alternatives provide for big game habitat through the dedication of or emphasis on management for winter range characteristics. The indicator for the responsiveness of the alternatives to this issue is the potential population levels of elk and deer that could be maintained. Table B-8-7 and Figure B-8-6 illustrate the responsiveness of each of the alternatives.

Table B-8-7 and Figure B-8-7 illustrate the areas allocated or dedicated to a wildlife management strategy (includes old growth and eagle roosting areas but is reflective of emphasis for big game).
Roadless Areas and Wilderness Study Areas

A number of the alternatives allocate or manage areas for unroaded recreation (nonmotorized and without roads). Table B-8-8 and Figure B-8-8 illustrate the area that will be maintained in an unroaded condition for the life of the planning period.

The North Fork of the Crooked River Wilderness Study Area, 1,125 acres, is incorporated in all the alternatives.

Old Growth

Old Growth areas have been designated according the Regional definition for all all the alternatives considered in this FEIS. The range of acreage allocated is presented in Table B-8-7 and Figure B-8-10. Those alternatives with higher emphasis on commodity outputs, such as Alternative B-Modified, have lower allocations with total existing old growth rapidly depleting over time. On the other end of the spectrum, alternatives such as C-Modified with amenity value emphasis, allocate larger areas to old growth and will retain larger acreages over time.

Scenic or Visual Resources

Public and management concerns for the maintenance of the scenic qualities on the Forest and Grassland resulted in provisions for scenic resource emphasis along key travel corridors for a number of the alternatives. This is in addition to the visual quality objectives assigned to all alternatives. Table B-8-7 and Figure B-8-9 illustrate the area allocated or dedicated to a visual resource management emphasis.

Fuelwood Supply

All the alternatives would supply a portion of the fuelwood demand on the Forest and Grassland. Those alternatives that have higher levels of timber harvest activity would supply a higher percentage of the demand. The amenity alternative, C-Modified, would provide the least amount of fuelwood. Those alternatives such as I, which would stabilize the timber supply over time, would provide a more consistent supply than alternatives which depart from an even flow of timber harvest and experience a long-term reduction in harvest. A similar reduction in available fuelwood would shadow the decline in timber harvest.
The fuelwood supply for each alternative for decades one and five is presented in Table B-8-7 and is illustrated in Figure B-8-11.

**Snag Dependent Wildlife**
All the alternatives provide for the maintenance of a portion of the potential snag dependent species habitat. The ability of any alternative to provide snag habitat is directly related to its timber harvest strategy. Those alternatives with the higher timber harvest levels over time will have less ability to provide a portion of the potential habitat. The percentage of potential snag habitat is presented by alternative in Table B-8-7 and is illustrated in Figure B-8-12.

**Winter Sports**
All the alternatives are responsive, to a degree, to the public interest in having areas available for winter recreation. All the alternatives except for NC and A would provide for winter recreation at Bandit Springs through a 1,580-acre management area allocation. This area is presently closed to snowmoblers to allow for cross-country skiing and similar nonmotorized winter recreation pursuits.

The top of Lookout Mountain would be open to snowmobile use on all the alternatives except for C-Modified and E-Departure.

**Anadromous Fish**
All the alternatives provide for the rehabilitation of key riparian areas along all anadromous fisheries, and schedule enhancement activities to provide for maintenance or enhancement of steelhead production. Estimated smolt production over time is displayed in Table B-8-7. It is planned to be the same for all the alternatives, that is anadromous fish production is assured at this level for all alternatives.

**Historic Trail Preservation**
The Summit Historic Trail is presently designated as a National Historic Trail and would retain that status for all the alternatives. Alternative I allocates 9,560 acres to protect the existing integrity of the trail and to preserve its historic and related scenic qualities.

**Off-Road Vehicle (ORV) Use**
The off-road vehicle use issue is an administrative problem for all the alternatives. At this point in time it is more of a social issue than one of resource impacts. All the alternatives would have adequate regulations in place to deal with resource impacts. Off-road use by ATV's, snowmobiles and motorbikes is seen as not being compatible with some resource emphases. Off-road use would be prohibited on all the alternatives for areas allocated as wilderness, wilderness study areas, and wild and scenic rivers - a total of 41,355 acres amounting to four percent of the Forest and Grassland.

Off-road use would be restricted to designated routes and prohibited from December 1 to May 1 for eagle roosting management areas (570 acres) for all alternatives.

The Bandit Springs area, in Alternatives B-Modified, E-Departure, I and C-Modified, would prohibit snowmobile use on 1,580 acres.

Alternative I would include a number of additional off-road vehicle use closures and restrictions. Motorized use would be prohibited on an additional eight management areas, a total of 35,580 acres amounting to four percent of the Forest and Grassland. Off-road use would be restricted to the summer months (closed December through April) to protect such resources as big game winter range on 186,790 acres amounting to 20 percent of the Forest and Grassland.
Alternatives B-Modified, C-Modified and I would begin to develop an ATV trail system to manage off-road use. The Forest and Grassland program for ATV trails is illustrated in Tables B-8-1 and B-8-7. The intent would be to move towards designating off-road use on specified trail networks and special areas over time. Alternatives NC, A and E-Departure would control ORV use through existing regulations with no special programs planned.

**Round Mountain**

None of the alternatives provide for any special resource allocations for the Round Mountain area, except for Alternatives B-Modified and I which allocate 1,000 acres along the Round Mountain National Recreation Trail corridor to provide for management of its scenic and recreational values. Activities and uses which take place on Round Mountain are considered to be part of the multiple uses which occur in the general forest.

Appendix C

Roadless Area Evaluation

Introduction

According to the Oregon Wilderness Act of 1984:

"... with respect to the National Forest System lands ... which were reviewed by the Department of Agriculture in the second Roadless Area Review and Evaluation (RARE II). . . (RARE II) shall be deemed for the purpose of the initial land management plans ... to be an adequate consideration of the suitability of such lands for inclusion in the National Wilderness Preservation System and the Department of Agriculture shall not be required to review the wilderness option prior to the revision of the [Forest] plans, but shall review the wilderness options when the plans are revised which will ordinarily occur on a ten-year cycle ... [Roadless areas] shall be managed for multiple use in accordance with land management plans pursuant to Section 6 of the Forest and Rangeland Renewable Resources Planning Act of 1974, as amended by the National Forest Management Act of 1976, provided that such areas need not be managed for the purpose of protecting their suitability for wilderness designation prior to or during revision of the land management plans ..."

(Appendix C describes each of the roadless areas on the Forest studied during the Roadless Area Review and Evaluation process (RARE II). It discusses the resources and values considered in each area, the range of alternative land uses considered for these during development of the proposed Forest Plan, and the effects of those alternatives on each area.

Approximately 115,700 roadless acres were evaluated during the RARE II process. Only the Black Canyon portion of the Canyon’s area was recommended for Wilderness through RARE II. The Deschutes Canyon-Steelhead Falls area was recommended for further planning. The remaining areas were recommended for nonwilderness uses.

During the Unit Planning process, the Mill Creek, Lookout Mountain, Black Canyon, and Silver Creek areas were designated as special management areas to provide high quality backpacking and hiking experiences away from roads and motorized vehicles. Roadless characteristics and wilderness qualities were also to be maintained in the Deschutes Canyon-Steelhead Falls area until this analysis is completed. The remaining six areas were to be managed for big game habitat and timber production.

The Oregon Wilderness Act of 1984 (Public Law 98-328) designated the Mill Creek, Bridge Creek, and Black Canyon areas as wilderness. The other areas not designated as wilderness may be managed for nonwilderness multiple use as determined through this environmental analysis. These areas, except Deschutes Canyon-Steelhead Falls, will not be considered for Wilderness during this initial planning period. The Deschutes Canyon-Steelhead Falls further planning area will be considered for a wilderness recommendation during this process.

Boundaries of the original RARE II areas have been adjusted to reflect changes from logging or other approved management activities that do not conform to the criteria for roadless areas.

Under the authority and direction of the current Ochoco-Crooked River Land Management Plan (February 2, 1979), specific timber sale plans have
been implemented in the Broadway area, and it is therefore no longer considered a roadless area and has not been analyzed as such in the development of alternatives.

This appendix describes the resource composition, use and potential, and environmental consequences of the alternatives for each of the remaining roadless areas (Lookout Mountain, Rock Creek, Cottonwood, Silver Creek, Green Mountain, and Deschutes Canyon-Steelhead Falls) in detail. As of December 1988, approximately 54,700 acres of the Forest and Grassland remain as roadless.

Lookout Mountain

Description

Location and Access
The Lookout Mountain unroaded area consists of approximately 14,273 acres in Crook County on the Big Summit Ranger District. It is 25 miles east of Prineville, off U.S. Highway 26, and is accessed primarily from National Forest Road 42 and a few of its tributaries. Trail access into the area can be found across Road 42 from the Big Summit Ranger Station. A series of closed and abandoned old roads are also utilized for nonmotorized access into the southern and eastern parts of this area. Private land borders on the southwest, but otherwise National Forest lands surround the roadless area. Access is normally not available through the private land.

History
The Lookout Mountain unroaded area has never been intensively managed for commodities production, and is presently considered and managed as a 16,577-acre “Special Management Area” for dispersed recreation and backcountry values. It was included in the RARE II inventory as #06214, but was not recommended for wilderness designation during that process and was not included in the Oregon Wilderness Act of 1984. The Senate Committee on Energy and Natural Resources recommended that the Forest Service “examine the feasibility of continuing the current use in the National Forest Plan and determine the land allocation in the Forest Plan.” Approximately 987 acres have been removed from the original RARE II acreage due to on-the-ground surveys and increased accuracy of mapping.

Geography and Topography
Lookout Mountain has unique topographic features that make it easy to distinguish from surrounding landforms. From the Big Summit Ranger Station, with a low elevation of 3,793 feet, it rises toward the southeast through dense vegetation of mixed conifer forests to a high point of 6,926 feet, where exposed, nontimbered grasslands and rock outcrops can be found. From this point, the terrain drops rapidly to the south, exceeding 100 percent slopes in isolated sections. A large acreage of relatively flat, open terrain lies in the center of the roadless area and is the favored area for winter sports activities.

From here the terrain drops off shortly again towards the northeast to the boundary of the roadless area, which borders another unique topographic feature - Big Summit Prairie.

Soils
The Lookout Mountain area contains several soil types that are common to much of The Blue Mountains of eastern Oregon, derived to a large extent, from volcanic ash depositions of thousands of years ago.

All soil types (referred to as soil mapping units) within the Lookout Mountain area, fall within three general categories:

- Higher elevation soils;
- Low to mid elevation soils - deep; and
- Low to mid elevation soils - shallow.

Higher elevation soils are contained in gentle to moderately steep, upland slopes and are derived from mixtures of ash, loess and residuum. Surface soils are very thin to moderately thick, sandy loams, loams and silt loams. Subsoils are absent to thin, gravelly to very gravelly loams, silt loams and silty clay loams.

Deep soils at low to mid elevations are represented by moderately deep to deep soils derived from volcanic ash over loess and residuum. Typically, these...
Figure C-1
LOOKOUT MOUNTAIN

RARE II BOUNDARY # 06214-15260 ACRES

BOUNDARY WHICH MEETS ROADLESS CRITERIA # 14,273 ACRES
soils occur on northerly aspects of gentle to steep terrain.

Shallow soils at low to mid elevations contain thin surface layers of nongravely to gravelly loams and subsoils that are either nonexistent or very thin clay loams to clays. These soils occur on all aspects of gentle, sloping basalt flow surfaces.

More than one-half of the acreage in the Lookout Mountain Roadless area exhibits severe erosion hazards.

**Vegetation and Ecosystem Type**

No less than twenty-eight different plant communities exist within the Lookout Mountain unroaded area, and contain a wide variety of plant species in various stages of succession. Many of these communities were historically maintained by fire, and are now undergoing change toward climax vegetation represented by species once restricted to isolated areas protected from fire.

Table C-2 contains a list of those plant communities, by acres, that exist in the Lookout Mountain roadless

</tbody>
</table>
area, according to resource inventories. They are organized by similarities in dominant plants and environment.

**Current Uses**

**Recreation**

Existing management of the Lookout Mountain unroaded area allows for semiprimitive recreational activities in the summer. Other activities currently occurring include mining and grazing by sheep, cattle, and wild horses.

Current recreation use is subdivided among primary user groups of cross-country skiers, snowmobilers, horseback rider, hikers, deer and elk hunters, and mountain bikers. Skiers and snowmobilers comprise the largest group of users. The estimated capacity with current access and trail system is 7.8 thousand recreation visitor days (MRVD’s). With a fully developed trail system, this area could support approximately 19.5 MRVD’s.

**Minerals**

Two semi-active mines lie within the boundary of the roadless area. These operate only at minimum levels in order to meet annual assessment requirements.

**Livestock**

Both a sheep and cattle allotment overlay into the Lookout Mountain unroaded area. The Brush Creek cattle allotment provides for 533 animal unit months (AUM’s) of grazing for local permittees. The Canyon Creek sheep allotment provides 3,850 sheep months of grazing.

**Scenic Resources**

From the west, Lookout Mountain appears somewhat ominous as it rises above the surrounding topography, especially during the winter months when snow-covered mountain meadows and rock outcrops become easily distinguishable from surrounding dense, mixed conifer forest.

Within the interior of the unroaded area, a variety of landforms and vegetative patterns are apparent. At the lower elevations, especially on southern exposures, open stands of ponderosa pine are still dominant. Even though this particular character type is slowly disappearing due to the elimination of fire, native grasses of fescue and wheatgrass, along with introduced species such as Kentucky bluegrass, complement these stands, providing a relaxing park-like setting.

At the mid to upper elevations, very dense stands of mixed conifer provide an extreme contrast to open pine stands. Large numbers of trees per acre, combined with a species mixture of ponderosa pine, Douglas-fir, western larch, white fir, and some lodgepole pine, provide a textural and color quality that is the dominant vegetation feature in the Lookout Mountain roadless area. As succession proceeds in a similar fashion to stands of ponderosa pine, white fir will become the dominant species in these stands, with western larch and ponderosa pine becoming insignificant components over time.

Interspersed throughout this large acreage of dense mixed conifer are small open meadows and draw bottoms that occasionally support groves of quaking aspen, providing the visitor with a refreshing and welcome change of scenery.

Approximately 2,500 acres of nonforested grasslands, alpine meadows and basalt rock outcrops are the dominant visual feature above 6,000 feet in elevation. Color and textural differences between these areas and adjacent timbered stands of subalpine fir, Engelmann spruce, lodgepole pine, and other more common mixed conifer species, provide a distinct visual character representation of many high altitude settings in the Blue Mountains of Eastern Oregon.

Spectacular scenery is abundant from the top of Lookout Mountain. Especially inviting is the view of the Oregon Cascade mountains to the west. No less than eleven major peaks are visible from this point. The area offers scenic beauty along all of the access trails while looking both into and out of the area.

**Wildlife**

The Lookout Mountain area is well-known locally for it’s production of trophy, multi-antlered bull elk.
This is probably the most significant wildlife attraction in the area. Mule deer, ruffed grouse, black bear and bobcat are other hunted wildlife species that draw visitors to the area.

Nongame species inhabiting the area include pileated woodpeckers, badgers, a variety of hawk species, an occasional eagle, and numerous other indigenous animal species common to the Ochoco Mountains.

History
Gold and cinnabar mining were once very important activities in and around the Lookout Mountain area. The historic significance is well-known and documented. Several small communities grew up, then quickly vanished. The remnants of these past activities are still apparent and are adjacent to the roadless area. Of particular attraction are the two existing operational mines, Amity and Independence, which still contain remnants of buildings and other structures associated with past mining activities.

Wilderness Capability (Potential)

Manageability and Boundaries
Three different boundaries have been defined for the Lookout Mountain roadless area. They are:

- RARE II Boundary - 15,260 acres
- Roadless Criteria Boundary - 14,273 acres
- Manageable Boundary for Semiprimitive Recreation - 15,660 acres

The Roadless Criteria Boundary is an updated RARE II boundary. The acreage differences shown are due to recent on-the-ground surveys which added some acres and deleted others because of (a) more accurate mapping and (b) re-examination of areas of past human disturbance. The boundaries resulting from these two categories are difficult to identify on the ground, especially on the south and east ends, because of indistinct topography and vegetation. The Manageable Boundary for Semiprimitive Recreation has been designated along more easily identifiable features such as roads, land survey lines, ridgelines and draws.

Natural Integrity and Appearance, Opportunities for Solitude

Even though the Lookout Mountain unroaded area has never been intensively managed for commodities production, such as timber, man's activities are apparent to the extent that most visitors would notice them. Approximately 6.1 miles of primitive road traverse the area, primarily in that portion most heavily used by sight-seers and outdoor recreationists - the summit of Lookout Mountain. Old stumps cut from previous salvage logging are visible to observant visitors, even though distributed in random fashion. Two operational mines are also distinct man-made features in easily observable locations.

National Forest Road 42 borders the unroaded area to the north and is the most heavily used timber haul road on the Big Summit Ranger District. Sites and sounds of human activity are obvious along this north face. As one approaches the top and walks into the interior or in the southern reaches of the area, the sites and sounds of this road are lost.

The most serious alteration of natural conditions in the Lookout Mountain roadless area relates to the initiation of fire prevention management at the turn of the century. Reduction of natural fire frequencies has resulted in vegetative changes that are not easily reversible. Natural fuel building is now such that allowing fires to burn uncontrolled could have serious, if not catastrophic effects on the roadless area and adjacent lands. Plant species changes are occurring rapidly to the point where once insignificant numbers of fire-intolerant Douglas-fir and white fir are becoming dominant vegetative features within the majority of roadless area timber stands. Within 75 to 100 years, succession to climax will be essen-
Appendix C

tially complete, barring some natural or human-induced disturbance. Ponderosa pine and western larch will be secondary species and, in fact, nonexistent within certain areas.

**Primitive Recreational Opportunities and Challenging Experiences**

The Lookout Mountain unroaded area has a Recreation Opportunity Spectrum (ROS) classification of semiprimitive, nonmotorized, under existing allocations. The estimated carrying capacity is 14.3 MRVD's without additional developments. Opportunities for additional primitive and unconfined recreation are somewhat restricted to certain uses, such as hiking, hunting, fishing, backpacking and photography. Because of the limited area conducive to snowmobiling and ski touring, conflicts are already apparent, and it is assumed that significant increases in these uses will further aggravate the problem. Opportunities for challenging experiences, such as mountain climbing and survival training, are limited, but dependent on the individual perceptions, age, and skills of visitors.

**Wildlife**

The Lookout Mountain unroaded area currently is capable of producing and maintaining an estimated 197 Rocky Mountain elk. Potentially, this can be increased to approximately 267 over time, but with a possible decrease in trophy, multi-antlered bulls.

Under existing land allocations, 5,316 acres of suitable old growth are available for supporting dependent species such as the pileated woodpecker. There is a potential for increasing old growth habitat to an estimated 10,200 acres, over time.

For cavity nesting bird species, current snag habitat is at the 100% level for maximum potential production of primary cavity users.

**Fisheries**

All Class II streams within the Lookout Mountain unroaded area support rainbow trout. One stream, Brush Creek, also supports brook trout. There are currently 38 acres of riparian areas in a degraded condition and 290 acres in an acceptable condition within the roadless area. Potentially, all 328 acres can be improved to produce more fish.

**Water**

All water resources within the unroaded area contribute to irrigation use downstream, which is essential to the agricultural stability of central Oregon. However, under current conditions, annual supplies of water for this use exceed demand. The Lookout Mountain roadless area contributes an estimated 9,940 acre feet of water per year for downstream use. At sustained yield timber harvest levels, there is a potential for increasing this by 248 acre feet per year. The maximum conceivable increase, which would result only from a type conversion to grasslands, is estimated at 5,600 acre feet per year.
Livestock
Both a sheep and a cattle allotment overlay into the unroaded area, and currently support 3,850 sheep months and 533 Animal Unit Months, respectively. Potentially, these can be increased by 28 percent through use of transitory range and improved water developments.

Timber
There are currently 10,224 acres of land suitable for timber production within the Lookout Mountain unroaded area. No timber harvest currently occurs. There is approximately 187 million board feet of standing volume at present and the potential long-term sustained yield is estimated at 2.75 million board feet per year.

Minerals and Energy
There are currently 200 gold and cinnabar claims held within the management area, and activity has been increasing in the last few years. There is some potential for a major gold or mercury operation in the area. The potential for energy production from wood is significant, based on potential yield of .5 to .7 million cubic feet per year.

Cultural Resources
The most significant cultural resource known to the area are remnants of an old fire lookout at the top of Lookout Mountain, with several trails and old roads leading to it. No prehistoric sites are known to be in the area, and the potential is unknown.

Management Considerations
Fire
Natural fire frequencies once played a significant role in development and maintenance of vegetation within the Lookout Mountain area. The following range of natural fire cycles by vegetation type provides an indication of the importance of fire in preventing excessive fuel accumulations and maintenance of several tree and shrub species.

<table>
<thead>
<tr>
<th>Vegetation</th>
<th>Natural Fire Cycle</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ponderosa pine</td>
<td>5-25 years</td>
</tr>
<tr>
<td>Mixed conifer</td>
<td>20-70 years</td>
</tr>
<tr>
<td>Grass, tree, shrub</td>
<td>5-15 years</td>
</tr>
</tbody>
</table>

Since the implementation of fire prevention measures at the turn of the century, fuels have been allowed to accumulate at unnatural rates, creating the potential for a major conflagration, given a certain set of environmental conditions.

Final Environmental Impact Statement Corrected Page, October 6, 1989
Insects and Disease
Infestations by a variety of insects have occurred, are occurring, and will most likely continue to occur in the Lookout Mountain roadless area. As recently as 5 years ago, a major infestation by mountain pine beetles resulted in the mortality of approximately 1,100 acres of lodgepole pine near the summit of Lookout Mountain. This was a natural event that, during historic times, was usually followed by an intense fire that prepared the site for stand regeneration.

The Lookout Mountain area, along with a large portion of central and eastern Oregon forest lands, is experiencing the end of a ten-year infestation of western spruce budworm. Continuous feeding by this insect causes a reduction in vigor and can kill trees over a period of time. Evidence shows that budworm outbreaks begin and are maintained on stands where species are unadapted to site conditions. Douglas-fir and white fir are the primary target species of the budworm. These species are dominant in the unroaded area due to a reduction in fire interactions in the environment. As long as this situation exists, there will be high potential for periodic outbreaks of spruce budworm.

Other insects that have potential for serious affects within the roadless area are:

<table>
<thead>
<tr>
<th>Insect</th>
<th>Target Species</th>
</tr>
</thead>
<tbody>
<tr>
<td>Larch casebearer</td>
<td>Western larch</td>
</tr>
<tr>
<td>Western pine beetle</td>
<td>Ponderosa &amp; lodgepole pine</td>
</tr>
<tr>
<td>Tussock moth</td>
<td>Douglas-fir and white fir</td>
</tr>
</tbody>
</table>

Among the diseases occurring in the roadless area are:

<table>
<thead>
<tr>
<th>Disease</th>

<tbody>
<tr>
<td>Various root rots</td>
<td>All</td>
</tr>
<tr>
<td>caused by fungi</td>
<td></td>
</tr>
<tr>
<td>Indian paint fungus</td>
<td>White fir</td>
</tr>
</tbody>
</table>

Neither of these is expected to cause serious problems under the current management allocation.

Wilderness Evaluation

Public Interest and Congressional Direction
An estimated 1200 comments concerning Lookout Mountain were received. A wide variety of opinions were voiced. Among the letters with comments on this subject were those of the Crook County Courthouse, Crook County, Oregon Department of Fish and Wildlife (ODFW), Oregon State Economist, and the Oregon Department of Geology and Minerals.

There were many comments dealing with roading versus unroaded recreation. Some wanted total unroaded designation. Others urged roading into part of the area for fire and timber management.

Crook County Courthouse pointed out the exclusion of senior citizens and the handicapped when areas are roadless. The Crook County letter, however, urged keeping the area unroaded.

Some comments urged backcountry designation. The Oregon State Senate suggested protection for the area. Some even suggested wilderness designation for Lookout Mountain.

Others were concerned about winter recreation, and keeping the area open for snowmobiling.

There were comments urging new developments for the area, such as new trails, warming huts, a day use area, and a wheelchair platform at the tower site. Others pointed out that the area is being discovered by mountain bike enthusiasts and urged no further developments in the area.

Many respondents requested the area be kept open for “multiple use,” in fairness to all users.

Most wished recreational values to be considered over timber interests. They stated that tourism outweighs the area’s timber potential. They also requested protection for the old growth.

Prior to the time that this input was received, Congress had reviewed the Lookout Mountain roadless...
area for inclusion in the National Wilderness System. Senate Report #98-465 states:

“This area is presently managed by the Ochoco National Forest as a “Special Management Area” for dispersed recreation and backcountry values. The area is not presently in the timber base. The Committee expects the Forest Service to examine the feasibility of continuing this use in the current National Forest Plan and determine the land allocation in the Forest Plan.”

Environmental Consequences

The variety of acre allocations shown in Table C-6 will result in an array of different outputs and environmental consequences for the Lookout Mountain area.

Table C-7 contains quantitative estimates of resource outputs and/or environmental consequences associated with each alternative. As an example, even though timber production per se is not an environmental consequence, the outputs shown indicate the increased productivity associated with long-term management of the timber resource in the Lookout Mountain area. Similarly, “Roads Built” by alternative is not an environmental consequence, but “Roads Open per square mile” indicates the emphasis of the prescription applied by alternative, which can result in an array of consequences for wildlife, water quality, and motorized recreation. Outputs shown for “Riparian” indicate the acres of riparian area that will be enhanced above minimum management requirements. Outputs shown for “Big Game” (number’s of elk) reflect the management prescriptions applied to the area by alternative and are an index of the quality of habitat produced. Outputs for “Recreation” are Recreation Opportunity Spectrum classifications and indicate the type of recreational opportunities available by alternative. For “Off-Road Vehicles,” a plus or minus indicates either an increase or a decrease in this type of opportunity. Outputs for “Snags” indicates the percentage of snag habitat available for maximum

MMCF - Million cubic feet  
SPNM - Semiprimitive Nonmotorized  
AUM's - Annual Unit Months  
MMBF - Million board feet  
RM/RN - Roaded Modified/Roaded Natural
potential production of primary cavity users, by alternative. Outputs for “Old Growth,” in acres, indicates either (a) the acres allocated by management for development alternatives, or (b) existing or potential old growth based on site capability. Outputs for remaining categories are self-explanatory.

**Alternatives A, NC, and C-Modified**

These alternatives would result in the highest amounts of semiprimitive environment. The entire Lookout Mountain roadless area would be allocated to this emphasis. No road building would occur and no scheduled timber harvest would result. Salvage harvest might be done, but only in order to maintain a healthy, attractive semiprimitive setting. All previously degraded riparian habitat (38 acres) would be improved to an acceptable condition by management. Big game habitat would change only through natural processes with a small projected increase in elk numbers (from 197 to 201). Old growth habitat would increase to a maximum of 10,200 acres, based on capability of the area. Snag habitat would increase to maximum potential for primary cavity nesters, but would fluctuate with natural environmental changes. Options for future wilderness designation would remain available.

**Alternative B-Modified**

This alternative would maintain the upper 7550 acres for semiprimitive recreational opportunities, reducing the potential by approximately 50 percent. The entire lower area would be managed with an emphasis on timber and livestock production. Approximately 65 miles of system roads would be built to access timber stands. A variety of timber management practices, such as uneven-aged selection harvest, clearcutting, shelterwoods, overstory removal, and thinning, would be applied to the lower timber stands in the Lookout Mountain area. This would reduce scenic quality and eliminate much of the opportunity for solitude. Natural processes would no longer be the major effect on succession, and species composition would be based on optimum commodities production. Even though all riparian areas would be maintained in an acceptable condition, stream sediment would increase. Forage production would increase by 192 AUM’s due to transitory range from timber harvest and investments in water developments. A ‘roaded modified’ type of recreational setting would be provided over the lower area. Old growth habitat would be reduced to 2,690 acres.

Opportunities for motorized recreation would increase, as will winter sports opportunities. Approximately 110 cords of firewood per year would be available to local citizens. Snag habitat would be reduced to minimum management levels of 20 percent of maximum potential. Big game habitat would be reduced with a resulting decrease in elk numbers to 110 animals. Timber harvest would occur at an average per year rate of 2 MMBF. Once under a fully regulated condition, a sustained yield of .55 MMCF per year would be produced. Options for future wilderness designation would be foregone.

**Alternative E-Departure**

These alternatives would substantially reduce semiprimitive recreational opportunities, but would maintain a 2,950-acre parcel on top of Lookout Mountain to provide this experience. The majority of timbered lands would be managed for timber production. A full array of timber management activities would be fully evident on these acres. Natural succession would dominate only in the 2,950-acre parcel. The sites and sounds of human activity would probably be noticeable from all areas. Motorized recreation and winter sports would increase with demand. Sixty miles of system roads would generally be open to provide access to recreationists and management. About 178 cords of firewood would be available yearly to local citizens. Snag habitat would be reduced to 20 percent on the majority of acres, but would remain at 100 percent potential levels in the 2,950-acre parcel. Old growth habitat would be maintained at about 1,285 acres. Stream sediment would increase from development activities, but would remain within constraints. All riparian habitat would be brought up to, and maintained in, an
acceptable condition. A “roaded modified” type of recreational setting would be available on the majority of the area. Options for future wilderness designation would be gone. Elk numbers will be reduced to about 66 animals.

Alternative I
This alternative would maintain the natural setting to provide high quality semiprimitive nonmotorized recreational opportunities in the summer. Some vegetative manipulation in the lower 8110 acres would be allowed for wildlife habitat improvement and for promoting healthy forests that are more resistant to catastrophic events. Snowmobile use would continue to be authorized during the winter months. Minimum standard roads might be designated for specific projects, but would be closed and seeded to improve wildlife habitat upon completion of the project. Projects would not dominate the landscape, nor be evident to the casual Forest visitor. As a result of these limited entries, the ponderosa pine and western larch that are valued for their appearance to recreationists would become more abundant over time. All riparian habitat (328 acres) would be improved to excellent condition by grazing management and other improvement practices. Big game habitat should be improved with these projects, and a large increase in elk populations might occur. The area would provide security from motorized activities in the summer, encouraging viewing of game and nongame species. This should also provide ideal backcountry trophy hunting opportunities. The existing old growth habitat would be maintained and levels are might increase as regulated harvest is excluded from the area. Snag habitat for cavity nesters would increase to maximum potentials, but would fluctuate with natural environmental changes. Options for future wilderness designations would remain for the upper 7550-acre area.

**Rock Creek**

**Description**

**Location and Access**
The Rock Creek unroaded area consists of approximately 11,414 acres in Wheeler County, Oregon, on the Paulina Ranger District. It is about 20 miles northeast of Paulina, 12 miles southeast of Dayville and is accessed primarily from National Forest Roads 38 and 32. A dirt road, #38-200, leads to Spanish Peak, which is a major viewing area for the interior of the unroaded area. Private land and public lands administered by the Bureau of Land Management border to the north, but otherwise the Rock Creek area is surrounded by National Forest lands.

**History**
The Rock Creek unroaded area has twice been considered for wilderness designation; once under RARE II and again during proceedings for the Oregon Wilderness Act of 1985. In both cases, the result was nonwilderness.

Under the existing land management plan, Rock Creek is allocated to many uses with an emphasis on big game production.

**Geography and Topography**
The Rock Creek area is a large north facing basin that includes the headwaters of Rock Creek and West Birch Creek. Significant topographic features include: the 800 to 1000 foot deep Rock Creek canyon, which runs from the southern to the northern boundaries of the roadless area; the high ridges which run east, west, and southeast from Spanish
Peak and Windy Point; the 800-foot fault escarpment formed by the north face of Spanish Peak—with the hummocky topography left by massive debris slides at its base; and the steep, open ridges which run north/south between the tributaries of Birch Creek. Slopes in two-thirds of this area exceed 55 percent.

Elevations in the Rock Creek area range from over 6000 feet on the ridges surrounding Spanish Peak (6871), to canyon bottoms around 4200 feet in Rock Creek and 5500 feet in Birch Creek where they cross the National Forest Boundary.

Soils
Three major soil types comprise most of the landbase within the Rock Creek roadless area. They are:

<table>
<thead>
<tr>
<th>Soil Type</th>
<th>% of Area</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moderately deep and deep,</td>
<td>50%</td>
</tr>
<tr>
<td>sandy loam volcanic ash</td>

<tr>
<td>sandy loam volcanic ash</td>
<td></td>
</tr>
</tbody>
</table>

Very shallow loamy and clay nonforest soils 40%

Moderately deep loams and clays 10%

Over 65% of these soils occur on slopes with potential erosion hazards.

Vegetation
Seventeen different plant communities exist within the Rock Creek unroaded area. Table C-8 lists those plant communities with acreages according to resource inventories. They are organized by similarity in dominant plants and environment.

Stream bottoms and north-facing slopes in the Rock Creek canyon are covered with dense mixed conifer forest. There are several stands dominated by lodgepole pine along Rock Creek. Ridges, and south and west facing slopes, are marked by shallow soils, basaltic cliffs, and mountain-mahogany/bunchgrass

</table>
interspersed with open ponderosa pine/Douglas-fir forest. The high ridges are dominated by native annuals and bunchgrass perpetuated by late snowpack, with "stringers" of mountain-mahogany and mixed conifer forest. The north slopes of Spanish Peak are covered with open talus slides and weather battered Douglas-fir which grades into closed ponderosa pine/mixed conifer forest on the gentler slopes of the landslide debris. Most of the Birch Creek watershed contains dense mixed conifer forest, with open ponderosa/Douglas-fir on the ridgetops.

Current Uses
Existing management of the Rock Creek area allows for a wide range of uses to occur, even though the magnitude of some uses is constrained by limited access.

Recreation
Backpacking, big-game hunting, horseback riding, hiking and fishing are the principal recreational uses presently occurring. No indicators of present use have been measured, but is estimated to be considerably less than the current potential of 3.1 thousand recreation visitor days. The potential for this area, with a completed trail system accessing all major areas, is estimated at 15.5 MRVD’s.

The area is served by 17 miles of unmaintained or user-maintained routes. Approximately 85 percent of the area is capable of supporting semiprimitive, nonmotorized recreation. The remainder supports semiprimitive motorized recreation in the southern plateau areas.

Outstanding views of the Rock Creek, Cottonwood, and Black Canyon roadless areas, large portions of the Ochoco and Malheur National Forests, the John Day River Valley, and the desert country south of the Ochoco National Forest are available from the high ridges and peaks in the Spanish Peak area.

Minerals and Energy
There has been no mineral development in the area. About 7,800 acres of oil and gas leases are held on the Rock Creek area.

Special Use Permits
One special use permit to operate and maintain a 1/4 mile water diversion ditch is held in the Rock Creek area.

Timber Production
Past timber activities have been limited primarily to salvage and selective harvest prescriptions.

Livestock Production
The Rock Creek area provides an equivalent of 410 AUM’s for two existing grazing allotments.

History
Historic features include the old China ditch, built by Chinese laborers during the mid-1800’s to supply water to the Spanish Gulch mining district, and a historic wagon road used to transport produce from the John Day River valley to the Paulina area. Indian artifacts are located at numerous sites in the Rock Creek area.

Fish
Rock Creek, and its major tributaries within the roadless area, provide 18.2 miles of excellent condition Class I and II streams to the John Day River. The tributaries of Birch Creek within the roadless area provide an additional 1.2 miles of excellent condition Class II stream to the John Day River. Both Rock Creek and Birch Creek support significant trout populations and is also important for spawning steelhead. It is an important supply of high quality water to the John Day River fisheries.

Wildlife
The diverse habitat types found in the Rock Creek area support a corresponding diversity of reclusive and old-growth dependent wildlife species. The area is believed to support wintering and/or breeding bald eagles and wolverines—both on the Oregon Threatened and Endangered Species list. Species of special interest which are known to nest in the area include: pileated woodpecker, goshawk, prairie falcon, and blue and ruffed grouse. Forty to fifty percent of the area is considered to be elk winter range. The Rock Creek area contains excellent habitat for a small population of older age class elk.
Wilderness Capability (Potential)

Managability and Boundaries
Three different boundaries have been defined for the Rock Creek unroaded area. They are:

- RARE II Boundary - 9,286 acres
- Roadless Criteria Boundary - 11,414 acres
- Manageable Boundary for Semiprimitive Recreation - 9,336 acres

The current boundary is an updated RARE II boundary. The acreage differences shown are due to recent on-the-ground surveys which added some acres and deleted others because of (a) more accurate mapping and (b) re-examination of areas of past human disturbance. The boundaries of these two categories are difficult to identify on the ground, except on the north boundary, because of indistinct topography and vegetation. The Manageable Boundary for Semiprimitive Recreation has been designated along more easily identifiable features such as roads, land survey lines, ridgetops and draws.

The Rock Creek unroaded area boundary is well defined by topographic features, roads, and the surveyed National Forest boundary. Topographic features serve to shield the roadless area from intrusion of activities taking place outside the area. Most of the Rock Creek and Birch Creek watersheds, which are administered by the Forest Service, lie within the roadless boundary.

A corridor along the high-clearance road to the top of Spanish Peak is the only substantial intrusion into the roadless area. This road provides access to the communications facility near the top of Spanish Peak, access to an undeveloped campsite used by one of the livestock permittees, and views of the surrounding country to motorized visitors. Elimination of this intrusion by closing and obliterating the road is possible but not necessary to manage the area for semiprimitive recreation.

Natural Integrity and Appearance, Opportunities for Solitude
The most extensive effect on the natural integrity of the Rock Creek area has been made by the elimination of fire as the principal factor controlling vegetative change.

The overall appearance of the area is very natural away from localized disturbances. Trails, low-standard roads, fences, and timber harvest activities are apparent but not overwhelming to most users on approximately 15 percent of the area. Developments outside the roadless area are apparent only to observant visitors. Historic and prehistoric cultural features, and the effects of past activities on natural processes, are apparent only to the most observant visitors at close range.

The dense vegetation and rugged topography in the area provides barriers against intrusion by the sight or sounds of other Forest users. Nonmotorized users within the roadless area will not be apparent to other users at distances greater than 200 yards in most cases. The sounds of aircraft overflights, timber harvest activities, and motor vehicles will be heard at times from some parts of the roadless area. Activities which occur outside the roadless area will only be visible from a few places, to observant visitors.

Primitive Recreational Opportunities and Challenging Experiences
Opportunities for semiprimitive nonmotorized recreation in the area include: backpacking, hiking, fishing, big-game and upland bird hunting, plant and wildlife observation, photography, riding (horse and bicycle), and backcountry ski camping.

Semiprimitive motorized recreational opportunities include on- and off-trail use of over-snow, two-, three-, and four-wheel off-road vehicles (ORV's). Motorized recreation may be combined with some of the described nonmotorized activities, or as recreation by itself. These activities are limited by
terrain to approximately 15 percent of the roadless area. The estimated carrying capacity is 1.9 MRVD's.

The Rock Creek area's steep and diverse topography, limited trail system, isolation, and low visitor density provide challenges in off-trail navigation and safe travel which require good judgement, self-reliance, and a high level of backcountry skills for most activities. All these factors are further accentuated by winter conditions. Winter recreation in this area requires complete self-reliance and a very high skill level for safe travel.

**Special Features, Historical and Scientific Study**

The wildlife supported by the Rock Creek area are species dependent on high quality streams (e.g. resident and anadromous fish), or upon old growth habitat or lack of human disturbance (bear, cougar, wolverine, some raptors, and "trophy" elk, among others). Rock Creek provides relatively large, contiguous areas of these habitats with minimal human intrusion.

The E. O. Waterman mining ditch is a significant feature of the Spanish Gulch Mining District. The Dayville-Beaver Creek wagon road is one of a very few remnants of pre-Forest Service development in the local area. Both of these nineteenth century cultural features have been largely obliterated by other activities where they cross private and public land outside the roadless area. Within the roadless area, fifty years of disuse has reduced the obtrusiveness of these developments, but the integrity of their original form remains largely intact for scientific and interpretive purposes.

**Wildlife**

Wildlife of particular significance in the Rock Creek area are those dependent on snags, old growth, and riparian habitats, those affected by human contacts, or activities; big game; and resident and anadromous fish. A list of old growth dependent and nonadaptive species believed to occupy the area includes: pilated woodpecker, black-backed three-toed woodpecker, northern three-toed woodpecker, flammulated owl, northern flying squirrel, mountain lion, marten, and fisher.

Forty to fifty percent of the area is considered elk winter range. The entire unroaded area is summer, or transitional, range for deer and elk. Forty-five to fifty percent of the summer range consists of good to excellent cover, well distributed over the area. Fifty to sixty percent of the winter range consists of good to excellent thermal cover. The distribution of cover in winter range is somewhat more clumped than in summer range. Because of the area's inaccessibility, it supports a higher proportion of the older age class animals attractive to trophy hunters.

Tributaries to Rock Creek and Birch Creek provide 19.4 miles of Class I and II streams in the unroaded area, with abundant spawning beds, riparian vegetation, and stream banks in excellent condition.

Dead and defective tree (snag) habitat within the unroaded area is capable of supporting greater than 80 percent of the biological potential for cavity dependent wildlife.

**Wilderness Availability**

**Recreation**

Present recreational use includes low levels of backpacking, hiking, fishing, big-game and upland bird hunting, plant and wildlife observation, photography, riding (horse and bicycle), and backcountry ski camping (sometimes in combination with summer and winter ORV use).

Demand for semiprimitive recreation in this area is projected to increase within the planning period, as pressure on other similar areas increases.

Carrying capacity for this area is estimated at 3.1 MRVD's per year for the manageable area without a developed trail system. Developing trails to major portions of the area could increase the capacity to 15.5 MRVD's. Present use levels have not been quantified.
Water
There are no existing uses of water within the unroaded area. A special use permit to divert water from Rock Creek at the northern boundary of the unroaded area, for irrigation use, caused the small area affected to be removed from the RARE II roadless area boundary. Water rights are held to tributaries of Rock Creek within the roadless area, but they have not been exercised within the past 20-30 years. The quality, timing, and amounts of water provided to the John Day River by Rock Creek and Birch Creek have been identified by the Oregon Department of Fish and Wildlife (ODFW) as important to maintaining the quality of the John Day fisheries.

Livestock
The unroaded area is part of two grazing allotments used to graze sheep and cattle on 38,761 acres, in and out of the area. The roadless area currently supports 410 AUM's of the 962 AUM total allowed by the grazing permits.

Timber
The Rock Creek unroaded area contains 6,467 acres of suitable forest land, mostly in old growth mixed conifer species. Net annual sustained yield, in existing conditions, is estimated to be .42 MMCF.

Minerals and Energy
Oil and gas leases are held on 7,800 acres of the Rock Creek area. There has been no mineral development in the area, and none is known to be planned.

Cultural Resources
Cultural resource inventories are incomplete in the Rock Creek area.

The E.O. Waterman mining ditch and the Dayville-Beaver Creek wagon road are known to be significant historic features which are minimally disturbed only where they are within the Rock Creek area.

Management Considerations

Fire
Natural fire frequencies once played a significant role in development and maintenance of vegetation within the Rock Creek area. The following range of natural fire cycles by vegetation type provides an indication of the importance of fire in preventing excessive fuel accumulations, and maintenance of seral tree and shrub species.

- Ponderosa pine: 5-25 years
- Mixed conifer: 20-70 years
- Grass, tree shrub: 5-15 years

Since the implementation of fire prevention measures at the turn of the century, fuels have been allowed to accumulate at unnatural rates, creating the potential for a major conflagration, given a certain set of environmental conditions.

Insects and Disease
Both natural and unnatural infestations by a variety of insects have occurred, are occurring, and will most likely continue to occur in the Rock Creek unroaded area. As recently as five years ago, an infestation of mountain pine beetles resulted in the mortality of lodgepole pine along Rock Creek. This was a natural event that, during historic times, was usually followed by an intense fire that served to prepare the site for stand regeneration.

The Rock Creek area, along with a large portion of central and eastern Oregon forest lands, are currently in the midst of an infestation of spruce budworm, an insect introduced to the western United States from the east coast at the turn of the century. Continuous feeding by this insect causes a reduction in vigor and can inflict death over a period of time. Evidence shows that budworm outbreaks begin and are maintained on stands where species are unadapted to site conditions. Douglas-fir and white fir are the primary target species of the budworm. These species are dominant in the roadless area due to loss of fire interactions in the environment. As long as this situation exists, there will be high potential for periodic outbreaks of spruce budworm.

Other insects that have potential for serious affects within the unroaded area are:

- Insect: Larch Casebearer
  - Target Species: Western Larch
- Insect: Western Pine Beetle
  - Target Species: Ponderosa and Lodgepole Pine
- Insect: Tussock Moth
  - Target Species: Douglas-fir and White Fir

Among the diseases occurring in the unroaded area are:

- Disease: Various root rots
  - Target Species: All
  - caused by fungus:
    - Disease: Indian Paint Fungus
      - Target Species: White Fir

Neither of these is expected to cause serious problems under the current management allocation.

Wilderness Evaluation

Public Interest
Public comments received concerning Rock Creek were usually in conjunction with the Cottonwood roadless area. Many perceive these two areas as one, sometimes referred to as the "Ochoco Canyon," even though a road divides the two. Two hundred forty-two comments were received on Rock Creek and Cottonwood Creek, and 44 addressed the 'Ochoco Canyons.' Among these was a comment by ODFW which suggested managing the entire area for semi-primitive nonmotorized recreation.

The comments favored keeping Rock and Cottonwood Creeks roadless. Wilderness designation for the area was desired by a few who wished to tie it to Black Canyon Wilderness. Adjacent roads no longer needed were recommended to be closed.

* Roadless Criteria Boundary Acres

Some recommended limited entry for logging, with roads gated or otherwise closed. Some requested the trail system be upgraded.

Reaction to timber harvest in the Rock and Cottonwood Creeks area was mixed. Some urged balloon or helicopter logging only. Others stated that the area should be logged with an emphasis on wildlife, on a 5-10 year entry. Some recommended clearcuts of under 20 acres, leaving culls standing for wildlife.

Individuals and groups provided strong support for the allocation of this area to management for wilderness, roadless, or other relatively undeveloped forms of management. This input reflected strongly held feelings about this particular area. The most common comments related to wildlife concerns were: that habitat for nonadaptive and old growth dependent wildlife should be provided in more and larger continuous areas, that on- and off-site impacts on fisheries would be too great under allocations which emphasized big game numbers or timber outputs; that old growth, nonadaptive, riparian, and stream habitat were more important than big game production in determining wildlife management objectives for the area; and that increasing numbers of elk was not the best game management goal for the area.

Environmental Consequences

The variety of acre allocations shown in Table C-12 will result in an array of different outputs and environmental consequences for the Rock Creek area. Table C-13 contains quantitative estimates of resource outputs and/or environmental consequences associated with each alternative. As an example, even though timber production per se is not an environmental consequence, the outputs shown indicate the increased productivity associated with long-term management of the timber resource in the Rock Creek area (e.g. 1.7 vs. 2.1 MMBF for B-Modified). Similarly, “Roads Built” by alternative is not an environmental consequence, but “Roads Open per square mile” indicates the emphasis of the prescription applied by alternative, which can result in an array of consequences for wildlife, water quality, and motorized recreation. Outputs shown for “Riparian” indicate the acres of riparian area that will be enhanced above minimum management requirements. Outputs shown for “Big Game” (number’s of elk) reflect the management prescriptions applied to the area by alternative and are an index of the quality of habitat produced. Outputs for “Recreation” are Recreation Opportunity Spectrum classifications and indicate the type of recreational opportunities available by alternative. For “Off-Road Vehicles,” a plus or minus indicates either an increase or a decrease in this type of opportunity. Outputs for “Snags” indicates the percentage of snag habitat available for maximum potential production of primary cavity users, by alternative. Outputs for “Old Growth,” in acres, indicates either (a) the acres allocated by management for development alternatives, or (b) existing or potential old growth based on site capability. Outputs for remaining categories are self-explanatory.

Alternatives A And NC

These alternatives would result in a big game management emphasis for the Rock Creek area. Opportunities for semiprimitive experiences would be substantially reduced. The sites and sounds of man’s intrusion would be obvious. The forces of natural succession would be substantially reduced because of vegetation manipulation for habitat. At least 50 percent of the area would be in an open (noncover) condition. Water quality would decrease as a result of road building and timber harvest, but would remain acceptable. About 382 acres of riparian habitat would be enhanced to an “exceeds acceptable” condition. Approximately 42 miles of road would be built, but only 2 miles per square mile would remain open, in order to maintain big game habitat. Elk production would increase, with the emphasis on summer range, to 96 animals. About 912 acres of old growth habitat would be maintained over time. Snag habitat would remain at relatively high levels of 80 percent of potential. Forage production would increase by about 26 AUM’s, due to increased transitory range and water developments. Motorized recreation and winter sports opportunities would increase because of access, but within limits to protect wildlife habitat. A “roaded modified” type of recreational setting would be available. Approximately 155 cords of firewood would be annually available to local citizens. Timber harvest would occur at an average rate of 1.48 MMBF per year for Alternative ‘A’. A sustained yield of 1.84 MMBF would be available once the area is in a regulated condition. Future options for wilderness consideration would be foregone.

Alternative B-Modified

This alternative would result in a timber/range management emphasis for the Rock Creek area. Opportunities for semiprimitive experiences would be eliminated. The sites and sounds of human activities would dominate the area. Old growth habitat would be reduced, from the current 3,036 acres, to minimum management levels of 358 acres. Vegetation manipulation would occur for maximum production of commodities (timber and forage). Natural succession would no longer be a dominant factor. About 42 miles of road would be built and generally kept open. Water quality would decrease as a result of road building and timber management activities, but would remain within limits established for the

1/ + or - indicates an increase or decrease in this type of opportunity

MMBF = Million board feet
MMCF = Million cubic feet
RM/RN = Roaded Modified/Roaded Natural
SPNM = Semiprimitive Nonmotorized
AUM's = Animal Unit Month
entire Ochoco National Forest. Elk populations would decrease to about 6 animals, over time. Three hundred and eight-two acres of riparian habitat would be improved to an “excellent” condition. Snag habitat would be reduced to 20 percent of potential for maximum production of primary cavity nesters, which is a minimum management level. Forage production would increase by 148 AUM’s to 558 AUM’s due to transitory range and water developments. Motorized recreation and winter sports opportunities will increase within a “roadded modified” recreational setting. About 179 cords of firewood would be annually available to local citizens. Timber harvest would occur at an average rate of about 1.7 MMBF per year. About .42 MMCF (sustained yield) would be available once the area was in a regulated condition. Options for future wilderness condition would be foregone.

**Alternative C-Modified and E-Departure**

These alternatives would result in semiprimitive management emphasis for 9,336 acres of the Rock Creek area, and a big game emphasis for the remaining 2,078 acres. No road building, or scheduled timber harvest would occur in the semiprimitive area, but about 8 miles of road would be built in the big game emphasis area. The sights and sounds of man’s activities would generally be minimal in the unroaded portion, and natural forces would continue to have a strong influence over succession. Old growth habitat would evolve naturally towards climax, with a maximum capability of about 3,036 acres, barring natural catastrophes such as fire or insect infestation in the unroaded area. Also within the unroaded area, snag habitat would be based on natural tree mortality and fluctuate around maximum levels. Options for future wilderness consideration would also remain available.

Within the developed, roadded portion, vegetation would appear manipulated in order to produce big game habitat. At least 50 percent of the area would be in an open (noncover) condition. Forage production would increase only slightly, to about 415 AUM’s due to transitory range. Snag habitat would be maintained at 80 percent of potential, a relatively high level. Opportunities of motorized and winter sports recreation would increase within a “roadded modified” recreation setting. Timber production would occur at an average rate of .3 MMBF per year with a sustained yield of .07 MMCF per year. Stream sediment would increase within constraints.

For the entire 11,414-acre combined area, elk production would increase to about 127 animals over time. About 351 acres of riparian habitat would be improved to “excellent condition.”

**Alternative I**

This alternative would emphasize semiprimitive nonmotorized management in the 6,198-acre core area, while managing the timber stands in the 4,516-acre southern plateau area and the 700-acre northern productive area. The sights and sounds of human intrusion would be obvious in the harvested portions, and might indirectly carry into the lower reaches of the unroaded portion. Old growth would be reduced from the current 3,036 acres to 2,390 acres. Natural succession would continue to dominate the timber stands within the unroaded area. Managed stands outside the core area would dominate. About 16 miles of road would be constructed and generally kept open. The potential for a minor decrease in water quality would exist as a result of timber harvest and road building. Elk numbers would decrease in time due to: 1) timber harvest, and 2) silvicultural treatments that maximize future timber volumes, and that decrease cover and security. Snag habitat would be reduced in the harvest areas, which would reduce potential for cavity nesters. Forage production would increase in the harvest areas as transition range. Motorized recreational opportunities would be increased within the harvest areas of the southern plateau, as would the potential to supply firewood. Options for future wilderness would be maintained in the roadless core area, but would be less desirable than if the whole area was managed for SPNM opportunity.
Cottonwood

Description
The Cottonwood unroaded area consists of approximately 9,777 acres in Wheeler and Grant Counties, Oregon, on the Paulina Ranger District. It is about 23 miles northwest of Paulina, 27 miles northwest of Mitchell and 8 miles southeast of Dayville. It is accessed primarily by National Forest Road 38. Private lands, and lands administered by the Bureau of Land Management, border to the north, east, and southeast. All other borders are surrounded by National Forest lands.

History
Prior to the Oregon Wilderness Act of 1984, the Cottonwood unroaded area was part of a much larger parcel referred to as the Canyons roadless area. This larger area also contained the now officially designated Black Canyon Wilderness Area. The Canyons roadless area was subdivided into Cottonwood and Black Canyon because of a major developed road that bisected it.

The Cottonwood roadless area was included in the RARE II inventory as #B6220, but was not recommended for wilderness designation and was not included in the Oregon Wilderness Act of 1984.

Under the existing Silvies Land Management Plan, Cottonwood is allocated to big game emphasis.

Geography and Topography
The Cottonwood unroaded area is comprised largely of a north-facing basin that includes the headwaters of Cottonwood Creek, Tunnel Creek, Brown Creek, Deep Creek and Battle Creek.

The most significant topographic features are the ridges and canyons which form a steep, deeply dissected landscape. The terraced cliffs of Young's Butte drop over 1700 feet toward the South Fork of the John Day River. Slopes in more than two-thirds of the area exceed forty percent. Eighty-five percent of the area is located on slopes with potentially severe erosion hazards. The soils are comprised of 50 percent moderately deep and deep fine sandy loam volcanic ash, 25 percent shallow and moderately deep loams and clays, and 25 percent very shallow loamy and clay nonforest soils.

The highest point in the Cottonwood area is the top of Battle Creek Mountain, at just over 6000 feet. Elevations of over 5000 feet, on many ridges, drop to around 3500 feet in the canyon bottoms where Cottonwood Creek and several others cross the Forest boundary.

Vegetation
Nine different plant communities exist within the Cottonwood unroaded area. Table C-14 contains a list of those plant communities with acreages according to resource inventories. They are organized by similarity in dominant plants and environment.

Stream bottoms and north-facing slopes in the Cottonwood area are covered with dense mixed conifer and ponderosa pine/Douglas-fir forest. Most south- and east-facing slopes, and ridgetops, are marked by shallow soils and mountain-mahogany/bunchgrass interspersed with open ponderosa pine/Douglas-fir forest. The terraces of Young's Butte are covered with scattered juniper, mountain mahogany, native bunchgrass, and a variety of smaller shrubs.

Current Uses
Existing management of the Cottonwood area allows for a wide range of uses, even though the magnitude of some uses is constrained by limited access.
Figure C-3
COTTONWOOD

LEGEND

RARE II BOUNDARY ≠ 86220-11051 ACRES

BOUNDARY WHICH MEETS ROADLESS CRITERIA ≠ 9,777 ACRES
Recreation
Backpacking, big game hunting, horseback riding, hiking and fishing are now the principal recreational uses. Recreational use is low and no indications have been measured, but is estimated to be considerably less than the current potential of 1.6 MRVD’s without a developed trail system. This potential increases to 15.9 MRVD’s with a developed trail system that accesses the interior of the area from various points.

The area is served by 4.8 miles of maintained trails. Approximately 95 percent of the area is capable of supporting semiprimitive, nonmotorized recreation. The remainder supports semiprimitive, motorized recreation.

Minerals and Energy
There has been no mineral development in the area. About 2,980 acres of oil and gas leases are held on the Cottonwood area.

Timber
Over most of the Cottonwood area, few timber-related activities have occurred.

Livestock Production
The Cottonwood area provides an equivalent of 252 AUM’s for four grazing allotments.

Scenic Resources
Outstanding views of Cottonwood Canyon, Black Canyon Wilderness Area, the John Day River Valley, and the canyon of the South Fork of the John Day River exist from the high points and ridges in the Cottonwood area.

Wildlife
The diverse variety of habitat types found in the Cottonwood area support a corresponding diversity of reclusive and old growth dependent wildlife species. The area is believed to support wolverine, black bear, and mountain lions. Bird species of special interest which are known to nest in the area include: pileated woodpecker, goshawk, prairie falcon, and blue and ruffed grouse. Sixty to seventy percent of the area is considered to be elk winter range. The Cottonwood area contains excellent habitat for a small population of older age class elk.

Fish
Cottonwood Creek, and its major tributaries within the area, provide 10.7 miles of excellent condition Class I and II streams to the John Day River. Stream habitat in the Cottonwood drainage supports significant trout and steelhead populations, and this drainage supplies important high quality water to John Day River fisheries.

History
Artifacts remaining from early Native American use are located at a number of sites in the Cottonwood area, along with historical features associated with early use and development on the Forest

Wilderness Capability (Potential)

Manageability and Boundaries
Three different boundaries have been defined for the Cottonwood unroaded area. They are:

- RARE II Boundary - 11,051 acres
- Roadless Criteria Boundary - 9,777 acres
- Manageable Boundary for Semiprimitive Recreation - 9,737

The Roadless Criteria boundary is the updated RARE II boundary. The acreage differences shown are due to recent on-the-ground surveys, which added some acres and deleted others because of (a) more accurate mapping and (b) re-examination of areas of past human disturbance. The boundaries of these two categories are difficult to identify on the ground, except on the north and east boundaries, because of indistinct topography and vegetation. The Manageable Boundary for Semiprimitive Recreation has been designated along more easily identifiable features, such as roads, land survey lines, ridgetops and draws.

The Cottonwood unroaded area boundary is well defined by topographic features, roads, and surveyed National Forest boundary. Topographic features serve to shield the unroaded area from intrusion of activities taking place outside the area. Most of the Cottonwood Creek watershed which is administered by the Forest Service lies within the roadless boundary.

Corridors along the high-clearance road which follows Cougar Ridge, and the high-standard road on the main ridge of Battle Creek Mountain, are substantial intrusions into the roadless areas. These roads were constructed to provide access for timber harvest. Currently, they are used for motorized access to Cottonwood Canyon by livestock permittees, recreationists, and hunters. Approximately 730 acres of timber harvest units and temporary roads are associated with the road on Battle Creek Mountain. Closure and obliteration of the road on Cougar Ridge is possible, but would cause minor inconvenience to some Forest users. The higher standard roads and the effects of logging on Battle Creek Mountain would be very difficult and expensive to restore to a natural appearance.

Natural Integrity and Appearance, Opportunities for Solitude
The most extensive effect on the natural integrity of the Cottonwood area has been made by the elimination of fire as the principal influence on vegetative change.

The overall appearance of the area is very natural, away from localized disturbances. Trails, low standard roads, and timber harvest activities are apparent, but not overwhelming, to most users. They involve less than five percent of the area. Developments outside the unroaded area are apparent from some points. Prehistoric cultural features and the effects of past activities on natural processes are apparent only to the most observant visitors at close range.
The dense vegetation and rugged topography in the area provide substantial barriers against intrusion by the sight or sounds of other Forest users. Nonmotorized users within the unroaded area will not be apparent to other users at distances greater than 200 yards, in most cases. Opportunities exist to reduce the probability of contacts by avoiding the few established trails and dispersed camps. The sounds of aircraft overflights, timber harvest activities, and motor vehicles will be heard at times from some parts of the unroaded area. Activities which occur outside the unroaded area will only be visible from a few places to observant visitors.

**Primitive Recreation Opportunities and Challenging Experiences**

Opportunities for semiprimitive nonmotorized recreation in the area include: backpacking, hiking, fishing, big game and upland bird hunting, riding (horse and bicycle), photography and observation of plants and wildlife. The estimated carrying capacity is 1.6 MRVD's without a developed trail system and is estimated at 15.9 MRVD's if a trail system was developed to access the interior from different points.

Semiprimitive motorized recreational opportunities include on- and off-trail use of two-, three-, and four-wheel off-road vehicles (ORV's). Motorized recreation may be combined with some of the described nonmotorized activities, or as recreation by itself. These activities are limited by dense vegetation and steep terrain to approximately five percent of the unroaded area.

The Cottonwood area's steep and diverse topography, limited trail system development, isolation, and low visitor density provide challenges in off-trail navigation and travel which require good judgment, self-reliance, and backcountry skills for most activities.

**Special Features**

The wildlife supported by the Cottonwood area are species dependent upon high quality streams (e.g. resident and anadromous fish), or upon old growth habitat or lack of human disturbance (wolverine, bear, mountain lion, some raptors, and "trophy" elk, among others). The Cottonwood area provides relatively large, contiguous areas of these habitats with minimal human intrusion.

**Wilderness Availability**

**Recreation**

Present recreational use includes low levels of backpacking, hiking, fishing, big-game and upland bird hunting, plant and wildlife observation, photography, and riding, sometimes in combination with ORV use.

Demand for semiprimitive recreation in this area is projected to increase within the planning period, as pressure on other similar areas increases.

Carrying capacity for this area is estimated at 15.9 MRVD's per year for the manageable area with a fully developed trail system. Present use levels have not been quantified.

**Wildlife**

Wildlife species dependent on snags, old growth, and riparian habitats; those adversely affected by human contacts, or activities; big game; and resident and anadromous fish are wildlife of particular significance in the Cottonwood area. A list of old growth dependent, and nonadaptive, species believed to occupy the area includes: pileated woodpecker, black-backed three-toed woodpecker, northern three-toed woodpecker, flammulated owl, northern flying squirrel, mountain lion, marten, and fisher. Black bear and wolverine are also believed to be in the area.

Sixty to seventy percent of the area is considered elk winter range. The entire roadless area is summer (transitional) range for deer and elk. Forty to fifty percent of the summer and winter range consists of...
good to excellent cover, well distributed over the area. Because of the area's inaccessibility, it supports a higher proportion of the older age class animals attractive to trophy hunters.

Tributaries to Cottonwood provide 10.7 miles of Class I and II streams in the roadless area, with abundant spawning beds, riparian vegetation, and stream banks in excellent condition.

Dead and defective tree (snag) habitat within the roadless area is capable of supporting greater than 80 percent of the biological potential for cavity dependent wildlife.

**Water**

There are no existing uses of water within the roadless area. The quality, timing, and amounts of water provided to the John Day River by Cottonwood have been identified by Oregon Department of Fish and Wildlife as important to maintaining the quality of the John Day fisheries.

**Livestock**

The 9777 acres in the Cottonwood area are a part of a 32,340-acre grazing allotment used for sheep and cattle. The roadless area is capable of supporting 252 AUM's of the 690 Aum total allowed by the grazing permits.

**Timber**

The Cottonwood unroaded area contains 6,640 acres of suitable forest land, mostly in old growth mixed conifer species. Net annual sustained yield is estimated to be .33 MMCF.

**Minerals and Energy**

There has been no mineral development in the area, and none is known to be planned. Some of the area has been leased for oil and gas or recommended for lease. No activity has occurred in this area.

Cultural Resources

Cultural resource inventories are incomplete for the Cottonwood area. Artifacts remaining from early Native American use are located at a number of sites in the Cottonwood area, along with historical features associated with early use and development of the Forest. Their integrity remains largely intact for scientific and interpretive purposes, but they are not known to be of major significance.

Management Considerations

Fire

Natural fire frequencies once played a significant role in development and maintenance of vegetation within the Cottonwood area. The following range of natural fire cycles by vegetation type provides an indication of the importance of fire in preventing excessive fuel accumulations and maintenance of seral tree and shrub species.

<table>
<thead>
<tr>
<th>Vegetation Type</th>
<th>Natural Fire Cycle</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ponderosa pine</td>

</tr>
<tr>
<td>Mixed conifer</td>
<td>20-70 years</td>
</tr>
<tr>
<td>Grass, tree shrub</td>
<td>5-15 years</td>
</tr>
</tbody>
</table>

Since the implementation of fire prevention measures at the turn of the century, fuels have been allowed to accumulate at unnatural rates, creating the potential for a major conflagration, given a certain set of environmental conditions.

Insects and Disease

Both natural and unnatural infestations by a variety of insects have occurred, are occurring, and will most likely continue to occur in the Cottonwood unroaded area.

The Cottonwood area, along with a large portion of central and eastern Oregon forest lands, is currently in the midst of an infestation of spruce budworm, an insect introduced to the western United States from the east coast at the turn of the century. Continuous feeding by this insect causes a reduction in vigor and can kill a tree in time.

* Roadless Criteria Boundary Acres
Other insects with potential for serious damage are:

- **Insect**
  - Larch Casebearer
  - Western Pine Beetle
  - Tussock Moth

- **Target Species**
  - Western Larch
  - Ponderosa and Lodgepole Pine
  - Douglas-fir and White Fir

Among the diseases occurring in the roadless area are:

- **Disease**
  - Various root rots caused by fungi:
    - Indian Paint Fungus
  - White Fir

Neither of these is expected to cause serious problems under the current management allocation.

### Wilderness Evaluation

#### Public Interest

Public comments received on the DEIS and Proposed Forest Plan concerning Cottonwood were usually in conjunction with the Rock Creek roadless area and are discussed there.

### Environmental Consequences

The variety of acre allocations shown in Table C-18 will result in an array of different outputs and environmental consequences for the Cottonwood area.

Table C-19 contains quantitative estimates of resource outputs and/or environmental consequences associated with each alternative. As an example, even though timber production per se is not an environmental consequence, the two different outputs shown indicate the increased productivity associated with long term management of the timber resource in the Cottonwood area (e.g., 1.47 vs. 1.67 MMBF for B-Modified). Similarly, “Roads Built” by alternative is not an environmental consequence, but “Roads Open per square mile” indicates the emphasis of the prescription applied by alternative, which can result in an array of consequences for wildlife, water quality, and motorized recreation. Outputs shown for “Riparian” indicate the acres of riparian area to be enhanced above minimum management requirements. Outputs shown for “Big Game” (number’s of elk) reflect the management prescriptions applied to the area by alternative and are an index of the quality of habitat produced. Outputs for “Recreation” are Recreation Opportunity Spectrum classifications and indicate the type of recreational experiences available by alternative. For “Off-Road Vehicles,” a plus or minus indicates either an increase or a decrease in this type of opportunity. Outputs for “Snags” indicate the percentage of snag habitat available for maximum potential production of primary cavity users, by alternative. Outputs for “Old Growth,” in acres, indicate either (a) the acres allocated by management for development alternatives, or (b) existing or potential old growth based on site capability. Outputs for remaining categories are self-explanatory.

1/ + or - Indicates an increase or decrease in this type of opportunity

MMEF - Million board feet
MMCF - Million cubic feet
RMIRN - Reduced Modified/Revised Natural
SPNM - Semiprimitive Nonmotorized
AUM - Animal Unit Months
Alternatives A and NC
This alternative would result in a big game management emphasis for the Cottonwood area. Opportunities for semiprimitive experiences would be substantially reduced. The sites and sounds of human intrusion would be obvious. Manipulation of vegetation for habitat production would substantially reduce the importance of natural succession. At least 50 percent of the area would be in an open (noncover) condition. Water quality would decrease as a result of road building and timber management, but would remain within limits. All riparian habitat would be maintained in an "acceptable" condition. Approximately 39 miles of road would be built to access the area, but only 2 miles per square mile would remain open. Elk production will increase to 137 animals. About 850 acres of old growth habitat would be maintained over time. Snag habitat would be maintained at relatively high levels - 80 percent of potential. Forage production would increase slightly, by about 16 AUM's due to increased transitory range. Motorized recreation and winter sports opportunities would increase because of access, but within limits to protect wildlife habitat. A "roaded modified" type of recreational setting would be available. Approximately 133 cords of firewood would be annually available to local citizens.

Alternative B-Modified
This alternative would result in a timber/land management emphasis for the Cottonwood area. Opportunities for semiprimitive experiences would be eliminated. The sites and sounds of human intrusion would dominate the area. Vegetation manipulation would occur for maximum production of commodities (timber and forage). Natural succession would no longer be a dominant factor. About 34 miles of road would be built and generally remain open. Water quality would decrease as a result of road building and timber management activities, but within constraints. All riparian habitat would remain in an "acceptable" condition. Elk numbers would decrease to about 5 animals over time. A minimum management level of 465 acres of old growth habitat would be maintained, and snag habitat would be reduced to 20 percent of potential, also a minimum management level. Forage production would increase by about 75 AUM's due to transitory range from timber harvest and increased investments in water developments. Motorized recreation and winter sports opportunities would increase within a "roaded modified" recreation setting. Timber harvest would occur at an average rate of 1.47 MMBF per year. Sustained yields of .33 MMCF would be produced once the area was in a fully managed condition. Options for future wilderness designation would be foregone. About 154 cords of firewood would be available annually to local citizens.

Alternatives C-Modified and E-Departure
These alternatives would maintain the Cottonwood area (9,737 acres manageable boundary) in a semiprimitive condition. The sites and sounds of human activities would be minimal. No road building or scheduled timber harvest would occur, and vegetation would continue to evolve under the forces of natural succession. Climax conditions would be reached, but fire-induced forces would eventually reduce areas to seral conditions because of natural fuel accumulations, insect and disease infestations, and predicted fire frequencies. About 3,832 acres of old growth habitat would naturally evolve, based on site capabilities. Snag habitat would be based on natural tree mortality and fluctuate around maximum levels. Elk production would increase slightly, to about 89 animals over time. Opportunities for motorized recreation would be reduced. Other winter sports opportunities would remain at about current levels. Opportunities for future wilderness designation would remain.

Alternative I
This alternative would emphasize semiprimitive nonmotorized recreation management in the 6,592-
acre core area, while managing the timber stands in the 1,365-acre southern plateau area and the 1,820-acre northern productive area. The sights and sounds of human intrusion would be obvious in the harvested portions and might indirectly carry into the lower reaches of the unroaded portion, especially during helicopter logging. Old growth would be reduced from the current 3,832 acres to 2,188 acres. Natural succession would continue to dominate the timber stands within the unroaded area. Managed stands outside this core area would dominate. About 11 miles of road would be constructed and generally remain open. The potential for a minor decrease in water quality would exist as a result of timber harvest and road building. Elk numbers would increase slightly to 99 animals. Snag habitat would be reduced in the harvest areas, which would reduce potential for cavity nesters. Forage production would increase in the harvest areas as transition range. Motorized recreational opportunities would be increased within the harvest areas of the southern plateau as would the potential to supply firewood. Options for future wilderness would be maintained in the roadless core area, but would be less desirable than if the whole area was managed for semiprimitive nonmotorized opportunity.

Silver Creek

Description

Location and Access
The Silver Creek area consists of approximately 7,459 acres in Harney County, Oregon, on the Snow Mountain Ranger District. It is about 40 air miles northwest of Burns and can be reached from National Forest Road 45, Road 4540 and Road 4150 via Howard Point. Private land and land administered by the Bureau of Land Management borders three sections to the southeast, but otherwise the entire area is surrounded by National Forest lands.

History
The Silver Creek area was included in RARE II studies and was not designated for further study. Under the existing Silvies-Malheur Land Use Plan, 2,510 acres are allocated to an unroaded management emphasis, 4,949 acres are allocated to a timber/range emphasis.

Geography and Topography
In general, the Silver Creek area contains gently sloping plateaus dissected by steep canyons, which are partially rimmed by basalt rock outcrops. It is the major confluence for Silver Creek, a Class I stream, and contains major stream lengths for Delinquent, Short, and Dodson Creeks. Elevations range from 4,400 to 5,600 feet and the major aspect is south.

Soils
Soil on the tablelands is generally shallow gravelly silt, or sandy loam. Sideslopes and draws have similar
soil characteristics but at greater depths. The side drainages and upper portions of the main tributaries contain many large boulders. Parent materials are rhyolites and/or welded tuffs.

**Vegetation**

Eleven different plant communities exist within the Silver Creek roadless area. Table C-20 contains a list of those plant communities with acreages according to resource inventories.

**Current Uses**

**Livestock**

The most pronounced use occurring in the Silver Creek area is livestock grazing. It contributes approximately 574 AUM's to five permittees within two allotments.

**Recreation**

Recreational use is low, but the potential is approximately 5,594 RVD's. The primary activities occurring are fishing, big game hunting, hiking and horseback riding. The area has no developed campsites or trail system.

**Research Natural Area**

Approximately 845 acres of the area currently provides a study area for ecosystem management.

**Minerals and Energy**

No oil and gas leases are held on the area. No mining development or exploration has occurred. Potential for mineral deposits is negligible.

**Timber**

Mature ponderosa pine with a pine understory dominates 72% of the area. Fifteen percent is open and the balance is mixed conifer stands. In the Silver Creek area, few timber related activities have occurred.

**Wildlife**

The Silver Creek area supports a year-round mule deer population. A resident elk herd and antelope

  2. Ponderosa pine / pinegrass
BOUNDARY WHICH MEETS ROADLESS CRITERIA # 7,457 ACRES
may be found adjacent to the open ridges on the south end of the area. There is a small beaver population.

Fish
A resident rainbow trout population has light fishing pressure due to limited access. It is found principally in Silver Creek, but there are limited numbers of fish in the feeder streams also.

Geology
An interesting geologic feature exists in the area in the form of Soda Spring. This spring emits water which has a high mineral content similar to soda. Algae growth in this spring is greater than in other spring locations throughout the Forest.

Cultural Resources
There are no known cultural features. It is possible, however, that the area has been frequented by Native Americans over time.

Wilderness Capability (Potential)

Manageability and Boundaries
Three different boundaries have been defined for the Silver Creek unroaded area. They are:

- RARE II Boundary - 11,670 acres
- Roadless Criteria Boundary - 7,459 acres
- Manageable Boundary for Semiprimitive Recreation - 3,226 acres

The RARE II and Roadless Criteria boundaries are, by definition, the same. The acreage differences shown are due to recent on-the-ground surveys which added some acres and deleted others because of more accurate mapping and of re-examination of areas of past human disturbance. The boundaries of these two categories are difficult to identify on the ground, except on the north boundary, because of indistinct topography and vegetation. The Manageable Boundary for Semiprimitive Recreation has been designated along more easily identifiable features such as roads, land survey lines, ridgetops and draws.

Natural Integrity and Appearance, Opportunities for Solitude
Livestock grazing and control of wildfires are the only elements affecting the natural integrity of the Silver Creek area.

The Silver Creek area has a very natural overall appearance, except where livestock grazing occurs. This activity occurs during the summer season for a period of one to two months within the roadless area. Forest management activities outside the area are usually not visible due to the terrain and timber canopy.

The activity of nonmotorized visitors will usually not be apparent due to vegetative cover and topography. The sounds of aircraft, timber harvest activity, and motor vehicles will be heard at times. The area has no trails to direct or concentrate visitors.

Primitive Recreational Opportunities and Challenging Experiences
Opportunities for semiprimitive nonmotorized recreation include camping, hiking, fishing, horseback riding and big game hunting. The estimated carrying capacity is 7.1 MRVD's.

Opportunities for semiprimitive motorized recreation are limited to off-trail use. The vegetation and steep terrain limit this use to about 5% of the roadless area. The estimated carrying capacity is 400 RVD's.

The Silver Creek area does not challenge backcountry skills. The lack of a trail system may challenge safe travel, good judgement, and physical condition.
Wilderness Availability

Recreation
Present recreational use includes low levels of backpacking, hiking, fishing, big game and upland bird hunting, plant and wildlife observation, photography, and riding, sometimes in combination with ORV use.

Demand for semiprimitive recreation in this area is projected to increase within the planning period, as pressure on other similar areas increases.

Carrying capacity for this area is estimated at 2.3 MRVD’s per year for the manageable area with a fully developed trail system. Present use levels have not been quantified.

Wildlife
Wildlife species dependent on snags, old growth, and riparian habitats; those adversely affected by human contacts or activities; big game; and resident and anadromous fish are wildlife of particular significance in the Silver Creek area. A list of old growth dependent, and nonadaptive, species believed to occupy the area includes: pileated woodpecker, black-backed three-toed woodpecker, northern three-toed woodpecker, flammulated owl, northern flying squirrel, mountain lion, marten, and fisher. Black bear and wolverine are also believed to be in the area.

Because of the area’s inaccessibility, it supports a higher proportion of the older age class animals attractive to trophy hunters.

Silver Creek provides opportunities for brook trout fishing. The potential for this fishery has not been assessed. Riparian vegetation and stream banks are in excellent condition.

Dead and defective tree (snag) habitat within the unroaded area is capable of supporting greater than 80% of the biological potential for cavity dependent wildlife.

</table>
Water
There are no existing uses of water within the unroded area.

Livestock
The Silver Creek area is capable of supporting 597 AUM's with transitory range. With water developments the capacity increases to 1,569 AUM's.

Timber
The Silver Creek area is dominated by old growth/mixed conifer forest. Net annual sustained yield is estimated to be 1.3 MMBF.

Minerals and Energy
There has been no mineral development in the area, and none is known to be planned. Oil and gas leases have been obtained on 5,450 acres of the area. The area is classified as being prospectively valuable for oil and gas.

Cultural Resources
Cultural resource inventories have not been initiated in the Silver Creek area. Minor occurrences of prehistoric artifacts probably exist.

Management Considerations
Fire
Natural fire frequencies for most of the area range from 5 to 25 years. Since the implementation of fire prevention measures at the turn of the century, fuels have been allowed to accumulate at unnatural rates, creating the potential for a major conflagration, given a certain set of environmental conditions.

Insects and Disease
Forest insects most likely to do damage in the Silver Creek area include various species of bark beetles. These can be kept to endemic levels with natural fire interaction in existing ecosystems. Elytroderma, a native needle disease agent on ponderosa pine, has had a historic, cyclical influence on the area, as has dwarf mistletoe.

Wilderness Evaluation

Public Interest
Ninety-three comments were received on the Silver Creek area. Among the respondents were the Oregon State Economist and Crook County.

Most of the comments dealt with the size of the roadless allocation in the area. Various recommendations were made ranging from dedication of 14,125 acres of Silver Creek as wilderness to opening the entire area to timber harvest.

Most of the comments, however, recommended retaining Silver Creek as roadless, and protecting the old growth and watershed values.

Those urging harvest of the old growth in the area suggested that it be spread over a two- to three-decade period to lessen impacts on riparian zones.

The Oregon State Economist agreed with semiprimitive nonmotorized recreation management and acreage allocated to that in Alternative E-Departure for Silver Creek.

Crook County desired the addition of roadless allocation acres to the Silver Creek roadless area identified in the DEIS.

* Roadless Criteria Boundary Acres

**Environmental Consequences**

The variety of acre allocations shown in Table C-24 will result in an array of different outputs and environmental consequences for the Silver Creek area. Table C-25 contains quantitative estimates of resource outputs and/or environmental consequences associated with each alternative. As an example, even though timber production per se is not an environmental consequence, the two different outputs shown indicate the increased productivity associated with long-term management of the timber resource in the Silver Creek area (e.g., 1.4 vs. 1.62 MMBF for B and B-Departure). Similarly, “Roads Built” by alternative is not an environmental consequence, but “Roads Open per square mile” indicates the emphasis of the prescription applied by alternative, which can result in an array of consequences for wildlife, water quality, and motorized recreation. Outputs shown for “Riparian” indicate the acres of riparian area that will be enhanced above minimum management requirements. Outputs shown for “Big Game” (number’s of elk) reflect the management prescriptions applied to the area by alternative and are an index of the quality of habitat produced. Outputs for “Recreation” are Recreation Opportunity Spectrum classifications and indicate the type of recreational experiences available by alternative. For “Off-Road Vehicles,” a plus

or minus indicates either an increase or a decrease in this type of opportunity. Outputs for “Snags” indicate the percentage of snag habitat available for maximum potential production of primary cavity users, by alternative. Outputs for “Old Growth” in acres, indicate either (a) the acres allocated by management for development alternatives, or (b) existing or potential old growth based on site capability. Outputs for remaining categories are self-explanatory.

Alternatives A and NC

This alternative would result in two different management emphases for the Silver Creek area. Out of the 7,459 total roadless criteria acres, 2,510 acres would be managed for semiprimitive nonmotorized recreation. The remaining 4,949 acres would be managed with a timber/range emphasis. This would foreclose on future options for wilderness consideration because of the limited size.

In the semiprimitive area, no road building or scheduled timber harvest would occur. The sites and sounds of human activities would still be somewhat noticeable because of the dimensions of the area, but would be substantially reduced below that of adjacent areas. Old growth habitat would decrease from 2,035 acres to 1,879 acres. Snag habitat would be based on natural tree mortality, and would generally be at optimum levels. Motorized recreational opportunities would decrease and winter sports opportunities would remain the same. Forage production would generally decrease as a result of tree canopy closure. Lack of fire or other disturbances would lead to species changes in tree stands from mostly ponderosa pine to a mixture of ponderosa pine, Douglas-fir, and white fir. Natural fuel buildup would result in a high fire risk condition, with an eventual fire induced return to seral conditions, depending on the degree of fire management/prevention in the area. Big game production would increase slightly due to increased cover.

In the developed area, tree stand composition would generally be based on maximum timber production. Trees would be widely spaced at regular intervals. Ponderosa pine would be the dominant species. About eight miles of road would be built and generally remain open. Forage production would increase, because of timber management activities and water developments, to 685 AUM’s. Elk numbers would decrease due to reduced cover and increased activity. Snag habitat would be managed at minimum management levels - 20 percent of potential. Motorized and winter sports opportunities would increase within a “roaded modified” recreational setting. Timber harvest would occur at an average rate of .67 MMBF per year with a sustained yield of .86 MMBF. Options for future wilderness designation would be eliminated.

Alternatives C-Modified and E-Departure

These alternatives are all similar in that the Silver Creek area is divided into three different management emphasis areas. For these alternatives, 3,226 acres would be managed for semiprimitive, nonmotorized recreation. Natural succession would remain intact, and old growth habitat will increase to about 2,035 acres under Alternative C-Modified, and to about 1879 acres under Alternative E-Departure. Human intrusions would be minimal, with no road construction or scheduled timber harvest. Motorized recreation would decrease and winter sports opportunities would remain the same.

Also, for all of these alternatives, 845 acres would be managed as a Research Natural Area. This is similar to semiprimitive in that no scheduled timber harvest or road building would occur. Natural succession would proceed, substantially unaltered, except for research purposes (such as prescribed burning)

For Alternative ‘C-Modified’, the remaining 3,388 acres would be managed for a big game emphasis. About 6 miles of road would be built for access, and timber management would proceed with an objective of habitat manipulation. Much of the area (at least 50%) would be in an open condition. Elk production would increase slightly, due to increased cover. Snag habitat would be available at relatively high levels - 80 percent of maximum. Timber harvest

C-45
would occur at an average rate of 0.41 MMBF per year with a sustained yield of 0.12 MMCF. The area would appear managed and stream sediment would increase, but would remain within constraints.

For Alternative 'E-DEPARTURE', the remaining 3,388 acres would be managed for a timber/range emphasis. Human intrusion into the area would be obvious. About six miles of road would be built for access, and timber management would proceed with an objective of maximum commodities production. Most of the area would be in an open condition, as trees would be spaced at wide, regular intervals. Snag habitat would be held at 20 percent of potential, or minimum management levels. Forage production would increase by 91 AUM’s due to transitory range and water developments. Timber harvest would occur at an average rate of 0.47 MMBF per year with a long-term sustained yield of 0.59 MMBF per year.

In total, the Silver Creek area would be subdivided by these alternatives into different management areas. The end result would be a likely foreclosure on future wilderness options because of the area’s dimensions.

Overall, the unique portion of the roadless ecosystem would be maintained for both wildlife and people searching for solitude. This small island in the midst of the intensively managed area of timber would become a refuge for both game and nongame animals, and for people. Options for wilderness designation would be moot due to the small size of the area.

Broadway

The Broadway area consists of approximately 6,461 acres in Wheeler County, Oregon, on the Paulina Ranger District. It is about 12 miles southeast of Mitchell and 23 miles north of the town of Paulina. Under the authority and direction of the current Ochoco-Crooked River Land Management Plan (February 2, 1979), specific timber sale plans have been implemented in the area, and it is therefore no longer considered a roadless area and has not been analyzed as a roadless area in the development of alternatives.

The specific timber sale implemented in the area is Fry Timber Sale, 14.1 MMBF, sold fiscal year 1985.
Figure C-5

BROADWAY

LEGEND

RARE II BOUNDARY # 06219-8680 ACRES

---

BOUNDARY WHICH MEETS ROADLESS CRITERIA # 6461 ACRES
Green Mountain

Description

Location and Access
The Green Mountain unroaded area consists of approximately 6,630 acres in Crook County, Oregon, on the Prineville Ranger District. It is about 12 air miles northwest of the city of Prineville and can be reached from National Forest Road 33 and one of its tributaries, Road 3380. Five sections of the roadless area border private land to the west, but otherwise it is surrounded by National Forest lands.

History
The Green Mountain unroaded area was included in RARE II studies and received a nonwilderness allocation. It was not included in the Oregon Wilderness Act of 1984.

Geography, Topography, and Soils
The terrain is rough and broken as a consequence of the canyons draining the area. Elevations vary from 3,500 feet in the valley bottom to 5,600 feet at the crest of Green Mountain. Three-fourths of the area is located on slopes with potentially severe erosion hazards. The soils comprise nearly 40 percent moderately deep, sandy loam, volcanic ash soils, 10 percent moderately deep loams and clays, and over 50 percent very shallow loamy and clayey nonforest soils.

Streams in the area include the main branches of McKay, Poppy, Water Trough and Lincoln Canyons.

Vegetation
Six different plant communities exist within the Green Mountain unroaded area. Below is a list of those plant communities and acreages, according to resource inventories.

Current Uses
Existing management of the Green Mountain area allows for a wide range of uses with an emphasis on big game production.

Figure C-6

GREEN MOUNTAIN

LEGEND

RARE II BOUNDARY # 06211-6630 ACRES

---

BOUNDARY WHICH MEETS ROADLESS CRITERIA # 6,630 ACRES
Recreation
Off-road vehicle use along the Green Mountain trail constitutes the majority of the recreational use. Hunting provides another significant recreational use.

Special Use Permits
A special use permit for a .09-acre water transmission line is held within the Green Mountain unroaded area.

Livestock Production
The Green Mountain area provides an equivalent of 650 AUM’s for two existing grazing allotments.

Timber Production
Intensive timber management has never occurred in the Green Mountain area because of the steep, rugged topography. As a result of previous wildfires, some areas have been planted with ponderosa pine and later thinned to recommended spacing.

Wildlife
Green Mountain, because of its unroaded character and vegetative mosaic, provides excellent habitat for deer and elk, with approximately 50 percent of the area located within a big game winter range. Additionally, the area provides habitat for numerous nongame birds and mammals, and designated old growth areas provide sufficient habitat for non-adaptive wildlife species.

Wilderness Capability
(Potential)

Manageability and Boundaries
Three different boundaries have been defined for the Green Mountain unroaded area. They are:

- RARE II Boundary - 6,630 acres
- Roadless Criteria Boundary - 6,630 acres
- Manageable Boundary for Semiprimitive Recreation - 7,000 acres

The RARE II and Roadless Criteria acres are the same. The boundary differences shown are due to recent on-the-ground surveys which added some areas and deleted others. This resulted from (a) more accurate mapping, (b) re-examination of areas of past human disturbance and (c) disassociated areas included in RARE II by error. The boundaries of these two categories are difficult to identify on the ground, except on the north and east, because of indistinct topography and vegetation. The Manageable Boundary for Semiprimitive Recreation has been designated along more easily identifiable features such as roads, land survey lines, ridgetops and draws.

Natural Integrity and Appearance, Opportunities for Solitude
The most extensive effect on the natural integrity of the Green Mountain area has been accomplished by the elimination of fire as a principal factor controlling vegetation changes.

The mixed stands of timber on the north slopes, coupled with the vegetative mosaic of the south slopes and associated draw bottoms, contribute to a high natural diversity for the area.

The opportunity for solitude is limited because of the size of the area. However, the broken terrain
provides an opportunity to travel throughout the area with minimal disruption from activities occurring adjacent to Green Mountain.

**Primitive Recreational Opportunities and Challenging Experiences**

There is very little opportunity for primitive recreation due to the small size and proximity to roads. ORV use is the main recreational use in the area, with occasional horseback riding and mountain biking. If motorized use were restricted, foot and horse travel would likely increase. Little change in hunting would result if motorized use was restricted.

The area is relatively small, and therefore is limited in offering challenging experiences. It is difficult to have a feeling of self-reliance or challenge knowing that the improved road system of Road 33 is just a short distance away.

</tbody>
</table>

**Wilderness Availability**

**Recreation**

Present recreational use is dominated by ORV use on the Green Mountain Trail. Carrying capacity for this area is estimated at 6.5 MRVD's per year for the manageable area with a fully developed trail system. Present use levels have not been quantified.

**Wildlife**

Wildlife species dependent on snags, old growth, and riparian habitats; those adversely affected by human contacts, or activities; big game; and resident and anadromous fish are wildlife of particular significance in the Silver Creek area. A list of old growth dependent, and nonadaptive, species believed to occupy the area includes: pileated woodpecker, black-backed three-toed woodpecker, northern three-toed woodpecker, flammulated owl, north-
ern flying squirrel, mountain lion, marten, and fisher. Black bear and wolverine are also believed to be in the area.

Because of the area’s inaccessibility, it supports a higher proportion of the older age class animals attractive to trophy hunters.

The fishery resource is limited.

Dead and defective tree (snag) habitat within the unroaded area is capable of supporting 80 percent of the biological potential for cavity dependent wildlife.

Management Considerations

Fire
Natural fire frequencies once played a significant role in development and maintenance of vegetation within the Green Mountain area. The following range of natural fire cycles by vegetation type provides an indication of the importance of fire in preventing excessive fuel accumulations and maintenance of seral tree and shrub species.

<table>
<thead>
<tr>
<th>Vegetation Type</th>
<th>Fire Cycle Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ponderosa pine</td>
<td>5-25 years</td>
</tr>
<tr>
<td>Mixed conifer</td>
<td>20-70 years</td>
</tr>
<tr>
<td>Grass, tree shrub</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5-15 years</td>
</tr>
</tbody>
</table>

Since the implementation of fire prevention measures at the turn of the century, fuels have been allowed to accumulate at unnatural rates, creating the potential for a major conflagration, given a certain set of environmental conditions.

Insects and Disease
Within the area, heavy infestations of root rot have been identified in localized areas. Additionally, the north slope along Poppy Creek contains varying degrees of Douglas-fir mistletoe, and spruce budworm occurs throughout the area.

Wilderness Availability

Public Interest
During the public review for the DEIS and Proposed Forest Plan, 41 letters, including one from ODFW, contained comments on Green Mountain. Most recommended semiprimitive nonmotorized recreation management, very few supported semiprimitive motorized recreation management for the area.

Some urged roaded recreation blended with timber and recreational activities be emphasized in the area. These respondents suggested a limited amount
of logging to maintain the natural appearance of the area.

Others desired protection from ORV's for Green Mountain. Those who supported motorized recreation urged further regulations to keep ORV's on established trails and out of wetland areas.

The damage to the Green Mountain trail system was noted by some. Recommendations were made to reconstruct trails or to ban motorized use in the area.

Several respondents voiced concern about protection of an old growth grove on the top of Green Mountain.

The status of the Rattle Pop timber sale was questioned and opposition was voiced to clearcutting in that area.

Environmental Consequences

The variety of acre allocations shown in Table C-30 would result in an array of different outputs and environmental consequences for the Green Mountain area.

Table C-31 contains quantitative estimates of resource outputs and/or environmental consequences associated with each alternative. As an example, even though timber production per se is not an environmental consequence, the two different outputs shown indicate the increased productivity associated with long term management of the timber resource in the Green Mountain area (e.g., .98 vs. 1.0 MMBF for B-Departure). Similarly, "Roads Built" by alternative is not an environmental consequence, but "Roads Open per square mile" indicates the emphasis of the prescription applied by alternative, which can result in an array of consequences for

* Roadless Criteria Boundary Acres
wildlife, water quality, and motorized recreation. Outputs shown for “Riparian” indicate the acres of riparian area that will be enhanced above minimum management requirements. Outputs shown for “Big Game” (number’s of elk) reflect the management prescriptions applied to the area by alternative and are an index of the quality of habitat produced. Outputs for “Recreation” are Recreation Opportunity Spectrum classifications and indicate the type of recreational experiences available by alternative. For “Off-Road Vehicles,” a plus or minus indicates either an increase or a decrease in this type of opportunity. Outputs for “Snags” indicate the percentage of snag habitat available for maximum potential production of primary cavity users, by alternative. Outputs for “Old Growth,” in acres, indicates either (a) the acres allocated by management for development alternatives, or (b) existing or potential old growth based on site capability. Outputs for remaining categories are self-explanatory.

**Alternatives A and NC**
These alternatives would result in a big game management emphasis for the Green Mountain area. Vegetation would appear manipulated in order to provide habitat conditions for big game. Natural succession would no longer proceed unhindered over most of the area, with the exception of 498 acres managed for old growth habitat. Timber harvest and road building would be evident and therefore, opportunities for semiprimitive recreation would be very limited. Options for future wilderness consideration would be foregone.

**Alternatives B-Modified and I**
These alternatives would result in a timber/range management emphasis for the Green Mountain area. Timber stands would be managed for maximum commodities production and an extensive road system would be visible and open. About 278 acres of old growth would be maintained over time.

**Alternatives C-Modified and E-Departure**
These alternatives would result in a semiprimitive motorized management emphasis for the Green Mountain area. Primitive type roads would be built and timber harvest would occur, but with an objective of maintaining a visual character consistent with a semiprimitive environment. Timber stands would have an uneven, more natural appearance, rather than an even, regulated appearance. About 844 acres of old growth habitat would be maintained over time. Options for future wilderness consideration would be foregone.

Deschutes Canyon Steelhead Falls Wilderness Study Area

Introduction

This report is an analysis of the Deschutes Canyon-Steelhead Falls Wilderness Study Area #6321. It provides the information concerning suitability, availability, need, and manageability to determine which management option to recommend from the following options:

1. Wilderness designation for the full area,
2. Wilderness designation for a modified area,
3. Special management area to maintain roadless character for semiprimitive nonmotorized recreation, or

This report is also designed to assist in developing long-term management direction for each of the alternatives considered in the Ochoco National Forest and Crooked River National Grassland's Forest Plan Final Environmental Impact Statement. The area was initially overlooked during the RARE II process due to the large percentage of the land that contained impacts of early development, homesteading, and previous overgrazing. Public support for this area influenced the decision to inventory it as area #6321 in 1978, and later designated as a "further planning area."

The Bureau of Land Management (BLM) inventoried the Steelhead Falls area (WSA OR 005-14) during its Wilderness Inventory Program in 1978. In 1982, it was agreed that the Deschutes Canyon area would be jointly studied by the Forest Service and BLM with the Forest Service being the lead agency.

While the wilderness study was underway, the Crooked River National Grassland completed its Land Management Plan EIS in 1982. The plan recommended that lands in the area under Forest Service jurisdiction should not become wilderness, but rather be used for dispersed recreation. This decision was appealed by various conservation groups on the grounds that the RARE II process had not been completed and the entire area had not been analyzed for wilderness designation. The appeal was upheld.

This report is the result of the combined efforts of both agencies, focusing on the wilderness characteristics and potentials for wilderness manageability. Total area included in this further planning area is 18,402 acres. (BLM - 3,240 acres, State of Oregon - 40 acres, Private Lands - 4,891, FS - 10,231.)

Summary

Results of this study indicate that the study area in its entirety is not very suitable or manageable for wilderness. There are many conditions, both past and current, that restrict the study area's manageability as wilderness: 1) included private land, 2) proximity to heavily developed areas like the Cove Palisades State Park, 3) the remains of early homesteading, and 4) existing improvements for current activities such as roads, powerlines, and fences. Wilderness management for the entire area would be very difficult or impossible. Management of this area as wilderness would eliminate the majority of the grazing due to the need for daily water haul by a motorized vehicle.

In order to consider a more manageable situation, the study area was further analyzed by dividing it into smaller areas called units, identified by letters A through M (see Figure C-13). Implementing a boundary change to exclude units A through K eliminates...
LEGEND

RARE II BOUNDARY # 06321-17482 ACRES

BOUNDARY WHICH MEETS ROADLESS CRITERIA # 18402 ACRES
the majority of the incompatible activities and features. Conflicts with motorized recreational uses, potential intensive range projects, and impacts on private property have also been minimized with this boundary adjustment proposal. Even with this boundary change, a good portion of the grazing would be eliminated due to the need for daily water haul. This modified area (Area II, Figure C-12) establishes a more suitable, manageable area for potential wilderness designation. A few potential wilderness manageability problems still exist in Area II.

A third area was developed and analyzed to eliminate conflicting, nonconforming features and the included private lands. This enhanced modified area (Area III, Figure C-14) is the preferred area to recommend for wilderness. This area contains approximately 5,200 acres, including 2,500 acres of land administered by the Grassland, 2,660 acres by the BLM, and 40 acres by the State of Oregon.

All other alternatives considered protecting the canyon areas either as a Scenic River Corridor with riparian enhancement in Squaw Creek, or with a semiprimitive nonmotorized recreation management emphasis. The degree of further management on the plateau area varies by alternative, from a no further development semiprimitive nonmotorized area, to a full grazing emphasis. In all cases, the canyons receive protection from development and motorized use.

Description

Location and Access
The Deschutes Canyon-Steelhead Falls Study Area (6321) is located in a triangle formed by the towns of Madras, Redmond and Sisters, in Central Oregon. The study area is roughly triangular in shape, about seven miles wide by eleven miles long. The study area boundary is a combination of property lines and roads (see Figure C-8, page C-82).

The Deschutes River and the one-half mile corridor associated with it (one-quarter mile each side of the high water line) has been designated as a National Scenic River by the Oregon Wild and Scenic Rivers Bill. This same bill federally designated the Crooked River as a Recreation River corridor.

The 18,402-acre area is composed of rocky sagebrush and juniper plateaus, and steep, rocky canyons with dramatic views. The Deschutes River and its tributary Squaw Creek meander in the canyon bottoms.

The land now receives widely varying use, including farming, grazing, hunting, hiking, and fishing. Twenty-seven percent of the study area is privately owned. The west half of the area is critical deer winter range, and the canyons are also winter habitat range for bald eagles.

The area is surrounded by the Crooked River Ranch (a private resort area) to the east, Lake Billy Chinook to the north, and by low-density rural populations to the west and south.

Some of the plateaus and valleys of the study area were once homesteaded, but many areas have returned to a more natural appearance. The rugged canyons do not contain road intrusions and remain essentially in a natural condition.

The general area of the Deschutes River Canyon Wilderness Study Area is accessible from all directions: Crooked River Ranch on the east, Road 63 through Cove Palisades State Park to the north, Road 6300 road systems on the west, and Lower Bridge Road to the south. There is no direct road access to the river on the Crooked River National Grassland. Year-round access is available to Steelhead Falls from a Crooked River Ranch road.

Although roads provide many convenient access opportunities to the plateaus, good access into the river is limited due to the steep cliffs and long rock areas. There are five routes into the canyon that are most frequently used. Users in these locations have developed path-of-least-resistance trails to the river:

1. Crooked River Ranch - BLM site at Steelhead Falls
2. Lower Bridge Road - access across private land to the west bank in the Steelhead Falls area.

3. Road 6370 - trail to Alder Springs on Squaw Creek - then down to the Deschutes River.

4. Road 6350 Geneva Overlook - trail down to river.

5. Road 6310 - trail down side canyon to the river.

Travel up and down the river is moderately difficult due to willow and alder thickets, rocky slopes, talus and cliffs. User-developed trails exist along the river in the easier areas.

History

Prehistoric Occupation
Cultural resources within the Deschutes River study area represent approximately 8,000 years of human land use and occupation. Earliest use was probably by hunter-gatherers from nearby basin-lake or river cultures.

Euro-American Occupation
Land surveyors under contract to the Federal government were the first to systematically observe, record, and report information about the soils and vegetation of central Oregon. This was in 1869, and the 1870’s, and they crisscrossed the country establishing township, section, and even quarter section corners. Soon, rumors of the lush western grasslands already spread by the U.S. Army were being confirmed by the official and specific surveyors’ notes. This was encouraging to the homesteading movement of the 1880's and soon the pioneers came. They staked out their 160 acres, cleared the bunchgrass off the land and began grain farming. Also a family found that they could not make a decent income on a 160-acre farm. The early travelers and surveyors had not recorded rainfall amounts, which as it turned out were inadequate for grain.

So the crops began to fail and homesteaders left, abandoning their farms and homes. The results were devastating and far reaching. Farmers had already removed much of the natural ground cover, including bluebunch wheatgrass. In the 50 years since then, bluebunch wheatgrass has been impossible to restore. Although Jefferson County issued a moratorium (in the 1920’s) on land takeover by tax delinquency, by 1935 about 35 percent of the 700 homesteads and ranches were taken over by Federal Land Banks and private mortgage banks in foreclosures. The balance of the land was still in private ownership.

Legislation soon began at the urging of local county officials. They had lost their tax base, the land was idle and bare. This was the time of the dustbowl and it was happening in Central Oregon, as well as in Oklahoma, Texas, Wyoming, Nebraska and the Dakotas. So the Federal government began, in 1935, to buy the land back from the homesteaders. This was done under the Resettlement Administration. On July 22, 1937, the Bankhead-Jones Farm Tenant Act was passed, authorizing and directing the Secretary of Agriculture to “develop a program of land conservation and land utilization....in order thereby to correct maladjustments in land use.” The repurchased lands were titled Land Utilization Projects, and management and restoration began under the jurisdiction of the Soil Conservation Service in 1937.

In January 1954, the jurisdiction of certain Land Utilization projects was transferred to the Forest Service.

On June 20, 1960, nineteen Land Utilization projects were officially designated as National Grasslands. Four days later the Secretary of Agriculture issued an Administrative Order that stated that all Forest Service regulations and policies apply to the Grasslands as well as issuing broad management guidelines. These guidelines provided that Soil Conservation Service concepts would be continued by directing that the Forest Service “...demonstrate sound and practical principles of land use for the areas in which the [grasslands] are located ...” and “...exert a favorable influence for securing sound land conservation practices on associated private lands...” In addition, this Administrative Order provided for multiple use management of the resources that occurred on the national grasslands. “The national grasslands shall be administered under sound and progressive principles of land conservation and
multiple use..." This additional direction had to be provided due to the fact that the Multiple Use Sustained Yield Act was passed on June 12, 1960, eight days before the grasslands became a permanent part of the Forest Service.

Geology
The geology of this area is, in general, that of younger volcanic formations superimposed on recent lake sediments and river deposits. The walls of the three canyons that converge at Cove Palisades State Park (the Deschutes, Crooked River, and Metolius River Canyons) have excellent examples of recent volcanic formations (lavas) and recent lake and river sediments. There are also examples of intricate relationships that exist between older and younger volcanic flows.

A visitor to this area can travel back through geologic time and history by descending from the top of the plateau near Culver, Oregon to the canyon bottom. Hundreds of thousands of years of geologic time and history can be seen with remarkable detail. Some of the features visible in this "geologic journey through time" include:

Faulting
Disconformities (ancient erosional surfaces)
Ancient depositional surfaces
Cross-bedding (caused by wind deposition) in ancient sand deposits.
Contract-metamorphic zones (changes in mineralization and texture of rock due to intensive heat) between volcanic flows and the sedimentary lake and river deposits over which lava flowed.
Spectacular examples of columnar jointing in lava flows (due to unusual cooling conditions).

Other geologic features that can be observed in these canyons include examples of massive and smaller landslides and mass-wasting landforms, along with spectacular discharges of many springs from the sides of these canyons into the rivers. Some of these spring discharges result in beautiful waterfalls or pools of water, enhancing the scenic quality of the geologic formations in this canyon.

Topography
The unit is characterized by plateaus eroded by the Deschutes River and Squaw Creek which is a tributary of this river. The plateaus are about 2700 to 2900 feet above sea level, and range from flat to gently rolling. The Deschutes River drops, from about 2400 feet above sea level at the southern end of the study area, to 1945 feet on Lake Billy Chinook at the northern end. Squaw Creek drops from about 2500 feet to 2100 feet in elevation where it flows into the Deschutes River. The canyons become deeper as the river and creek flow northward (see Figure C-9, page C-83). One of the highest viewpoints is called Geneva at 2785 feet. It is located along the western canyon rim and looks down 735 feet into the canyon to the river. Back from the canyon rims one can look across from plateau to plateau and barely perceive the existence of the canyon.

Soils
Soils in the upland areas are generally shallow, somewhat rocky, and of low productivity. Surface layers are composed of ash, weathered material and some aeolian (windblown) accumulation. They are well drained. Surface soils lie over a volcanic (basalt) substrate.

Soils over 50 percent of the area are arid, light brown loams less than 20 inches deep to a sandstone bedrock. These contain less than 10 percent cobbles and gravels.

About 30 percent of the area soils are brownish gray to dark brown grassland soils. These average 20 inches deep and gradually increase in gravel content to a calcium hardpan at 25-30 inches.

The remaining 20 percent of the area is rubble or scabland. These have very shallow, stony soil.
Vegetation

The vegetation varies greatly from the plateaus to the canyon bottoms. The vegetation on top consists of juniper, big sage, bitterbrush, rabbitbrush, and numerous grass species.

The canyon walls are very sparsely vegetated due to the near vertical character of the slope and the constant erosive forces and natural weathering of the basalt cliffs. There are numerous talus slopes at the base of the cliffs that are devoid of vegetation.

Riparian vegetation occurs along the streambanks. The riparian vegetation includes willow, alder, juniper, spirea sedges, wildrose, Redoiser Dogwood, and Penstemon.

There are also a few ponderosa pine and unusually large juniper along the streambank. There is one small side canyon in the southwest corner of the study area which has a small, open stand of ponderosa pine.

Grazing has eliminated the shrubby vegetation in a few places along the streambanks and has also contributed to bank erosion.

Upland and canyon sideslope plant associations are:

CJSB-11 Western juniper/big sagebrush/blue-bunch wheatgrass - Idaho fescue (mound), and Sandberg bluegrass (swale).

SD91-31 Stiff sagebrush/Sandberg bluegrass - bigseed lomatum, scabland.

CJS2-31 Western juniper/sagebrush - rock spirea/bluebunch wheatgrass - arrowleaf balsamroot, (steep s. canyon).

CJS2-32 Western juniper/big sagebrush - green rabbitbrush/Idaho fescue - arrowleaf balsamroot, (steep n. canyon).

CJS2-91 Western juniper/gray rabbitbrush - big sagebrush/crested wheatgrass. (This is the only non-native type).

Streamside riparian vegetation types occur along perennial and intermittent water in canyons and foothills and are characterized by rose, currant, willow, snowberry, alder, dogwood, Kentucky bluegrass, monkey flower, bedstraw, veronica herbaceous sage and other riparian forbs and grasses.

Seeps and springs are characterized by western juniper, big sage, willow, mockorange, baltic rush, Kentucky bluegrass, sedge and numerous other forbs and grasses.

According to the Baily-Kuchler Classification System, the Deschutes Canyon-Steelhead Falls Study Area contains 17,482 acres of the Intermountain-Sagebrush/sagebrush-steppe ecosystem. The classification of ecosystems is based upon climate, vegetation, soils, and landform.

Wild and Scenic Rivers

The one-half mile corridor along the Deschutes River was designated as a national Scenic River corridor by the Omnibus Oregon Wild and Scenic Rivers Bill of 1988.

Current Uses

The public lands within the area are currently used for grazing, hunting, fishing, hiking, sightseeing and nature studies.

Privately owned land (27 percent of the entire area) within the study area is used for dryland and irrigated farming or ranching, or is combined with Federal land into grazing allotments.

Both Forest Service and BLM public land is partially fenced into grazing allotments. There are three small BLM allotments (111 AUMs total), three Forest Service allotments (759 AUMs total), and parts of three other Forest Service allotments (526 AUMs).

Currently, recreational use of the area is low. However, the area has a high level of significance to a variety of users. The area is not well known and most users are local people, or people introduced to the area. No comprehensive Recreation Visitor Days estimates are available. However recent fish and wildlife data indicated over 4,000 RVD's from fishing occur annually within this study area.
Types of recreational use are varied. Most use is during deer hunting season due to easy access and short distance to local population centers. Limited bird hunting occurs, although there are only small populations of upland game birds. Fishing is excellent for trout and other game fish. On the opening weekend of fishing season there are fishermen at most accessible fishing locations.

The majority of campers and hikers in the area use the river canyon and stream areas. However, hiking the canyon bottoms is rough and difficult in many areas, so some hikers walk overland to their destination. Distant landmarks provide many points of reference for cross country hiking.

Bird watching for songbirds, waterfowl, and raptors encompassing over 200 different species is a popular recreational activity.

Four-wheel drive and motorcycle travel is another recreational pursuit, although the area is bisected by many small drainages. Plateaus covered with rock also limit vehicle use mainly to existing roads and established trails.

**Appearance**

**Landform**
The main canyons are very scenic with steep cliffs and talus slopes. The canyons terrace down in multiple layers in many places. Although the smaller side canyons are not as deep as the Deschutes Canyon, they often have unusual geologic formations and layering. The plateaus are rolling and bisected by side canyons. The upland plateaus also offer many spectacular views of the Cascade Mountains.

**Water**
The Deschutes River and Squaw Creek are the scenic focal points of the area. The water changes from the quiet pools to rushing whitewater rapids and falls.

**Vegetation**
The study area vegetation is composed mainly of juniper, sagebrush and grasses. The size of juniper and distribution of sagebrush and bitterbrush forms a mosaic pattern depending on historic fire frequency and extent.

The predominate colors are dusty desert greens, golds and browns. The area is also highlighted with golden yellows when bitterbrush and rabbitbrush are blooming. Tall pines in the canyon bottoms are an interesting contrast to the steep canyon walls. Green riparian canyon vegetation creates an oasis effect that forms a strong color contrast with the surrounding canyon desert vegetation.

**Surroundings**
Lands immediately surrounding the study area are generally rural. The primary industries of the local communities of Madras, Culver, Metolius, and Terrebonne are farming and ranching. Timber is another local industry that helps support the towns of Redmond, Madras, Prineville, and Sisters.

Seven miles east of the study area is Highway 97, which is a major route north to the Columbia River and south to California.

Bordering the study area to the east is the 11,000-acre Crooked River Ranch. This popular resort development area is divided into 2,600 lots. Most have been purchased. Currently there are approximately 250 year-round residences and 90 vacation homes constructed. The resort also offers a golf course, club house, and other facilities.

The land south and west of the planning area is either undeveloped Federal or private land, or is farmed in small areas by isolated land owners. Some undeveloped private and public land is fenced together into large Federal grazing allotments.

Immediately north of the study area is Cove Palisades State Park and Lake Billy Chinook which are popular developed camping and boating areas. Lake Chinook Village and Airpark is a small private resort area located just north of the study area, west of the peninsula.

Four miles north, across the Metolius River Canyon, is the southern border of the Warm Springs Indian Reservation.
Wildlife
This plateau and canyon country provides both dry-land range and complex riparian habitat types that support a large number and variety of wildlife species.
Mule deer, coyote, cottontail and jack rabbits, ground squirrels, marmot, and porcupine are commonly seen on the upland areas. In addition, beaver, river otter, badger, owls and numerous song birds frequent the river and stream edges. Eagles and hawks may be observed within the canyon, and swallows nest along the cliff edges.
The streams and rivers contain at least four species of game fish (German Brown, Rainbow, Dolly Varden, and Kokanee) as well as nongame species such as squawfish and suckers. Reptiles include garter, gopher, racer, and rattlesnakes, and several species of lizards.
The bald eagle is the only federally listed threatened or endangered fish or wildlife species known to occur in the area.

Major Streams, Lakes, and Scenic Landmarks
Two rivers and one creek are associated with this study area. The Crooked River is to the east of the study area, and its gorge rim top forms part of the eastern study area boundary along the area labeled “The Penninsula” (Figure C-7). The Deschutes River flows from the southeast corner of the study area and along the west side of “The Penninsula,” where it also empties into Lake Billy Chinook. Squaw Creek flows from the southwest part of the study area to the center of the study area, where it empties into the Deschutes River.
The Deschutes River flows through a canyon which has eroded through basalt and sandstone formations to a depth of approximately 400-1,000 feet. Side canyons enter the main river canyon and enhance the scenic quality of this canyon. The river channel occupies 85 percent to 95 percent of the canyon floor. Although the stream gradient is not steep, there are several short rapids and the river meanders.

Wilderness Capability (Potential)
Manageability and Boundaries
There are many conditions both past and current that restrict the Study Area’s manageability as wilderness. Included private land; proximity to heavily developed areas like the Cove Palisades State Park and Crooked River Ranches; the remains of early homesteading; and existing improvements for current activities, such as roads, powerlines, and fences make wilderness management for the entire Study Area very difficult or impossible.
In order to consider a more manageable area, the Study Area was further analyzed by dividing it into smaller areas called Units. These Units, identified
by letters A through M (see Figure C-14) were separately investigated for compatibility and manageability based upon the wilderness qualities such as naturalness, opportunities for solitude and primitive recreation. The following are the results of this analysis:

**Unit A** - Known as The Peninsula, this area contains a number of man-made improvements such as dirt roads, allowing vehicles access and a large woodpole utility powerline which bisects the area in an east-west direction. In addition, the area was once homesteaded, as evidenced by rock walls and cleared fields. Modern off-site human impacts include powerlines, water tanks and water ponds.

Outside sights and sounds from Lake Billy Chinook significantly depreciate the quality of solitude and primitive recreational opportunities. These include powerboats on the lake as well as traffic on local roads below The Peninsula. Unit A has limited opportunities for experiencing solitude or primitive types of recreation. The quality of naturalness in this area is also depreciated by the imprints of man

**Unit B** - Approximately nine areas labeled “B” are located above the canyon rim on the east side of the Deschutes River. This part of the study area is either heavily influenced or subject to influence by the Crooked River Ranch homes and related developments. Approximately 1500 feet of the Deschutes River runs through private, Crooked River Ranch property.

Additionally, there are several vehicle access routes bisecting these areas and conflicts would occur. For these reasons, manageability, naturalness, and the ability to experience solitude are very limited in area B.

**Unit C** - Area C is a 920-acre “arm” of public land projecting south of the study area. Its small size and shape and immediate proximity to working farms precludes the ability to experience outstanding opportunities for solitude or primitive, unconfined types of recreation. A pumping facility down by the river also significantly reduces the naturalness of this area.

**Unit D** - Most of this area is privately owned farmland. Public lands within area D are very limited, irregular in shape and easily accessed by vehicles from private and public land. Private farms can be seen and farm operations are also heard from most locations. These factors significantly affect its ability to offer naturalness, solitude, primitive types of recreation for manageability as wilderness.

**Unit E** - Area E is a high juniper covered plateau. Although tall water storage tanks are visible in the distance from various locations there are no on-site signs of human activity. However, a large percentage of the area is privately owned, which creates size and shape manageability problems.

Although the area is in a natural condition, the ability to experience solitude or primitive types of recreation are limited due to its size, topography, vegetative features, close proximity to a public access road, and private lands within the same unit. Manageability of the area as wilderness would also be limited for these reasons.

**Unit F** - This small area is physically cut off from the rest of the study area by a constructed road. It is unlikely that this road could revert back to a natural condition. For this reason, this road itself became part of the boundary of area II.

Although area F itself is essentially natural in appearance, the ability to experience solitude is severely compromised due to its limited size, and by the presence of this road and occasional traffic on it. In addition, opportunities for primitive types of recreation are also limited.

**Unit G** - The southern half of area G contains limited naturalness because it is heavily influenced by ranching and farming activities. These impacts include roads, fences, powerlines, and water ponds.

The northern half contains the old Geneva townsite. Two old homestead structures also remain. Most of the northern half of the area has primitive vehicle routes, fences, and water developments. Opportunities for solitude and primitive recreation are insufficient due to limited topographic and vegetative screening qualities.

---

1This area includes the dispersed camping sites for high clearance vehicles in the Steelhead Falls area
Much of area G also contains privately owned ranchland and farmland. This presents a manageability problem, as well as potential conflicts with motor vehicles.

Unit H - Most of this unit is privately owned and has a cabin with a dirt road to it. A natural appearance dominates most of the area, due to the rolling topography which masks the human imprint on the area. The area is just south of an interesting side canyon of the Deschutes. The area's southern border is the road to Geneva Viewpoint. Unit H would present manageability problems however, because of the 160 acres of private land and the road to Geneva Viewpoint. Opportunities for outstanding solitude or primitive types of recreation are also limited, due to the limited size and shape of public lands in this unit.

Unit I - This 160 acres is very rocky juniper-covered private property with one cabin on it. This area could provide access to nearby areas having a high degree of naturalness and solitude. Access across this private land, however, would not be encouraged without the consent of the private landowner.

Unit J - This area is heavily imprinted by an airstrip with associated structures, a borrow pit, and numerous primitive vehicle routes. It is not natural in character or appearance and does not contain opportunities for solitude or primitive, unconfined types of recreation.

Unit K - This area is the upper part of Lake Billy Chinook where Lake Billy Chinook is backed up to a gauging station along the Deschutes River. Solitude could be interrupted at any time by a powerboat, or by vehicle traffic on the bridge just north of this area. During the BLM Wilderness Intensive Inventory it was determined that 720 acres of this area is part of an active power withdrawal (project numbers 2030 and 2259). It is no longer considered under BLM jurisdiction and was excluded from the BLM Intensive Wilderness Inventory. Based on these facts and the dominant outside sights and sounds resulting from Lake Billy Chinook, it was determined that unit K contained limited opportunities for solitude and primitive, unconfined types of recreation, and was not manageable as wilderness.

Units L & M - These areas are privately owned and have been imprinted by a few roads and primitive vehicle routes. However, approximately 500 acres of these two Units have outstanding scenery with tall pines, and the meandering Deschutes River and Squaw Creek Canyons which have steep and generally vertical walls. These areas, even with their imprints, would be valuable additions, have generally retained their naturalness, and provide opportunities to experience solitude.

This analysis concludes that by implementing a boundary change to exclude Units A, B, C, D, E, F, G, H, I, J, and K; the majority of the incompatible activities can be eliminated. The remaining area (Area II, as shown in Figure C-13, page C-87) would be more capable and more manageable as wilderness. This area generally encompasses a high degree of natural appearance and integrity, few manageability problems, and has wilderness qualities. Area II is the heart of the entire Study Area.

Area II, approximately 8,513 acres in size, contains 7,933 acres of public land administered by the U.S. Forest Service and BLM, 540 acres of private land, and 40 acres of State Fish & Wildlife Department lands. Conflicts with motorized recreational uses, potential intensive range projects, and conflicts with private property owners have been minimized but not eliminated with this boundary adjustment proposal.

A few potential wilderness manageability problems still exist in Area II. These include the following:

- The wood pole utility powerline crossing Squaw Creek;
- Private land of the Crooked River Ranch along 1500 feet of the Deschutes River in NENE Sec. 17, T.13S., R.12E;
- Approximately 540 acres of private lands (Units L & M) along two portions of Squaw Creek;
- Existing road systems on the plateau area in sections 22, 23, 24, 25, T.13S., R.11E, and sections 19 and 30, T.13S., R.12E; and
Allotment boundary and pasture fences would remain in the area. Grazing would continue if the area is designated for wilderness.

Area III, approximately 5200 acres, eliminates these nonconforming features and included private lands. This area is suitable and manageable as wilderness. Opportunities for solitude away from nonwilderness features are high in this area.

Within the Deschutes River Canyon, however, are two areas with outside sights and sounds that limit naturalness, solitude, and primitive types of recreation. Both are north of Steelhead Falls. The Crooked River Ranch property crosses to the west and contains a small portion of the Deschutes River. A subdivision with houses overlooks the eastern canyon rim. The other area is also private land that extends down from the western canyon rim, to the Deschutes River. A water pump, road and powerlines dominate the landscape in this location.

Within most of this canyon and the Squaw Creek canyons, however, the topographic and vegetative screening qualities completely shield visitors from all other outside imprints. One's attention becomes focused on the canyon walls, the meandering river, riparian vegetation and the sounds of the river rapids. Although the outside sights and sounds in the Deschutes Canyon do adversely affect naturalness, solitude, and primitive uncontained types of recreation within their immediate vicinity, they do not adversely affect these qualities beyond a short distance due to the excellent topographic and vegetative screening qualities within these canyons. For these reasons wilderness qualities within both canyons was still determined to be high. There is concern that this area is too small and tied to the canyon to be managed as wilderness. The designation of wilderness in this confined small area may attract more attention than the area can support.

Natural Integrity

Natural integrity refers to long-term ecological processes and the extent that human influences have altered these processes.

The Deschutes Canyon and western plateaus remain essentially primeval in character. The area has been utilized by Euro-Americans for 130 years, resulting in impacts ranging from imperceptible to substantially noticeable. Yet, due to low rainfall, shallow soil and the barriers of the Deschutes and Squaw Creek Canyons, the area remains essentially unaffected.

In general, the natural integrity of the canyon area is still intact. This is evidenced by the type and variety of plant and animal life present. There are several naturalist groups (Oregon Native Plant Society, Portland Audubon Society) currently using the canyons, primarily in undisturbed native communities, for field study of Central Oregon plants and animals.

Natural integrity on the plateaus has been somewhat compromised. Over time, the major deviations from "natural ecological processes" are due to fire suppression and overgrazing by both livestock and wildlife. These changes in ecological condition have resulted in the proliferation of shrubs and juniper trees over native bunch grasses. This area at one time appeared more open with juniper trees confined to rocky rims and canyons. More obvious changes in natural integrity have resulted from rock piles, rock fences, range improvements, such as water developments, fences, and vehicle ways. Some crested wheat plantings were also completed in the 1940's. These are noticeable, but have largely grown over with native shrubs and junipers.

The ecological connections between canyon and plateau, have not been well documented. It is known that deer herds primarily use the plateau areas, but also utilize the canyons for up to several weeks during very severe winters. Raptors also nest in canyon areas and use the plateaus for hunting territory. The Metolius deer herd, raptor species, and other native animals use these plateaus.

In summary, natural ecological processes are somewhat intact within the canyons. The natural integrity on the plateaus has been somewhat compromised.
Natural Appearance
Although portions of this study area contain some imprints of humans, a large portion of this area still appears to be natural. Many changes to the landscape have weathered and faded to obscurity.

A field survey was made, both within and outside the WSA, to inventory imprints which affect naturalness.

Evidence of past homesteads remain in places on the plateaus, indicated by piles and walls of rock which had been cleared to prepare the land for farming. These old fields are generally natural in appearance, since time has rendered them almost indistinguishable from the native surroundings, except for the remaining rock piles and rock fences.

There are several unimproved vehicle routes on the plateaus. They could be rehabilitated through scarification and reseeding.

There are two powerlines within the WSA that significantly detract from the area’s natural appearance. These powerlines are one-and two-pole wood towers. They are difficult to distinguish from distances greater than one-quarter mile, except in places where they are skylighted on ridgelines.

Other imprints within the area include water troughs, fences, water ponds, and seeded fields.

Practically all of the canyon areas within the Deschutes and Squaw Creek Canyons have retained their natural appearance. Human imprints are limited and influence small areas due to excellent topographic and vegetative screening qualities. Some examples of these imprints include fences, an old mining building, an abandoned water pump sled, a road, and a powerline.

Natural appearance and integrity on 4,891 acres of private land (over 27 percent of this study area) is generally very limited except for private lands in the Squaw Creek and Grandview areas. Most of the remaining private lands are either dry farmed, irrigated, or managed for beef production. Most of these lands also contain homes, other ranch buildings, and roads leading to these locations. Human activity associated with these lands also depreciates both natural area solitude and primitive recreational opportunities on adjacent public lands.

It is not realistic to assume that all of these lands could be exchanged into public land ownership. Some of these private lands significantly depreciate naturalness, solitude, some types of primitive recreation, and adversely affect wilderness manageability.

Opportunities for a Wilderness Experience
Opportunities for Solitude
The Deschutes River, Squaw Creek, and their tributary side canyons, afford the best opportunity to be alone. They start out at the south end as small narrow canyons and become progressively deeper and wider downstream. It is difficult to follow the river or creek far because, in many places, the canyons get very narrow, steep, and rocky. Access into the canyons is also limited. There are three or four primary access points with unmaintained trails into established dispersed campsites. Encounters with other hikers and backpackers can be expected in the Deschutes and Squaw Creek Canyons. In order to find solitude, users have to travel into more difficult areas in the side canyons, away from trails and traditionally used camp spots. The side canyons offer the best opportunities to find a secluded spot. Some of the plateaus west of Deschutes Canyon are also good places to find secluded spots because they are outside major travel corridors and high use areas.

As soon as one travels from the high plateaus and into the inward oriented canyons, the topographic screening is dramatic. It is a completely different feeling. One's attention becomes focused on the river or stream in the bottom or focuses on the interesting canyon walls and riparian vegetation. The canyons also meander, creating more topographic screening. Topographic screening also exists on a few plateaus surrounding these canyon areas.

The juniper trees and tall sage hide many imprints once the viewer is several hundred feet away from
them. The small, unmaintained dirt road and fence near Geneva Point illustrate this point. The impact of human development such as water troughs, fences and trailers is also less intrusive and apparent, due to the sage and juniper vegetation in many areas.

Opportunities for Primitive Recreation

Opportunities for primitive and unconfined recreation are outstanding in portions of the study area. Topographic diversity is provided by the open rolling country and table top plateaus, bisected by deep canyons, ravines, and rimrock ridges. Rivers, waterfalls, springs, and streams flowing through riparian vegetation and numerous species of fish and wildlife provide outstanding opportunities for several different types of primitive recreation, such as hiking and fishing.

Within most of the Deschutes River and Squaw Creek Canyons, the topographic and vegetative screening qualities completely shield the visitors from all other outside imprints. One's attention becomes focused on the canyon walls, the meandering river, the sounds of river rapids and riparian vegetation. The outside sights and sounds in the Deschutes Canyon do not adversely affect naturalness beyond a short distance, due to the excellent topographic and vegetative screening qualities within these canyons.

Hiking and Backpack Camping

A valuable characteristic of this study area is its location and wide-open appearance. The looming snow capped peaks of the Cascades dominate the western landscape. In addition, the desert plateaus evoke a strong sense of a natural environment to the cross country hiker.

Feelings of discovery and challenge are enhanced as one hikes across the study area. From a distance the country appears relatively smooth and easily negotiable to the hiker. However, ravines, draws, streams, and precipitous cliffs, unnoticed from afar, reveal themselves as impediments to straight line travel. These features force the hiker to climb, wade, or backtrack.

Most camping occurs in the canyon bottoms where water is available. Easily accessible sites show some signs of regular camping use. However, more remote stretches are accessible only on game trails, and are seldom used. Springs and streams also provide excellent camping spots. Camping between towering walls of rock, highlighted by sounds of roaring water, provide campers with a sense of remoteness, despite the close proximity of population centers.

Fishing

Fishing in the study area is outstanding. There are four species of game fish. These include rainbow and German Brown trout, Dolly Varden, and Kokanee. Other species include squawfish and suckers. Numerous springs and pools, and the riparian vegetation provide excellent water quality and temperature for these species. However, some stretches of the river are rarely fished due to difficult access, rocky terrain, and rattlesnakes. For the intrepid fisherman willing to venture into these canyons, however, the chances of catching a large fish are good.

Hunting

This study area receives heavy deer hunting pressure in the fall, due to easy road access, mainly around the perimeter, and close proximity to local communities. However, most hunters do not venture far from the roads. A few parties backpack during hunting season, but hunter success ratios for deer is low because most deer are at higher elevations during hunting season.

Upland game hunting is also popular in the area although game bird populations are moderate to low.

Rock Climbing

Although the Deschutes Canyon area appears to have excellent opportunities for rock climbing with steep canyons and tall rock pinnacles, the structure of the rock does not lend itself to safe climbing. The rock, as evidenced by the talus piles beneath canyon walls, is easily separated from its parent slope. However, those hikers and climbers content to scale
less challenging escarpments than those found at nearby Smith Rock, will find many opportunities. Climbing out of box canyons and ravines and bouldering are some of the opportunities available to a person with an inkling to climb.

Bird Watching
Bird watching is outstanding. More than 200 species of birds have been identified in and around the study area. The river canyons, cliffs, plateaus, and grasslands within the study area provide habitat for a wide assortment of birds. Among these are owls, eagles, ospreys, hawks, swallows, water fowl, and numerous song birds. Bald eagles are the only known threatened and endangered species found in the area.

Sightseeing and Photography
Scenic views from the study area on a clear day are impressive. The Cascade peaks and surrounding desert country provide excellent scenery for sightseeing and photography. Opportunities for these activities are also excellent from the canyon rims. Visitors only need to walk a short distance to get a look at the dramatic views of the Deschutes River canyon.

Water Sports
Squaw Creek is too shallow and rough for rafting or kayaking. Although the Deschutes River is very rocky and rough, it is not known if kayaking or rafting is possible. In the summer, swimming in the cool clear pools is excellent and secluded in all but the most easily accessible spots.

Challenging Experiences
The study area offers some unusual opportunities for challenge. Cross-country travel can be especially challenging in this area.

The Deschutes Canyon-Steelhead Falls area is an excellent area for a hiker to travel cross-country. The open country, with numerous landmarks, allows a hiker to set out on a course of his choosing without benefit of trails and signs. The challenge of discovery, the need to conquer natural barriers by climbing down ravines and fording rivers or streams, offers exciting opportunities to experience wild country like those who first passed through it. This activity, when combined with fishing, also provides a very different kind of primitive recreational experience, and is also very challenging.

Special Features
Features which contribute to the uniqueness of this area are:

- A significant and diverse sport fishery resource;
- Numerous Native American and Historical sites;
- Metolius deer herd winter range;
- Bald eagle winter range;
- Great horned owl wildlife nesting area;
- Opportunities for botanical and geological study; and
- Desert and canyon ecosystems providing habitat for otter, raccoon, skunk, badger, bobcat, and beaver.

Wildlife species of interest are discussed in more detail in the wildlife section.

The bald eagle is the only federally listed threatened or endangered species known to occur within the study area. However, there are several unusual species located immediately upriver which have a high probability of occurring in the study area even though no comprehensive survey has been done.

Two species of rare plants, *Artemisia ludoviciana ssp estesi*—Prairie sage and *Hackelia hispida*—rough stickseed) are believed to exist within the Study Area but have not been verified.

The *Hypsiglena torquata* (desert night snake), an animal on the review list has also been reported near the Study Area.

The following educational, historical, and scientific opportunities exist for a number of disciplines:

1) Geology

The study area is in a zone where a number of geologic strata merge
2) Archaeology

Several major archaeological surveys have been conducted in the Deschutes River Canyon. These surveys documented numerous native American and historical sites. However, a survey of the Deschutes River Canyon from the south end of Lake Billy Chinook to the southern Grassland border (including this study area) has never been conducted.

3) Terrestrial and Aquatic Biology

The interface between Cascade and Desert-Canyon ecosystems provides an unusually rich array of wildlife. Many species are dependent on the availability of caves, rock shelves, or talus, such as many raptor species which inhabit the area. The fisheries resource is also outstanding due to a high availability of riparian habitat river/creek characteristics and many natural springs and seeps which supplement the Deschutes River and Squaw Creek.

4) Botany

The springs, seeps, and shelter provided by these canyons support many interesting plants. Currently the Audubon Society of Portland, the Native Plant Society, and other naturalists use this area for study of native Central Oregon vegetation in a primarily undisturbed ecosystem. Due to warmer sheltered conditions of the canyons in spring, many plants are blooming up to a month earlier than in more exposed desert ecosystem plant species.

Effect of Size and Configuration

The study area totals 18,402 acres. Although this area is quite large, it is relatively narrow in several locations. The area generally follows the Deschutes River Canyon and its tributary, Squaw Creek. There are also several interesting side canyons. The study area varies in width from less than one-half mile to more than four miles, with an average of about two miles. Its length also varies from seven to ten miles.

Human activities on lands surrounding the study area adversely affect the quality of naturalness in some portions. Outside sights are particularly significant in some places. The Cove Palisades State Park is a popular water recreation area north of this study area. Motor boats can travel up to three miles on either side of The Peninsula, into and around the northern plateau rim of the study area. Sights and sounds from this recreational activity are significant and detract from naturalness in this portion of the study area.

The Crooked River Ranch borders most of the study area to the east. This ranch is a planned community with permanent residences and summer vacation homes. Some lots overlook the Deschutes River Canyon, and a few homes are visible from the canyon bottom and western canyon rim. However, most homes in this community cannot be seen because they are away from this canyon rim and are surrounded by juniper trees.

There are two farms that visually dominate in the southern portion of this study area. Several roads, primitive vehicle routes, irrigation systems, and distant farmlands are also visible from high elevation points in this study area. There are also three water tanks located together, northeast of this study area (T.12S., R.12E., Section 3). These tanks are a silver-gray color and contrast sharply with the brown hills behind them.

Except for a few vantage points on the canyon rim, and the higher elevated plateaus, outside sights and sounds do not have a significant adverse effect on the overall naturalness of this study area. Vegetative screening from juniper trees and sagebrush helps camouflage many of these intrusive sights.

Within the Deschutes River Canyon, however, are two areas where outside sights and sounds do limit naturalness, solitude, and primitive types of recreation. Both are north of Steelhead Falls. The Crooked River Ranch property crosses to the west and contains a small portion of the Deschutes River. A subdivision with homes overlooks the eastern canyon rim. The other area is also private land that extends down from the western canyon rim, down to the Deschutes River. A water pump, road and powerlines dominate the landscape in this location. Vegetative and topographic screening limit the impacts of these intrusions.
Impacts of sounds on this study area are generally limited to the north end, where water ski boats and vehicle traffic can be seen and heard from the Cove Palisades State Park. Although these sights and sounds do not totally dominate these units, they do have an adverse effect on the quality of naturalness and solitude in these areas. Although aircraft may occasionally be heard in this study area, these sounds do not adversely affect naturalness or solitude.

Wilderness Availability

Recreation

Recreation use on the river is low, and the area does not significantly contribute to current recreational use patterns in central Oregon. However, the area has a high level of significance to users in Central Oregon. Low use could also be attributed to the area not being well known. Users tend to be local people. The area has a great potential for recreational opportunities. Total recreation visitor days information for most recreational activities in the Study Area is generally not available. However, recent Oregon Department of Fish and Wildlife data indicates that over 4,000 fishing visitor days occur annually in the Deschutes River and Squaw Creek areas.

The plateau portions of units A-O would classify as "semiprimitive motorized" characterization as delineated in the ROS Users Guide. These categories include the physical setting, evidence of humans, remoteness, capacity, size, ongoing activities, and experience potential.

Area II fits closer to the primitive end of the ROS spectrum but most of this area would classify as a semiprimitive nonmotorized area due to the proximity of the roads. Within the canyon areas, there is a high to moderate probability of experiencing isolation from the sights and sounds of humans, a closeness to nature and tranquility, and self-reliance through application of outdoor skills in an environment which offers challenge.

Wildlife

The variety of wildlife in the study area is similar to that found on the Grassland and other lands in the area. The study area, a large section of public land, affords an excellent opportunity to manage for all types of indigenous wildlife within its boundary.

Major wildlife habitat categories that occur on the study area include: Mule deer winter range (see Figure C-10, page C-84), riparian, fish, raptor, and cavity nester’s habitat. There is also upland game and nongame habitat.

The Deschutes River and its tributary Squaw Creek (lower portion) support excellent cold water fisheries. Rainbow and German brown trout, dolly varden, and kokanee can be caught along the portion of the Deschutes River from Lake Billy Chinook to Steelhead Falls. The kokanee spawn upstream from Lake Billy Chinook within this study area. From Steelhead Falls up river, the predominant trout species is the German Brown trout. Nongame fish, such as Squawfish and suckers can also be caught down river from Steelhead Falls, which precludes them from going further up river.

Some fishermen claim to have caught Chinook salmon in the study area, and claim that there are land-locked Chinook salmon spawning in the Deschutes River and Squaw Creek. The Oregon Department of Fish and Wildlife has netted Chinook salmon in Lake Billy Chinook, but has not been able to verify that they spawn in the Deschutes or Squaw Creek (based on personal conversation with Ted Fies, Oregon Department of Fish and Wildlife, Bend, Oregon).

This diverse fishery is maintained by adequate water flow levels on the Deschutes River and the excellent habitat condition, a result of the numerous springs, seeps and lush streambank riparian vegetation.

A portion of the Deschutes in the Study Area also supports an unusually large and vigorous population of fresh water mussels (Margaritifera sp.). In some places it completely covers the river bottom and sides. This freshwater mollusk has proliferated here for some time. It was well known and utilized by aboriginal peoples.
Although the Grassland, on the East Cascades Plateau, contains less than eight percent of the winter deer range for the Metolius herd, it contains 70 percent of the winter population of about 5,600 animals. The study area comprises about one-third of this winter range. However, a large portion of the most heavily used winter range next to the Grassland is private property, where the government has no game habitat control. This makes the Grassland winter range, especially the study area portion, very critical winter habitat for this deer herd.

Possible habitat improvement on public deer winter range includes the use of prescribed fire to control juniper encroachment on large areas. This is discussed in more detail under the Fire section.

Upland birds include populations of chukar, quail, Hungarian partridge and doves.

The canyons, cliffs, talus slopes, and caves provide unique habitats for raptors. These are characterized by relatively high, secluded canyon environments, and predictable airflow patterns.

Many raptors, including golden eagles and numerous species of hawks, can be observed. Bald eagles commonly spend the summer at higher elevations and concentrate on Lake Billy Chinook and Lake Simtustus (downstream from Lake Billy Chinook) during the winter months. The Study Area is within the bald eagle’s winter range. They are often observed soaring the canyons. Actual nesting populations of bald eagles within the Study Area are low, (3-4 documented sites). The bald eagle is the only federally listed threatened or endangered species known to occur on the Study Area (listed as threatened by the U.S. Fish and Wildlife Service).

Water
Two thousand two hundred acres of BLM public land are under a power site withdrawal. A power withdrawal classification on public land means that there is a potential for the canyons to be flooded through the creation of a power dam. This does not mean that the area will be inundated by a dam, only that one could be built if it becomes economically advantageous to do so. The Federal Energy Regulatory Commission could issue a Power Project Withdrawal to the utility company, giving them jurisdiction over these public lands.

On May 6, 1981, the Bureau of Land Management State Office requested that the Minerals Management Service Conservation Division, based in Portland, Oregon, consider a partial revocation of Power Site Reserves 26 and 480, and Power Site Classification 25. The Minerals Management Service denied this request July 27, 1981. The denial was due to their value for “waterpower potential.” Correspondence with a representative of this agency (Mr. Kenneth J. St. Mary, Conservation Division, Waterpower Section) on October 13, 1982, indicated that the portion of the Deschutes River within this study area could be developed for hydroelectric power by diversion-conduit methods, by a high dam with an adjacent powerhouse, or by a series of low dams and adjacent powerhouses. Mr. St. Mary further stated that Steelhead Falls and Geneva Sites have been considered for such development, and are described in a 1969 report, Review of Waterpower Classifications and Withdrawals, Deschutes River Basin, Oregon. Mr. St. Mary concluded his memorandum by stating, “...Although this reach does have significant hydroelectric power potential, we are not aware of any active plans to develop this potential.” (This letter is filed in both the USDA and BLM offices. The BLM public comment letter is OR-5-C-97.)

Dam construction would conflict with Wilderness Management designation of these areas.

United States Geologic Survey gauging station #76,500 is located in the Deschutes River near Culver and measures the combined flow of Squaw Creek and the Deschutes River before entering Lake Billy Chinook. Average discharge over 30 years is 655,700 acre ft./yr.

There is an irrigation diversion located within the Study Area at T.13S, R.12E., Sec. 20, NESE.

Spring runoff is controlled by upstream reservoirs on the Deschutes River.

Water flow in Squaw Creek and the Deschutes River greatly decreases after the spring runoff.
However, they are kept flowing by numerous springs and seeps along the banks.

Livestock
Currently the total AUMs present on both Forest Service and Bureau of Land Management allotments within the WSA total 1396 AUMs yearly. This is equivalent to 212 cows and calves for a five month grazing season.

There are a number of range improvements in these pastures and allotments. These include several wells, water pipelines, water troughs, and storage tanks, fences, and vehicle ways. Most of these developments are in fair or poor condition. Water must be trucked into most pastures on a daily basis.

Several crested wheat seedings, done in the 1940's are located within the area. These have largely been inundated by native shrub species or juniper seedlings.

There is no cattle access into the river canyon within the F.S. allotments. The Clevenger and Falls pastures in Sections 21, 28, and 33, T.13S., R.12E. extend to the canyon rim and include areas within the 1/2 mile corridor along the river. The Squaw Creek pasture also extends down to the river. However, due to topography the cattle do not travel down into the lower portion of the pasture or to the river. BLM allotments are located along the southern portions of the Deschutes River and allow cattle access to some segments of the river.

Ecological
The management strategy to maintain bald eagle winter range and nesting habitat is to continue to provide a secluded environment by restricting development near habitat areas.

Other species currently inhabiting the Study Area do so because the unique environment satisfies critical needs at one or more periods during their lifecycle. The winter range is very important for survival of the Metolius Deer herd. Restricting human harassment during winter months conserves energy for these animals.

Also range improvements, such as prescribed range burning, would provide increased deer forage in some areas. In very hard winters, deer are known to descend into Squaw Creek and the Deschutes River Canyon seeking food and shelter. Maintaining proper use by cattle in the riparian areas therefore has a direct effect on survival rates on this wintering herd.

Excellent water quality and riparian vegetation condition is necessary to maintain and support the diverse fishery resource in the Deschutes River and Squaw Creek segments of the Study Area.

Timber
There is no merchantable timber available in the Study Area. Isolated ponderosa pines grow in the Deschutes and Squaw Creek Canyons. There are 83 acres of noncommercial ponderosa pine timber land located within the Study Area near Squaw Flat.
There are juniper trees in the canyon and above the rim, but not in sufficient quantities to be utilized in the firewood program.

Minerals and Energy
No mining claims have been identified on the USFS/BLM public lands within this study area. The 1983 U.S. Geological Survey summary report (Mineral Investigation of the Deschutes Canyon RARE II Area (no. 6321) Jefferson and Deschutes Counties, Oregon on file at Supervisor’s Office USFS, Prineville) states: “There are no producing or developing mines, or active mining claims in the Deschutes Canyon RARE II Study Area. Only two prospects were found; they have no identified potential for mineral resources. Thin diatomite deposits occur in the Pliocene Madras Formation. Development of sand and gravel deposits in the area could not favorably compete with similar deposits in the surrounding area which are closer to points of use.”

The subsurface rights of all USFS/BLM public lands within this study remain with these respective public land managing agencies, according to the most current BLM Master Title Plat records reviewed on October 6, 1982.

A spot check of Leasable Mineral Plat Records (dated April 1984) indicates that oil and gas leases have either been issued or applied for on all federal lands within the area. No exploration activities have occurred in the area.

According to the most current information available, no geothermal resources are known to exist within the Study Area.

Cultural Resources
Surveys Completed
Several extensive cultural resource surveys have been conducted along the lower Deschutes drainage north of the Study Area, mostly in conjunction with development projects (Round Butte Dam and Reservoir Area). These surveys identified a large number of both Native American and Euro-American sites.

The lower Deschutes River and adjacent land in T.13S., R.12E., from Lake Billy Chinook to the southern boundary of the Crooked River National Grassland has never been systematically surveyed for cultural resources. The information described from surveys in the vicinity of Lake Billy Chinook suggests that structures, sites, and surface features relating to prehistorical and historical development of the greater central Oregon region are well represented. Parts of the Peninsula have been surveyed (Ochoco National Forest Report Cove Land Exchange). Several homestead sites were found there.

Along the river south of Lake Billy Chinook (T.13S., R.12E.) Native American sites have been recorded on land administered by the Bureau of Land Management.

Typical Site Types
The Lower Deschutes River Cultural Resource Survey (Hibbs, 1976) identifies the general categories of sites indicative of typical aboriginal occupation: house depressions, rock shelters, campsites, shell middens, quarry sites, flaking stations, talus depressions, cairns, petroglyphs and pictographs.

Euro-American sites along the river are also numerous in type deriving primarily from mining, homesteading, stock grazing, roads and trails and hunting and fishing activities.

There are fifteen known historical sites in the Study Area. These are old homesteads on the plateaus. The land was originally prairie grassland and was homesteaded around 1900. After the government began managing the lands following the Great Depression, almost all the structures were dismantled, burned or bulldozed over, with much of the debris shoved down and covering the old wells. Very little remains of these homesteads except for the piles and walls of rocks made when the land was cleared for farming.
Land Use Authorization

Much of the canyon (2,200 acres) is under power withdrawals. The canyoned area closest to Lake Billy Chinook is under an active power withdrawal encompassing 720 acres (see Map 4 and the Water Resources section).

There are two utility powerline rights-of-way within the Study Area. One is a single wood-pole utility powerline that runs in an east-west direction for two miles, and also crosses Squaw Creek Canyon. The other powerline right-of-way is in the north end of the Peninsula, Unit A. The two wood-pole powerlines branch in two directions, north-south and east-west, for a total of 2.5 miles.

Numerous access roads exist in the plateau areas, none of which are under permit. They are mainly wheel tracks.

Land Ownership

The entire Study Area contains approximately 18,402 acres. Of this total: U.S. Forest Service (USFS) manages 10,231 acres, Bureau of Land Management (BLM) manages 3,240 acres, private parties (non-Federal) own 4,891 acres, and the State of Oregon owns 40 acres. See Figure C-8 for the location of these areas.

Management Considerations

Fire

Historically, fire was a key element of Grassland ecosystems. Most of the Grassland was probably burned on a frequency of less than thirty years by lightning-caused fires. Portions of the Grassland now support mature juniper stands with little or no grass or brush understory. These stands are generally fireproof and will only carry fire under high wind conditions. Fire will generally retard ecological succession of communities that would move toward a climax of juniper. Hall (1973) and Volland (1976) cite several plant communities which may move toward juniper dominance without the disturbing influence of fire or a similar agent. In the pioneer stage, grasses and forbs generally dominate. Rabbitbrushes and horsebrush may be common, depending on their frequency before burning and availability of seed after burning.

As succession proceeds into the seral stages, sagebrush and bitterbrush may become dominant, depending on the site. Grasses generally become less prominent, and composition may change from the pioneer types, such as bottlebrush squirreltail, to the wheatgrasses and fescues. Heavy grazing may enhance movement toward shrub and juniper dominance, and also reduce the frequency and cover of wheatgrass and fescue in favor of the pioneer grasses or the exotic cheatgrass. Scattered juniper of varying sizes and ages now appears.

Historic fire management in the Grassland's ecosystems has been suppression. This has retarded ecological succession. Historically, fire has long been a key element of juniper, shrub, and grass ecosystems.

With time and the absence of fire, succession would probably proceed to a juniper dominated climax in which the shrubs and grasses are very much subdued. Under present conditions, allowing fire to again become a part of the natural succession could become damaging if not reintroduced gradually in the form of planned ignitions.

Insects and Disease

There are no known problems with insects or disease. Potential for these problems is low.

Non-Federal Lands

It is not realistic to assume that all the private lands (4,891 acres) could be exchanged into public ownership. Most of this private land is a vital part of the local ranch/farm operations. Few of these lands would meet wilderness standards.
Wilderness Evaluation

Public Input
The information regarding the Deschutes Canyon-Steelhead Falls Area was gathered from several procedures.

The Bureau of Land Management conducted public meetings and gathered public comments for wilderness studies to determine potential for wilderness. The Forest Service conducted public meetings and gathered comments for the RARE II Analysis and the Crooked River National Grassland Unit Plan which included the Deschutes Canyon Area.

During the more recent planning efforts for Forest Planning, the two areas were combined into one WSA as directed by the Oregon Wilderness Act of 1984. A Memorandum of Understanding between the Forest Service and BLM was developed, and the Forest Service, by virtue of the percentage of land involved, was identified as the lead agency.

Information obtained prior to the joint effort was considered with input gained during Forest planning and during the BLM Wilderness Study. These are on file at the Forest Service Office.

When the BLM requested public input for the Steelhead Falls Study Area in 1980, they received letters from 62 individuals. Sixty expressed support of the proposal to designate Deschutes-Steelhead Falls as a wilderness study area. Many desired the BLM canyon area to be managed as wilderness, even though it was less than 5,000 acres in size. Two comments were against the designation of WSA for the Deschutes Canyon. One expressed concern that wilderness would limit fish management activities.

The WSA was supported for wilderness designation by local chapters of several organizations, including the Oregon Environmental Council, Wilderness Society, Sierra Club, Mazamas, Audubon Society, Central Oregon Fly Fishers, and the SAGE Desert Study Group. These organizations exhibit varying degrees of involvement, from very active support specifically for the Deschutes Canyon, to general listing of support for a number of wilderness study areas, including the Deschutes Canyon/Steelhead Falls area.

The Jefferson County Comprehensive Plan recommended against any additional wilderness within the county.

During the public review period for the DEIS/Forest Plan, 135 letters were received with comments on Deschutes Canyon/Steelhead Falls WSA. Among these were letters from ODFW and the Oregon Parks and Recreation Division.

The majority favored wilderness designation for the river corridor, and many proposed enlarging the wilderness acreage to include all or part of the canyon rim and the Squaw Creek area. Most respondents felt that the proposed 5,200 acres was too small, and recommended a range of acreages up to 20,000 for the wilderness area.

Some of those responding did not favor wilderness designation, believing that semiprimitive nonmotorized recreation management was more appropriate.

Respondents generally opposed any development in the area and urged protection for the area's wildlife, scenic, and recreation values. They generally opposed livestock grazing and timber harvest in the area.

ODFW supported the 5,200 acres of wilderness classification proposed in Alternative E-Departure. This alternative proposed protection for the canyon rim.

The Oregon Parks and Recreation Division supported the Forest Service requirement to maintain wilderness values until the area was designated wilderness or released from consideration by Congress.

In summary, the Deschutes Canyon-Steelhead Falls WSA received some support for wilderness recommendation. Others felt the wilderness character had already been compromised. Most respondents did appreciate the scenic and recreational qualities of what they considered to be a rather noteworthy canyon area.
Congressional Interest
This study area has not surfaced in any new bills presented at the Congressional level. It apparently has not generated Congressional interest to date. The release language of the Oregon Wilderness Act formally designated the WSA directing decisions on it be made through the Forest Plan.

Need for Ecosystem Representation
Ecosystem/landform diversity was determined by using the Bailey-Kuchler system to classify ecosystem geography. The classification of ecosystems is based on climate, vegetation, soils, and landform.

Utilizing the Bailey-Kuchler Classification System, the Deschutes Canyon/Steelhead Falls Study Area contains 17,482 acres of Intermountain-Sagebrush/sagebrush-steppe ecosystem. According to a BLM State Officer’s Wilderness Report in August 1981, this ecosystem was not currently represented in the National Wilderness System. However, the Poker Jim Ridge managed by the U.S. Fish and Wildlife Service may be the first area with this ecosystem type that is recommended for wilderness designation. (Poker Jim Ridge is on the Hart Mountain National Wildlife Refuge in Southern Oregon, approximately sixty miles northeast of Lakeview.) This area encompasses 15,500 acres and has been endorsed by the President. It is also pending before congress, according to the same BLM State Office report. In addition, this report identified 63 other BLM study areas encompassing over 1.7 million acres, (primarily within the State of Oregon) having the same ecosystem type. (A list of these study areas is available at the BLM State Office or the Prineville District Office.) Some of these study areas may eventually be included within the National Wilderness Preservation System. In addition, U.S. Forest Service correspondence, in response to an appeal over the most current Crooked River National Grassland preferred land use alternative for this area, indicated that the Jarbidge Wilderness, on the Humboldt National Forest in Nevada, also contains landforms, ecosystem, and wildlife similar to Deschutes Canyon Study Area. The same base vegetative type, landform, waterflow, and ecosystem type can also be found in the Owyhee and Snake River Canyon areas.

Distance from Population Centers
Population centers are defined as standard metropolitan statistical areas having population areas of at least 100,000. There are six population centers within a one day drive (determined by Wilderness criteria to be five hours) to the Deschutes Canyon/Steelhead Falls Study Area These areas are: Eugene-Springfield, Portland, and Salem, Oregon; and Richland-Kennewick, Tacoma, and Yakima, Washington.

Nearby Wilderness Areas and Their Use
There are several wilderness areas managed by the Forest Service relatively close to the Deschutes Canyon/Steelhead Falls Study Area. These areas are Mt. Jefferson Wilderness 30 air miles to the northwest, Mt. Washington Wilderness approximately 30 air miles to the west, and the Three Sisters Wilderness approximately 40 air miles to the southwest along the Cascades. Black Canyon Wilderness approximately 80 air miles to the east, Mill Creek Wilderness approximately 30 air miles to the east, and Bridge Creek Wilderness approximately 50 air miles to the east are recently designated in the Ochoco National Forest. Strawberry Mountain, also on the Oregon Wilderness Bill, lies approximately 120 air miles to the east and is located on the Malheur National Forest. These areas generally do not provide year-round recreation use as they are generally not accessible during the winter months.
Environmental Consequences

Some resources are determined to be unaffected, or insignificantly affected, by the different management activities prescribed by the various alternatives. The canyon area is protected from development in all alternatives by the lack of commodity production potential, steep terrain, and potential adverse impact to soil and water resources. The plateau area is currently partially developed for livestock production, with primitive roads, water developments, and fences. Commodity oriented alternatives further develop the plateaus. All wilderness alternatives call for the removal of roads and other nonconforming features when feasible.

Wilderness designation also eliminates the opportunities to improve wildlife habitat. These wilderness alternatives would also withdraw the areas from mineral entry, and included energy leases would be terminated according to the lease stipulations.

Nonwilderness alternatives keep open the option to develop for energy production and mineral exploration, and allow opportunities to improve wildlife habitat. Since there is no commercial timber land included in any of the areas, timber is unaffected by the various alternatives. Cultural resources are protected in all alternatives and potential for impact varies only slightly in the plateau areas between alternatives. Possible ground disturbing activities on the plateaus vary from removing facilities for wilderness to a limited improved transportation system designed to accommodate grazing and protect or

1/ Based on Wilderness Capability Acres
enhance wildlife habitat. Water quality should remain relatively constant due to the limited activity proposals in all alternatives.

The key resources affected by the differences between alternatives are wilderness, recreational opportunities, land uses, livestock grazing, and the associated social and economic effects. These will be discussed in the following alternatives comparison.

Alternatives A and NC
This alternative would focus on the current management situation. The existing direction for wilderness study requires that the wilderness quality and attributes be maintained, and current resource activities would continue at current levels.

Effects on Wilderness Attributes
The current wilderness attributes of the area would be protected. Nonconforming features and uses would continue at the current levels and no new commitments would be made that would adversely affect future designation as wilderness.

Effects on Nonwilderness Resources
Recreation
Motorized vehicles would be restricted in the canyon areas which are managed for semiprimitive, nonmotorized recreational opportunities. Limited motorized use of the plateau areas would continue. Hunting in the plateaus utilizing vehicles would continue.

Livestock Grazing
Grazing would continue at the current levels. Water would be trucked into the area on a daily basis.

Land Uses
Nonconforming features and uses would continue.

Land Ownership
Existing situation of ownership would continue.

Social/Economics
The existing conditions would remain unchanged.

Alternatives B-Modified and I
These alternatives were developed in response to public input to the DEIS and Proposed Forest Plan and to management concerns. The ideas incorporated into these alternatives focused on maintaining a pristine area while enlarging the area to make it more manageable for the more primitive backcountry recreation opportunities. Enlarging the area brought in features that were not acceptable for inclusion of wilderness but did not detract from the overall backcountry opportunities. Enlarging the area also included going outside this Wilderness Study Area, crossing the main access in this part of the Grassland to include the upper reaches of Squaw Creek. This portion offers additional canyon opportunities for backcountry recreation even though it is bisected by the access road. The road will be closed seasonally during the winter period that is so critical for the Metolius deer herd. The main Deschutes River and Crooked River canyons are protected through Wild and Scenic River management.

Effects on Wilderness Attributes
The area within the wilderness study area that is included in the Squaw Creek management area and the Wild and Scenic corridors will have the included wilderness attributes protected under the backcountry recreation emphasis. The area outside of the Squaw Creek management area is not included in the Wild and Scenic River corridor will be managed for the wintering deer herds and may require vegetative manipulation that could conflict with preserving the wilderness attributes.

Effects on Nonwilderness Resources
Recreation
The Squaw Creek management area emphasizes the backcountry semiprimitive nonmotorized recreation opportunities. Trails will be developed to offer some challenge and maintain the pristine nature of the area as well as providing access to the Wild and Scenic River corridors. Current off-road motorized recreation will be eliminated.
Livestock Grazing
Grazing would continue at the current level unless conflicts with the wintering deer herds begin to occur. Trucking of water to maintain grazing will continue as needed.

Land Use
The powerlines thru the Squaw Creek area will be allowed to remain until they are no longer needed. The main access road through the Squaw Creek area will be open to use outside of the winter period which requires closure to protect the wintering deer herds.

Land Ownership
Private lands within the Squaw Creek management area should be acquired as they become available.

Social and Economic
A small increase in the local economy may occur from additional backcountry recreation opportunities as more people become aware of the Squaw Creek and the Wild and Scenic River areas.

Alternative C-Modified
This alternative emphasizes “nonmarket” resources such as water, visuals, fish, wildlife and dispersed recreation. The full area is recommended for wilderness in this alternative.

The total area will be closed to motorized vehicles and the access routes rehabilitated as necessary to prevent erosion and eliminate future motorized use. Overall, the area will appear similar to the existing condition with many of the non-conforming features and included private lands remaining. The plateaus will not offer a challenging, remote natural wilderness experience. There would be little opportunity for solitude away from the influence of the sounds and sights of human activity from the outside area.

Effects on Wilderness Attributes
There are many conditions both past and current that restrict the plateau portion of the study area’s manageability as wilderness. Included private land, developed areas like the Cove Palisades State Park and Crooked River Ranches, the remains of early homesteading, and existing improvements such as roads, power lines, and fences make wilderness management for the entire study area very difficult.

The canyon areas offer opportunity for a more primitive type of recreational experience and can be managed for wilderness. This portion of the area generally has a high degree of natural appearance and natural integrity, with limited manageability problems.

Effect on Nonwilderness Resources
Recreation
Management under the Wilderness Recreation Opportunity Spectrum (WROS) would be directed toward the semiprimitive management classification objectives. These objectives would be accomplished in the canyon areas, but not in the plateaus. Current motorized use of public lands on the plateau area would need to be eliminated and this would create a difficult law enforcement problem.

Livestock
Livestock grazing would essentially be eliminated unless use of motorized vehicles on a daily basis to haul water could be approved. Current administration of wilderness areas allows occasional use of vehicles for established grazing needs. Stock watering on the allotments within the study area requires hauling in water on a daily basis. There is a possible loss of 900 to 1000 AUM/Year.

Land Use
Nonconforming features such as roads and power lines would need to be removed and their evidence obliterated as much as feasible. Power line rerouting will be very expensive. Private lands that become public through exchanges will require extensive work and costs to remove nonconforming features. Even after rehabilitation, most of these lands would still have very limited wilderness qualities.

Land Ownership
It is not realistic to assume that all private lands could be exchanged into public ownership. Most of these lands have features that do not conform to
wilderness standards and are important to the local ranch operations.

**Social/Economic**
The impact due to the loss of grazing could put three or four ranchers out of business. Extensive tracts of private lands exchanged into public ownership would no longer be included in the county tax base. There would be a loss of revenue with the loss of 1000 AUM/year. The loss of motorized access on the plateaus will shift the demand for this recreation to other areas.

**Alternative E-Departure**
This alternative emphasizes the “nonmarket” resources and roadless area management. The enhanced modified area (Area III), approximately 5200 acres, is recommended as wilderness. Of this 5200 acres approximately 2500 acres is administered by the Grassland, 2660 acres by the BLM, and 40 acres by the State of Oregon (see Figure C-14). Management of lands outside this recommended wilderness would be managed for big game/wildlife. The plateau area will show patterns of man’s manipulation to improve wildlife habitat.

**Effects on Wilderness Attributes**
Area III is manageable area for wilderness, due to the elimination of the majority of the manageability problems. The adjusted boundary for this area eliminates the private lands and most of the nonconforming features on public administered lands. Opportunities for solitude and challenging experiences are great in this area with current use. Wilderness designation could attract too much use to maintain the wilderness standards due to the small size and the area that would concentrate use.

**Effects on Nonwilderness Resources**

**Recreation**
Management would be guided by the Wilderness Recreation Opportunity Spectrum (WROS) for the semiprimitive management classification objectives. These objectives can be met on the majority of the area. The plateau area outside wilderness will be managed for wildlife and range resources, and the transportation system would allow for the semiprimitive, motorized as well as some roaded natural recreation opportunities. Hunting opportunities will increase.

**Livestock Grazing**
Grazing would continue at the current level and would possibly be increased as range improvements in the plateau area increase capacities. The trucking of water to maintain grazing would continue as the watering tanks and access routes are outside the wilderness.

**Land Uses**
All nonconforming land uses, including access roads and power lines, are outside the wilderness.

**Social/Economic**
There will be no effect on the social/economic status by this alternative. The ranching community dependent on this area is unaffected and the people dependent on the power line will not be affected.

Purpose

This appendix contains the Forest and Grassland standards and guidelines that are used by several of the alternatives identified in Chapter 2 of the FEIS. The standards and guidelines included in this appendix are associated with Alternatives E-Departure, A, and C-Modified. The Forest and Grassland-wide standards and guidelines are applied within all of these alternatives. The management area standards and guidelines are applied according to the amount of land allocated to each management area (See Table 2-7, Acreage in Management Areas by Alternative, in Chapter 2 of this FEIS).

The standards and guidelines in this appendix apply to the draft management areas and are identified by a 'D' in front of the management area number. For example, the draft management area known as General Forest is identified as MA-D1, draft management area number 1. Here are all of the draft management areas and their identifiers.

Riparian in Acceptable Condition MA-D13
Riparian in Excellent Condition MA-D14

See Chapter 2 - Alternatives Including the Proposed Action, Comparison of Alternatives, for emphasis and desired future condition statements for each of the draft and final management areas.

Alternatives B-Modified and I use a different set of forest-wide and management area standards and guidelines. These are not included in this appendix since they are discussed in Chapter 4 of the Final Land and Resource Management Plan documents for the Forest and Grassland.

Between the Draft and Final EIS, some alternatives were dropped and others (three) were modified. Alternatives E-Departure, A, and C-Modified now include additional management areas; they are:

- Black Canyon Wilderness MA-F1
- Bridge Creek Wilderness MA-F2
- Mill Creek Wilderness MA-F3
- North Fork Crooked River Wilderness Study Area MA-F4
- Eagle Roosting Areas MA-F12
- Bandit Springs Recreation Area MA-F16
- North Fork Crooked River Recreation Corridor MA-F23
- North Fork Crooked River Scenic Corridor MA-F24
- Facilities MA-F28
- Crooked River Recreation Area MA-G6
- Deschutes River Scenic Corridor MA-G7

The standards and guidelines that apply to the above management areas are not included in this appendix, but can be found in Chapter 4 of the Final Land and Resource Management Plans for the Forest and Grassland. “F” refers to Forest, and “G” refers to Grassland.

**Organization**

Standards and guidelines state the bounds or constraints within which all practices are to be carried out. They are intended to supplement, but do not replace policy direction found in Forest Service Manuals and Handbooks, and the Regional Guide for the Pacific Northwest Region. They also must comply with applicable State and Federal laws and regulations.

Forest- and Grassland-wide, and management area standards and guidelines are grouped together by resource (or functional area), so that the user will have the total management direction available in one package, as opposed to sifting
through separate sections of the document in order to get a total understanding for a particular use. Management area standards and guidelines are more site-specific than Forest- and Grassland-wide standards and guidelines, and must be in compliance with them as well as higher order policy, regulation and law.

Some resource direction is only applicable on a Forest- and Grassland-wide basis and does not vary by management area. Hence, no management area standards and guidelines are presented for the following resources: Air Quality, Biological Diversity, Old Growth, and Social and Economic.

Air Quality

Forest-and Grassland-Wide Standards and Guidelines
Comply with regulations of the Clean Air Act, as amended, and coordinate activities with the Oregon State Department of Environmental Quality and the Oregon State Department of Forestry.

Demonstrate reasonable progress in reducing total suspended particulate (TSP) emissions from prescribed burning. Monitor particulate emissions originating from Forest and Grassland activities.

Conduct prescribed burning in accordance with State smoke management plans.

Follow Regional standards and guidelines for smoke emissions as stated in Regional Vegetation Management Final Environmental Impact Statement.

Use the best available predictive methods and Modifiers and most cost-efficient technologies to minimize the impact of prescribed burning on designated smoke sensitive areas and Class I areas. Comply with regulations of the Oregon State Implementation Plan for Protection of Visibility in Class I Areas.

Protect the Forest air resources against pollution sources outside the Forest boundaries through application of the Prevention of Significant Deterioration (PSD) regulations contained in the Clean Air Act. Take appropriate action to contact the Oregon State Department of Environmental Quality when outside air pollution sources, in particular that originating on a regular seasonal basis from the Madras basin and Willamette Valley, exceed Forest standards.
Biological Diversity

Forest and Grassland-Wide Standards and Guidelines

Protect Research Natural Areas (RNA's) from influences which detract from their purposes. Monitor vegetation to ensure that all major vegetative types and unique plant communities are preserved for future knowledge and gene pool diversity.

Manage and protect wildernesses in a manner that allows ecological processes, succession, fire, and similar influences to play a natural role, while protecting resources outside the areas from unnecessary risk of catastrophic fire.

A minimum of two percent of the Forest and Grassland, in addition to areas in wilderness and some RNA's, will be managed for old growth, representing climax or near climax forest stand conditions.

Identify and protect unique ecological situations, through the Forest and Grassland implementation and monitoring process. Examples of these include: eagle roosting, anadromous fish spawning, representative examples of old growth forest, aspen clones, river canyons, riparian areas and important connective habitat.

Disperse created openings and limit their size(s) to that described under the timber management guidelines.

Maintain soil productivity through management practices which reduce erosion, and the application of guidelines that limit use of heavy equipment and skid road densities.

Incorporate plant association information (Hall, 1973 and 1989; Hopkins, et al, 1983) and their management implications, into project design and implementation.

Protect fragile sites such as shallow soil areas (scablands) and natural meadows.

Incorporate and design habitat specific species requirements--such as those for cavity excavators--into guidelines and prescriptions for individual projects.

Monitor plant communities/associations to determine conditions and trends. Encourage recovery or prevent deterioration where activities may be leading to poor conditions, downward trends, the displacement of native plants or plant communities by undesirable weedy, annual or noxious vegetation, or where cover is unusually low for the particular plant associations (see Hall, 1973 and Hopkins et al, 1983). Manage aspen stands to produce a vigorous population, Forest-wide.

Limit the frequency of underburning of plant communities to the natural fire cycle, or less frequently, until research is completed on ecological effects of burning.
Cultural Resources

Forest-and Grassland-Wide Standards and Guidelines

Update the existing Cultural Resource Overview each decade to incorporate all known cultural resource information on each District. The Overview will provide a framework for evaluating cultural resources located through survey efforts, will assist in the development of a Forest Inventory Plan approved by the Oregon State Historic Preservation Office (SHPO), and will help to identify opportunities for site interpretation.

Conduct cultural resource surveys (inventories) in advance of all ground-disturbing actions. This will be accomplished through the implementation of the Interim Inventory Design (Dyrden 1988) or Forest Inventory Plan (when formally approved) during the earliest stages of the planning (NEPA) process for individual projects (e.g. timber sales); both project and non-project areas will be surveyed. Submit project Cultural Resource Reports for SHPO review and Section 106 (National Historic Preservation Act, as amended) compliance prior to issuance of the Decision Notice and Environmental Assessment or Environmental Impact Statement.

Evaluate cultural resource properties located during inventory to determine their eligibility to the National Register of Historic Places. This will be accomplished through the Lithic Scatter Programmatic Memorandum of Agreement (PMOA), individual site and thematic Determinations of Eligibility.

Develop contexts and themes from which to evaluate all classes of sites through thematic Determinations of Eligibility. Develop management plans, Memorandums of Agreement, and PMOA’s in cooperation with the State Historic Preservation Office, the Advisory Council on Historic Preservation, and other interested publics (Native Americans, local historical societies, groups and professional organizations) to facilitate cultural resource treatment and future management.

Document through the NEPA process the results of cultural resource surveys for all proposed ground-disturbing projects (Federal, Federally-funded or permitted) or projects determined to have an effect upon cultural resource sites or values.

Prepare a Determination of Effect for all projects and submit for Oregon SHPO review and consultation (i.e. No Effect, No Adverse Effect, or Adverse Effect).

Mitigate adverse effects to eligible and significant sites under consultation with the Oregon SHPO, Advisory Council on Historic Preservation, and interested publics. In ranked order of preference, the following treatment options will be considered:

Avoidance through project design modification or abandonment (No Effect).
Combination of project modification and scientific data recovery under an
approved data recovery plan (No Adverse Effect or Mitigation of Adverse Effect).

Data recovery and analysis such that cultural resource values are protected and preserved in forms useful to various scientific, government, ethnic and local groups (Mitigation of Adverse Effect).

Cultural resource sites, districts and thematic classes of such will be nominated to the National Register of Historic Places.

Schedule nominations incrementally until the Forest-wide inventory of cultural resources is completed.

Protect significant sites from degradation due to public use or natural deterioration.

Protection methods may include, but are not limited to, scientific study and collection, the use of fences or barriers, prudent use of signs, site stabilization, closure orders, site monitoring, area patrolling, and restriction of access to site locational information as provided for under the provisions of the Freedom of Information Act.

Interpret and enhance selected sites for the education and enjoyment of the general public. A priority will be given to sites within or adjacent to public use areas, and which are being degraded through natural or human impacts.

Produce scientifically accurate and culturally sensitive displays, brochures, posters, tours, lectures, etc.

Support the distribution of scientific reports, monographs, video tapes, and books for the benefit of interested members of the public.

Promote public-private partnerships which will benefit Forest visitors through enhancing and interpreting sites.

**Burial Sites**

Treat historic or prehistoric burial remains as follows:

Evaluate the site to determine if the skeletal material is human and to what time period or ethnic group it may be ascribed.

Contact local authorities, Native American Tribal Group(s), other ethnic groups and County Historical Societies where appropriate.

For Native American burials, reinter in-place with involvement by the appropriate representatives of a federally recognized Tribe or Native American group. Project planning for management activities in the site vicinity shall consider burial location in planning decisions and if necessary modify implementation so as to avoid direct and indirect impacts to the burial site.

Where reinterment in-place is not feasible or prudent, alternative locations for reinterment will be reviewed and selected in consultation with the appropriate Indian Tribal representatives. In situations where a direct link cannot be made
to an existing Federally recognized Tribe, this consultation shall take place with
the nearest tribe or confederation.

Religious Freedom
Meet all requirements of the American Indian Religious Freedom Act (AIRFA).
This law makes it the policy of the Federal government “to protect and preserve
for American Indians their inherent right of freedom to believe, express, and
exercise [their] traditional religions.” This protection includes, but is not limited
to, access to sites, use and possession of sacred objects, and the enactment of
ceremonies and traditional rites. Related activities include the gathering and
processing of plants for food, medicinal, or craft uses, the construction of sweat
lodges, or “vision quest” structures, and the like.

AIRFA addresses the religious freedom of all Native Americans without regard
for Federal tribal recognition, but does not convey exclusive use of areas or free
use of Forest products. In considering access to properties or sites within its
boundaries, the Forest will examine other potential or existing uses and activi-
ties. Publicly owned properties, sites, objects of antiquity, etc. remain the
property of the United States government. Activities which may effect such
properties, sites, or objects are subject to existing laws, regulations and treaties.

Treaty Rights
Honor the rights reserved by the Confederated Tribes of Warm Springs Indians
for lands ceded to the Federal Government through the Treaty of 1855.

On the ceded lands, the Tribes have the right to take fish in streams running
through and bordering the Reservation and at all other usual and accustomed
stations in common with the citizens of the United States.

The right of hunting, gathering roots and berries, and pasturing stock on
unclaimed lands in common with citizens was also secured within the ceded
lands.

Management Area Standards and Guidelines
(Forest Only)

Resource - Cultural Resources

Practice
Enhancement and Interpretation

Standard and Guideline
On-site interpretation and enhancement of cultural resources will not be done.
Off-site interpretation and enhancement is permissible.
Applicable Management Area
MA-D8 Wilderness
MA-D12 Research Natural Areas
MA-D13 Riparian in Acceptable Condition

Standard and Guideline
Enhancement and interpretation of cultural resources will not be emphasized. Significant cultural resource sites and features may be enhanced and interpreted if the action does not detract from the management area objectives.

Applicable Management Area
MA-D4 Old Growth
MA-D9 Semiprimitive Nonmotorized
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Selectively enhance and interpret cultural resources, with priority on identifying sites that will complement the management emphasis of the specific areas.

Applicable Management Area
MA-D11 Developed Recreation
MA-D10 Semiprimitive Motorized

Standard and Guideline
Enhance and interpret cultural resources while meeting Forest-wide standards and guidelines.

Applicable Management Area
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D5 Retention Foreground
MA-D6 Partial Retention -Foreground
MA-D7 Partial Retention -Middleground

Practice
Structures

Standard and Guideline
Structures, such as old fences, that do not qualify for the National Register of Historic Places, will be removed or allowed to deteriorate naturally.

Applicable Management Area
MA-D8 Wilderness
MA-D12 Research Natural Areas
Management Area Standards and Guidelines  
(Grassland Only)

Resource - Cultural Resources

**Practice**  
Enhancement and interpretation

**Standard and Guideline**  
Do not enhance or interpret cultural resources in this area.

**Applicable Management Area**  
MA-D4 Old Growth  
MA-D8 Wilderness  
MA-D13 Riparian in Acceptable Condition

**Standard and Guideline**  
Reserve cultural resources for the purposes of research. Generally, do not enhance or interpret cultural resources.

Evaluate research proposals on a case-by-case basis.

**Applicable Management Area**  
MA-D12 Research Natural Areas

Facilities

**Forest-and Grassland-Wide Standards and Guidelines**

Buildings, utility systems and related facilities should be planned, developed, maintained and operated for safe use, support of Forest and Grassland resource programs, and cost effectiveness. Historic buildings will be managed in accordance with the Programmatic Memorandum of Understanding (PMOA) for Depression-Era Administrative Buildings.

Construction of new buildings, or additions to existing buildings and utility systems, shall comply with approved site development plan.

Provide and manage administrative facilities in a manner sufficient to accomplish land and resource management and protection objectives of the Forest. Prepare administrative site development plans for all Forest administrative sites. Long-term development and maintenance costs will be a consideration in facilities planning.
Management Area Standards and Guidelines  
(Forest Only)

Resource - Facilities

Practice  
Construction, Reconstruction and Maintenance of Administrative Buildings and Structures

**Standard and Guideline**  
No administrative buildings or structures allowed.

**Applicable Management Area**  
MA-D8 Wilderness  
MA-D12 Research Natural Areas

**Standard and Guideline**  
Allow no administrative facilities within floodplains unless no feasible alternative sites exist (Executive Order 11988).

**Applicable Management Area**  
MA-D13 Riparian in Acceptable Condition  
MA-D14 Riparian in Excellent Condition

**Standard and Guideline**  
Locate and design facilities to blend into the natural terrain as much as possible; properly utilize the site; and provide for traffic control, sanitation, public safety, site protection, and use distribution. New and upgraded facilities will incorporate a barrier-free design in order to be accessible to the physically handicapped.

**Applicable Management Area**  
MA-D11 Developed Recreation

Practice  
Nonconforming Structures

**Standard and Guideline**  
Except for facilities necessary to protect fragile resources, limit to trail shelters, sanitary and safety needs. All should be of simple design, and of native, rustic-like materials. Site Modification for facilities should be very minimal to none.

**Applicable Management Area**  
MA-D9 Semiprimitive Nonmotorized
Management Area Standards and Guidelines
(Grassland Only)

Resource - Facilities

Practice
Construction, Reconstruction and Maintenance of Administrative Buildings and Structures

Standard and Guideline
Construct no buildings or other facilities.

Applicable Management Area
MA-D4 Old Growth
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D12 Research Natural Areas

Standard and Guideline
Develop no facilities.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Fire

Forest-and Grassland-Wide Standards and Guidelines

Fire Management

Planning
Use the National Fire Management Analysis System to determine the most cost-efficient fire protection organization. Reevaluate organization as conditions change and better information is developed. Due to the nature of intermixed land ownerships, including a number of wildland subdivisions, interagency cooperation must be considered in the planning process.

Prevention
Monitor current and recent fire reports to target specific risks. Coordinate
activities through the Central Oregon Fire Prevention Cooperative (or its equivalent).

Detection
Periodically review the mix of aerial and ground detection activities to maintain the most cost-effective combination.

Initial Attack
Apply aggressive suppression action to wildfires that threaten life, private property, public safety, improvements, or investments.

Where wildfires do not threaten to exceed acceptable sizes and intensities, apply the lowest cost suppression option.

If a wildfire escapes initial action and threatens to exceed established limits, prepare an escaped fire situation analysis. Weigh the cost of suppression against the resource potential losses. Suppression costs should be commensurate with the values threatened.

Secondary Attack Forces
Provide equipment and training for Forest Service employees outside of the fire management organization to assist in initial attack.

Fuel Treatments
Burn excess residues from management activities or natural events only after an interdisciplinary team evaluation of site needs and appropriate utilization efforts have been considered. As a guide, the Ochoco National Forest Residue Management Plan, 3/89, will be used for identifying site-specific treatment selections. All treatments will comply with Forest-wide Standards and Guidelines and Management Area Standards and Guidelines for Forest Residues, of this chapter.

A desired “protection” residues profile will be identified using an economic efficiency model, such as the Fuels Analysis Process recently developed by Region 6. This will be a guide for developing the appropriate share of cost in helping meet the overall desired residue profile(s) described in Forest-wide and management area standards and guidelines for “Forest Residues” (this Section)

Prescribed Fire
All planned prescribed fires will have prescriptions approved by the appropriate line officer.

Unplanned ignitions may be used as prescribed fires if: 1) a prescribed fire plan has been prepared and approved, 2) the fire is burning within prescription, and 3) there are enough personnel and equipment available to provide the staffing necessary to carry out the existing prescribed fire plan.

Conduct prescribed burns within existing Federal and State regulations affecting
the timing, duration, and dispersal of emissions. Coordination with adjacent local smoke management groups and local agency offices will be required.

Construct water diversions on firelines in hilly or steep terrain to drain water into areas with sufficient vegetation or other protection to avoid erosion.

Provide for a protective strip of undisturbed surface between the prescribed burn area and perennial water courses, considering local topographic, vegetation, and soil characteristics.

Avoid intense prescribed fires on soils that are highly erodible and/or are subject to the development of hydrophobic (nonwettable) conditions.

Fuelbreaks
Use existing transportation and topographic features as much as possible for planned fuel breaks.

Use fuelbreaks only where risk analysis indicates this to be the most economically viable alternative treatment, and where doing so meets the objectives of management area prescriptions, listed in Section 2, this chapter.

Piling and Burning
Locate piles outside of the normal high water flow area of natural and man-made drainages or water courses.

Burn slash piles located within mapped floodplains within one year after piling.

Remove slash created within the normal highwater zone of a stream, unless needed for soil protection purposes.

Slash will not be piles on scablands unless there is no other feasible location, i.e. under circumstances dictated by topography or at a skyline landing (See Soils Standards and Guidelines).

Chipping, Burning, Lopping and Scattering
Dispose of material so it will not reach stream courses.

Disperse material over a wide area when practical.

Management Area Standards and Guidelines
( Forest Only )

Resource - Fire

Practice
Fire Suppression (P04)
Standard and Guideline
Confine and contain will be the principle suppression strategies on most natural ignition (lightning) fires. The control strategy will be invoked when lightning fires threaten to escape the Wilderness Areas or pose unacceptable risks to life or wilderness values. Utilize the “light hand on the land” techniques.

Suppression activities should minimize disturbances of the land surface.

Use of chainsaws, helicopters, air tankers, or pumps must be approved by the Forest Supervisor. Allow no heli-spot construction for initial attack.

Crawler tractors will not be used without prior approval from the Regional Forester.

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
Fire encroaching on research natural areas should be contained or controlled as quickly as possible. Confine and contain will be the principle suppression strategies on most natural ignition (lightning) fires.

Ground disturbing activity to suppress fires will be avoided if possible, and only water will be used as fire retardant.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Wildfires within or threatening designated old growth areas will be suppressed with emphasis on the tactical strategy of “contain.” The objective is to minimize the acreage affected by wildfire. Minimize damage from suppression activities

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
The confine, contain and control strategies may be considered as per preattack block economic efficiency analysis. However, confine and contain will receive emphasis. Emphasize minimum physical disturbance by suppression activities.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized
MA-D10 Semiprimitive Motorized
Standard and Guideline
Suppression activities in these prescriptions should emphasize minimum physical disturbance. Confine, contain or control strategies are to be considered and utilized as directed in preattack block economic efficiency analysis.

Applicable Management Area
MA-D6 Partial Retention - Foreground

Standard and Guideline
Strategy is to control all wildfires. Suppression should emphasize minimum physical disturbance.

Applicable Management Area
MA-D11 Developed Recreation

Standard and Guideline
Suppression activities should be very limited within the riparian zone. The objective is to minimize soil and vegetation disturbance. Confine and contain are the principle strategies.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
All three suppression strategies (confine, contain, or control) will be utilized in accordance with the economic efficiency analysis for each Preattack Block.

Applicable Management Area
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D7 Partial Retention - Middleground

Standard and Guideline
Maximum acceptable individual wildfire size by Fire Intensity Level, and total area by decade can be found in Fire Management Direction Table, in Appendix A3, Forest Plan, for all management areas.

Practice
Treatment of Activity Fuels (P11)
Standard and Guideline
Fuel treatment (particularly mechanical treatments) should be very limited within riparian areas. In particular, activities which would reduce the shading potential or woody debris sources of the site should be avoided. Greater levels of wildfire risk are acceptable in these areas.

Nonmechanical treatments will receive preference. When mechanical treatments are necessary they shall be carefully managed to meet the objectives of the management area.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Projects will meet retention visual objectives and emphasis will be on non-mechanical treatments.

Applicable Management Area
MA-D5 Retention
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Use nonmechanical treatments where possible. Manage to meet visual quality objective of partial retention.

Applicable Management Area
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D10 Semiprimitive Motorized

Standard and Guideline
Fuels usable by recreationists should be stacked or piled in convenient locations. Unusable fuels should be piled and burned.

Applicable Management Area
MA-D11 Developed Recreation

Standard and Guideline
Meet Forest-wide Standards and Guidelines.

Applicable Management Area
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
**Practice**
*Treatment of Natural Fuels (P12)*

**Standard and Guideline**
With the consent of PNW Station Director, manage prescribed fire in natural fuels to perpetuate conditions that the RNA represents, but with prudent measures to avoid catastrophic fire within, and outside the RNA.

**Applicable Management Area**
MA-D12 Research Natural Areas

**Standard and Guideline**
Naturally caused ignitions may be allowed to burn if they meet conditions in an approved prescribed burn plan, if the funds are available, and the necessary staffing is available.

Planned ignitions may be utilized within wilderness areas if that is the best way of returning fire to its natural role, and thus reducing the fuels profile to one more natural and lessening the risk of damaging the wilderness resource. Planned ignitions within the Wilderness are also permitted if there is no other practical and economic way to lessen the likelihood of the escape of damaging wildfire from the Wilderness.

**Applicable Management Area**
MA-D8 Wilderness

**Standard and Guideline**
Ponderosa pine old growth may treated with prescribed fire approximately every 25 years to control the encroachment of other tree species. Downed logs will be protected to the degree possible.

**Applicable Management Area**
MA-D4 Old Growth

**Standard and Guideline**
Fuel treatment (particularly mechanical treatments) should be very limited within riparian areas. In particular, activities which would reduce the shading potential or woody debris sources of the site should be avoided. Greater levels of wildfire risk are acceptable in these areas.

**Applicable Management Area**
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition
**Standard and Guideline**
Maintain a vegetative type similar to natural conditions as identified through fire history and to meet specific visual resource management objectives on each corridor plan. Planned ignition prescribed burns will be scheduled as follows:

<table>
<thead>
<tr>
<th>Vegetation Type</th>
<th>Years</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ponderosa pine</td>
<td>20-25</td>
</tr>
<tr>
<td>Non-commercial</td>
<td>20-25</td>
</tr>
<tr>
<td>Grassland</td>
<td>20-25</td>
</tr>
<tr>
<td>Mixed Conifer</td>
<td>50-60</td>
</tr>
<tr>
<td>Tree shrub</td>
<td>Spot burning</td>
</tr>
</tbody>
</table>

**Applicable Management Area**
MA-D5 Retention  
MA-D6 Partial Retention - Foreground  
MA-D7 Partial Retention - Middleground

---

**Standard and Guideline**
Maintain a vegetation type similar to natural conditions as identified in the desired residue photos. Planned ignition prescribed burns should be scheduled as follows:

<table>
<thead>
<tr>
<th>Vegetation Type</th>
<th>Years</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ponderosa pine</td>
<td>20-25</td>
</tr>
<tr>
<td>Non-commercial</td>
<td>20-25</td>
</tr>
<tr>
<td>Grassland</td>
<td>20-25</td>
</tr>
<tr>
<td>Mixed Conifer</td>
<td>50-60</td>
</tr>
<tr>
<td>Tree shrub</td>
<td>Spot burning</td>
</tr>
</tbody>
</table>

**Applicable Management Area**
MA-D9 Semiprimitive Nonmotorized  
MA-D10 Semiprimitive Motorized

---

**Standard and Guideline**
Natural fuels on managed stands may be treated by prescribed fire where stand age is 25 years or more when necessary to maintain desired protection residue profile if this activity is consistent with other management objectives. Special emphasis is placed on consideration of cover objectives.

**Applicable Management Area**
MA-D2 Big Game Winter Range  
MA-D3 Big Game Summer Range

---

**Standard and Guideline**
Natural fuels on managed stands may be treated by prescribed fire where stand age is 25 years or more, when necessary to maintain desired protection residue...
profile if this activity is consistent with other management objectives.

**Applicable Management Area**
MA-D1 General Forest

---

**Practice**
Fuel Break Construction and Maintenance (P13,14)

**Standard and Guideline**
Limited shaded fuelbreak segments may be constructed along boundaries to take advantage of logical natural terrain features aiding in the prevention of fire spread across management area boundaries. The majority of such fuel break systems will be outside of the area.

**Applicable Management Area**
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D10 Semiprimitive Motorized
MA-D12 Research Natural Areas

---

**Standard and Guideline**
Construct and maintain no fuelbreaks.

**Applicable Management Area**
MA-D4 Old Growth
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

---

**Standard and Guideline**
Use fuel breaks only where they do not conflict with management area emphasis. Also, see Forest-wide Standards & Guidelines.

**Applicable Management Area**
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range

(Grassland Only)

Resource - Fire

Practice
Suppression

Minimize acreage affected by wildfire. Suppress fires using the tactical strategy of control. Minimize damage from suppression activities.

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
Permit no suppression of natural fires on the Island RNA. Suppress natural fires on Haystack Butte if facilities or resources outside the RNA are threatened.

Use only water as a retardant.

Applicable Management Area
MA-D12 Research Natural Areas

Practice
Prevention

Standard and Guideline
Encourage State to post appropriate fire prevention. Inform visitors about fire prevention needs and regulations.

Applicable Management Area
MA-D11 Developed Recreation

Practice
Prescribed Fire

Standard and Guideline
Normally, utilize manual and mechanical methods of fire hazard reduction. Prescribed fire may be used under limited circumstances.

Applicable Management Area
MA-D11 Developed Recreation
Standard and Guideline
Allow the use of managed or naturally occurring fire as needed to perpetuate the plant community the RNA is meant to represent.

Where prescribed fire is used to perpetuate a plant community, it should mimic a natural fire, but be managed prudently to avoid catastrophic.

Allow fuels to accumulate at natural rates unless they threaten the objectives of the RNA.

Applicable Management Area
MA-D12 Research Natural Areas

Practice
Treatment of Natural Fuels

Standard and Guideline
Emphasize protecting cover needs.

Applicable Management Area
MA-D2 Big Game Winter Range

Forage and Livestock Use

Forest-and Grassland-Wide Standards and Guidelines

Forage Utilization
Utilization tables have been developed for “Primary Range” (Except Riparian) and “Riparian” (see Tables D-1 and D-2). In addition, special seasonal restrictions have been directed for individual management areas (i.e. for fall green-up). See Management Area Standards and Guidelines, Forage for detailed information.

Administration and Grazing Systems
Identify allotments with riparian areas in less than satisfactory condition

Range allotment management plans will include a strategy for managing riparian areas to meet the emphasis and desired future condition stated in management area prescriptions (See MA-D14, Chapter 2, Alternatives Including the Proposed Alternative) The process recommended in Managing Riparian Ecosystems (Zones) for Fish and Wildlife in Eastern Oregon and Eastern Washington,

</tbody>
</table>

1/ Incorporate into annual operating plans and allotment management plans. Allotment management plans may include utilization standards that are either higher or lower when associated with intensive grazing systems and specific management objectives that meet other resource objectives.

2/ Utilization based on percent by weight of total annual forage production removed for grass, grasslike, and forbs, and percent of current years growth removed for shrubs. See example in riparian table for shrubs.

* For satisfactory and unsatisfactory condition see Glossary in FEIS
1979, was used in establishing these conditions, and management objectives in grazing allotment plans should follow these. When the current riparian condition is less than that described, allotment objectives will include a schedule for improvement. Measurable objectives will be set for key parameters, such as stream surface shaded, streambank stability, and shrub cover. Allotment plans will address the monitoring needed to determine if the desired rate of improvement is occurring, and those plans currently not consistent with this direction will be developed or revised on a priority basis under a schedule established by the Forest Supervisor.

Develop, revise, and maintain allotment management plans to incorporate other Forest Plan direction.

Administer lands available and suitable for domestic livestock grazing according to the Forest Service grazing permit system.

Utilize intensive grazing management systems where feasible.

Coordinate transitory range management with timber management.

Encourage demonstration projects when they are compatible with other standards and guidelines.

Grazing on scablands will occur through planned use of other plant communities within an allotment. As a result, scablands will contribute some forage, however, they will not be considered or mapped as primary range in an allotment. The installation of structural improvements, or various types of livestock management will not be used to specifically concentrate livestock use on scablands.

Wild Horse Management

The Big Summit Ranger District Wild Horse territory will be managed for a base herd of 60 head of horses, as is outlined in the Wild Horse Management Plan, on file in the Ochoco National Forest Administrative Record, and Appendix I of the Forest Plan.
Management Area Standards and Guidelines

MA-D7 Partial Retention - Middleground

Practice
Structural Improvement

Standard and Guideline
Construct and maintain fences needed to exclude livestock.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Maintain existing improvements where they are not in conflict with the primary objectives of the management area.
Construct additional improvements where they will aid in improved livestock management.

Guidelines for constructing or reconstructing fences:
(1) Top wire: Not more than 40 inches above the ground.
Bottom wire: Smooth wire at least 16 inches above the ground.
(2) Use white-topped fence posts.
(3) Tie white flagging to top wire to increase visibility.
(4) Install no stays between posts.
After the livestock are off the Grassland in the fall, leave gates open to facilitate antelope passage (except where needed for road management objectives).
Applicable Management Area
MA-D2 Big Game Winter Range (Antelope)

Standard and Guideline
Encourage developments to disperse livestock away from riparian areas.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Maintain existing improvements. Permit new improvements only when they are compatible with the primary objectives of the management area.

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
Maintain existing developments where they are not in conflict with the primary objectives of the management area.

Construct additional developments as needed to aid in livestock distribution and facilitate using domestic livestock as a management tool to improve the palatability and availability of winter deer forage.

Forest and Grassland Health

Forest and Grassland-Wide Standards and Guidelines
Use Integrated Pest Management (IPM) strategies to manage pests within the constraints of laws and regulations, and meet Forest management objectives. IPM strategies include manual, mechanical, cultural, biological, chemical, prescribed fire, and regulatory means. Select strategy through the environmental analysis process, and in compliance with the Regional Vegetation Management, Environmental Impact Statement, 1988.

Coordinate strategies with the Agricultural Pest Health Inspection Service (APHIS).
Pesticide application, if used, will conform with EPA regulations, label restrictions, and the Regional EIS on pesticide or herbicide applications.

Use the Integrated Pest Management strategies on forested types as shown in Table D-3. Exceptions for individual management areas are listed in management area standards and guidelines, Forest Health (Table D-4).

Noxious Weeds
Control noxious weeds and invader plants to prevent threats to adjacent agricultural lands or to prevent unacceptable loss of range productivity.

Management Area Standards and Guidelines
(Forest Only)

Maintenance of a healthy forest resource is important as it relates to the ability of the forest stands to meet the objectives of each management area. The major factor in the overall health of the forest is the vigor of the trees and other forest vegetation. If the majority of the trees in a given area have reached or exceeded their pathological age, or have densities that result in stagnated stands, then trees become vulnerable to attack by insects and disease.

The Ochoco National Forest will use a combination of silvicultural practices and the concept of Integrated Pest Management to manage the health of the Forest resource. Integrated Pest Management (IPM), is a process that incorporates all factors and strategies for evaluating and treating pest and host conditions to manage pest populations.

Stands of trees on the Ochoco Forest will be managed according to the objectives of each management area. The health of the Forest resource will be managed to meet the objectives, within the management constraints, for each management area. Some management areas will be more restrictive in treatment options, and may also accept more risk to the forest from pest damage.

Table D-4 will be used to guide forest health management practices for each management area. The table provides guidance for the identified major insects and diseases affecting the Ochoco National Forest.
### TABLE D-3
FOREST PEST MANAGEMENT STRATEGIES

<table>
<thead>
<tr>
<th>Host Type</th>
<th>Pest</th>
<th>Conditions Favoring Damage</th>
<th>Management Strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ponderosa Pine</td>
<td>Mountain Pine Beetle</td>
<td>Overstocked Stands</td>
<td>Control stocking levels by thinning, cleaning, or prescribed burning. Keep stands in vigorous condition, i.e., growth at least one inch per decade</td>
</tr>
<tr>
<td></td>
<td>Western Pine Beetle</td>
<td>Overmature, low vigor trees</td>
<td>Employ rotations of 150 years or less when possible. Where large, old trees are desired in the stand: (1) Salvage infested trees as rapidly as possible, (2) remove high risk trees that exhibit declining crown vigor preferentially during normal entries, and (3) decrease intertree competition by thinning, cleaning, or under burning</td>
</tr>
<tr>
<td></td>
<td>Western Dwarf Mistletoe</td>
<td>Multistoried host stands with already-infected overstories</td>
<td>Eliminate inoculum by regeneration harvest of infected stands. If a seed tree system is employed, remove infected seed trees before regeneration is 3 feet tall or 10 years old. Establish mistletoe-free unit boundaries</td>
</tr>
<tr>
<td>Lodgepole Pine</td>
<td>Mountain Pine Beetle</td>
<td>Stands of low vigor trees due to overstocking and old age</td>
<td>Keep lodgepole pine stands vigorous. Control stocking by thinning, cleaning, or prescribed fire to insure that crop trees are free to grow. Use rotations of 80 years or less</td>
</tr>
<tr>
<td></td>
<td>Lodgepole Dwarf Mistletoe</td>
<td>Multistoried host stands with already infected overstories</td>
<td>Eliminate inoculum by regeneration harvest of infected stands. If a seed tree system is employed, remove seed trees before regeneration is 3 feet tall or 10 years old. Establish mistletoe-free unit boundaries</td>
</tr>
<tr>
<td>Mixed Conifer*</td>
<td>Defoliating insects (western spruce budworm and Douglas-fir tussock moth)</td>
<td>Stands with major true for/ Douglas-fir components, multistoried stands</td>
<td>Long-term strategy—develop stands composed of larch and pines. Short-term strategy—treat infested fir stands with biological or chemical insecticides</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Host Type</th>
<th>Pest</th>
<th>Conditions Favoring Damage</th>
<th>Management Strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root Diseases** (Laminated root rot, Armillaria root disease, and annosus root disease)</td>
<td>Stands with major true fir/Douglas-fir components where inoculum is present</td>
<td>Remove all hosts in root disease centers and 50 foot buffers. Regenerate these areas with tolerant or resistant tree species. For laminated root rot and Armillaria root disease, discriminate against white and Douglas-fir, favor pines and larch. For annosus root disease, discriminate against white fir, favor any other species. In areas where white fir management is desired, consider stump treatment with borax within 48 hours of cutting to prevent annosus infection.</td>
<td></td>
</tr>
<tr>
<td>Douglas-fir Dwarf Mistletoe</td>
<td>Multistoried host stands with already infected overstories</td>
<td>Alternative I—eliminate inoculum by regeneration harvest. If a seed tree system is employed and Douglas-fir regeneration is desired, remove infected seed trees before regeneration is 3 feet tall or 10 years old. Establish mistletoe-free unit boundaries. Alternative II—favor non-hosts (any species but Douglas-fir).</td>
<td></td>
</tr>
<tr>
<td>Larch Dwarf Mistletoe</td>
<td>Multistoried host stands with already infected overstories</td>
<td>Alternative I—eliminate inoculum by regeneration harvest. If a seed tree system is employed and western larch regeneration is to be managed, remove infected larch seed trees before regeneration is 3 feet tall or 10 years old. Establish mistletoe-free unit boundaries. Alternative II—favor non-hosts (any species but western larch and lodgepole pine).</td>
<td></td>
</tr>
<tr>
<td>White Fir Stem Decays (mainly Indian paint fungus)</td>
<td>Stands that contain a major component of white fir and have a history of tree suppression and wounding</td>
<td>Do not manage high risk understories. Eliminate and start over. Where white fir management is desired, keep rotations under 120 years and promote tree vigor throughout the life of the stand. Avoid wounding of white fir crop trees.</td>
<td></td>
</tr>
</tbody>
</table>

**Fir engraver beetles and Douglas-fir beetles are common associates of root diseases. Management of the diseases will usually also minimize beetle damage.

Insects and Disease

Standard and Guideline
Take no action to control insects, disease or noxious weeds unless the outbreak drastically alters the natural ecological processes within the RNA.

Applicable Management Area
MA-D12 Research Natural Areas

Forest Residues

Forest-Wide Standards and Guidelines

Residue Management
Retain the kind and amount of residues needed on-site for the benefit of multiple resources (soil, water, wildlife).

If residues need to be removed, encourage the use of these residues for a mix of appropriate products.

Provide for individual firewood gathering and other family oriented endeavors centered around residue use.

Table D-5 shows Forest-wide averages and ranges of acceptable residue combinations identified from the Photo Series for Natural Forest Residues in Common Vegetation Types of the Pacific Northwest. They provide target levels for average loadings in the stand size classes represented by the photos. These are arranged by stand types found on the Forest and provide general guidance on acceptable residue loads on both natural and managed stand conditions. The photo series can be consulted for specific break down into smaller size class combinations that are considered acceptable.

A series of desired residue profiles have been developed to meet the management emphasis for each of the 8 draft management areas on the Forest. See Management Area Standards and Guidelines, Forest Residues, and Table D-6.
Management Area Standards and Guidelines  
(Forest Only)

Resource - Forest Residues

Practice  
Residue Management

Standard and Guideline  
Manage residues through the natural processes of accumulation and decomposition (including natural fire). In the event of activity fuel generation, residues shall be treated to a level consistent with the immediate surroundings in the wilderness and which will protect wilderness values.

Applicable Management Area  
MA-D8 Wilderness

Standard and Guideline  
Manage residues through the natural processes of accumulation and decomposition (including natural fire regimes). In the event of activity fuel generation, such residues shall be treated to a level consistent with the immediate surroundings. Vegetation and residue mosaic management guidelines may be developed for each area in the future. At that time a mix of desired residue profiles may be identified.

Applicable Management Area  
MA-D9 Semiprimitive Nonmotorized  
MA-D10 Semiprimitive Motorized  
MA-D12 Research Natural Areas*  
* Only with approval of PNW Station Director

Standard and Guideline  
Manage residues to allow natural accumulations of dead and down woody debris. Reduce fuel load only if created or natural fuels accumulate to a level likely to result in a catastrophic fire. Fuel reductions should leave adequate downed material to meet the criteria for old growth. Desired residue profiles for this prescription area are approximated by the residue photos in Table D-6 (except for Grassland Old Growth).

</table>

1/ 3-LP-3 For discouraging livestock use
2/ 8-PP-4 For more open conditions
3/ All thinning photos contain too much slash
4/ Jackpot burn recommended if area is greater than 40 acres
5/ The fuel bed depth in this photo is too high. Lopping is needed to bring high particle intercept to less than 19°

These are found in "Photo Series for Quantifying Forest Residues," a cooperative publication by the Pacific Northwest Forest and Range Experiment Station, U.S. Department of Agriculture, Forest Service, Portland, Oregon (1976-1980) PNW 52, PNW 95, and PNW 105
Standard and Guideline
Manage residues to allow natural accumulations of dead and down woody debris. A natural appearance consistent with riparian stand types is the goal of activity fuel treatments and vegetation management. Desired residue profile for this management area are approximated by the residue photos in Table D-6.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Allow natural accumulations of dead and down woody debris. Desired residue profiles for this management area are approximated by the residue photos in Table D-6.

Applicable Management Area
MA-D5 Retention

Standard and Guideline
Manage residues to allow light natural accumulations of dead and down woody debris. A natural appearance consistent with stand types is the goal of activity fuel treatments and vegetation management. Desired residue profiles for this prescription area are approximated by the residue photos in Table D-6.

Applicable Management Area
MA-D6 Partial Retention - Foreground
MA-D11 Developed Recreation

Standard and Guideline
Manage residues to maintain site productivity, protect wildlife habitat, and reduce the loss of thermal cover to wildfire. Desired residue profiles for this management area are approximated by the residue photos in Table D-6.

Applicable Management Area
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range

Standard and Guideline
Manage residues to maintain site productivity, reduce the chance of wildfire damage to timber, enhance forage productivity and access, and provide for wildlife habitat needs. Desired residue profiles for this management area are approximated by the residue photos in Table D-6.

Applicable Management Area
MA-D1 General Forest
MA-D7 Partial Retention - Middleground
Fuelwood

Forest-and Grassland-Wide Standards and Guidelines

General
The fuelwood program should be considered as a means to meet resource objectives in appropriate areas, such as low productivity lodgepole pine stands and bug-killed material in mixed conifer understory.

Fuelwood availability, as well as public demand, will be considered during preparation, administration, and post sale activities associated with timber sales.

Permit removal of only standing dead or down lodgepole pine and juniper for firewood unless otherwise specified.

Sign wildlife trees, which are not to be cut, that are near roadsides or otherwise accessible to firewood cutters.

Commercial Fuelwood
Make commercial fuelwood sales available in areas less accessible to the general public, areas where National Forest funds are expended to make wood available, and areas where control is needed to meet environmental concerns. Examples are:

Contract areas with concentrations of slash where heavy equipment may be required for removal (timber sales, backlog slash, thinning areas).

More remote areas where hauling costs make large loads more economical to haul than small loads.

Areas where timing or environmental constraints require special control.

Beetle or insect infested low value green trees.

Personal Use
The following areas will be used for gathering personal firewood:

Areas with easy access (landings, extensive areas of dead trees, slash piles, forest fires, etc.).

Areas designated and reserved for fuelwood gathering.
Management Area Standards and Guidelines
(Forest Only)

Resource - Fuelwood

Practice
Commercial and Personal Gathering

**Standard and Guideline**
Commercial and personal use prohibited.

**Applicable Management Area**
MA-D4 Old Growth
MA-D12 Research Natural Areas

**Standard and Guideline**
Commercial use prohibited, personal use of down material for on-site use only.

**Applicable Management Area**
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D10 Semiprimitive Motorized
MA-D11 Developed Recreation
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

**Standard and Guideline**
All firewood gathering prohibited from December 1 to May 1.

**Applicable Management Area**
MA-D2 Big Game Winter Range

**Standard and Guideline**
Firewood gathering subject to permit regulations only.

**Applicable Management Area**
MA-D1 General Forest
MA-D3 Big Game Summer Range
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
Management Area Standards and Guidelines  
(Grassland Only)

Resource - Fuelwood

Practice
Commercial and Personal Gathering

Standard and Guideline
Allow no fuelwood gathering.

Applicable Management Area
MA-D4 Old Growth
MA-D11 Developed Recreation (Cove Palisades State Park)
MA-D12 Research Natural Areas

Standard and Guideline
Allow fuelwood gathering for on site use only.

Applicable Management Area
MA-D5 Retention
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D11 Developed Recreation

Standard and Guideline
Fuelwood cutting areas will only be provided where they will be a tool to provide a proper cover forage ratio for optimum deer winter range.

Do not allow fuelwood cutting when deer are concentrated on the winter range.

Applicable Management Area
MA-D2 Big Game Winter Range (Metolius Deer Winter Range)
Lands

Forest- and Grassland-Wide Standards and Guidelines

Special Uses

Utility Corridors
Coordinate analysis of utility corridors with other Forests and land management agencies. Determine the lead agency and develop a study plan prior to the start of any analysis. Develop environmental analysis and documentation in compliance with the Forest and Grassland Plans, and with procedures set forth in the Regional Guide. Determine the compatibility of each alternative with the management areas affected.

Designation of corridors does not imply entitlement of use and environmental review must precede occupancy on a project-specific basis. Whenever possible, utility rights-of-way will be designated to allow joint use of the right-of-way.

Electronic Sites
Manage Round Mountain Electronic site in accordance with the approved site plan (Ochoco National Forest Analysis File). In accordance with Environmental Assessment Report “Selection of Sites for Electronic Communication Facility Development,” 1979, (also Forest Analysis File), the following sites are designated as electronic sites:
- Drake Butte
- Dry Mountain (existing site)
- Mt. Pisgah
- Round Mountain (existing site)
- Wolf Mountain

Other Uses
Review applications for other uses through the NEPA process

Review special use fees in accordance with the special use fee review schedule (see Appendix A).

Issue special use permits through a prospectus process when a competitive interest has been identified.

Recreation Special Uses
Issue recreational special use permits only after a public need has been demonstrated that applies to a significant number of the recreating public, which may not necessarily include business opportunities.

The experience provided through the permit must be compatible with the Recreational Opportunity Spectrum classification of the management area.

Limit the number of special use permits for a specific use, to the extent possible, in order to minimize administrative costs and to create economic conditions that
provide a high quality public service.
Minimize the impact of special use permits on other users through the operating plans.

**Land Ownership Adjustment**
Acquire and dispose of lands in accordance with the Land Ownership Map (map packet) and Lands Management Area Standards and Guidelines in the Forest Plan.

Survey and mark property boundaries to prevent encroachments, protect present corners or references where the possibility of disturbance exists, and assist in administration of the Forest.

Public and private land adjustment opportunities have been classified and prioritized.

---

**Management Area Standards and Guidelines**
**(Forest Only)**

**Resource - Lands**

**Practice**
Special Use Permits

**Standard and Guideline**
Compatible uses, such as nondestructive research projects, may be permitted with Regional Forester approval. Land occupancy permits are prohibited. Terminate existing noncompatible permits as opportunities arise. Award outfitter guide permits only when it will meet management objectives to provide a needed wilderness opportunity.

**Applicable Management Area**
MA-D8 Wilderness

**Standard and Guideline**
Compatible uses, such as nondestructive research projects and simple fish habitat improvement projects, may be permitted with consent of PNW Station Director. Land occupancy permits are prohibited. Terminate existing noncompatible permits as opportunities arise

**Applicable Management Area**
MA-D12 Research Natural Areas
Standard and Guideline
Compatible uses, such as nondestructive research projects and simple fish habitat improvement projects, may be permitted with Line Officer approval. Land occupancy permits are prohibited. Terminate existing noncompatible permits as opportunities arise.

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
Compatible uses are permitted. Terminate existing noncompatible permits as opportunities arise. Land occupancy permits are prohibited.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized
MA-D10 Semiprimitive Motorized
MA-D11 Developed Recreation

Standard and Guideline
Compatible uses are permitted.

Applicable Management Area
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Practice
Land Ownership and Adjustment

Standard and Guideline
Retain and acquire lands that are necessary to maintain or enhance the management emphasis of the specific areas.

Applicable Management Area
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D4 Old Growth
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D10 Semiprimitive Motorized
MA-D11 Developed Recreation
MA-D12 Research Natural Areas

**Standard and Guideline**
Consolidate land ownership to increase management efficiency by reducing administrative costs and increasing goods and services.

**Applicable Management Area**
MA-D1 General Forest
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

---

**Practice**
Rights-of-Way Grants for Roads and Trails, and Cost-Share Agreements

**Standard and Guideline**
Grant no rights-of-way; enter into no cost-share agreements, except as prescribed by law.

**Applicable Management Area**
MA-D8 Wilderness
MA-D12 Research Natural Areas

---

**Standard and Guideline**
Grant rights-of-way, and enter into cost-share agreements, only when no other reasonable alternatives exist to maintain the integrity of the management area.

**Applicable Management Area**
MA-D4 Old Growth
MA-D9 Semiprimitive Nonmotorized
MA-D10 Semiprimitive Motorized
MA-D11 Developed Recreation
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

---

**Standard and Guideline**
Grant rights-of-way, and enter into cost-share agreements, only when no other reasonable alternatives exist to maintain the integrity of the management area. Include stipulations to prohibit activities from December 1 to May 1.
Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Grant rights-of-way, and enter into cost-share agreements, that are compatible with the management areas emphasis.

Applicable Management Area
MA-D1 General Forest
MA-D3 Big Game Winter Range
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground

Practice
Federal Energy Regulatory Commission Licenses and Permits

Standard and Guideline
Allow uses that are compatible with management emphasis for the specific areas.

Applicable Management Area
All Management Areas except wildernesses and RNA's

Standard and Guideline
Stipulate additional restrictions to prohibit activities from December 1 to May 1.

Applicable Management Area
MA-D2 Big Game Winter Range

Practice
Utility and Transport Corridors

Standard and Guideline
Exclusion Areas for utility corridors; significant barriers in which legislation exists to preclude establishment and use.

Applicable Management Area
MA-D8 Wilderness
MA-D12 Research Natural Areas

Standard and Guideline
Category 1 Avoidance Areas for utility corridors; establishment and use of corridors conflict with management objectives.
Applicable Management Area
MA-D4 Old Growth
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Establishment and use of utility corridors must be compatible with management emphasis for the specific areas. Additional stipulation to prohibit activities from December 1 to May 1.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Establishment and use of utility corridors must be compatible with management emphasis of the specific areas.

Applicable Management Area
MA-D1 General Forest
MA-D3 Big Game Summer Range
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D10 Semiprimitive Motorized
MA-D11 Developed Recreation
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Management Area Standards and Guidelines
(Grassland Only)

Resource - Lands

Practice
Land Ownership and Adjustment

Standard and Guideline
Cooperate with the State in defining optimum ownership patterns and lease terms.

Applicable Management Area
MA-D11 Developed Recreation (Cove Palisades State Park)
Standard and Guideline
Retain and acquire all lands in National Forest System ownership. Seek transfer of Bureau of Reclamation (BOR) lands to the Forest Service.

Applicable Management Area
MA-D11 Developed Recreation (Haystack)

Standard and Guideline
Retain old growth lands unless they are small isolated blocks surrounded by privately owned lands.

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
Retain all lands and acquire inholdings.

Applicable Management Area
MA-D12 Research Natural Areas

Practice
Special Uses

Standard and Guideline
Allow only minimal, temporary or semipermanent research facilities and installations.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Consider relocating the existing powerline outside the area when the special use permit comes up for renewal.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized (Squaw Creek)

Standard and Guideline
Allow only special use permits for activities that are consistent with the visual management objectives for the area.
Applicable Management Area
MA-D5 Retention
MA-D6 Partial Retention - Foreground

Practice
Rights-of-Way

Standard and Guideline
Obtain the right-of-way for the trail to Alder Springs. Permit private landowners access only to private land during seasonal road closures.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized (Squaw Creek)

Standard and Guideline
Establish no exclusion areas on the Grassland. Avoidance areas include Squaw Creek, Haystack RNA, Island RNA, Rimrock Springs, and antelope winter range.

Corridor widths are 1000 feet for each existing corridor. Discourage development of additional facilities. Confine additional facilities to existing corridors. Require present facilities to be upgraded before allowing new facilities.

Designation of corridors does not imply entitlement of use.

Evaluate application for use on a project-by-project basis.

Where possible, encourage joint use of the rights-of-way.

Additional utility rights-of-way or corridors may be identified and approved subject to site specific environmental analysis.

Applicable Management Area
All management areas.

Minerals & Energy

Forest- and Grassland-Wide Standards and guidelines

Leasing
Include stipulations needed to protect surface resources and/or meet management objectives in leases. Refer to management area standards and guides for specific guidance.
Issue leases with a stipulation stating "no surface occupancy" on slopes greater than 40 percent.

Evaluate surface-use plans of operation through the environmental analysis and documentation process.

**Common Variety Minerals**

Use existing sources instead of developing new sources; exceptions include:

- when existing sources are unable to economically supply the quantity and quality of material needed; and
- when conflicts with other resource uses are found to be unacceptable.

Cinder, hardrock, and gravel sources which are available for use during the planning period are designated on the Material Source Map (Grassland Plan, Appendix I).

Evaluate the supply of gravel or aggregate on the Forest before selling to the private sector. Insure that the public interest is being maintained during this process.

Sell minor amounts of clay, sand, and stone to the public on a case-by-case basis.

Develop a management plan describing development and reclamation for each mineral material source to be developed or used during the planning period.

Proposals for capital investments and improvements on structures, which may occur on known material source deposits, should be analyzed within the context of management direction within this plan. Do not unnecessarily reduce options for future removal of materials, by making significant investments on sources when equally viable options exist in other areas.

**Mining Claim Administration**

Administer appropriate laws and regulations relating to minerals in a reasonable and consistent manner.

Assure that operating plans include reasonable and operationally feasible requirements needed for timely and effective coordination with other resources.

Require that reclamation plans describe final management objectives for specific mined areas and detail reasonable procedures and time frames which will be followed to accomplish those objectives. Formulate reclamation bond amounts on actual reclamation costs.

Under the mining laws, claimants are entitled to access to their mining claims. Analyze access for exploration and development of locateable mineral resources through the environmental analysis process, and include reasonable provisions for access in operating plans.

Notify mining claimants of impending Forest Service actions that may affect their claims. Protect claim corners and mine workings from disturbance resulting from Forest Service activities.
Recommend withdrawal from mineral entry when an established or anticipated use is not compatible and cannot be mitigated as part of the mineral entry.

**Rockhounding**

Rockhounding (hunting and collecting rocks and minerals as a hobby) on land under Forest Service jurisdiction will be allowed without a permit, provided: the activity does not conflict with existing rights, and specimens are used for personal, noncommercial use. Activities involving other than casual removal of small amounts of material with minimal surface disturbance are provided for under the mining laws or Materials Act.

**Management Area Standards and Guidelines**

*(Forest and Grassland)*

**Resource - Minerals and Energy**

---

**Practice**

Oil And Gas Leasing

**Standard and Guideline**

Issue no leases.

**Applicable Management Area**

MA-D8 Wilderness

---

**Standard and Guideline**

Issue leases with consent of PNW Station Director only. Include a "no surface occupancy" stipulation.

**Applicable Management Area**

MA-D12 Research Natural Areas

---

**Standard and Guideline**

Issue leases with a "no surface occupancy" stipulation.

**Applicable Management Area**

MA-D4 Old Growth

MA-D11 Developed Recreation

MA-D9 Semiprimitive Nonmotorized
Standard and Guideline
Issue leases with a seasonal use stipulation prohibiting exploration, drilling and other development activity from December 1 to May 1. This limitation does not apply to maintenance and operation of producing wells.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Issue leases with a stipulation requiring drilling and storage facilities to be set back a specified distance from the area or feature.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition (Outside of management area)
MA-D14 Riparian in Excellent Condition (Outside of management area)

Standard and Guideline
Issue leases with a stipulation requiring all permanent and semipermanent facilities to blend into the surrounding landscape or be located out of view.

Applicable Management Area
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground

Standard and Guideline
No special restrictions.

Applicable Management Area
MA-D1 General Forest
MA-D3 Big Game Summer Range

Practice
Locatable Minerals (Mining Claims)

Standard and Guideline
The following areas are withdrawn from mineral entry under the mining laws. Prospecting will be allowed if conducted in a manner compatible with the wilderness environment.

Applicable Management Area
MA-D8 Wilderness
(except existing valid claims)
Standard and Guideline
The following areas are withdrawn from mineral entry under the mining laws.

Applicable Management Area
MA-D12 Research Natural Areas (Ochoco Divide only)
MA-D11 Developed Recreation (Delintment Lake and Walton Lake Campgrounds only)
MA-D5 Retention (600 ft. right-of-way corridor only)

Standard and Guideline
Recommend withdrawal from mineral entry.

Applicable Management Area
MA-D12 Research Natural Areas (Dry Mountain, Silver Creek and Stinger Creek)

Standard and Guideline
Include reasonable measures in operating plans in order to meet management emphasis for the specific areas. Include stipulation to prohibit activity from December 1 to May 1.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Include reasonable measures in operating plans in order to meet management emphasis for the specific areas.

Applicable Management Area

MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Do not remove material from sources from December 1 to May 1.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Material sources development allowed.

Applicable Management Area
MA-D1 General Forest
MA-D3 Big Game Summer Range

Old Growth

Forest- and Grassland-Wide Standards and Guidelines
All old growth stands meeting the definition stated in the Regional Guide, 1984 will be periodically inventoried and monitored. Juniper old growth on the Grassland does not meet this definition.
Specific allocations have been made to provide habitat for old growth dependent species, with the pileated woodpecker as the indicator species. A portion of these acres are included in wilderness, roadless areas, and Research Natural Areas due to the distributional needs of dependent species. See management area standards and guidelines for Wildlife and Fish.

Other old growth (including juniper on the Grassland), outside of that allocated for wildlife habitat, is also available throughout the Forest, but subject to less stringent standards and guidelines, depending on the management area in which it is found.

For example, old growth stands currently existing in visual management areas, or riparian areas are available for management and will decline over time.

Old growth in research natural areas, wilderness, and roadless areas, but not included in the wildlife habitat allocation, are also subject to the standards and guidelines for the respective management areas (i.e. underburning in wilderness and research natural areas).

Recreation

Forest- and Grassland-Wide Standards and Guidelines

General
Recreational activities will be managed to prevent site deterioration within riparian areas.

Developed Sites
Prepare comprehensive and detailed site plans prior to rehabilitation, expansion, or construction projects.

Dispersed Recreation
Provide facilities needed to protect public health and safety (e.g. portable toilets, campfire rings, and environmental protection)

Off-Road Vehicles (ORV’S)
ORV use varies by management area.
ORV use will be limited to over snow vehicles on scablands (See Soils Standards and Guidelines).

Trails
Construct and maintain the trail system to standards suitable for type and amounts of use. Maintain trails to prevent resource damage, protect the
investment in the system and provide for user safety. In areas of concentrated use, trails should be designed and maintained to minimize impacts on riparian communities.

Encourage volunteer groups or individuals to maintain or construct parts of the trail system.

Additional direction on trails is contained in specific management area prescriptions.

MA-D11 Developed Recreation

Practice
Developed Recreation

Standard and Guideline
Develop no interpretive, demonstration, or recreational sites.

Applicable Management Area
MA-D4 Old Growth
MA-D8 Wilderness
MA-D12 Research Natural Areas

Standard and Guideline
Do not locate developed sites in floodplains unless no feasible alternative sites exist outside floodplains. (Executive Order 11988).

All activities within floodplains must meet water quality standards and goals.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Trails, trail heads and trail shelters may be built to facilitate nonmotorized recreation. Minimum site modifications are allowed. Some minor improvements at high use camp sites, such as fire pits, may be allowed.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized
Standard and Guideline
Developed camp sites may be opened to the public from May 1 to December 1. New or additional developed campgrounds must be analyzed in a site specific plan.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Prepare environmental assessments, design narratives and site plans prior to rehabilitation, expansion, or construction projects.

Applicable Management Area
MA-D11 Developed Recreation

Practice
Dispersed Recreation

Standard and Guideline
Discourage recreational activities and use, including overnight camping, and pack and saddle stock use.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Manage to protect the naturalness of the areas. Use of the areas for nonmotorized recreation is acceptable, but should not be encouraged

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
Where conflicts develop, riparian objectives will take precedence over dispersed recreational needs.

Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Promote driving for pleasure and mountain biking.
Applicable Management Area
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground

Standard and Guideline
Develop a variety of ATV routes for a variety of terrain and experience levels.

Applicable Management Area
MA-D1 General Forest
MA-D10 Semiprimitive Motorized

Standard and Guideline
Promote backcountry recreational opportunities for hiking, horseback riding, and mountain biking.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Camp Sites
Discourage development of "permanent" dispersed campsites. Disguise, obliterate, or rehabilitate such campsites when found.
Allow no caching of camping supplies.
No more than two campsites will be visible or audible from any other campsite (within 500 feet).

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
Encounters
Primitive Area, encounters per day 80% of the time: seven or less

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
Semiprimitive Area, encounters per day 80% of the time: 12 or less

Applicable Management Area
MA-D8 Wilderness
Standard and Guideline
Group Size
Maximum permissible group size: 12 people

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
Camp Sites
No more than two camp sites should be visible or audible from any other camp site (within 500 feet).

Encounters
During all use periods there should be no more than 10 other groups encountered per day.

Group Size
The maximum permissible party size is 12 people with 18 head of livestock.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Close area to camping from December 1 to May 1 except within 300 feet of designated access roads.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Utilize minimum on-site controls and restrictions to protect resources and promote safe use of the area.

Applicable Management Area
MA-D10 Semiprimitive Motorized

Standard and Guideline
Provide recreational improvements where needed to protect the resources or sites.

Sites receiving recurring use should be checked periodically for safety considerations (water sources, hazard trees).
Recommend the “pack it out policy” for garbage. Promote “leave no trace” camping techniques.

Applicable Management Area
MA-D1 General Forest
MA-D3 Big Game Summer Range

Practice
Search and Rescue

Standard and Guideline
Use of motorized vehicles for search and rescue must be approved by the Forest Supervisor.

Applicable Management Area
MA-D8 Wilderness

Practice
Signing

Standard and Guideline
Use minimum natural-appearing signing in wilderness areas identifying destinations, but not mileages.

Applicable Management Area
MA-D8 Wilderness

Practice
Trails

Standard and Guideline
Coordinate trail and trailhead planning to disperse users and offer a range of challenges. Design trails to blend with landscape, and construct with native materials.

Applicable Management Area
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
Standard and Guideline
No motorized or mechanized use allowed on trails.

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
No motorized use allowed on trails.

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
No motorized use of trails, except snowmobiles operating on designated routes, and on an adequate snow base between December 1 and May 1.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Motorized use on designated trail routes is allowed. Restrict motorized use during the period December 1 to May 1.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
No motorized use of trails except on designated routes for research purposes.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
No motorized use of trails except on designated routes.

Applicable Management Area
MA-D10 Semiprimitive Motorized

MA-D3 Big Game Summer Range
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

**Standard and Guideline**
Motorized use of trails encouraged on designated routes. Off-trail use will be discouraged.

**Applicable Management Area**
MA-D1 General Forest

**Management Area Standards and Guidelines**
*(Grassland Only)*

**Resource - Recreation**

**Practice**
Recreation Opportunity Spectrum

**Standard and Guideline**
Semiautomatic nonmotorized except for Road 6360 corridor.

**Applicable Management Area**
MA-D9 Semiautomatic Nonmotorized

**Practice**
Dispersed Recreation

**Standard and Guideline**
Protect the environment in and around dispersed camp sites.

Do not encourage dispersed recreational use during the time antelope and deer are concentrated on the winter range.

**Applicable Management Area**
MA-D2 Big Game Winter Range

**Standard and Guideline**
Use of the area for nonmotorized recreation is acceptable.

**Applicable Management Area**
MA-D4 Old Growth
**Practice**

**Trails**

**Standard and Guideline**
Allow existing trails to remain as long as the RNA objectives are not compromised.

Construct no new trails unless needed for research purposes.

**Applicable Management Area**
MA-D12 Research Natural Areas

**Standard and Guideline**
Relocate trails to avoid wet areas.

**Applicable Management Area**
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

**Practice**

**Off-Road Vehicle Use**

**Standard and Guideline**
Allow ORV use on designated routes where such use will not conflict with other resources. Restrict ORV use when conflicts with management area objectives will occur.

**Applicable Management Area**
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
Scenic Resources

Forest- and Grassland-Wide Standards and Guidelines
Manage for the visual quality objectives (VQO's) listed for each management area. See management area standards and guidelines for SCENIC RESOURCES. Where natural catastrophes such as large wildfires, insect epidemics, or windthrows occur, management activities may differ from stated visual quality objectives.

In areas of the Forest managed for “modification” or “maximum modification,” be sensitive to the needs of the viewing public by utilizing cost-effective visual management techniques while meeting the emphasis of the management area. Examples of these techniques may include:

- Leaving desirable looking seed-trees in regeneration units.
- Modifying harvest boundaries to eliminate “sharp line” effects.
- Construction of facilities, roads and other physical structures, with native materials, where possible.

---

**Social and Economic**

**Forest- and Grassland-Wide Standards and Guidelines**

**Human Resources**
Minimize social, cultural and administrative barriers to legitimate uses of the Forest, within the legal authority of the agency.
Maintain and implement an affirmative action plan.
Consider needs of the handicapped in the design of facilities and in other possible ways.
Conduct compliance reviews as required by the Title VI of the Civil Rights Action of 1964
Inform the general public, including minorities and the underprivileged, of benefits they are eligible to receive from Forest and Grassland programs. Use techniques and the media best suited to increase awareness and participation.
Protect and preserve for American Indians, access to, and use of traditional sites, possession of sacred objects, and the freedom to worship through ceremonials and traditional rites. Coordinate location and protection of these areas with representatives of the Confederated Tribes of the Warm Springs Indian Reservation and Burns Paiute tribes. Consider the plans and policies of other Federal, State, local, and American Indian tribal governments in plan implementation.

Consider and provide for the ceded land rights (treaty rights) of the Warm Springs Confederated Tribes in all Forest related management activities (cf. Middle Oregon Treaty of June 25, 1855)

Coordinate resource activities with the designated representatives of the Confederated Tribes of the Warm Springs Indian Reservation.

Soil

Forest- and Grassland-Wide Standards and Guidelines

General
The standards and guidelines stated below apply to all proposed activities occurring on the Ochoco National Forest. Other standards and guidelines are specific to certain types of activities, such as timber harvesting and road building, and are listed under those sections in order to increase the ease and effectiveness of management direction.

Compaction, displacement, puddling, and severely burned soils are to be considered collectively, when assessing impacts.

Watershed Management
Even though watershed effects are the cumulative result of all activities occurring in a particular watershed (including road building, recreation, grazing, etc.), timber management has the greatest potential for detrimental impacts. Therefore, Forest-wide standards and guidelines have been established and designed in the appropriate context, towards timber harvest scheduling and dispersion (see Forest-wide Standards and Guidelines-Timber).

Soil Compaction and Displacement
The threshold level of detrimental compaction is defined as any bulk density increase of 15 percent or more, or any macro pore space reduction of 40 percent or below 15 percent. These values are critical changes over the natural state in the top 12 inches of soil.

In order to maintain site productivity, all project activities will be planned to reduce soil compaction and displacement to the lowest reasonable level. Strive
to reduce compaction and displacement to get as close to 90% of the total activity area (including permanent, rocked, and non-surface roads) remaining in a non-compacted/non-displaced condition, as realistically possible, one year after any land management activity. The minimum will be 80 percent of the total activity area. Existing areas exceeding these standards will be scheduled for rehabilitation as soon as possible.

Surface Soil Erosion
Land management activities will be planned to achieve effective ground cover as defined by the classes shown in Table D-7.

**TABLE D-7**

Soil Resource Inventory Minimum % Effective Ground Cover

<table>
<thead>
<tr>
<th>Erosion Hazard Class</th>
<th>First Year</th>
<th>Second Year</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low</td>
<td>20-30</td>
<td>30-40</td>

<tr>
<td>Severe</td>
<td>50-60</td>
<td>60-75</td>
</tr>
<tr>
<td>Very Severe</td>
<td>60-75</td>
<td>75-90</td>
</tr>
</tbody>
</table>

Effective ground cover is defined as the basal area of perennial vegetation, plus litter and coarse fragments (greater than 2mm sizes), including tree crowns and shrubs that are in direct contact with the ground. Exceptions may occur where specific projects meet erosion control objectives without meeting the ground cover objectives stated above.

Soil Mass Wasting
When a project could result in an increased potential for mass wasting, which could cause significant soil loss or sedimentation, hazards to property, loss of fish habitat, or damage to other resource values, alternative project proposals will be evaluated and documented through the project’s environmental analysis.

An activity area is the total area for which a ground-impacting activity is planned, for example, a unit for a timber sale, slash disposal project, grazing allotment. The area would also include transportation systems within and directly adjacent to the project.

Fragile Areas
Recognize the sensitivity and potential of certain areas and/or situations to be adversely affected by management activities and plan accordingly to minimize those effects. Fragile areas include scablands (shallow soil areas), elk wallows, and other isolated soil areas which exhibit sensitivities that require special care.
Scablands

Scablands are recognized as among the most fragile ecosystems on the Ochoco National Forest. Damage to the soil and vegetation as a result of management activities is nearly impossible to mitigate. This is a result of their having very shallow soils which are subject to severe water saturation and frost heaving during winter, thus making revegetation virtually impossible. For this reason, all management activities will be analyzed as to their affect on scablands, prior to implementation. Use *Plant Communities of the Blue Mountains in Eastern Oregon and Southwestern Washington*, Hall, 1973, to identify scabland plant communities.

Other standards and guidelines for scablands are specific to certain types of activities, such as timber harvesting, livestock grazing, and road building, and are listed under those sections.

</tr>
</tbody>
</table>

**Standard and Guideline**

Limit displacement and erosion to a rate that approximates natural processes. Soil compaction should not exceed limits that prevent plant establishment except at some campsites and in designated trail tread.

Locate, relocate, or close campsites to prevent excess soil erosion and compaction when necessary.

Correct areas of human-caused soil instability which contribute to resource degradation, utilizing measures compatible with the Wilderness objectives.

Manage for no human-caused change in rock formations.

**Applicable Management Area**

MA-D8 Wilderness

**Standard and Guideline**

Allow activities that do not conflict with the objectives of RNA’s, such as special studies, monitoring, and research. Develop soil rehabilitation plans to implement in the event of soil disturbing activities such as fire suppression.

Timber

Forest-Wide Standards and Guidelines

Suitable Forest Land
Regulated timber harvest will only be allowed on lands classified as available, capable and suitable. Lands currently classified as suitable but found unsuitable in project analysis will be identified as such on planning maps and treated as unsuitable.

Where unmapped, unsuitable lands are found, project implementation will recognize these areas and plan mitigation measures to avoid adverse impacts. An example of this may be small slumps (unstable soil areas) where soil disturbing activities are avoided.

Silviculture
Prepare silvicultural prescriptions for all activities proposing the management of trees or timber stands to meet resource management objectives. Prescriptions will be recorded in analysis files and stand records.

All prescriptions will be prepared or approved by a Certified Silviculturist.

Elements required in a silvicultural prescription are documented in FSH 2470, the Silvicultural Examination and Prescription Handbook, and by Regional direction. No standardized format will be required, but all requirements must be addressed in the prescriptions or through project environmental analysis.

Plant communities of the Blue Mountains in Eastern Oregon and Southeastern Washington, Hall, 1973, or any future accepted guide, will be used as a guide to site productivity of forest communities and for other applicable management considerations.

The silvicultural prescription should consider integrated pest management. Pests refer to any biotic or abiotic influence on the Forest, including insects, diseases, atmospheric deposition, silvicultural treatments, harvesting practices, and competing vegetation.
Develop site-specific prescriptions to provide for biological diversity and ecosystem function, including consideration for long-term productivity. Vegetation management should allow for all natural species to function. None should be eliminated from the site.

Silvicultural prescriptions must provide for snags, and trees for future snags, that will meet the habitat requirements for cavity nesting species, according to management area objectives (see Management Area Standards and Guidelines for Wildlife and Fish); exceptions could be fuelbreaks or situations where snags could cause a safety hazard. During preparation of marking guides, include provisions which specify that damaged, defective, or low value trees be used for replacement snags as much as possible, especially in commercial thinnings. However, take precautions not to leave disease ridden trees that may spread infection to adjacent healthy trees.

Retain trees whose roots stabilize streambanks along Class III and IV streams, especially where fair to poor streambank stability conditions exist. Generally large mature trees provide bank stability for a distance of 5 to 10 times the diameter of the trunk, though this area of influence may be considerably larger. Understory trees and juniper play a role in bank stability in an area approximately equal to their crown diameter. Merchantable trees may be removed if sufficient trees remain to provide root strength for bank stability or if streambank stability is good or excellent and shade and large woody debris are present in sufficient amounts.

Stand examinations and/or other data gathering processes will be used to verify or develop silvicultural prescriptions.

A regeneration system providing the desired establishment conditions will be selected. Leave trees per acre and leave basal area per acre for seed tree or shelterwood systems will be silviculturally prescribed on a site specific basis.

Uneven-aged Management
The application of uneven-aged management is characterized by stands which contain at least two well defined age classes. Even-aged aggregations of trees within these uneven-aged stands should be of a size such that regeneration never loses the protection of the adjacent older age classes. Regulation of the rate of harvest within uneven-aged stands requires the control and maintenance of a desired distribution of size classes.

Uneven-aged management can be applied using either individual tree or group selection silvicultural systems. The decision to apply either system should be based on actual stand and site conditions.

Uneven-aged management is applicable to immature, mature, and overmature stands of essentially pure ponderosa pine within the ponderosa pine community types. Uneven-aged management can be most readily applied to relatively vigorous pure stands of ponderosa pine which display an uneven or mixed stand structure.
Uneven-aged management is most applicable to the mature and overmature stands within the pine/associated community types, but only where silvicultural activities will result in stands dominated by early successional species, including ponderosa pine and western larch. Dominance in these community types is established when stocking by early successional species can be maintained at or above 50 percent of the minimum stocking level basal area established in the silvicultural prescription, on 80 percent of the treated acres. As an objective, dominance by early successional species should assure long-term stand health and vigor, as well as provide for the final harvest of preferred species as planned in the silvicultural prescription.

Stands which are severely understocked, overmature and single-storied, decedent, heart-rotted, or are producing little net growth are generally poor candidates for uneven-aged management.

Uneven-aged management is not recommended in lodgepole pine community types.

Uneven-aged management is applicable where there is reasonable assurance that natural regeneration of acceptable genetic quality and diversity will occur within 10 to 15 years. Planting or interplanting is also appropriate to maintain acceptable genetic quality and/or diversity, dominance by early successional species, or to assure timely regeneration under extremely harsh site conditions.

Uneven-aged management is most applicable on slopes less than 30 percent where tractors normally operate.

Uneven-aged management is most applicable where the total area impacted by detrimental soil compaction, erosion or displacement can be restricted to less than 20 percent of the stand.

Uneven-aged management is most applicable where stands are free from dwarf mistletoe. Where stands are lightly infected, uneven-aged management is applicable only where dwarf mistletoe can be confined to the lower half of the tree crowns and within a single canopy layer. The infection of lower canopy layers by upper canopy layers should be avoided. The objective is to maintain stand growth within 80 percent of its disease-free potential.

Uneven-aged management is most applicable where stands are free from root rots. Where stands are lightly infected, uneven-aged management is applicable only where root rot can be managed to maintain stand growth within 80 percent of its disease-free potential. Root rot centers should be managed using even-aged systems.

Silvicultural prescriptions should be designed to maintain or improve the existing size class diversity and uneven-aged structure. Emphasis should be given to managing the existing growing stock. The existing relationship between trees in all size classes, and the condition of those trees, should be considered first as a basis for developing marking guidelines, rather than the ultimately desired size class distribution or upper diameter limit.
Timber harvest and post sale activities should generally be planned on a 20-year entry cycle. All post sale activities should be completed within nine years following the harvest entry. Stands should not be salvage logged at other than the prescribed entry cycle except where wildfire, bark beetles, disease, or other conditions have created catastrophic mortality.

No minimum or maximum sized stand treatment units are specified where an uneven-aged structure can be maintained throughout the stand treatment unit. An average treatment unit of approximately 100 acres or larger is recommended to facilitate inventory and record keeping needs.

Timber marking guidelines should be developed which retain the most vigorous trees of best quality. First priority for leave trees are those with demonstrated good vigor. Second priority are those trees which will produce high value products in the future.

Following each commercial harvest entry, post sale activities should emphasize natural regeneration and stocking level control. Where natural regeneration is a planned objective, post sale activities should be closely coordinated to produce disturbance to the litter and vegetation as necessary for natural regeneration to occur.

Timber harvest, fuel treatment, and site preparation activities should strive to avoid damage to residual trees.

Treatment areas will be coordinated with wildlife habitat needs for cover. Silvicultural prescriptions will address the size, spatial arrangement, and opportunities presented by the existing vegetation within a treatment area.

Pruning may be done where it is economically efficient to produce clear, quality lumber.

**Even-aged Management**

*General*

Size of units for intermediate treatments, over-wood removal treatments, and precommercial thinning will be determined through the interdisciplinary process during environmental analysis. Normally these units will not exceed 100 acres. Possible exceptions are stands which have a high susceptibility to insects and disease or where they are exhibiting retarded growth due to disease.

Vegetation diversity will be considered when preparing prescriptions and schedules for large homogenous areas that are generally the same age, in order to provide a mosaic of stands at different conditions and ages.

*Rotation Age*

The minimum rotation age (at which stands are scheduled for harvest) will be the age at which the mean annual increment (MAI) is equal to or greater than 95 percent of culmination of mean annual increment (CMAI). Harvesting may be at older stand ages to meet specific management objectives (see management area standards and guides for Timber).
Dispersion
The maximum size of a created opening will be 40 acres, except when openings up to 60 acres will be allowed:

When larger created openings will reduce the disturbance to soil, water, fish, or riparian resources, and residual vegetation by: (1) allowing economically feasible logging systems that reduce landing and road construction, or (2) locating roads away from unstable soils, and (3) reducing soil and vegetation disturbance from dragging logs.

Where groups of dwarf mistletoe or root rot disease infected trees need to be incorporated into the created opening to avoid infection, and their inclusion cannot be achieved by centering the created opening over the area of infection.

Where the visual quality objectives require shaping and blending of openings to fit landforms.

When natural catastrophic situations such as fires, windstorms, or insect and disease attacks occur.

On an individual case basis, after a 60-day public notice and review by the Regional Forester.

A harvested area will no longer be considered a created opening when (a) trees are four and one half (4.5) feet tall, free to grow, and meet minimum stocking requirements, or (b) when the vegetation in the harvested area meets the management area objectives, emphasis and desired future condition as stated in Section 3, Management Area Prescriptions, this chapter.

Created openings will be separated by blocks of land generally not classed as created openings as described above. The blocks of land between created openings shall vary in size and contain one or more logical harvest units. These blocks of land shall be large enough and of a stand structure appropriate to meet resource requirements of the Forest Plan.

Openings to be created contiguous to natural openings should receive an exceptional level of attention during the analysis and prescription for treatment since natural openings are recognized as important or critical. The decision to create openings contiguous to natural openings shall be supported by prescriptions specific to individual natural openings or to a group of natural openings where their importance is diminished by more frequent occurrence. Created openings should generally not exceed 1/3 the size and/or be contiguous to more than 1/3 the edge of a natural opening where the natural opening exceeds 30 acres in size. Limitations for created openings contiguous to natural openings less than 30 acres in size will be subject to the interdisciplinary decision making process and its review of land management objectives.
Reforestation

Stocking

Forest stocking guides will be utilized to assess adequate stocking on all regeneration units prior to certifying them as being satisfactorily reforested (See Table D-8 below).

**TABLE D-8**

**STOCKING STANDARDS AT 4.5 FEET**

<table>
<thead>
<tr>
<th>Level</th>
<th>Recommended</th>
<th>Minimum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pine Low Site Tractor 1/</td>
<td>50-200</td>

<tr>
<td>Mixed Conifer Tractor</td>
<td>150-350</td>
<td>3/ 75</td>
</tr>
<tr>
<td>Cable</td>
<td>150-300</td>
<td>3/ 75</td>
</tr>
</tbody>
</table>

1/ No reforestation work planned for cable ground on low site

2/ Overstory will not be removed if stocking is below this level

3/ Replanting or additional effort will be required if stocking is below this level. Area can not be certified as stocked, and will need to be reported as a failure.

Standards are established for each of the three timber types (low site pine, ponderosa pine, and mixed conifer) and by logging method (tractor or cable). They are based on 4.5 feet tall crop trees (usually between five and ten years of age). Make allowances for expected mortality and natural fill in that will occur prior to crop trees reaching 4.5 feet, based on staked tree and/or stocking surveys of similar stands. If rework is necessary, the stocking should be brought to the recommended level.

Recommended range of stocking is that which will produce the yields predicted in the Forest Plan. A variety of harvesting and cultural activities are allowed for, so recommended stocking varies to cover this range.

Tree species used in planting harvest units should be based on the potential of the site as indicated by plant communities. Consideration should be given to regenerating and maintaining a mixture of species, where appropriate for the site.
The recommended stocking for each stand will be established by the silviculturist in the prescription, based on local conditions and objectives, with consideration given to meet costs and outputs projected in the Forest Plan.

Natural regeneration opportunities will be taken advantage of if acceptable genetic quality and diversity is likely to result. If artificial regeneration is necessary, the recommended method will be to plant.

Planting should generally not be prescribed for low site pine types.

In clearcut units, site preparation should normally be completed within two years of harvest. Planting shall occur within one year of site preparation. Exceptions can occur, but only for resource objectives that have been documented through environmental analysis. These units should be suitable and certified as satisfactorily reforested three years after planting.

Planting will be done with seed from selected trees for all ponderosa pine seedlings and for other species when available.

Precommercial Thinning

Precommercial thinning is recommended when:

Existing overstocking will reduce future yields below predicted or planned levels (1973, op cit) which varies by Hall's Community Types and management emphasis.

The expected return from increased timber production and value exceeds the cost of precommercial thinning.

It is consistent with management objectives.

Stands with an average DBH over six inches should not be precommercially thinned, except when threatened by insects and disease. Sanitation cutting may be done to control mistletoe, or to remove defective or damaged trees that will not make a merchantable product.

The maximum acceptable stocking for ponderosa pine is 450 trees per acre, and for mixed conifer 500 trees per acre. If the DBH for the stand is under three inches (excluding trees planned for overstory removal, if any) include all trees. If DBH is three inches or larger, exclude seedlings under 4.5 feet high from the trees per acre calculations.

There needs to be at least minimum stocking in trees capable of responding to release. This includes a minimum of 30 percent with live crown ratio, and sufficiently free of disease (such as mistletoe) or damage, to make a merchantable product.

Consider economics, as well as stocking, mistletoe (disease), and management objectives as criteria before arriving at decisions to precommercially thin stands. Thinning must be determined to be economically viable and to meet management prescription objectives.

Thinnings should retain a diversity of species based on site potential.
Harvest Schedule

Allowable Sale Quantity
The allowable sale quantity (ASQ) is planned to remain constant over the next five decades and beyond (See Objectives for Timber, Section 1 of this Chapter). The ASQ represents projected, potential outputs based on available inventory and assumptions, and accountability is on a decade basis. The planned harvest does not infer a commitment on the part of the Forest to supply the stated level on a regular basis, but rather states the maximum output available, subject to budgetary constraints and the broad discretion of the agency.

Salvage
Salvage volume is standard sound material from dead or dying trees, standing or down, that is calculated outside of the planned ASQ. Harvest levels will vary from decade to decade and from year to year within a decade depending on mortality, economics of harvesting, etc. but total timber sold (ASQ plus salvage) for the decade will not exceed planned level by more than five percent (10 MMCF or 62 MMBF). If a catastrophic event makes more salvage volume available, it will be substituted for ASQ volume to keep total sale volume within five percent per decade. The salvage program may be increased up to 10 percent of ASQ (12 MMBF) to harvest timber killed by a catastrophic event. Any increase above this will require an equal reduction in the ASQ sell volume. The amount of salvage available may be constrained by snag habitat requirements for the Forest, in any one year (See Cavity Nester Habitat, Wildlife and Fish Standards and Guidelines, this section of this chapter).

Harvest Levels by Forest Watershed
Based on current conditions, the following equivalent harvest acres (EHA) guidelines will be in effect and will remain in effect until updated or changed in the Forest Plan. This guideline assumes that suitable dispersion of harvest within a given watershed is achieved as well (also use for meeting water quality objectives).

Logging Methods
Ground skidding and slash piling equipment will be avoided on slopes exceeding 35 percent, and on soil conditions with high compaction, erosion or displacement hazards, or wherever soil productivity standards cannot be met.

Designated skid trails will be confined to 20 percent or less of the activity area for all timber harvest practices (including disposal of slash), unless it can be demonstrated beyond a reasonable doubt, that particular circumstances or equipment exist which will not detrimentally impact soils as stated in Soils Forest-Wide Standards and Guidelines.

Locate skid trails and roads to avoid paralleling stream channels. New landings should not be placed in riparian areas. Existing landings within streamside areas which are impacting or could impact water quality should be rehabilitated.

</table>
Scablands will not ordinarily be used for landings and skid trails. An exception to this would be in the case of skyline logging where a particular location would necessitate using a scab. Should this occur, the affected area will be erosion-proofed through use of rock or other appropriate methods.

Low Productivity Lands
On timbered lands where site productivity is expected to be less than 20 cu.ft./acre/year, the regeneration method will be natural regeneration. This will be accomplished under the shelterwood method. Overstory will not be removed until regeneration is securely established.

Christmas Trees
Consistent with other resource objectives, Christmas trees will be offered for sale. Emphasis will be placed on personal use by individuals. Special restrictions are to be applied to prevent indiscriminate cutting of trees.

Management Area Standards and Guidelines
(Forest Only)

Resource - Timber

Practice
Scheduled Harvest

Standard and Guideline
No timber harvest allowed (including salvage).

Applicable Management Area
MA-D4 Old Growth
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D12 Research Natural Areas

MA-D11 Developed Recreation

Harvest Scheduling
Harvest only for the purpose of maintaining safe and attractive recreational sites. No scheduled timber harvest.

Reforestation
Rely on natural regeneration. Planting may be done to meet management area objectives.
Visual Influence Area

Silvicultural System
Both even- and uneven-aged silvicultural systems may be used. Emphasize maintenance of large, yellow bark ponderosa pine and western larch.

Uneven-aged management systems will follow Forest-wide standards and guidelines.

Cultural Treatments
Precommercial thinning and commercial thinning may be done to meet the visual quality objectives and maintain healthy stands.

Harvest
Cutting practices may be used that meet the objectives shown in Table D-11.

1/ Actual harvest entry cycle will be prescribed in a site-specific silvicultural prescription

2/ The indicated diameter is an average end point diameter at rotation age for even-aged stands. For uneven-aged stands, the indicated is a target diameter

Manage ponderosa pine to encourage large trees and open park-like stands. Manage mixed conifer for a mix of species with emphasis on maintaining western larch where possible. Provide views of scenic features, such as aspen stands and rock outcroppings.
MA-D10 Semiprimitive Motorized

**Silvicultural Systems**

Harvest ponderosa pine on an uneven-aged management system as follows:

1. 40 year entry cycle
2. Basal area 40 - 80 sq. ft./ac.
3. Maintain 5 - 10 trees per acre in 20"+ size class

Harvest mixed conifer stands using the patch cut system on a 200 to 220 year rotation. Harvest patch size will be 2 - 5 acres in size.

**Reforestation**

Rely on natural regeneration in ponderosa pine. Plant mixed conifer where necessary.

**Intermediate Harvest**

Two entries in mixed conifer stands.

If logging cannot be done while meeting road objectives, then delay logging until it is economical or practical to meet road objectives. Helicopter or logging to the existing road system should be considered in lieu of building high standard roads in these areas.

MA-D13 Riparian in Acceptable Condition

MA-D14 Riparian in Excellent Condition

**Silvicultural Systems**

Even-aged and uneven-aged systems may be used. Select the system that best meets the shading and woody debris objectives.

**Even-aged Systems**

Reforest by natural regeneration or plant. Select the method that creates the least soil disturbance. Schedule harvest on a 200 year rotation (five percent per decade). Limit the size to 180 linear feet along streams. Design harvest units (shape, size, and distribution) to meet shading objectives over time.

**Uneven-aged Systems**

Use a forty-year entry cycle. Maintain basal area at 50 - 90 square feet per acre. Maintain 5 - 10 trees per acre greater than 20 inches in diameter.

**Reforestation**

Rely on natural regeneration or plant to obtain desired stocking. Allow no mechanical site preparation, application of herbicides, or fertilization.

**Precommercial Thinning**

May be used to obtain desired stocking levels.

**Commercial Thinning**

May be used to obtain desired stocking levels.

3/ Does not apply to intermediate treatments such as commercial thinnings, or single tree selection.
MA-D5 Retention

Silvicultural Systems
Utilize both uneven-aged and even-aged systems where ecologically suitable. Manage ponderosa pine for a combination of: 1) multiple age class stands, and 2) open, park-like stands. Manage mixed conifer for a mix of species with emphasis on maintaining western larch where possible. Provide views of scenic features such as distant landscapes, aspen stands and rock out-crops.

Uneven-aged management systems will follow Forest-wide standards and guidelines while protecting the scenic qualities in these areas.

A silviculturist will model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the objectives shown in Table D-12.

MA-D6 Partial Retention - Foreground

Silvicultural Systems
Utilize both uneven-aged and even-aged systems where ecologically suitable. Manage ponderosa pine for a combination of: 1) multiple age class stands, and 2) open, park-like stands. Manage mixed conifer for a mix of species with emphasis on maintaining western larch where possible. Provide views of scenic features such as distant landscapes, aspen stands and rock out-crops.

Uneven-aged management systems will follow Forest-wide standards and guidelines while protecting the scenic qualities in these areas.

A silviculturist will model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the objectives shown in Table D-13.

MA-D7 Partial Retention - Middleground

Silvicultural Systems
Cutting practices may be used that meet the partial retention objectives shown in Table D-14.

For Alternatives E-Departure and A
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range

Reforestation
Practices may vary from natural regeneration to planting at normal or increased stocking depending on target acres. Select the most productive and accessible lands for increased stocking. Utilize natural regeneration on lower productivity sites and where natural regeneration is likely to be successful.
Precommercial Thinning
Thin according to management objectives. Stocking should be within 50 trees per acre of what is shown in the appropriate yield table.

Commercial Thinning
Select areas to thin based on management objectives and economic feasibility.

Regeneration Harvest
At culmination of mean annual increment or later as scheduled.

Silvicultural Systems
Both even- and uneven-aged management systems will be practiced. Uneven-aged management is the preferred management system on low sites. Uneven-aged management systems will follow Forest-wide standards and guidelines.

For Alternative C
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range

Silvicultural Systems
Mixed conifer stands and stands on slopes greater than 30% will be managed using even-aged systems. Ponderosa pine stands, on slopes less than 30% and with suitable age class distributions, will be managed using uneven-aged systems. Uneven-aged management systems will follow Forest-wide standards and guidelines.

A silviculturist will model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the objectives shown in Table D-15.

Reforestation
Plant at normal or increased stocking levels. Select the most productive and accessible sites for increased stocking as shown in the model component. Utilize natural regeneration on lower productivity sites and where natural regeneration is likely to be successful.

Cultural Treatments
Precommercial and commercial thinnings will be done according to Management Objectives and economic feasibility. For precommercial thinning, stocking should be within 50 trees per acre of the number shown in the appropriate Managed Yield Table. Pruning may also be done where economically feasible in ponderosa pine stands to improve wood quality.

Uneven-aged Stands
Uneven-aged management is the preferred silvicultural system within portions of these Management Areas. This system should be prescribed within ponderosa pine stands where stand and site conditions are appropriate, and no other resource objectives which preclude the use of uneven-aged management have been identified and documented during the project planning process.

</table>

1/ The indicated diameter is an average end point diameter at rotation age for even-aged stands
MA-D1 General Forest

Silvicultural Systems
In this management area, either present net value or timber production will be maximized by utilizing a number of cultural practices, including:

- Planting of genetically improved trees at two stocking levels.
- Natural regeneration,
- Precommercial thinning;
- Commercial thinning from one to three times; and
- Rotation ages from 95 percent of culmination of mean annual increment (CMAI) (usually from 80 to 90 years) to 150 years.

Timber stands will be managed using even-aged systems with trees uniformly spaced and fully occupying sites except in the seedling and sapling stages. Stands will be treated to meet the objectives shown in Table D-16.

Reforestation
Plant at normal or increased stocking levels depending on target acres. Select the most productive and accessible sites for increased stocking as shown in the model component. Utilize natural regeneration on lower productivity sites and where natural regeneration is likely to be successful.

Cultural Treatments
Precommercial and commercial thinnings will be done according to Management Objectives and economic feasibility. For precommercial thinning, stocking should be within 50 trees per acre of the number shown in the appropriate Managed Yield Table.

Regeneration Harvest
At Culmination of Mean Annual Increment (CMAI), unless blowdown, insect infestation, or other such events interrupt rotation.
Transportation System

Forest- and Grassland-Wide Standards and Guidelines

Planning
Transportation systems will be planned to support resource activities in the management areas and to serve multiple resource needs rather than individual project proposals.

Roads and trails will be at the lowest density which meets long-term resource needs. Where existing roads or trails are impacting water quality steps will be taken to mitigate the problem.

The planned transportation system will be constructed to the required standards to meet the needs of the planned resource activities of the area. This standard will be such that repeated reconstruction to upgrade any given section of the system will be minimized during the planning period.

Prepare and maintain road management objectives (RMO's) for proposed and existing system roads and identify roads not needed for future maintenance.

Coordinate with the State and Counties on management of their roads to complement Forest uses.

Identify roads that require Forest Service jurisdiction to meet resource objectives.

Update the “Forest Sign Plan” annually to reflect road management objectives.

Traffic Management
General
The adequacy and safety of the transportation system will conform to the Forest Service Manuals and Handbooks. If a road does not exist at an adequate and safe standard for the traffic expected to use it, traffic can be restricted to a level where the existing road is adequate. This could eliminate the need to reconstruct the road.

Manage traffic as needed to control access due to structural limitations of the road, safety, or to meet resource objectives, such as those to meet wildlife needs or off-road vehicle (ORV) travel management needs.

Strategies for managing traffic will range from highly restrictive low impact, single user, short-term roads to unrestricted long-term roads.

Strategies for managing traffic could include prohibiting use on a seasonal or year long basis, or eliminating all standard vehicle use for more than one year.

Put sign traffic control devices (such as gates) to let users know why use is restricted and for what period of time.
No construction or logging equipment parking or turn around will be allowed on scablands except under landings.

Commercial Hauling
During commercial hauling activities, public access will generally be discouraged or prohibited on single user local access roads.

Generally, primary commercial haul routes are reconstructed, operated and maintained to permit low clearance (passenger car) traffic. However, some commercial haul routes may be maintained for high clearance vehicles, maintenance Level 2.

Recreation
Encourage ORV use only on roads where all standard vehicle use has been eliminated, or on roads which have no current or planned future use where appropriate with other resources.

Access routes to developed sites will generally be reconstructed, operated and maintained to permit low clearance (passenger car) traffic. However, public use may be seasonally discouraged, or restricted.

Local road access to historical dispersed recreation sites are generally graveled to prevent investment loss and resource damage during wet periods of the year. Road access management strategies to the dispersed sites will generally be “accept” or “encourage” use by dispersed recreationists.

Construction and Reconstruction
Design, construct, and reconstruct roads according to standards based on the following criteria: resource management objectives, environmental constraints, safety, physical environmental factors, traffic requirements, traffic service levels, vehicle characteristics, road users, and economics.

Roads will not be constructed through the length of a riparian area. Roads crossing a riparian area will not alter stream or groundwater flow characteristics to a degree which will impact the riparian characteristics.

Road drainage will be designed and maintained to eliminate any influx of sediment road runoff directly into stream channels, to the extent possible.

Road construction activities will be managed to minimize the amount of unprotected soil surfaces when heavy rain or heavy surface runoff are most likely to occur.

Ensure that erosion control measures are completed prior to times of year when heavy rain or heavy runoff are normally expected.

Whenever practical, roads should be located on areas with the lowest erosion hazard.

Provide cost effective timber haul based on the various seasons of the year.

Ensure that temporary culverts or bridges are used where stream bottoms or banks would otherwise be damaged, and that these temporary structures are removed after use.
Roads which pass through high water table areas should be constructed in a manner which does not alter the flow characteristics of the groundwater.

Stream Crossings
Design and construct the transportation system to minimize the numbers of stream crossings.
Locate stream crossings and the approach alignment to minimize stream damage.
Bridge approach fills should be riprapped or protected by wing walls.
Ensure adequate sizing of culverts or bridges to accommodate anticipated high streamflows and to allow fish passage.
Schedule stream crossing construction during low streamflow and/or outside fish spawning periods.
Stream crossings should not change floodplain or streamflow characteristics.
Maintain existing riparian communities both upstream and downstream from the crossing.

Scablands
Road construction on scablands will be limited to long-term collector, arterial and local roads. Temporary or short-term roads or trails will not be constructed across scablands unless there is no other feasible alternative. Should a specific activity necessitate the construction of temporary access, the area affected will be completely erosion proofed through use of crushed rock and other appropriate methods.
Thoroughly analyze the long term need before establishing borrow pits on scablands.

Visuals
Include parking areas and viewpoints in road plans and designs where appropriate.
Locate material stockpiles out of site of the main travel route.
Gravel pits, barrow areas, landings, etc. should meet visual objectives for the management area.
Avoid locating roads in the visual foreground other than at junctions. Design roads to fit the topography, minimizing cuts and fills. Roads should not dominate the natural pattern of line, form or color.
Necessary road closures in visual management areas should be designed and constructed to blend with the natural characteristics of the landscape.

Road Operations and Maintenance
Operate and maintain all roads within available financing according to maintenance levels established in Road Management objectives and standards defined in Table D-17.
TABLE D-17
Definitions of Road Management Objectives and Standards

<table>
<thead>
<tr>
<th>Minimum Maintenance Level</th>
<th>Use</th>

<td>No current use, planned future use</td>
</tr>
<tr>
<td>2</td>
<td>High clearance vehicles</td>
</tr>
<tr>
<td>3, 4, 5</td>
<td>Low clearance vehicles</td>
</tr>
</tbody>
</table>

If funding is inadequate to maintain some roads at the intended maintenance level, maintain roads at a lower maintenance level, such as high clearance access (Level 2) to a closed level (Level 1).

Stabilize and re-establish vegetation on obliterated roads.

Ensure that necessary road and trail maintenance is performed on all runoff control and drainage structures (dips and culverts).

Provide for additional maintenance of road drainage and crossing structures during periods when unusual runoff is expected.

Ensure that appropriate traffic management is established to prevent the creation of pollution-generating conditions, such as deep wheel tracks in roads during wet weather.

Management Area Standards and Guidelines
(Forest Only)

Resource - Transportation System

Practice
Construction and Reconstruction

Standard and Guideline
None allowed.

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
None allowed except for research purposes, and approved by PNW Station Director.
Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Develop no permanent roads. Develop and maintain trails and trailheads to meet semiprimitive recreational objectives.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Allow no road construction unless there are no reasonable alternatives. When essential, allow construction or reconstruction only between July 15 and January 31 to protect wildlife values, such as nesting.

Applicable Management Area
MA-D4 Old Growth

Standard and Guideline
Construct primitive roads and trails of varying levels of difficulty for recreation and limited timber harvest. Manage road density to maintain the semiprimitive character of the area.

Applicable Management Area
MA-D10 Semiprimitive Motorized

Standard and Guideline
Construction and reconstruction are allowed to access Forest resources, according to management area emphasis, subject to Forest-wide Standards and Guidelines.

Applicable Management Area
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D11 Developed Recreation
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition
Practice
Operations and Maintenance

**Standard and Guideline**
Obliterate and revegetate and revegetate all existing roads except those authorized for mining operations. Where appropriate, utilize the old road system for a nonmotorized trail.

**Applicable Management Area**
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized

**Standard and Guideline**
Hazard tree felling is permitted. Felled trees shall remain in place unless lying across an approved road or trail.

**Applicable Management Area**
MA-D12 Research Natural Areas

**Standard and Guideline**
Hazard tree felling is permitted for public safety.

**Applicable Management Area**
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D4 Old Growth
MA-D5 Retention
MA-D6 Partial Retention - F

MA-D10 Semiprimitive Motorized
MA-D11 Developed Recreation
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

 Practice
Traffic Management

**Standard and Guideline**
No access permitted except for authorized mining claims.

**Applicable Management Area**
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
**Standard and Guideline**
Access routes will be restricted to administrative use and use by permit for research related purposes only.

**Applicable Management Area**
MA-D12 Research Natural Areas

---

**Standard and Guideline**
Except for constant service through routes and short existing open local access, use will be restricted to approved projects designed to meet management area objectives. These will be closed to motorized use at the end of the projects.

**Applicable Management Area**
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

---

**Standard and Guideline**
Limit open roads to two miles per square mile following timber harvest and post-sale activities. Close roads following timber sales if post-sale activities are delayed longer than one year.

Keep roads closed unless needed in emergencies for protection of life or property.

**Applicable Management Area**
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range

---

**Standard and Guideline**
Certain local roads may be restricted to administrative use and use by permit only.

**Applicable Management Area**
MA-D11 Developed Recreation

---

**Standard and Guideline**
Constant service roads will remain open. Use on all other roads across the management areas will be eliminated.

**Applicable Management Area**
MA-D4 Old Growth
Standard and Guideline
Generally, access routes will be open subject to Forest-wide Standards and Guidelines.

MA-D1 General Forest
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground
MA-D10 Semiprimitive Motorized

Practice
Off-Road Use

Standard and Guideline
No motorized use allowed.

Applicable Management Area
MA-D4 Old Growth
MA-D8 Wilderness
MA-D9 Semiprimitive Nonmotorized
MA-D11 Developed Recreation
MA-D12 Research Natural Areas

Standard and Guideline
Allow no off-road use from December 1 through April 15, including snowmobiles. Use a road closure system (such as the Green Dot System) to protect wildlife habitat, minimize harassment, maintain escapement opportunity, and promote quality hunting.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Restrict off-road use where needed to protect wildlife habitat, minimize harassment of wildlife and to promote quality hunting. Use a system similar to the Green Dot System.

Applicable Management Area
MA-D3 Big Game Summer Range

Standard and Guideline
Discourage off-road use.
Applicable Management Area
MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Where off-road use impacts are evident, close areas to use and rehabilitate.

Applicable Management Area
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground

Standard and Guideline
Motorized use encouraged on designated routes.

Applicable Management Area
MA-D1 General Forest
MA-D10 Semiprimitive Motorized

Management Area Standards and Guidelines
(Grassland Only)

Resource - Transportation System

Practice
Operations and Maintenance

Standard and Guideline
Generally maintain roads for high clearance vehicles. County roads are generally maintained for low clearance vehicles.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Generally maintain roads for low clearance vehicles. However, some roads may be maintained only for high clearance

Applicable Management Area
MA-D1 General Forest

**Standard and Guideline**
Maintain roads for low clearance vehicles.

**Applicable Management Area**
MA-D11 Developed Recreation

---

**Standard and Guideline**
Design and maintain transportation systems needed to support the installation and maintenance of the structures associated with the utility corridors. Normally, close roads to public use.

**Applicable Management Area**
Utility Corridors within all management areas.

---

**Practice**
Traffic Management

**Standard and Guideline**
Transportation within the park boundary is the responsibility of the State.

**Applicable Management Area**
MA-D11 Developed Recreation (Cove Palisades State Park)

---

**Standard and Guideline**
Control access to protect old growth habitat.

**Applicable Management Area**
MA-D4 Old Growth

---

**Standard and Guideline**
Limit open roads to one mile per square mile.

**Applicable Management Area**
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range

---

**Standard and Guideline**
Close Road 6360 seasonally to protect deer winter range. Close all other roads in the management area to public use year-round, allowing only administrative and permittee use.

**Applicable Management Area**
MA-D9 Semiprimitive Nonmotorized (Squaw Creek)
Practice
Off-Road Access

Standard and Guideline
Allow no vehicle use off designated routes, except for administrative use.

MA-D11 Developed Recreation (Haystack)

Water

Forest- and Grassland-Wide Standards and Guidelines

Water Quality

In cooperation with the State of Oregon, the Forest will use the following process:

Select and design BMP's based on site-specific conditions, technical, economic, and institutional feasibility, and the water quality standards for those waters potentially impacted.

Implement and enforce BMP's.

Monitor to ensure that practices are correctly applied as designed.

Monitor to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards.

Evaluate monitoring results and mitigate where necessary to minimize impacts from activities where BMP's do not perform as expected.

Adjust BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level. Evaluate the appropriateness of water quality criteria for reasonably assuring protection of beneficial uses. Consider recommending adjustment of water quality standards.

**Temperature**

The requirements for shade along streams will generally correspond to provisions for more than 80 percent of the surface shaded. Where this can not be attained, 100 percent of the potential for shade is the standard.

Shade requirements may be reduced in cases where management is necessary to sustain a thrifty community of shade providing species over time, e.g., in the case of local infestation or disease, or for managing for future shade in a decadent stand, but activities may not result in an increase in temperatures above the limits specified.

**John Day River System, Silver and Emigrant Creeks, and Associated Tributaries.**

Existing temperatures at or below 66°F may be raised a maximum of 2°F. Where stream temperatures exceed 68°F, management activities will include objectives for reducing temperatures to levels that will improve fish habitat capability.

**Deschutes River, Crooked River, and Associated Tributaries.**

Existing temperatures at or below 56°F may be raised a maximum of 2°F. Where stream temperatures exceed 58°F, management activities will include objectives for reducing temperatures to levels that will improve fish habitat capability.

**Turbidity**

Stream channel cutbanks should not exceed an average of 20 percent for any given stream drainage.

Allow no more than 10 percent cumulative increase in stream turbidity. Short-term deviations (50 years) from this standard to accommodate emergency or other legitimate activities will comply with state requirements for notification and approval.

**Waste Disposal**

Dispose of waste effluents (e.g. sanitary waste, fuels, solvents, and pesticides) in a manner that will prevent contamination of surface or subsurface water.

**Project Planning**

See Forest-wide Standards and Guidelines for TIMBER for direction on equivalent harvest acres (EHA) guidelines.

Plan for no management activities in and around Class III and Class IV streams that contribute to the deterioration of water quality below standards set for downstream Class I and II streams. Protection will be provided primarily through mitigation measures. Some short-term temperature and/or turbidity increases may be allowed, providing the standards for Class I and II streams.
continue to be met. Consider the potential for cumulative impacts. Provide suitable amounts of woody material based on specific characteristics of individual stream courses.

Develop specific objectives for the management of streams through the NEPA process for all projects that could impact water quality.

**Floodplains and Wetlands (including springs and wet meadows).**

Riparian areas are a unique and biologically important system on the Forest. Special attention shall be given to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes, and other bodies of water. This area shall correspond to at least the recognizable area dominated by the riparian vegetation. No management practices causing detrimental changes in water temperature or chemical composition, blockages of water courses, or deposits of sediment which seriously and adversely affect water conditions or fish habitat shall be permitted within these areas. Topography, vegetation type, soil, climatic conditions, management objectives, and other factors shall be considered in determining what management practices may be performed within these areas, or the constraints to be placed upon their performance. (36 CFR 219.27e.)

Give preferential consideration to riparian-dependent resources over other resources in case of unresolvable conflicts.

Consider the presence of, and potential impacts to any inventoried floodplain in project area environmental analysis.

Do not locate major structures, roads, or other facilities within floodplains unless no feasible alternative sites exist outside floodplains.

Allow projects causing short-term impacts on floodplain values only if specific mitigation measures designed to minimize the impacts are documented in the project environmental analysis. Restore natural floodplain characteristics after the activity has ceased.

Discuss the presence of potential impacts to riparian areas in all project-level environmental documents.

**Vegetation and ground cover requirements:**

Where site potential and topographic factors permit, manage riparian areas to provide the shade necessary to meet stream temperature goals.

Maintain upper streambanks in a stable condition along at least 80 percent of the length of a stream.

Retain at least 80 percent of the potential ground cover in grass-forb riparian communities. Also, retain at least 80 percent of the potential tree or shrub cover in riparian areas dominated by trees or shrubs. In riparian areas with mixed layers, the cover requirement may be met by taking credit for the
effective cover provided by all vegetative layers of the riparian community including shrubs, tree understories, and the dominant overstory. Consider the mitigating effect of stream size and orientation, as well as surrounding topography, when determining the amount of cover that may be removed.

Management Area Standards and Guidelines
(Forest and Grassland)

Resource - Water

Practice
Water Quality Improvement Projects

Standard and Guideline
Enhancement of riparian vegetation or other water related resources, is restricted to research purposes, unless authorized by PNW Station Director.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Use of motorized equipment for water improvement projects will be approved by the Regional Forester on a case-by-case basis.

Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
Construction and maintenance for water improvement projects allowed, subject to Forest and Grassland-Wide Standards and Guidelines.

MA-D14 Riparian in Excellent Condition
Wildlife and Fish

Forest- and Grassland-Wide Standards and Guidelines

Planning
Coordinate activities that affect fish or wildlife resources with the Oregon Department of Fish and Wildlife, Columbia River Inter-tribal Council, Bureau of Land Management, and the U.S. Fish & Wildlife Service. The level at which coordination occurs will be based on the magnitude of proposed activities, and the species involved.

Structural improvements to provide water, or otherwise concentrate wildlife (big game) use will not be planned specifically for scablands (See Forest and Grassland-wide Standards and Guidelines, Soils).

Management Indicator Species
Determine if the species’ use of the area is incidental or if it is essential habitat. If it is determined to be essential habitat (roosting sites, for example) protect it from adverse modification through curtailment of conflicting activities, modification of activities, seasonal restriction of activities, or avoiding the area. For bald eagles, request an informal consultation with the Endangered Species Branch of the Fish and Wildlife Service on proposed actions which may adversely affect the species.

For newly discovered essential habitat, conduct environmental analysis under the NEPA process to determine if it is necessary to designate the area as essential habitat. If so, the Forest or Grassland Plans will be amended or supplemented where appropriate, and the essential habitat designation will supersede previous land allocations or can be substituted for other habitat allocated to threatened or sensitive species.

Pileated Woodpecker
Approximately 19,250 acres of old growth, and another 19,250 acres of supplemental feeding habitat have been allocated across the Forest (outside of wilderness and Research Natural Areas) to meet the needs of old growth dependent wildlife, with the pileated woodpecker as the major indicator species.

Another 2,100 acres of old growth within wilderness and Research Natural Areas are considered necessary to meet the distributional needs of the woodpecker, but have not been specifically allocated, due to legal precedence for these areas. Natural processes (natural fire ignitions, etc.) shall continue to occur in these stands and may circumvent management desires to maintain them for wildlife habitat. But, any planned management activities in wilderness and RNA’s (planned ignitions or research) should be done in such a way as to protect the integrity of these areas. See management area standards and guidelines for specific management direction. Also, see locations of old growth stands for habitat (both inside and outside wilderness and Research Natural Areas) on the Alternative I map.
Primary Cavity Excavators

Primary cavity excavators create cavities for themselves and other cavity users. In addition to the ecological diversity provided by these species, they also play an economic role in the forest environment. These species, plus the secondary cavity nesters, consume insects that are destructive to forests. While these birds may not prevent epidemic populations from building, many authors have indicated a suppressive influence on insects at endemic levels. For these reasons, more than a minimum population of the primary excavators is desirable. Effective population levels of these excavators is believed to be above 40 percent of their potential population levels, as compared to a viable population of only 20 percent. See Wildlife Habitats in Managed Forests, the Blue Mountains of Oregon and Washington, Thomas, 1979, for further discussion of management of this specialized habitat.

Provide habitat to support populations of cavity nesters at various levels by management area in order to achieve a Forest-wide objective of 47% of maximum potential over the first decade (see management areas standards and guidelines, Wildlife and Fish).

Snag Distribution

Provide snags within areas that are generally no larger than normal harvest unit size (40 acres). These snags will be maintained through the full rotation on these areas by providing for green replacement trees that will become snags of adequate size when existing snags fall. It is not intended or possible that dead and defective tree habitat be uniformly distributed over every acre. But, do not (arbitrarily) combine areas with high concentrations of dead and defective tree habitat with non-adjacent areas devoid of dead and defective habitat to arrive at a prescribed average number per acre. Plan dead and defective tree habitat by units, such as project planning areas or subdrainages (3,000 to 5,000 acres maximum) where specific management levels can be monitored.

Where adequate snags are not currently available to meet the desired level (40%, etc.), created snags should be used to meet the direction as nearly and as soon as possible.

If snags are not present and cannot be created, higher snag levels can be managed in adjacent areas and averaged with the low levels in deficient areas to meet management objectives. However, averaging should be done over as small an area as possible, and replacement snags should be planned for in the deficient areas to meet the distribution requirements as soon as possible.

In a forested setting (uneven-aged management or mid to late successional stages in even-aged management), either clumped or evenly distributed snags are acceptable.

In early successional stages (grass/forb, seedlings and saplings) of even-aged management areas (i.e. clearcut and overstory removal), it is more desirable to manage snags in patches because

Snag patches can provide foraging as well as nesting habitat;

Snag patches are more likely to support species that won’t nest in the open
than are single, uniformly distributed snags;

It is operationally safer and more efficient to provide snags in patches rather than in single, uniformly distributed patterns, and

Snag patches better provide opportunities for live trees that can become replacement snags throughout the rotation of a stand.

**Golden Eagle and Prairie Falcon**

Carefully evaluate activities having the potential to alter or disturb cliffs, talus, or cave habitats.

**Bald Eagle**

Preserve the integrity of actual and potential bald eagle winter roost sites. Utilize the findings and recommendations of a bald eagle winter roost survey, conducted by the Oregon Cooperative Wildlife Research Unit in 1986 through 1987. See Eagle Management Prescription (Management Area Fl2-Eagle Roosting Areas), and FEIS Chapter 2, Alternatives Including the Proposed Action.

**Rocky Mountain Elk and Mule Deer**

Big game capability models should be used in project planning to determine habitat effectiveness (HE), as affected by quality and quantity of cover and forage, and open road density. Resulting HE values will be compared with those predicted for future outputs, to determine whether or not big game objectives are being met. Specific actions should be taken when project alternatives chosen for implementation are shown to reduce HE values below those predicted over the planning period. See management area standards and guidelines for Wildlife and Fish, this chapter for predicted HE values and specific actions to take. Also see Chapter 5, Implementation of the Forest Plan, for monitoring requirements.

The model used to predict the influence of forest management on elk is a Habitat Effectiveness model. It is a biologically based model that tells us how effective an area will be in supporting elk. The model was designed to measure effectiveness on a scale of 0 to 180, with 180 representing the highest potential effectiveness and 0 representing the least desirable situation for elk. It is intended to be only a relative measure of effectiveness, and does not consider many factors that would influence the actual number of elk found in an area. These additional factors include the effects of hunting, predators, disease, yearly changes in weather and forage production, competition with other animals, and the rate at which elk populations can change from one level to another.

To make the results of the model easier to interpret, the effectiveness index was translated into a number of animals that could be supported on an area. This was done by estimating the density of animals that could be supported on an area if the habitat were maintained at optimum effectiveness. It was then assumed that a habitat effectiveness value of 180 translated to this highest possible density of elk, and that lower values would translate to proportionally lower densities. The numbers shown in Chapter 2 are those numbers of elk that could potentially be supported on the area. The numbers are not projections of actual elk populations. As noted above, many additional factors would have to be considered in
order to project actual elk populations. It is especially important to note that the current elk numbers on an area may not be the direct result of factors that are measured in the habitat effectiveness model. The current population in an area could be limited by the availability of winter range on private land, by hunting pressure, or by any of the other factors discussed above. In this case, habitat effectiveness might decline but have no real influence on the number of elk that occupy the area, or habitat effectiveness might increase but still have no net influence on the number of elk. Because the numbers shown as outputs in Chapter 2 for Wildlife only represent habitat effectiveness, it is important to read the full text in order to understand the effect of forest management on the elk population.

Protect the character of elk calving sites. Minimize disturbance from human activity during calving season (approximately May 15 to June 30). Also protect wallows during rutting season (September 1 to October 15).

Provide forage sufficient to meet management objectives for population levels of Rocky Mountain elk and mule deer.

**Rainbow Trout, Brook Trout, Steelhead**

Provide habitat by managing as per riparian prescriptions (Chapter 2).

**Threatened, Endangered, and Sensitive Plant and Animal Species**

Inventory and protect threatened and endangered species and their habitat(s).

Cooperate with State and Federal fish and wildlife agencies in developing and implementing recovery plans for threatened or endangered species.

Consult with the U.S. Fish and Wildlife Service when conflicts between project activities and habitat needs cannot be resolved, or when uncertainty exists.

Maintain inventories of essential or critical habitats including their locations and distribution.

Maintain contacts with Federal, State, and other agencies, groups, and individuals concerned with the management of threatened, endangered, and sensitive species. Consult with the Oregon Department of Fish and Wildlife, Oregon Natural Heritage Data Base and U.S. Fish and Wildlife Service for technical assistance in developing species management guides and in determining viable population levels.

During environmental analysis of each project activity, available habitat, location records, and other information should be reviewed to determine whether known or suspected locations of sensitive species or their habitat occur.

If no suitable habitat or reported locations of sensitive species are identified, these findings should be documented, and no further investigation is required.

When suitable habitats or reported locations are suspected to occur in the area of influence of the project, a field reconnaissance will be performed to more precisely verify the presence, abundance, and distribution of the sensitive
species. If the search is conducted during a season of the year when positive identification is probable and no listed species are found, this fact should be documented and no further investigation is needed.

If listed species are found in the project influence area, their actual distribution and current status will be determined. Informal consultation with the Endangered Species Branch of the Fish and Wildlife Service will be initiated if the species is Federally listed. If the proposed project would jeopardize the existence of the species it would be modified or curtailed.

Identified safeguards will be clearly spelled out in the environmental analysis and project plan and project personnel will be fully responsible for being aware of and implementing them. Supervision of the activity must assure that actions which jeopardize the listed species do not occur.

If actions which may adversely affect habitat for Federally listed endangered or threatened species cannot be avoided, the activity will be deferred until a formal consultation with the Endangered Species branch of the Fish and Wildlife Service is completed to determine a course of action.

In cases where other high values or uses would be foregone if the proposed activity were modified or deferred, a full investigation of the species involved may be conducted. Management guidelines will be developed that will make possible an assessment of the significance of the specific population involved. Based on these findings and consultation with appropriate state and federal agencies, a course of action will be determined.

Coordinate with the Native Plant Society of Oregon to exchange information on local plant distributions and status.

Other Species

**Antelope**
Manage antelope habitat on the Forest in accordance with Oregon Department of Fish and Wildlife population objectives. Population control necessitated by conflicts will also be dealt with by that agency.

**Raptor Habitat**
Protect active bird of prey nests from human disturbance until nesting, feeding, and fledging are completed. Provide protection of nest sites and nesting habitat sufficient for the species involved.

**Bald and Golden Eagles**
Nesting sites, and roosting sites used in conjunction with nesting sites, will be protected under the “Act for Protection of Bald and Golden Eagles” ref. title 50 CFR, USC 668-668d.

**Nesting**
Eagle nesting territories are divided into primary and secondary management zones.
Primary
The boundary of the primary zone shall not be less than 20 chains from the nest.

Human activities should be controlled during the critical period. The critical period is the time between arrival of adults at the nest site and three weeks after the fledging of any young. The critical period will usually fall between March 1 and August 15.

Secondary
The purpose of this zone is to further minimize disturbance.

The size of the secondary zone will be determined by local topography and resulting visibility from the nest. It shall lie outside the primary zone and be approximately circular with a minimum boundary of 40 chains from the nest.

Human activities into the secondary zone should be restricted during the critical period.

Roosting
Within 1/2 mile (40 chains) of existing nests, save three to five old growth trees for potential roost and perch trees during the breeding season.

Hawks and Owls, Except Prairie Falcons
Nesting
Nesting areas are divided into primary and secondary zones.

Primary
The boundary of the primary zone should not be less than five chains. The management objective for this zone will be to maintain the present habitat characteristics.

The critical period, during which human activities should be restricted, will usually fall between March 1 and August 1.

Secondary
The boundary of the secondary zone should be an additional five chains radius beyond the primary zone (total 10 chain radius). In this secondary zone, modified treatments will be required. "Modified" means intermediate between that required in the primary zone, and that normally prescribed outside of the whole protection zone.

The critical period is the same as for primary zone 'Hawks' above.

Prairie Falcons
Nesting
Nesting areas are divided into primary and secondary zones.

Primary
Size: same as for primary zone Hawks.
Critical period: same as for primary zone Hawks.
Secondary

The boundary of this zone should be an additional 15 chains beyond the primary zone. The management direction for this zone will be a modified treatment between the primary zone, and full treatment beyond the secondary zone.

Critical period: same as for primary zone Hawks.

Species Associated with Dead and Downed Logs
Down dead log requirements for wildlife are expected to be met through attrition of standing snags as they fall. Removal of these logs will not be allowed for other purposes. Wherever possible, two uncharred logs per acre should be left for wildlife habitat. These logs should be at least 12 inches in diameter or greater, and at least 20 feet in length.

Species Associated with Various Plant Communities and Successional Stages
Diversity is to be provided for by maintaining representative portions of all plant associations and having various successional stages represented in an area through time.

Species Associated with Springs, Bogs, and Other Unique Habitat
Seeps, springs, bogs, wet areas, and any other unique habitats, often or generally less than 10 acres in size, will be identified and evaluated on a project level basis and given appropriate protection.

Introduced Species
Evaluate proposals for introducing wildlife (case-by-case) through the National Environmental Policy Act (NEPA) process.

Management Area Standards and Guidelines
(Forest Only)

Resource - Wildlife and Fish

<table>
<thead>
<tr>
<th>Practice</th>
<th>Habitat Management</th>
</tr>
</thead>
</table>

General

Standard and Guideline
Manipulation of habitat to sustain the value of wilderness or to perpetuate a Threatened or Endangered wildlife species may be allowed with approval of the Chief of the Forest Service.
Applicable Management Area
MA-D8 Wilderness

Standard and Guideline
Manipulation of habitat will be allowed only for research purposes, with consent of the PNW Station Director.

Applicable Management Area
MA-D12 Research Natural Areas

Standard and Guideline
Habitat improvement projects are acceptable providing they meet the visual objective.

Applicable Management Area
MA-D9 Semiprimitive Nonmotorized

Standard and Guideline
Habitat improvements that do not dominate the landscape may be implemented.

Applicable Management Area
MA-D5 Retention
MA-D6 Partial Retention - Foreground
MA-D7 Partial Retention - Middleground

Standard and Guideline
Habitat improvements that meet the partial retention visual quality objective are acceptable.

Applicable Management Area
MA-D10 Semiprimitive Motorized

Standard and Guideline
Allow activities that meet the visual quality objectives and do not detract from the recreational value of the area.

Applicable Management Area
MA-D11 Developed Recreation

Standard and Guideline
Construct needed fish and wildlife habitat improvements.
Applicable Management Area
MA-D13 Riparian in Acceptable Condition

Standard and Guideline
Manage habitat for maximum populations of brook, rainbow trout, and steelhead.

Applicable Management Area
MA-D14 Riparian in Excellent Condition

Standard and Guideline
Permit habitat improvements compatible with the primary objectives of the management area.

Applicable Management Area
MA-D1 General Forest
MA-D2 Big Game Winter Range
MA-D3 Big Game Summer Range
MA-D4 Old Growth

Pileated Woodpecker Habitat

Standard and Guideline
300 acres or more is the optimum size stand, but clusters and smaller blocks (50 acre minimum) that are no more than 1/4 mile apart and total 300 acres are acceptable. Within a 1000 acre unit, which includes and surrounds each old growth habitat allocation, maintain a minimum average of two hard snags per acre greater than 10 inches DBH, on an additional 300 acres for feeding.

Standards by forest types are as follows:

Ponderosa Pine

Stands will contain at least 10 mature to overmature trees per acre with ponderosa pine representing 75 percent of the overstory.

Stem size will be 21 inches or greater in the overstory tree layer. Broken topped trees may be present. Overstory canopy closures will seldom exceed 50 percent on poor sites. A minimum of one standing snag per acre with at least 1.5 tons of down material, including three logs per acre will be present.

Mixed Conifer

Stands include both intolerant and tolerant species. The stands should contain at least 15 trees per acre, 21 inches or more in diameter; and two snags with at least three tons of down material, including three logs per acre. Broken-topped trees may be present. Overstory canopy closure will be 70%.
**Applicable Management Area**  
**MA-D4 Old Growth**

---

**Big Game Habitat**

**Standard and Guideline**
Manage to provide high capability for elk and deer use on winter range.

- Manage 50 percent of the total area in thermal cover. Cover types may include mountain mahogany for deer and elk, and juniper for deer but not for elk.
- Maximum distance from cover to any point in a forage area should not exceed 400 feet.
- Treat isolated cover producing lands to produce the best balance of cover over time when the general area inherently has a low cover production potential.
- Limit open roads to two miles per square mile following timber harvest and post-sale activities.

**Applicable Management Area**  
**MA-D2 Big Game Winter Range**

---

**Standard and Guideline**
Manage 40 percent of the area in thermal cover. Thermal cover patches should be 30 to 60 acres each.

- Maximum distance from cover to any point in a forage area should not exceed 600 feet.
- The spacing of thermal patches will be controlled when these patches are isolated by noncover producing lands. Thermal cover patches, when adjacent to each other will not be treated simultaneously if the treatment results in thermal cover spacing greater than 1800 feet.
- When an island of thermal cover is partially treated, the remaining portion will not be scheduled for treatment until the first portion is again in a thermal cover producing condition.
- Forested stands, that have been previously treated in a manner that precludes development of thermal cover will be scheduled for treatment at the earliest possible time to meet cover management objectives.
- Limit motorized access to two miles per square mile following completion of timber harvesting and post-sale activities.

**Applicable Management Area**  
**MA-D3 Big Game Summer Range**
Standard and Guideline
Maintain hiding cover in big game travel corridors.

Applicable Management Area
MA-D5 Retention
MA-D6 Partial Retention - Foreground

Cavity Nester Habitat
Strive to provide snag habitat at the levels shown in Table D-18, while meeting the primary management emphasis for the specific area. The 40 percent level is the lowest level for any management area, except where safety is involved.

* These levels are hard target objectives, even though not specifically required as minimum. Others are anticipated and predicted results of implementation of the primary prescription.

Snag habitat may be provided through either identifiable snag patches, or even distribution. Snag patches (clumping) is the preferred method in most cases.

Snag Patch Method (Clumping)
When using the snag patch method, the acreage and number of the untreated clumps or units will vary according to timber type and acres treated. These areas may be managed on a double rotation, and made available for harvest in the future when adjacent and previously harvested areas are suitable for snag habitat production.
Snag patches should be distributed as evenly as possible, and located (on the average) one per 10 acres. This is necessary to meet the smallest territory size needs of a pair of excavator species.

Permanence of snag patches is more effectively achieved when size of snag patches exceeds one acre. But, it may be necessary to designate patches less than one acre in size in order to meet the territory need stated above, which is the more important habitat need.

Table D-19 shows the size of areas needed to be left for a double rotation based on major species groups and snag level. Areas selected for double rotation should be fully stocked and have a variety of size and tree conditions. In two-story pine types, full stocking may very often not occur. When this is encountered, use the Individual Snag Distribution Method instead.

1/ Assumes 100 years before large snags will be produced
2/ Assumes 120 years before large snags will be produced

For Both Clump and Individual Tree Method

The size of residual stocking and adjacent stand conditions need to be considered to ensure a supply of small snags. If there is a predicted shortage of small snags, then additional trees in the 10 inch plus size class should be left within the managed stand to meet this need.

Species Management

Native animal species will be maintained. Allow no intentional introduction of non-native wildlife species

Applicable Management Area

MA-D8 Wilderness
MA-D12 Research Natural Areas
Management Area Standards and Guidelines
(Grassland Only)

Resource - Wildlife and Fish

Practice
Habitat Management

Big Game

Standard and Guideline
Maintain 75 percent of the area in a natural ecological condition.
Provide 20 to 40 percent cover.
Cover units may vary in size from 10 to 20 acres.
Encourage shrub components within different plant communities and successional stages.

Applicable Management Area
MA-D2 Big Game Winter Range

Standard and Guideline
Maintain a good ecological condition while managing for 15 to 20 percent deer cover.
Cover units may vary from 5 to 20 acres.
Encourage the shrub component within communities and successional stages.
Manage antelope fawning areas to protect their value and character.
Restrict vehicle use in antelope fawning areas from May 15 through June 15.

Applicable Management Area
MA-D3 Big Game Summer Range

Common Flicker

Standard and Guideline
Old Growth Juniper: 40 acres minimum; may be composed of scattered stands as small as five acres in size located no more than 1/8 mile apart. Spacing of old growth units (totaling 40 acres) should be a minimum of two miles and a maximum of five miles apart.
Juniper stands should contain 50 to 150 trees per acre with an average age greater than 150 years. Decadence within the stand is common, at least one juniper snag greater than 12 inch DBH present per acre. Percent crown closure will be low, 10 to 25 percent. The majority of the trees are large with hollow centers.

**Applicable Management Area**
MA-D4 Old Growth

---

**Standard and Guideline**
Manage riparian vegetation to provide cover for upland game birds.

**Applicable Management Area**

MA-D13 Riparian in Acceptable Condition
MA-D14 Riparian in Excellent Condition
Appendix E

Selection of Harvest Cutting Methods
Appendix E

Selection of Harvest Cutting Method

Harvest Cutting Methods

Harvest cutting methods include both even-aged and uneven-aged silvicultural systems (see Figure F-1). Even-aged harvest cutting methods generally include clearcutting, shelterwood cutting and seedtree cutting. Uneven-aged harvest cutting methods generally include individual tree selection and group selection cutting. The intent here is to document the rationale for selection of harvest cutting methods (even-aged or uneven-aged) to be applied on the Forest. The specific harvest treatment methods (such as clearcutting, seedtree cutting or group selection) will be selected on a site specific basis as identified in project level environmental analyses, or in silvicultural prescriptions written or approved by a certified silviculturist. Although even-aged management will generally be favored for reasons given below, this does not preclude the use of some tree or group selection cutting methods where they may be applicable.

Regional Guide Criteria

1. The method must permit the production of a volume of marketable trees sufficient to utilize all trees that meet utilization standards and are designated for harvest.

2. The method must permit use of a logging system which can remove designated trees without excessive damage to the residual stand and while meeting other established land management objectives. Table 3-1 in the Regional Guide displays the compatibility of logging systems with common harvest cutting methods. Generally, ground based logging methods, helicopters, and cable methods using slack pulling carriages are appropriate for all harvest methods, while cable methods without slack pulling carriages and balloons are appropriate only for clearcuts.

3. The harvest method must be capable of providing special conditions that are required to meet resource management objectives. Table 3-2 in the Regional Guide displays commonly used harvest methods which achieve desired forest character. Generally, both even-aged and uneven-aged methods can meet desired forest character with the exception of a mosaic of forest and opening, and maximum wildlife species diversity. Here, uneven-aged methods are not applicable.

4. The method must permit control of vegetation to establish desired numbers and rates of growth of trees as well as other vegetation needed to achieve special management objectives. Tables 3-3 and 3-4 in the Regional Guide outline these harvest cutting methods. Generally, both even-aged and uneven-aged methods can be used in vegetation zones occurring on the Forest, however uneven-aged methods are not applicable for maximum forage production or optimum tree seedling and sapling growth.

5. The method must promote a stand structure and species composition which minimizes serious risk from insects, disease, animal damage and wildfire, and will allow treatment of exist-
Forest stands can be harvested to produce a subsequent stand that is either even-aged or uneven-aged. Even-aged stands are ones in which all the trees are relatively close in age—uneven-aged stands are comprised of trees that are in two or more age classes. To achieve either type of stand certain harvesting methods are generally employed. One of these methods can be used to ensure reproduction of an even-aged stand—clearcutting, seed-tree, or shelterwood. For an uneven-aged stand, only the selection method can be used. Let’s examine the advantages and disadvantages of each of these four methods.

A selection harvest is the removal of mature timber, usually the oldest or largest trees, as single scattered individuals or in small groups. Cutting is done fairly often and is repeated indefinitely to maintain the uneven-aged structure of the stand. Advantages of using a selection cut are that the stand is less susceptible to disease insects and fungi that would attack one species or age/class a continuous forest cover helps protect steep slopes from erosion, and such timber cutting is aesthetically most favorable. On the other hand, the method requires greater skill and more time in marking trees rather than boundaries of a sale area or trees to be left. It is also more costly to return to a stand area and time again for a partial harvest and in doing so is difficult to prevent logging damage to immature trees. Perhaps the biggest drawback of the selection method is that of the four methods, it has the greatest potential for degrading the genetic quality of the stand by eliminating the best trees. With clearcutting, an entire stand is harvested in one cutting and reproduction is obtained either artificially (by planting) or by natural seeding from adjacent stands or trees killed as part of the harvest. Clearcutting is less expensive than the selection method, does no damage to the subsequent stand, and takes less time to mark. However, there is a greater risk of disease and insect attack to the even-aged stand, a clearcut reduces protection from erosion and flooding, and it results in the least attractive appearance of the forest. Most importantly, if reproduction on a clearcut fails, the resource manager may have to resort to planting, which is costly and time consuming.

The seed-tree method is similar to the clearcut except that a few of the best trees on each acre are left singly or in groups to provide a seed source for getting the next stand started. Thus it has the benefits of clearcutting along with a better chance for natural seeding. A disadvantage is that harvesting the seed trees after they have done their job can damage part of the forest they have helped create. And many times the seed trees do not last that long, because they are more subject to the forces of nature when standing alone or nearly so.

In a shelterwood cutting, there is even greater insurance for reproduction as more trees are left to encourage even-aged regeneration in partial shade of the trees that are left.

ing insect, disease and fuel conditions. Table 3-5 in the Regional Guide displays harvest cutting methods favorable to the reduction and treatment of these agents. Generally, uneven-aged methods are not applicable where dwarf mistletoe and root disease present serious risks.

6. The method must meet multiple use management objectives identified in the Regional Guide and Forest Plan.

36 CFR 219.27(b) Criteria
The seven criteria identified in 36 CFR 219.27(b) which direct management prescriptions for the manipulation of tree cover are summarized as follows:

1. Be best suited to multiple use goals, considering biological, environmental, engineering, economics, and other impacts.
2. Assure that lands can be adequately restocked.
3. Not be chosen primarily because of the greatest dollar return or timber output, although these factors should be considered.
4. Consider the potential impacts on residual trees and adjacent stands.
5. Avoid permanent reduction of site productivity and ensure conservation of water and soil.
6. Provide the desired effects to meet special management objectives.
7. Be practical in terms of transportation and harvesting requirements, and total costs of timber sale preparation, logging, and administration.

Combined Criteria for Harvest Cutting Method
The criteria identified in the Regional Guide and in 36 CFR 219.27(b) were subsequently combined to eliminate duplication of intent and simplify the rationale for selecting the harvest cutting methods used to implement the Forest Plan. The seven criteria combined are summarized as follows:

1. The method must produce a volume of marketable trees that meet utilization standards and are designated for harvest. (Regional Guide: criteria 1.)
2. It must use available and acceptable logging systems. (Regional Guide: criteria 2, 36 CFR 219.27(b): criteria 4.)
3. It must be capable of meeting special management and multiple use objectives. (Regional Guide: criteria 3 and 6; 36 CFR: criteria 1 and 6.)
4. The method must permit control of vegetation to establish desired species composition, density, and rates of growth (Regional Guide: criteria 4; 36 CFR: criteria 4 and 6.)
5. It must promote a stand structure and species composition which minimizes risks from insects, disease and wildfire. (Regional Guide: criteria 5.)
6. The method must assure that lands can be adequately restocked (36 CFR: criteria 2.)
7. It must be practical and economical in terms of transportation, harvesting, preparation and administration of timber sales. (36 CFR: criteria 7.)

Forest Types and Management Areas
Both even-aged and uneven-aged harvest cutting methods are acceptable and were evaluated for selection within the two major Forest types and management areas where timber harvesting is scheduled. Management areas were grouped based on rationale for selecting the harvest system. Groups with similar rationale are summarized as follows:

<table>

Rational for Determining Harvest Cutting Method

The following analysis documents rationale for determining the harvest cutting method within each forest type (ponderosa pine and mixed conifer) and management group based on those combined criteria which have a significant effect on the method selected.

Ponderosa Pine Forest Types

Ponderosa Pine/General Forest
Lands within this management area will be managed for both timber and forage production. Thermal and/or hiding cover for big game will be provided on at least ten percent of the area that is in winter range. Satisfactory tree growth rates should be maintained and stands should be protected from insects, disease and damaging agents. Both even-aged and uneven-aged methods are biologically acceptable (Barrett, 1979; Burns, 1983). Even-aged methods generally provide enhanced forage production and maximize wildlife species diversity (combined criteria 3). Even-aged methods generally provide for enhanced seedling and sapling growth rates because of the significant effect of mature or larger trees on height and diameter growth of the understory (Barrett, 1979) (combined criteria 4). Clearcutting or shelterwood cutting with planting allows the introduction of genetically improved stock. Where dwarf mistletoe and root disease are present, uneven-aged methods are not applicable (combined criteria 5). Even-aged methods are more economical and practical in terms of transportation, harvesting, preparation and administration (Barrett, 1979; Burns, 1983) (combined criteria 7). Uneven-aged stands are generally more aesthetic and are best suited for the production of high quality trees and provide better distribution of snags (combined criteria 3). With uneven-aged systems thrifty (fast growing) black-bark pines and more thrifty old growth can be retained to supply a more continuous supply of large pine. Within this working group, periodic use of prescribed burning reduces fuel accumulations and eliminates undesirable competitive vegetation (Burns, 1983). Even-aged methods are more compatible with this treatment, but with care and proper timing prescribed burning can be done in uneven-aged stands.

Ponderosa Pine/Big Game
Vegetation will be managed to provide optimum habitat for deer and elk. Special conditions required to meet the resource management objectives include providing thermal cover over 20 percent of the area as well as a vigorous forage base. Prescribed burning is recommended for site preparation and

1The management prescriptions contained in Appendix D provide more specific direction.
forage enhancement. Although both even-aged and uneven-aged harvest cutting methods are biologically acceptable, even-aged methods can best provide for the special conditions (cover) within this management area (combined criteria 3). Uneven-aged methods are generally not applicable where the desired character is a mosaic of dense forest, 30 to 60 acres in size, and openings of similar size. In addition, the transportation system and entry frequency necessary for management of uneven-aged stands results in more big game harassment.

**Ponderosa Pine/Riparian**
Vegetation will be managed to provide streambank stability, stream shading, and a supply of large woody debris. Timber production and economic returns is a secondary consideration. Both even-aged and uneven-aged methods can provide these conditions (combined criteria 3). Either harvesting method may be used based on specific site and stand characteristics, as documented in the project level environmental analysis.

**Ponderosa Pine/Recreation and Other**
Ponderosa pine managed in these areas will maintain visual diversity through variations of stand densities and size classes. Large, old growth trees will provide an important stand component. Both even-aged and uneven-aged methods are biologically appropriate and can provide for the visual variety and maintenance of a large tree component. Here, the special conditions required to meet management objectives take precedence over economic considerations or timber volume production (combined criteria 3). Tree growth rates should be sufficient to produce the characteristic large tree component within the rotation age and maintain trees in a healthy condition (combined criteria 4). In addition, trees should be managed to minimize risks from insects, disease and wildfire (combined criteria 5). Either even-aged or uneven-aged harvest cutting methods may be selected here. The ultimate selection should be based on specific site and stand characteristics as documented in project level environmental analyses.

**Ponderosa Pine/Visual Corridors**
Management requirements are similar to Developed Recreation but with more emphasis on open park-like stands of ponderosa pine. Either even-aged or uneven-aged management could be used but even-aged management with extended rotations can best meet the size requirements (combined criteria 4) and the park-like condition (combined criteria 3).

**Mixed Conifer Forest Types**

**Mixed Conifer/General Forest**
Lands within this management area will be managed for both timber and forage production. Thermal cover for big game will be provided on at least ten percent of the area that is in winter range. Satisfactory growth rates should be maintained and stands should be protected from insects, disease and damaging agents. Species composition in this working group should be controlled to produce trees which can maintain satisfactory growth rates and resistance to insects, disease and damage (Schmitt, 1984). Both even-aged and uneven-aged methods are biologically acceptable here. The selection decision is weighted heavily by successional trends and upon the relative shade tolerance of species present within the mixed conifer working group (Burns, 1983; Minore, 1979). Here, shade intolerant species, including ponderosa pine and western larch, are more desirable and better meet management objectives for growth and resistance to insects, disease, and damage. Even-aged management is most desirable to convert over-mature, old growth stands to vigorous stands of shade intolerant species (Burns, 1983) (combined criteria 4 and 5). Also, on the Ochoco National Forest, mixed conifer stands frequently occur on slopes greater than 30 percent where acceptable logging systems and fuels treatment favor even-aged methods (combined criteria 2). These methods are generally more practical and economical in terms of transportation, harvesting, preparation and administration of timber sales (combined criteria 7). Even-aged methods will generally be selected for mixed conifer/timber, but uneven-aged may be used where thrifty, disease free, multi-age stands occur with acceptable species mix.
Mixed Conifer/Big Game
The objective in this management area is to maintain 40 percent cover in stands 30 to 60 acres in size. This can be met with minor modifications to the Timber-Range prescription (see the Forest Plan, Management Prescriptions). Even-aged management is the only system that will provide the cover requirements in the size of area needed to meet the management objectives. Even-aged is selected for this reason (combined criteria 3). Other reasons as discussed in Timber-Range above also apply.

Mixed Conifer/Riparian
Vegetation here will be managed to provide stream-bank stability, stream shading, and a supply of large woody debris. Timber production and economic returns are secondary considerations. Both even-aged and uneven-aged methods can provide these conditions (combined criteria 3). Either harvesting method may be used based on specific site and stand characteristics as documented in project level environmental analyses. When uneven-aged is selected, it will be by group selection method rather individual selection.

Mixed Conifer/Recreation and Other, and Visual Corridors
Mixed conifer stands managed in this area will provide a variety of species, snags and size classes. Large, old-growth trees will provide an important stand component. Both even-aged and uneven-aged harvest cutting methods are biologically applicable and can provide for the visual variety and maintenance of the large tree component. Here, the special conditions required to meet visual management objectives are the primary consideration (combined criteria 3). While economic returns and timber volume production are also important, they play a secondary role in this management area. Tree growth rates should be sufficient to produce the characteristic large tree component and maintain trees in a healthy condition (combined criteria 4). In addition, trees should be managed to minimize risks from insects, disease and wildfire (combined criteria 5). Either even-aged or uneven-aged methods may be selected here. Uneven-aged methods may require artificial regeneration to maintain the appropriate species composition and may be restricted to sites where acceptable logging methods can be applied (combined criteria 2). Uneven-aged methods are not applicable where insect or disease conditions cannot maintain stands relatively free of risk (combined criteria 5). Where even-aged management is used it will use small patch cuts, and where uneven-aged management is used it will be group selection. The ultimate selection should be based on specific stand and site characteristics as documented in project level environmental analyses.

Literature Cited or Reviewed
The evaluation of harvest cutting methods is based on operational experience and research findings published in the following documents:

Appendix F

Management Requirements
Appendix F

Analysis of Management Requirements

This appendix presents information responding to decisions of the Chief of the Forest Service and the Deputy Assistant Secretary of Agriculture regarding Appeal Number 1770, brought by the Northwest Forest Resource Council on September 18, 1986. The appeal centered on direction from the Regional Forester to incorporate management requirements (MR's) into Forest Plan alternatives.

The appellant requested that the appropriateness of the management requirements be examined through the environmental impact statement process. This analysis is intended to address the issue raised by the appellant. In the analysis, alternate ways of meeting the management requirements are examined and certain opportunity costs (losses in economic efficiency and timber available for harvest) are considered.

Background

What are Management Requirements?

Many laws and regulations guide Forest Service activities. One law in particular, the National Forest Management Act of 1976 (NFMA), and its implementing regulations, provides direction for the forest planning process. The regulations for National Forest System Land and Resource Management Planning, in Section 36 of the Code of Federal Regulations, Part 219 (36 CFR 219) specify: 1) the minimum specific management requirements to be met in accomplishing the goals and objectives of the National Forest System (36 CFR 219.27) and 2) the minimum requirements for integrating individual forest resource planning into the forest plan (36 CFR 219.14 through 219.26). The term “management requirement” will be used in this appendix to refer to these NFMA regulations. Previously, the term “minimum management requirements” or “MMR’s” was applied. The regulations do not use either of these terms and their use is discontinued thereafter.

Some requirements are procedural and need not be dealt with here. Some were analyzed and available for public review during the Regional Guide Environmental Impact Statement process and are also not dealt with here. The primary management requirements applying to the Ochoco National Forest are summarized in Table F-1. The management requirements treated in this supplement that required additional analysis are: size and dispersion of created openings, providing adequate habitat to maintain viable populations of existing native vertebrate species and water quality. Each of these is discussed in more detail later in this appendix. Additional information on management requirements and process may be found in Appendix B.

Legal Requirements vs. Implementing Methods (Ends vs. Means)

The management requirements from the planning regulations (36 CFR 219.27) are legal requirements, and as such are ends that must be achieved on-the-ground when the forest plan is implemented. For example, NFMA implementing regulations require that fish and wildlife habitat be managed to maintain viable populations of existing native vertebrate species and desired non-native vertebrate species in the planning area. Whatever implementation methods are chosen, this—and all other management requirements—must, by law, be met.

</table>
Specifications or standards for achievement for each management requirement are established at the national level or through analysis at the regional level for most of the management requirements. These are listed in the regulations or as standards and guidelines in the Regional Guide. Additional specifications identified on the Forest are listed as standards and guidelines in the Final Environmental Impact Statement (FEIS) Appendix D. The specifications must be based on knowledge of the resources involved. For example, in meeting the management requirements for viable populations of vertebrate species, it is necessary to define the type of habitat required by the species, the maximum distance between habitats which will still provide reasonable assurance of genetic interaction, and the size of habitat area needed to support a breeding pair.

Often, the pool of scientific knowledge is insufficient to provide the entire basis for defining the specific conditions or standards that will satisfy or meet a management requirement. When this happens it is necessary to rely on field experience and the professional judgment of knowledgeable professionals, and to establish monitoring and research that will provide better information for future planning efforts.

Implementation methods are the means or ways of meeting the ends (management requirements). Using the pileated woodpecker as an example, the end is to provide adequate habitat to maintain a viable population of pileated woodpeckers into the foreseeable future. The means of providing this habitat involves designing and implementing a set of practices that will assure that nesting and feeding areas meeting the needs of pileated woodpeckers are available in the future, and that these habitats are located closely enough together to allow woodpeckers occupying adjacent habitat areas the opportunity to interact, thus assuring continued genetic diversity and continued viability of the species.

Unfortunately, the distinction between ends and means is not always clear. For example, the requirement regarding viable populations of vertebrate species, stated above, is well defined. In contrast, the size and dispersion of created openings management requirement (end) is rather general: NFMA specifies that maximum size limits for areas to be cut in one harvest operation be established for areas to be clearcut (Sec. 6(g)(3)(F)(iv)), but does not specifically state the objective (end) to be accomplished by doing so. Nonetheless, the implementing regulations and the Regional Guide have specified maximum unit sizes and dispersion requirements.

### How Implementation Methods for Management Requirements are Developed

Often there is more than one way of achieving a management requirement. Considering and analyzing different means (or ways) of meeting a specific management requirement are particularly important if there are potentially large opportunity costs involved.
A six-step process was used for identifying alternative ways and means of meeting management requirements. The steps used are as follows:

1. Identify the desired “end” for each management requirement.
2. Assemble information about the resources affected by each management requirement.
3. Analyze the existing information to determine what conditions or specifications need to exist on-the-ground (specifications) to assure that the management requirement would be met.
4. Develop the ways, means, or methods to achieve the desired conditions. Usually, conditions were simulated using the FORPLAN model.
5. Evaluate the effectiveness of the alternative ways, means, or methods in meeting the management requirement. The opportunity costs, that is, the effect on both economic efficiency as measured by present net value (PNV) and timber availability as measured by allowable sale quantity (ASQ), were analyzed for each alternative way or means.

6. If the opportunity costs of meeting a management requirement with the most efficient means were found to affect the PNV or ASQ of a maximum present net value benchmark by two percent or more, the process used to determine the optimum means was analyzed further and is presented in this appendix. Two percent was used because differences less than two percent would not be significant in terms of the opportunity costs of the alternatives.

- Meet Clean Water Act Standards |
and the alternative means analyzed for opportunity costs on the Ochoco National Forest. Table F-2 also displays the management requirements analyzed for opportunity costs and a summary of the specifications or standards used to measure the achievement of those ends. Complete specifications are noted in the FEIS.

In analyzing the effects that alternative ways of meeting the management requirements had on PNV and ASQ, FORPLAN runs were made with and without constraints designed to simulate meeting the management requirement. A run that portrays the mix of management activities that would result in the highest level of economic efficiency (PNV) in managing the Ochoco National Forest resources (run #3 of the benchmark run sequence, 1920, 5/17/83) was used for this analysis. This benchmark contains no management requirements, therefore, inserting one management requirement at a time would likely result in higher opportunity costs than if the same analysis was conducted in a fully developed benchmark or alternative. It also identifies the ASQ associated with the most economically-efficient mix of management activities and the maximum opportunity costs. A benchmark rather than an issue-based Forest Plan alternative was used for the comparison because management practices used to meet other objectives of an issue-based alternative might have partially or fully met the management requirement, thus clouding any analysis of opportunity costs induced by the management requirement. The true effect when measured against a fully developed alternative is significantly less because the objectives of that alternative may satisfy the management requirements to a large extent.

Results of this analysis are displayed in Table F-3,

1\ These effects represent the maximum potential impact since the efficiency of methods meeting more than one MR, or other resource objectives for an alternative were not considered. The potential effects of MR's are displayed as if they were additive, although there may be overlap.

2\ PNV figures taken directly from FORPLAN reports and are not fully comparable to PNV's displayed elsewhere in DEIS. For comparison purposes here, however, the figures are applicable.
including the PNV and the first-decade ASQ for a maximum PNV benchmark as shown in the FEIS (Appendix B, Table B-6-1, pg. B-92), the reduction in PNV and ASQ resulting from application of the selected means of meeting the management requirements, and the percent change in ASQ and PNV.

Where the opportunity costs exceeded two percent, the analysis of the alternative means for meeting management requirements is presented in subsequent discussion. The following sections present an analysis of the management requirements where alternative ways of meeting that requirement were considered.

Significant Management Requirements

Management Requirements for the Size and Dispersion of Created Openings

Source of the Management Requirement

Direction for the size and dispersion of created openings comes from the National Forest Management Act (NFMA)(Section 6 (g)(3)(F)), the planning regulations (36 CFR 219.27(d), and the Regional Guide (pp. 3-7 and 3-8).

Specifications for the Management Requirement

The specifications or standards for achievement of the size and dispersion of created openings management requirement have been published in the 1984 "Regional Guide for the Pacific Northwest Region" and are as follows:

1. A harvested area will no longer be considered a created opening for silvicultural purposes when stocking surveys carried out in accordance with Regional instructions indicate that prescribed tree stocking is at least 4 1/2 feet high and free to grow.

2. The maximum size limit of harvest openings on the Ochoco National Forest is 40 acres. Some exceptions may be permitted in specific situations.

3. Harvested openings will be separated by blocks of land that are adequately stocked with trees that are at least 4 1/2 feet high and that contain one or more logical harvest units of similar size.

4. Harvested openings that touch each other are not precluded, but will be considered a single opening in determining harvest area maximum size limits.

5. Harvested openings contiguous to 30-acre or larger natural openings are subject to the 40 acre maximum size limit, but normally should not exceed one-third the size of the natural opening and not occupy more than one-third of the natural opening perimeter.

6. Harvested openings should not be created adjacent to any natural openings (regardless of size) unless adequate vegetation along the edge of the natural opening can be developed or retained in sufficient density to protect wildlife and meet visual management objectives.

Alternative Ways of Meeting the Management Requirement For the Size and Dispersion of Created Openings.

As required in the planning regulations (36 CFR 219), standards were developed in the Regional Guide for controlling the size and dispersion of created openings. The Regional Guide allows some flexibility in applying these standards by permitting exceptions to the maximum opening sizes. These however are exceptions and not relief from the standards themselves. That is, these exceptions may be considered when deciding how the standards should be reflected in the planning process, not if the standards should be reflected.
Original Regional direction relating to the size and dispersion of created openings did not focus on how the various Forests should interpret the requirements, but instead repeated the dispersion requirements of the Regional Guide, recommended computer modeling techniques, and established documentation and review procedures. The responsibility for determining how to meet the dispersion requirements was deferred to the Forests.

The Region's initial effort in addressing this management requirement focused on how to develop a dispersion factor to be applied in FORPLAN to represent the limitation on harvest location that the dispersion requirement imposes. This factor was intended to represent the percentage of lands that could be assigned to a regeneration timber harvest prescription creating an opening in a single FORPLAN period. A recommended process was developed for Forests to use if they chose, or for Forests to use as a check on any other process they thought would serve the same purpose. The recommended process consisted of developing a theoretical dispersion factor based on specific Forest conditions, and then testing this factor on sample areas of the Forest to verify or adjust it.

This testing was designed to recognize the limitations of the theoretical factor. First, the theoretical factor assumed that the area to be harvested was homogeneous, when in fact most acres outside roadless areas already have existing harvest patterns that affect the flexibility to lay out harvest units. Second, the theoretical factor assumed that all harvest units were the same size, when in fact the size of logical harvest units necessary to separate created openings does not have to be the same size. Therefore, Forests were advised to examine their own situations to determine if the theoretical results could be applied to a sample area for the first harvest period. If harvesting up to the theoretical percentage was difficult, they were to look for possible reasons why, and adjust the dispersion factor accordingly.

Once an appropriate factor was determined to ensure compliance with the requirements for the size and dispersion of created openings, a corresponding constraint in FORPLAN was applied as a maximum percentage of the acres allocated to a timber harvest prescription that could be final harvested by period in an analysis area.

The requirement specifications were incorporated into the Ochoco FORPLAN model. The theoretical dispersion factor was developed and validated by extensive mapping (1920 5/31/84) and the factor was evaluated by the Forest interdisciplinary team. This analysis indicated that a 33 percent limit on regeneration harvest by analysis area was appropriate.

An assumption was made in the model that it takes twice as long for an area left to natural regeneration to grow out of the opening stage than it does for an area that is planted. This was portrayed by modeling created opening regeneration rates and allowing the linear program to select from various management intensities using either planting or natural regeneration to most efficiently meet the minimum requirement.

Because many of the Forest's issues and concerns, as well as costs and values, revolve around harvest scheduling, another option was considered. It used a different modeling approach where alternative harvest schedules would be determined prior to running the model and averaged over time to reflect harvest dispersion, and input to the model. This scheme for modeling dispersion was eventually dropped because only a few of the hundreds of potential schedules available for an analysis area could be represented with this approach, thus unnecessarily limiting PNV.

Evaluation of Implementing Methods to Meet the Size and Dispersion of Created Openings Management Requirement

Opportunity Costs and Consequences of Methods (Ways and Means)

The opportunity costs associated with achieving the requirement of limiting the size and dispersion of created openings has only a minor effects on the
allowable sale quantity (Table F-3, Pg. F-7), but does affect the PNV by 3.3 percent. Alternative practices for implementation such as regeneration methods, which can affect the rate or time it takes to recover, were analyzed and employed in the modeling. An assumption was made that natural regeneration takes approximately twice as long to establish a 4 1/2 foot tall stand of trees in created openings as would planting. This assumption is reflected in the opportunity cost in the PNV. The potential alternative means of a priority harvest schedule development, and adjustment of dispersion factors, were determined to be impractical solutions to satisfy the requirement. In reality, the costs of this management requirement are masked by the method employed to meet the water quality minimum requirement which is similar in application, but more stringent. The opportunity costs reflect the regeneration methods chosen.

Rationale for Selected Method
The means to achieve the requirement were selected through processes developed by specialists at the regional and forest level, and reviewed by the interdisciplinary teams. The 33 percent factor developed was determined to have the least effect on efficiency and harvest scheduling while still meeting the intent of the management requirement. To assist rapid recovery of created openings, artificial regeneration is chosen as the primary means. The model does have the potential to select natural regeneration where it is more efficient. Artificial regeneration adds to the cost of stand establishment, thus decreasing the PNV. It does, however, provide more flexibility in scheduling and a potential positive effect on the ASQ.

The Wallowa-Whitman National Forest assessed the option of a longer time period for trees to attain the 4 1/2 foot height requirement for a stand to convert from an opening to a forested area. This option was not analyzed on the Ochoco National Forest because it was felt that the 4 1/2 foot standard is still the real means to the end. The longer time frame option did not present a real alternative means. A true alternative would have been to alter the height requirement. This was not done because of the Regional direction to use the 4 1/2 foot standard.

Implications for Forest Plan Alternatives
The alternatives and benchmarks considered in the FEIS have no direct opportunity costs associated with meeting the size and dispersion of created openings management requirement. This is because the means used to meet the water quality management requirement are more restrictive than those for the size and dispersion of created openings. In the context of an alternative, if the requirement for water quality was abolished, the opportunity cost for the size and dispersion of created openings would be less than displayed in Table F-3. The opportunity costs displayed, as discussed above, reflect regeneration methods. All alternative means incorporate the management requirement for the size and dispersion of created openings.

Role of Monitoring and Research
The size and dispersion of created openings requirement will be monitored to determine whether actual outputs are consistent with those projected by the FORPLAN model. The actual time required for new stands to reach 4 1/2 feet in height will be monitored for both natural and artificially regenerated stands. This is important in testing the appropriateness of the selected modeling assumptions.

Management Requirements for Providing Adequate Habitat to Maintain Viable Populations of Existing Native Vertebrate Species

Source of the Management Requirement
The planning regulations state:

"Fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area. For planning purposes, a viable population shall be regarded as one which has the estimated numbers and distribution of reproductive individuals to insure continued existence in the planning area. In order to insure that viable populations will be main-
tained, habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area” (36 CFR 219.19).

Description of the Management Requirement

In assessing those wildlife species that could be put at risk as a result of future management activities, the types of habitat existing today and how they would change in the future were examined. Through this review, it was determined that most types of habitat existing on the Forest today would continue to exist in similar quantities in the future. The significant exception to this was the old growth/mature forest habitat type. Unless management activities were specifically designed to retain a component of old growth and mature forest, it was apparent that wildlife species dependent on this habitat could experience significant reductions in their population sizes and distribution.

Management requirements also exist for primary cavity excavators, bald eagles, and peregrine falcons, but there are no measurable opportunity costs associated with providing adequate habitat to maintain viable populations on the Ochoco National Forest. Consequently, they were not analyzed here.

There are approximately 100 wildlife species on the Ochoco National Forest that use old growth or mature forests to some extent. In this analysis, pileated woodpecker requirements were used because they

1/ The species listed were selected as management indicators because they are representative of all species requiring the identified habitats

2/ The Ochoco National Forest has little habitat for Marten or Northern 3-toed Woodpeckers (or the species they represent). Consequently, the Regional Forester in September 1984, agreed that the pileated woodpecker would serve as the sole indicator species for old growth species on the Ochoco.
best represent other species dependent on old growth or mature forest habitats occurring on the Ochoco. That is, by managing and monitoring in a way that will ensure the woodpeckers viability, it is believed that the other species with similar habitat requirements will be protected. Habitats descriptions were based on broad seral stages of groups of plant communities from Kuchler’s vegetation classification system. For example, the pileated woodpecker habitat represents mature and old growth timber across 12 different plant communities.

Identification of management requirement species was made on a Regional (all the National Forests in Oregon and Washington) and a subregional basis. The results, by subregion, are shown in Table F-4. The Ochoco National Forest is a part of the Blue Mountain subregion. The Regional Forester made an exception to management requirement species for the Ochoco National Forest in September 1984. In Table F-4, Pileated Woodpecker, marten and the Northern Three-toed Woodpecker would all be indicator species for the Blue Mountain subregion forests. The Ochoco however has very little habitat for marten and the Northern Three-toed Woodpecker. Because of the insignificant amount of habitat for these two species, and hence associated species, and the impracticability of managing this small area forest wide, the pileated woodpecker was selected to represent the old growth dependent species across the Forest.

Once the management requirement species were identified, the Region defined habitat requirements and biological characteristics for the species. These are the basis for providing for species habitat, and also for deciding how best to represent the species’ needs in the planning process and in the FORPLAN model. Habitat needs were defined using information from Wildlife Habitats in Managed Forests: The Blue Mountains of Oregon and Washington, Thomas, J. W., 1979 and other resources (see bibliography for this appendix). This information was used to define the habitat conditions, habitat dispersal, and habitat sizes necessary to meet the management requirement. When information was available, but did not exactly fit the management requirement context, professional judgment was used to apply the information in estimating habitat needs. When information was not available, habitat needs were developed from the professional judgment of a number of the more knowledgeable biologists on the subject. Information from existing research was used whenever possible.

This information for each species was provided for three habitat factors described below and presented specifically thereafter for each indicator species.

(1) Principal Habitats Used

Information about the seral stages and Kuchler vegetation types used by the various species is documented in many research papers for individual species. Information as to which Kuchler type and/or seral stage are primary or secondary habitat, and the amount of dependency upon each habitat, is based mostly on professional judgment. (Guenther and Kucera, 1978, Phillips, et al, 1981.)

(2) Dispersal Distance Between Habitats

Research information is generally not available for optimum dispersal distance between habitats. As a result, dispersal distance is based on observations, experience, and professional judgment. Dispersal distance is determined by the ability of an individual species to travel to the next habitat with a frequency to prevent isolation of subpopulations. Distances are adjusted to consider the network and overlap of habitat formed by the species (e.g., pileated woodpecker and marten).

(3) Size of Habitat Areas

The size of individual habitat areas provided for each wildlife species is based on the habitat acreage needed to support the basic social or reproductive unit of the species, in this case breeding pairs. Both home range and species density information are used to estimate the needed size of habitat area. Again, professional judgement is used where data is not available for the specific habitat types being managed.

The specific Regional direction for the identified indicator species and the scientific source of that direction are discussed in the following section. This direction is summarized from “A Report on Mini-
Pileated Woodpecker

Principal Habitats Used
Pileated woodpeckers represent species that need mature or old growth stands of timber for nesting and feeding. Habitats were identified in Bull and Meslow (1977), Guenther, et al. (1978), and Thomas (1979).

Dispersal Distance Between Habitats
The initial five-mile maximum dispersal distance between habitats was the result of professional judgment as documented in Phillips and Roberts (1985). In June 1986, the distance between habitats was changed to one habitat for every 12,000 to 13,000 acres to allow greater flexibility in application.

Irwin (1987) has pointed out the distance could probably be greater, but given the uncertainty of information on the subject, the Forest Service has chosen (in the judgement of professional biologists)

Dispersal Distance Between Habitats
One habitat area for every 12,000 to 13,000 acres

Size of Area to Which Wildlife Prescriptions Apply
600 acres per pair

Habitat Requirements To Be Used in Analyses (Within a 1,000 acre unit)
- Maintain 300 acres of conifers in seral stages VI and/or V, per pair for reproducing
- Maintain a minimum average of 2 hard snags per acre greater than or equal to 12 inches DBH, within the 300 acre reproductive area. Forty-two of these 600 snags should be greater than or equal to 20 inches DBH
- When possible, maintain reproductive area in 300 contiguous acres. If not possible, habitat may be arranged in blocks no less than 50 acres and no more than 1/4 mile apart
- Maintain a minimum average of 2 hard snags per acre greater than or equal to 10 inches DBH, or an additional 300 acres for feeding
to maintain the June 1986 spacing. The original alternative of five-mile maximum distance was not used in the Final.

**Size of Habitat Areas**

The size of nesting areas in Region 6 for the pileated woodpecker has been identified as falling in the range of 100 to 540 acres. The Region defined 300 acres of old growth or mature timber as nesting area, plus 300 acres of feeding area as a Region-wide requirement to meet the needs of pileated woodpeckers both east and west of the Cascades. Three hundred acres of nesting area appears to be an average for different habitats. As more data, specific to westside and eastside habitats (eastside may be further subdivided), becomes available, the size of the nesting area may be adjusted (Bull and Meslow, 1977, Bull, 1975; Mannan, 1982). A 1,000-acre unit was established as the size of territory that a pair of woodpeckers would defend as determined from research data. Snag size and density were taken from Thomas (1979), and acreage figures from Bull (1975), and Bull and Meslow (1977). Habitat specifications for the pileated woodpecker are summarized in Table F-5.

**Alternative Ways of Meeting the Management Requirement for Providing Adequate Habitat to Maintain Viable Populations of Existing Native Vertebrate Species**

The Region provided the following direction (filing designation 1920, November 10, 1983) for determining requirements for old growth: (1) distribute habitat in a way that minimizes impacts on the commercial forest land base while still achieving the necessary distributional needs of the species, and (2) conduct analysis to determine whether set asides (“dedicated” approach) or long rotations (“managed” approach) would minimize effects for the species.

The Ochoco National Forest constructed maps of alternative levels of old growth habitat needed to provide habitat following recent revision of Regional direction (filing designation 1920, April 16, 1984). The distributional needs of the pileated woodpecker limit the flexibility in applying the requirements in a manner that minimizes the impact on the timber land base. However, by considering habitat provided in wilderness, research natural areas, and in other allocations with less intensive timber management and reduced yields, impacts to the timber base may be reduced.

Application of the Regional direction for size and dispersal of habitats to the Ochoco National Forest requires that a minimum of 18,000 acres of old growth forest, outside of wilderness or other lands not suitable for timber production, be retained as wildlife habitat for the pileated woodpecker and other species occupying the same habitat.

Another aspect related to dedicated areas is introduced here, the relationship of other non-dedicated areas such as riparian corridors and others that provide “connective habitat” or travel lanes likely to be utilized by species traveling between existing areas of old growth.

In the FEIS the Ochoco National Forest elected to provide old growth habitat by dedicating areas through the allocation of lands to a management area for old growth. Two other ways of meeting the management requirement were considered prior to selecting this strategy: (1) managed old growth on a 240-year rotation, and (2) managed old growth on a 320 years rotation.

Under a dedicated old growth strategy, each acre of old growth is withdrawn from timber production. Dedication of existing old growth stands assures that desired structural characteristics will be available for wildlife, but risks the loss of individual stands through catastrophe or decay. However, more recent research suggests that such risk is much less than once thought. Management of old growth on a long rotation may not provide all the characteristics important to old growth and may hasten the decline of the residual stand (Franklin, 1981). In managed old growth strategies it is assumed that existing old growth stands will be harvested and that other stands will grow into an old growth condition to replace them. Failure of the replacement stands to develop desired structural characteristics on schedule would
mean that old growth would be lost for a period of
time or that harvesting of existing old growth stands
would be delayed.

Under a managed old growth approach, harvest
would be delayed on existing old growth stands
reserved for wildlife habitat, and harvest would be
prohibited on additional replacement stands. De-
pending on the rotation age (240 or 320 years),
harvest would be restricted on an additional two to
three stands. If a long-term replacement stand was
also provided, harvest would be restricted on two ad-
ditional stands.

Requirements for Providing
Adequate Habitat to Maintain Viable
Populations of Existing Native
Vertebrate Species

Opportunity Costs

Table F-6 displays the opportunity costs associated
with the three ways of meeting the management
requirement. The cost of the feeding area require-
ment has been determined to be insignificant (0.2
percent), and is not discussed further. Present net
value for the managed old growth methods is not
displayed since opportunity costs were calculated by
means other than the FORPLAN model.

NE = Not estimated ASQ opportunity costs were estimated outside of FORPLAN, and no PNV estimate was produced. Since a larger number of acres are affected when "managing" for old growth, PNV opportunity costs would likely be larger, particularly when managing for immediate and long-term replacement.

MMCF/yr = Millions of cubic feet per year
MM$ = Millions of dollars

1/ Percent change calculated on cubic foot basis
Consequences of Methods (Ways and Means)
Populations of pileated woodpeckers and other old growth forest-dependent species would not be expected to differ significantly under any of the different ways considered to meet the management requirement. There are, however, differences in the opportunity costs, as previously stated.

Rationale for the Selected Method
Based on the preceding analysis, it was determined that the dedicated old growth approach would best ensure achieving desired old growth/mature forest habitat, while having the least effect on outputs of other resources. The technology of managing stands on long-term rotations to provide old growth conditions is theoretically possible but has not been demonstrated through actual management. The dedicated approach to old growth carries a lower risk into the future, and because its opportunity costs are not significantly different, it is the logical means to apply at this point in time.

Implications for Forest Plan Alternatives
Alternatives were designed to address public issues. As a result, most alternatives, including the preferred alternative, incorporate objectives for the retention of old growth and mature timber, for wildlife, for visual purposes, and for recreational purposes at levels higher than needed to meet the basic management requirement. Consequently, there are no significant differences in opportunity costs between the various alternatives.

The range of alternatives also shows the range and variation in harvest levels within the available decision space as needed to respond to public issues. If these alternatives had been formulated without adding the constraints necessary to meet the management requirement, there would have been some increase in ASQ and PNV. The gains, however, would be less than the costs calculated in Table F-6.

Role of Monitoring and Research
The monitoring plan (Forest Plan, Chapter 5) calls for monitoring populations and habitats of pileated woodpeckers. In future planning efforts, this data will be used to help determine the suitability and effectiveness of the selected means of meeting the management requirement. In this manner, the appropriateness of the selected means will be tested over time.

Management Requirements for Water Quality
Source of the Management Requirement
The management requirements for water quality are based on the planning regulations which direct forests to:

- Comply with requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State, and local governmental bodies with respect to the provisions of public water systems and the disposal of waste water [36 CFR 219.23(d)].
- Evaluate existing or potential watershed conditions that will influence soil productivity, water yield, water pollution, or hazardous events [36 CFR 219.23(e)].
- Conserve soil and water resources and not allow significant or permanent impairment of the productivity of the land [36 CFR 219.27(a)(1)].

The Clean Water Act seeks to control non-point sources of water pollution. To comply with Section 208 of the Act, Region 6 of the Forest Service, the states of Oregon and Washington (which manage implementation of the Act in the respective states) and the Environmental Protection Agency (EPA) agreed on what constitutes compliance with the Act. This agreement, contained in memoranda of understanding between the Forest Service and the respective states, established a process whereby each state certified the best management practices (BMP’s) needed to meet or exceed state water quality standards (FSM 1561.5, R-6 Supplement 67, 4/88).
Specifications for the Water Quality Management Requirements

State of Oregon water quality standards (Oregon Administrative Rules 340-41-205 through 325) provide specifications to be met by implementation methods selected by the forest. They are summarized as follows:

Dissolved oxygen concentration shall not be less than 90 percent of saturation at the seasonal low, or less than 95 percent of saturation in spawning areas during spawning, incubation, hatching, and fry stages of salmonid fishes.

On the Deschutes and Crooked Rivers and associated tributaries, no measurable increases shall be allowed when stream temperatures are 58 degrees Fahrenheit or greater, and no more than two degrees increase due to all sources combined when stream temperatures are 56 degrees or less shall be allowed. On the John Day River, Silver and Emigrant Creeks, and associated tributaries, no measurable increases shall be allowed when stream temperatures are 68 degrees Fahrenheit or greater, and no more than two degrees increase due to all sources combined when stream temperatures are 66 degrees or less shall be allowed.

No more than a 10 percent cumulative increase in natural stream turbidity shall be allowed, as measured relative to a control point immediately upstream of the turbidity causing activity.

pH values shall not fall outside a range of 6.5 to 8.5.

Analysis of Methods Designed to Meet Water Quality Management Requirements

Two non-point source pollution parameters, namely water temperature and suspended sediment, are the major determinants of water quality on the Forest. Higher water temperatures encourage the growth of certain nuisance organisms such as bacteria, algae and fungi, that in turn affect the levels of dissolved oxygen, pH, and turbidity, and the production of undesirable tastes and odors. The amount of shading in riparian areas determines the extent streams are warmed by solar radiation. The riparian prescription (Land and Resource Management Plan, Chapter 4, pp 4-74) contains the water temperature standards and the amount of shade necessary to meet those standards. Special riparian area alternatives for shade were not examined individually because of their effect on PNV would be less than one percent.

Sediment yield is largely determined by the amount and erodibility of exposed soil in a watershed. Timber harvest activities, including road construction, slash treatment and site preparation, not only affect the amount of exposed soil, but also alter the timing and quantity of water leaving a watershed. Following harvest activities, watersheds become more hydrologically sensitive for a period of time with storm events exhibiting more rapid and extreme responses. This greater sensitivity level to storm events results in more energy being available to transport sediment to stream channels. Thus the primary effort in maintaining water quality is directed at the timber harvest program and related rate of vegetation removal in a watershed over time.

There is potential to misinterpret findings on timber harvest/watershed interactions. It is possible to refer to literature elsewhere which reports results contrary to those found locally (Megahan, Umatilla N.F., et al). However, upon close inspection these vagrancies are generally related to local geoclimatic, geomorphic, or vegetation differences between study areas, and not to methods. Or methods may be applied with different assumptions. For example, watershed studies on the Umatilla National Forest were conducted on dry soils and <20 percent slopes with two times greater precipitation than the Ochoco receives. The findings there are generally not directly applicable to the Ochoco N.F. Likewise, Megahan's work was done in the Idaho batholith.

Preliminary analysis of FORPLAN runs indicated that if unconstrained, over 90 percent of the timber harvest in the first decade of the Plan would be scheduled on the high value, extensively roaded ponderosa pine stands located in drainages with predominantly south and southwest aspects.

Further analysis showed that up to 70 percent of the acres in some drainages would be treated in the first
decade. This would result in over 40 percent of a drainage being in an equivalent harvest (EHA) condition, a situation judged to have potentially unacceptable impacts on water quality. In addition, in the second decade the harvest would shift to the steeper, mixed conifer drainages characterized by more erosive soils and high value anadromous fishery streams, further exacerbating potential watershed damage (see FEIS Chapter 4, pg. 4-83).

The Forest Service Manual directs that where prescribed cutting methods may be detrimental to watershed conditions, including water quality, limits be set on the timing of operations and the percent of watershed coverage per entry (FSM 2405.13, 3b).

Research indicates that measurable changes in runoff occur when 20 to 30 percent of a drainage is in a cut over condition (Brown, et al, 1974; Rich and Thompson, 1984; Troendle and Leaf, 1980). Water quality and quantity and timing of runoff may all be affected. These changes may be negative and often are cumulative. The rate timber is harvested or vegetation removed is a major contributor to this effect. To assess the effect of the rate of harvest, a Forest-wide threshold value (EHA) of 30.1 percent was established. This assumes up to 30.1 percent of the Forest can be in a harvested condition at any one time without exceeding watershed capabilities to absorb the impacts of management activities. The 30.1 percent is an average for the 22 major watersheds on the Forest. The actual EHA values ranged from 25 to 35 percent. This is further discussed in Chapter 3 of the FEIS, pp. ?? and Appendix ?? of the Land and Resource Management Plan.

The principle behind managing a watershed at or below a threshold value is to utilize the natural ability of a watershed to withstand management induced impacts or changes (such as changes in runoff patterns, soil moisture, site disturbance, or sediment yield) while protecting other resource values (such as water quality, fisheries, and soil productivity).

Exceeding the threshold value over time involves risk and the need to apply additional and often costly specific mitigation measures. Mitigation might be, for example, installation of devices to trap and store sediment.

Alternative Ways of Meeting the Management Requirements for Water Quality

Other methods of achieving water quality requirements were considered (see also FEIS Appendix O):

1) Changing the threshold level: the amount of disturbance allowed in a particular watershed may be changed based on the results of monitoring and evaluation.

2) Dedicated riparian areas (no timber harvesting).

3) The amount and kind of silvicultural activity allowed, e.g. selective harvesting under uneven-aged management, within the streamside buffer as well as the width of the buffer itself, are ways that were considered to assist in protecting riparian areas.

4) Use of in-stream structures to mitigate the effects of harvesting timber (see FEIS Chapter 4, pg. 4-88). Structures and devices to mitigate effects are employed by most alternatives. Exclusive reliance on this method alone is expensive and seldom totally effective.

The role riparian areas play in helping to meet the management requirement for water quality is separate and distinct from the management requirement for riparian areas per se. The management requirement for protection of riparian areas [36 CFR 219.27(e)] does not in itself significantly affect ASQ or PNV.

Evaluation of the Implementing Methods to Meet the Water Quality Management Requirements

Consequences of Methods (Ways and Means)

The threshold level of 30.1 percent across the Forest was developed by an interdisciplinary team and represents the best estimate attainable with present information. A higher or lower level of threshold could be used. A lower threshold level would appear to unnecessarily constrain development activities while a higher level would exceed research recom-
mendations that a 25 to 30 percent EHA be set to avoid unacceptable changes in watershed characteristics (water quality and quantity, and timing of flows).

The riparian area means alone, such as dedicated areas and in-stream structure methods, deal with sediments as they are leaving a watershed and as a consequence do not address the loss of productivity and the need to protect the soil resource. Furthermore, approximately half (412 miles) of the riparian areas on the Forest are in less than acceptable condition and consequently not fully effective in maintaining water quality. Many of these areas have suffered the cumulative effects of past practices, and the loss of riparian vegetation following decades of grazing.

Additional methods for shade management along riparian areas have not been analyzed for the Forest. The condition of many of the riparian areas would not provide the opportunity for additional alternatives as they presently are below the desired shade conditions. The recovery and, or rehabilitation of riparian area vegetation is slow on the Ochoco and shade development may take up to 25 years in some areas to attain the desired 80 percent shade level.

In-stream structures (e.g., log weirs, loose rock, check dams) are expensive to construct and maintain, and benefits from them may not be realized for many years. While fairly effective at trapping and holding sediments, they do so at the expense of fish habitat as silt and sediment trapped by these structures cement spawning gravels, thus reducing rearing habitat.

Maintaining water quality at the expense of fish habitat is not a desired practice and the rehabilitation of spawning areas is expensive.

In view of the above, constraining the rates of disturbance and vegetation removal over time, within watersheds, is presently believed to be the most reasonable and effective way to protect soil, water, and riparian resources. The wisdom that an ounce of prevention is worth a pound of cure is particularly appropriate in dealing with watersheds.

Opportunity Costs
The opportunity costs of meeting the water quality minimum requirement are displayed in Table F-3. They are a 4.3 percent change in the ASQ and 9 percent in PNV.

Rationale for Selected Method (see also Consequences)
Harvest scheduling constraints provide the best means for controlling the rate and amount of change in vegetation and soil disturbance across the Forest. The method relates to the ability of a watershed to absorb disturbance, both natural and human-caused, and recover in a reasonable period of time. It is assumed that recovery mechanisms (vegetation, bank stability, large woody debris, etc.) are functioning or can be improved (e.g. revegetation or use of in-stream structures) to an effective level. The FEIS, Chapter 4, (pp. 88) describes the methodology and amount of disturbance allowed by watershed by decade. The harvest constraints (threshold values) for the various watersheds were established through professional judgement, local experience, and watershed research.

Managing above a threshold level requires that the decision maker consider both the magnitude and duration of the expected impact. Magnitude is the intensity of the effect or impact. Duration is that period of time (window of vulnerability or period above the threshold) during which the hydrologic sensitivity of a drainage, following activities, is such that the occurrence of a major natural event (e.g., 10 to 25 year storm runoff) could combine to produce undesirable effects within the drainage or on downstream resources. The probability of this occurrence is part of determining the risk in making management decisions.

To aid the decision maker in evaluating risk, the Ochoco Harvest Effect Model accesses a standard probability table with the number of years harvest effects are above the assigned threshold value (window of vulnerability). From this we predict the probability of experiencing a 10, 25, or 50 year storm event on the watershed in question. For example, if the threshold were exceeded for six years, the chances
of experiencing a 10-year storm would be 40 percent, and a 25-year storm 26 percent. The longer a watershed exceeds the threshold, the greater the chance it will experience a damaging storm event.

Implications for Forest Plan

Alternatives
All the alternatives incorporate and meet the basic management requirement.

Role of Monitoring and Research
The probability of experiencing or not experiencing a 10 or 25 year storm event during a fixed period of time may help explain the wide variability of effects recorded in monitored watershed experiments. In other words, a small test watershed may not experience a major climatic event while it is hydrologically sensitive regardless of whether it is harvested at 20, 50 or even 70 percent. Research studies simply have not treated large enough areas nor monitored them long enough to have witnessed a full range of possible climatic events. In this regard, managing a Forest through a rotation is strikingly different than a research study, for what is a statistically probable event on an individual test unit will occur with a high degree of certainty over time on a Forest. Only by monitoring a Forest, watershed by watershed, are we likely to develop a true understanding of the role chance events and natural variability play in determining actual threshold values for a drainage. The threshold value proposed compared against calculations of harvest effect will provide for the first time a baseline against which the Forest can monitor and evaluate the effects of harvest management activities. Monitoring and evaluation will provide the information to base any changes in future watershed threshold values. Threshold values and conversion factors can be modified in the future to reflect information obtained.

Appendix G

Best Management Practices
Appendix G

Best Management Practices

Definitions

Nonpoint sources refers to diffuse or unconfined sources of pollution where wastes can either enter into, or be conveyed by the movement of water to, public waters (Oregon Water Quality Standards, 340-41-007(17)). Silvicultural sources, such as erosion from a harvest unit or surface erosion from a road are considered nonpoint sources.

Best Management Practices are defined as “methods, measures or practices selected by an agency to meet its nonpoint source control needs. BMP’s include, but are not limited to, structural and nonstructural controls, operations, and maintenance procedures BMP’s can be applied before, during, and after pollution-producing activities to reduce or eliminate the introduction of pollutants into receiving waters.” (40 CFR 130 2, EPA Water Quality Standards Regulation.)

Usually BMP’s are applied as a system of practices rather than a single practice. BMP’s are selected on the basis of site specific conditions that reflect natural background conditions and political, social, economic, and technical feasibility (EPA Interagency Nonpoint Task Force, 1985)

BMP’s are basically a preventative rather than an enforcement system. BMP’s are a whole management and planning system in relation to sound water quality goals, including both broad policy and site-specific prescriptions.

Introduction

Best Management Practices are the primary mechanism to enable the achievement of water quality standards (Environmental Protection Agency 1987) BMP’s will be selected and tailored for site specific conditions to arrive at the project level BMP’s for the protection of water quality. The process for determining appropriate BMP’s and for ensuring their implementation at both the Forest Plan and Project level is described. Following is a description of the methods and procedures that will be used to control or prevent nonpoint sources of pollution from resource management activities and to ensure compliance with the Clean Water Act of 1972, as amended (1977 and 1987). Section 319 of the Clean Water Act Amendments of 1987 requires that the States determine those waters that will not meet the goals of the Act, to determine those nonpoint source activities that are contributing pollution, and to develop a process of determining BMP’s to reduce such pollution to the “maximum extent practicable.” This Appendix is designed to fulfill the intent of the requirements of Section 319.

Oregon Administrative Rules (Chapter 340-41-001-975). Department of Environmental Quality (DEQ). Oregon’s Administrative Rules contain water requirements for the protection of identified beneficial uses of water.

Memorandum of Understandings: The Oregon Department of Environmental Quality and U.S. Department of Agriculture, Forest Service (2/12/79 and 12/7/82), and “Attachments A and B” referred to in this MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest 12/78 and Best Management Practices for Range and Grazing Activities on Federal lands, respectively)

California's Porter-Cologne Water Quality Control Act (California Water Code, Division 7). The Water Quality Control Plan for the North Coast Region was approved by the North Coast Regional Water Quality Control Board on April 28, 1988. It is pending approval by the State Water Resources Control Board and the Environmental Protection Agency.

The Draft North Coast Regional Water Quality Control Plan contains water quality objectives that are considered necessary to protect those present and probable future beneficial uses of water.

The EPA has certified the Oregon Forest Practices Act and Washington Forest Practices Rules and regulations as BMP's. The State of Oregon compared Forest Service practices with these State practices and concluded that Forest Service practices meet or exceed State requirements. As state practices change, comparisons are made to ascertain that Forest Service practices meet or exceed these changes. Monitoring and evaluation will determine the need for changes in BMP's and/or state standards.

Forest Services management practices will meet, as a minimum, the substantive State BMP requirements, and other considerations required by the National Forest Management Act (NFMA), and other authorities, for the protection of the soil and water resource.

The general BMP's described herein are action initiating mechanisms which call for the development of detailed, site-specific BMP prescriptions to protect beneficial uses and meet water quality objectives. They are developed as part of the NEPA process, with interdisciplinary involvement by a team of individuals that represent several areas of professional knowledge, learning, and/or skill appropriate for the issues and concerns identified. BMP's also include such requirements as Forest Service manual direction, contract provisions, environmental documents, and Forest Plan Standards and Guidelines. Inherent in prescribing project-level management requirements is recognition of specific water quality objectives which BMP's are designed to achieve.

**BMP Implementation Process**

In cooperation with the State, the primary strategy for the prevention and control of nonpoint sources is based on the implementation of BMP's determined necessary for the protection of the identified beneficial uses.

The objective is to identify the most practical means of attaining water quality objectives. Water quality objectives include water quality measures that adequately reflect the needs of identified beneficial uses.

The Forest Service Nonpoint Source Management System consists of:
1. Selection and design BMP’s based on site-specific conditions, technical, economic and institutional feasibility, and the water quality standards of those waters potentially impacted.

2. Implementation and enforcement of BMP’s.

3. Monitoring to ensure that practices are correctly applied as designed.

4. Monitoring to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards. Evaluation of the appropriateness of water quality criteria to reasonably assure protection of beneficial uses.

5. Evaluation of monitoring results and mitigation where necessary to minimize impacts from activities where BMP’s do not perform as expected.

6. Adjustment of BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level. Evaluate possible adjustment of water quality standards.

**BMP Selection and Design - Step 1**

Scoping: Potential concerns are identified, e.g., mass wasting, water quality, etc. as part of the NEPA process for environmental analysis. Public notices are dispersed inviting comment and participation in the process. Alternatives are developed to address potential problems and to accomplish project objectives.

Environmental Analysis: Each alternative is evaluated for its potential effect on different resources, including water. From this analysis, a preferred alternative is identified, along with the measures (BMP’s) needed to reduce risk and increase the potential for success.

**BMP Implementation and Enforcement - Steps 2 and 3**

The site-specific BMP prescriptions are taken from plan-to-ground by a combination of project layout and resource specialists (hydrology, fisheries, soil, geology, etc.). Final adjustments to fit the BMP prescriptions to the site are made before implementing the resource activity.

When the resource activity (e.g., timber harvest or road construction) begins, timber sale administrators, engineering representatives, resource specialists, and others ensure that the BMP’s are implemented according to plan. A similar implementation process is used for other resource activities (range management, mining, etc.) on national forests.
BMP implementation monitoring is done before, during, and after resource activity implementation. This monitoring answers the question: Did we do what we said we were going to do? Some examples of implementation monitoring for a streamside management unit BMP prescription may be:

1. Before project: checking Stream Management Units (SMU's) along streams to see if layout meets the objectives of the BMP prescription, or if the road crossing of a stream is properly located and designed per estimates made during the environmental analysis.

2. During project: during timber felling, the timber sale administrator checks to see if the timber fallers understand marking prescription for timber to be felled in the SMU. The timber sale administrator also observes ongoing harvest operations to see if the activity meets the objectives defined in the project plan.

3. After project: measuring canopy stream shading to see if the amount specified in the BMP prescription was retained, or monitoring a beneficial use of the water to determine a change or trend in use.

Enforcement is carried out primarily through internal project reviews and contractual enforcement, e.g., timber sale contract, grazing or special use permit, etc.

Contract enforcement is a more formal method used to achieve desired results. Normally, each project is assigned a person as a contracting officer. For timber sales, that person is called a timber sale administrator. The project is routinely monitored to ensure that practices are being carried out in the manner and method prescribed in the contract, permit, etc. When a contractor or permittee is not in compliance, they can be held in breach with penalties (e.g., bond forfeiture) until remedies are implemented. Often during the course of an activity, adjustments are made if it is determined that unsatisfactory results are currently resulting or may occur. This can often mean that a contract modification may be necessary (as in the case of a timber sale).

**BMP Monitoring - Step 4**

Once BMP's have been implemented, further monitoring is done to evaluate their effectiveness. BMP "effectiveness monitoring" answers the question: Are BMP's effectively meeting management objectives and protecting water quality?

Water quality standards are the "yardstick" against which the effectiveness is tested. If, through objective monitoring, BMP's do not meet prescribed objectives, then information is available to modify either the BMP's for future management, or the objectives, or both.

The natural variability of water quality under unmanaged conditions is an important factor that will be considered during the monitoring and evaluation. Additionally, effectiveness monitoring will include measurement against land management objectives, as well as water quality objectives.

Some examples of the types of BMP effectiveness monitoring to be conducted are:

1. Measuring stream temperatures to see if the riparian prescriptions in a watershed are maintaining water temperature.

2. Storm period surveillance monitoring of a road system to see if road rocking is effectively preventing road surface erosion.

Another type of more costly and time consuming monitoring is "validation." The purpose of validation monitoring is to answer the question of whether standards, coefficients, requirements, and guidelines are appropriate to meet objectives, e.g., protect beneficial uses.
Examples:

(1) Did the change in water temperature impact the fish population?

(2) Did the soil compaction affect tree growth?

Validation Monitoring will need to be closely coordinated with, or in some cases, conducted by research. It may require the establishment of permanent plots or administrative studies. This kind of monitoring will be very limited and will require coordination to select projects with broad application and to prevent duplication. Only those coefficients and standards that are not reasonably validated by existing research or documentation should be candidates for this monitoring.

The monitoring and evaluation section of the Forest Plan, Chapter 5, contains more detailed monitoring descriptions. Once a specific project is designed, a site-specific monitoring plan may be developed.

Results of monitoring should be shared with State and local agencies as well as available to the public. Monitoring design, sampling, and laboratory analyses will be coordinated.

**BMP Evaluation and Adjustment - Steps 5 and 6**

The technical evaluation and monitoring described above will determine how effectively BMP's protect and/or improve water quality. If the evaluation indicates that water quality objectives are not being met and/or beneficial uses are not being protected, corrective action will consider the following three components:

1. The BMP: Is it technically sound? Is it really best, or is there a better practice which is technically sound and feasible to implement?

2. The implementation program or processes: Was the BMP applied entirely as designed? Was it only partially implemented? Were personnel, equipment, funds, or training lacking which resulted in inadequate or incomplete implementation?

3. The water quality standards: The water quality standards are established to protect the beneficial uses of water. They include numeric and narrative criteria that, when exceeded, are assumed to indicate detrimental impacts on beneficial uses. They are intended to provide a benchmark for evaluating harm to beneficial uses.

Assessing the applicability of the standards is a responsibility of the State. The Forest Service will provide information to the State to address the following types of questions:

- Do the standards describe the conditions necessary for protecting beneficial uses?
- Are standards higher or lower than that necessary for protecting beneficial uses?
- Do the standards reflect the natural variability occurring within the natural and human-affected ecosystem?
- Do the parameters and criteria that constitute water quality standards adequately reflect (are they sensitive enough) human-induced changes to water quality and beneficial uses?

Corrective action may be initiated once the reason for failing to achieve the management objectives is understood. The management practice may have to be changed, the water quality objectives modified, or both.

**Training**

National Forest personnel involved with project location, design, layout, administration, and maintenance activities will receive BMP training. The training will consist of BMP awareness, as well as the more technical aspects such as planning, implementation, monitoring, and evaluation.
General Best Management Practices and Examples

Individual general Best Management Practices are described in General Water Quality Best Management Practices, Pacific Northwest Region, 11/88. Also included in this document is a description of the process, and limitations and use of these BMP’s. Each BMP listed includes the Title, the Objectives, the Explanation, Implementation and Responsibility, and Monitoring. Evaluations of ability to implement and estimated effectiveness are made at the project level.

Not all of the general BMP’s listed will normally apply to a given project, and there may be specific BMP’s which are not represented by a general BMP in this document.

The sensitivity of the project determines whether the site-specific BMP prescriptions are included in the EA/EIS or in the sale/project plan, or the analysis files.

Following is an example of a general BMP, as described in this document, along with an example of a site-specific BMP which is developed at the project level.

General BMP

T-5. Title: Limiting the Operating Period of Timber Sale Activities

Objective: To ensure that the Purchaser conducts operations in a timely manner, within the time period specified in the Timber Sale Contract (TSC).

Explanation: The TSC specifies a Normal Operating Season, during which, operations may generally proceed without resource damage. Operations are permitted outside the Normal Operating Season only when they can be conducted without damage to soil, water, and other resources. Where determined to be necessary through the environmental analysis, the TSC will limit operations to specific periods or weather conditions. Operations are not permitted to continue if damage will occur.

Implementation & Responsibility: Limited operating periods are identified and recommended during the Timber Sale Planning Process by the interdisciplinary team and followed through the life of the timber sale primarily by the Sale Administrator.

Ability to implement: Add at project level.

Effectiveness: Add at project level.

Monitoring: Done during implementation of timber sale activities by the Sale Administrator, Forest Service Representative (FSR), engineers, and watershed specialists. Also see Appendix D monitoring plan item: Water Resource Monitoring.

Specific BMP

PT-5. Title: Limiting the Operating Period of Timber Sale Activities

Objective: To ensure that the Purchaser conducts operations in a timely manner, within the time period specified in the Timber Sale Contract (TSC).

Explanation: The Ship Mountain Timber sale contains sensitive soils that are subject to soil compaction during tractor skidding, and a non-surfaced road that is not suitable for wet weather haul.

The normal operating season for the Forest will be enforced for the Ship Mountain Timber sale. All operations off Forest Road 10 (non-surfaced) will be halted at the onset of wet weather to prevent erosion and damage to the road. Tractor skidding on units 1-5 will be restricted if soil moisture is above the level established by the soil scientist. Other operations can continue outside the normal operating season if they can be conducted without damage to soil, water, and other resources.

Implementation and responsibility: For the Ship Mountain Timber sale the normal operating season for the Forest will be enforced. All operations off of Forest Road 10 (non-surfaced) will be halted at the onset of wet weather to prevent...
erosion and damage to the road. Other operations can continue outside of the normal operating season if they can be conducted without damage to soil, water, and other resources. The forest watershed specialists will work with the timber sale administrators to evaluate the potential for resource damage if operating outside of the normal operating season.

Ability to implement: High

Effectiveness: High

Monitoring: Monitoring identified for this BMP in the Forest Plan BMP Appendix applies.

Summary of Wild and Scenic River Study Report for Squaw Creek

The report evaluated and determined the eligibility of the portion of the Squaw Creek that flows through lands administered by the National Grassland for possible classification under the Wild and Scenic Rivers Act of 1968. Squaw Creek was presented at a public hearing for inclusion in the Oregon Wild and Scenic Rivers Bill by several citizens.

The study does not officially designate Squaw Creek as a scenic or recreational river. That determination can only be accomplished by legislation by Congress. The report does find that Squaw Creek, on the National Grassland, meets the criteria for classification as either “recreational” or “scenic,” but does not meet the criteria for “wild.” This report recommends that the 7.5 mile segment at Lower Squaw Creek be recommended for designation as a “scenic river” in the Wild and Scenic River System.

The following chart outlines the status of the river miles inventoried:

1\ complete report on file at the Forest Headquarters in Prineville, Oregon. This report covers the eligibility and suitability of Lower Squaw Creek for designation as a "scenic river."
## General Location and National Significance

The study segment begins at the confluence with the Deschutes River in Section 7 of T 13 S., R. 12 E. and ends at the Grassland boundary in Section 34 of T. 13 S., R. 11 E. Squaw Creek, in the Crooked River National Grassland, flows through a canyon that is both outstanding and remarkable. The canyon has regional significance. The canyon is in an Intermountain Sagebrush/sagebrush steppe ecosystem, according to Kuchler Vegetation Classification system. A portion of the creek corridor was included in the Deschutes Canyon - Steelhead Falls Wilderness Study Area. All of the creek corridor is included in the Squaw Creek Management Area, designated for semiprimitive nonmotorized recreation and big game winter range in the Grassland Plan.

## Outstanding Remarkable Values

Squaw Creek has several outstanding remarkable values: an excellent fishery, spectacular canyon scenery, scenic geologic formations, large natural springs, exemplary natural riparian vegetation, important deer winter range and unique canyon semiprimitive recreational opportunities.

## Potential Classification for Squaw Creek, Confluence with the Deschutes River and the Crooked River National Grassland Boundary

MA-GI Antelope Water Range - Manage for optimum Winter Range conditions for Antelope in conjunction with the Oregon Department of Fish and Wildlife.
MA-G2 Milk River Winter Range - Manage for Big Game Winter Range habitat.
MA-G4 General Forage - Manage for forage production and utilization in a manner consistent with Forest-wide Standards and Guides for other resources.
MA-G5 Research Natural Area - Provide opportunities for research, education, and demonstration of knowledge in managing ecosystems where natural processes are maintained.
MA-G8 Juniper Old Growth - Provide habitat for wildlife species dependent on Old Growth

MA-G4 Crooked River Recreation River - Manage for the improvement of natural landscapes to enhance and protect areas affected.
MA-G8 Parry Creek - Provide opportunities for non-timber benefits to the public and society.
MA-G8 Pinnacles River - Manage for the improvement of natural landscapes to enhance and protect areas affected.

MA-G1 Lake Billy Chinook View - Maintain the natural appearance of the surrounding lake.
MA-G14 Dispersed Recreation - Provide for small scale, non-specialized, non-camping recreation opportunities.
MA-G15 Gifford Pinchot National Forest - Provide for small scale, non-specialized, non-camping recreation opportunities.

Alternatives A, C—Modified, and E—Departure

MA-G3 Crooked River Recreation River - Maintain the appearance of natural landscapes to enhance and protect areas affected.
MA-G8 General Forage - Provide a scenic, natural landscape in the manner that it is maintained.
MA-G1 Big Game Winter Range - Manage for Big Game Winter Range habitat.
MA-G15 General Forage - Provide a scenic, natural landscape in the manner that it is maintained.
MA-G8 Partial Recreation Forage - Provide a scenic, natural landscape in the manner that it is maintained.
MA-G8 Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve wilderness.

MA-G8 Sonoma Prehistoric Sites - Provide non-timber benefit opportunities to the public and society.
MA-G12 Research Natural Area - Provide opportunities for research, education, and scientific studies to enhance and protect areas affected.

MA-F1 Black Canyon Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

MA-F2 Bridge Creek Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

MA-F3 Mill Creek Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

MA-F4 North Fork Crooked River Wilderness Study Area - Management will maintain the existing conditions of the area for potential wilderness designation pending a decision by Congress or until released from further consideration.

MA-F12 Eagle Roosting Areas - Provide winter roosting habitat for migrating bald eagles during the period December through April, annually.

MA-F23 North Fork Crooked River Recreation Corridor - Management will maintain the appearance of a natural landscape in the foreground view from Road 43 to enhance recreational and scenic values. Management activities will protect and enhance public use and enjoyment of the river segment.

MA-F24 North Fork Crooked River Scenic Corridor - Management will maintain and enhance a natural appearing landscape and protect the scenic river designation.

MA-01 General Forest - Production of timber and forage, while meeting the Forest-wide Standards and Guidelines for all resources.

MA-02 Big Game Winter Range - Manage for Big Game Winter Range habitat.

MA-03 Big Game Summer Range - Manage for Big Game Summer Range habitat.

MA-04 Old Growth - Provide habitat for wildlife species dependent on Old Growth stands.

MA-05 Retention Foreground - Provide a scenic, natural view so that management activities are not evident in the foreground.

MA-06 Partial Retention Foreground - Provide a scenic, near natural view where management activities remain visually subordinate to the natural landscape in the foreground.

MA-09 Semiprimitive Nonmotorized - Provide roadsides unsanitized for recreation opportunities in a natural or natural appearing setting with minimum sights and sounds of human activity.

MA-011 Developed Recreation - Provide and maintain safe, healthful, and attractive facilities for people to utilize, within a relatively natural outdoor setting, while permitting a variety of recreational experiences.

MA-012 Research Natural Areas - Provide opportunities for research, education, and ecological benchmarks in naturally occurring ecosystems where natural processes are maintained.

1. The positions of the six Eagle Nesting Areas are not shown on this map. They are shown on the maps for Alternative A and Alternative B—Modifed.

2. The Bandit Springs area is shown as visual isolation on this map. It is shown separately on the map for Alternative A and Alternative B—Modifed.

3. The positions of the thirty Development Recreation areas are not shown on this map.
MA-61 Black Canyon Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

MA-62 Bridge Creek Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

MA-63 Mill Creek Wilderness - Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

MA-64 North Fork Crooked River Wilderness Study Area - Management will maintain the existing conditions of the area for potential wilderness designation pending a decision by Congress or until released from future consideration.

MA-65 Eagle Roosting Areas - Provide winter roosting habitat for migrating bald eagles during the period December through April, annually.

MA-66 Randi Springs Recreation Area - Dispersed, nonmotorized recreational opportunities, within a setting where management activities are generally not evident to the casual observer. The recreational activities and opportunities will be expanded beyond winter recreation to year round activities.

MA-67 North Fork Crooked River Recreation Corridor - Management will maintain the appearance of a natural landscape in the foreground view from Road C to enhance recreational and scenic values. Management activities will protect and enhance public use and enjoyment of the river segments.

MA-68 North Fork Crooked River Scenic Corridor - Management will maintain and enhance a natural appearing landscape and protect the scenic river designation.

MA-69 General Forest - Production of timber and forage, while meeting the Forest-wide Standards and Guidelines for all resources.

MA-69 Big Game Winter Range - Manage for Big Game Winter Range habitat.

MA-69 Big Game Summer Range - Manage for Big Game Summer Range habitat.

MA-70 Old Growth - Provide habitat for wildlife species dependent on Old Growth stands.

MA-71 Retention Forground - Provide a scenic, natural view so that management activities are not evident in the foreground.

MA-72 Partial Retention Foreground - Provide a scenic, near natural view where management activities remain visually subordinate to the natural landscape in the foreground.

MA-73 Partial Retention Middleground - Provide a scenic, near natural view where management activities remain visually subordinate to the landscape in the middleground.

MA-74 Semiprimitive Nonmotorized - Provide roadless nonmotorized recreation opportunities in a natural or naturally appearing setting with minimal sights and sounds of human activity.

MA-75 Semiprimitive Motorized - Provide nonmotorized recreation opportunities, without developed roads, highway vehicles, or concentrations of people in a relatively natural appearing environment.

MA-76 Developed Recreation - Provide and maintain safe, healthful, and aesthetic facilities for people to utilize, within a relatively natural outdoor setting, while pursuing a variety of recreational experiences.

MA-77 Research Natural Area - Provide opportunities for research, education, and ecological endeavors in naturally occurring ecosystems whose natural processes are maintained.

Legend:
- Wilderness
- Semiprimitive
- Motorized
- Winter Range
- North Fork Crooked River
- Scenic Corridor
- Recreation Corridor
- Summer Range
- General Forest
- Old Growth
- Semiprimitive Nonmotorized

1) The positions of the six Eagle Roosting Areas are not shown on this map. They are shown on the map for Alternative 1 and Alternative 2 Modified.
2) The Randi Springs area is shown on visual inspection on this map. It is shown separately on the map for Alternative 1 and Alternative 2 Modified.
3) The positions of the thirty Developed Recreation areas are not shown on this map.

Land and Resource Management Plan

Part 1

Ochoco National Forest

Caring for the Land...
The Ochoco National Forest Land and Resource Management Plan (Forest Plan) was prepared in compliance with 36 CFR 219, based on the Forest and Rangeland Renewable Resources Planning Act (RPA) as amended by the National Forest Management Act of 1976, and in compliance with 40 CFR 1500 based on the National Environmental Policy Act of 1969.

Because the Plan is a major Federal action significantly affecting the quality of the human environment, an environmental impact statement (EIS) was prepared. The Plan provides direction for implementing the preferred alternative selected in the EIS.

If any particular provision of this Forest Plan, or the application of the action to any person or circumstance, is found to be invalid, the remainder of the Forest Plan and the application of that provision to other persons or circumstances shall not be affected.

Additional information about the Plan is available from:

Forest Plan
Introduction
Chapter 1

Forest Plan

Introduction

Purpose

Although Crooked River National Grassland is an administrative unit of the Ochoco National Forest, it is addressed in a separate plan. The Grassland has land and resource characteristics, management activities, and parent laws and regulations which are
generally distinct from those of the Ochoco National Forest. This, coupled with public response, led to a separate land and resource management plan for the Grassland.

The decisions of the Regional Forester in approving a Forest Plan may generally be categorized as:

- establishment of Forest-wide multiple-use goals and objectives [36 CFR 219.11(b)];
- establishment of Forest-wide standards and guidelines to fulfill requirements of the National Forest Management Act (NFMA) applying to future activities [resource integration requirements of 36 CFR 219.13 to 219.26, and the requirements of 36 CFR 219.27];
- establishment of management area direction including management area prescriptions and standards and guidelines applying to future management activities in that management area [36 CFR 219.11(c)];
- establishment of allowable timber sale quantity and designation of land suitable for timber management [36 CFR 219.16 and 219.14],
- nonwilderness multiple-use allocations for those roadless areas that were reviewed under 36 CFR 219.17 and not recommended for wilderness designation and,
- monitoring and evaluation requirements [36 CFR 219.11(d)].

The Forest Plan embodies the provisions of NFMA, the implementing regulations, and other guiding documents. Land use determinations, prescriptions, and standards and guidelines are statements of the Plan's management direction. However, the projected outputs, services, and rates of implementation are dependent on the annual budgeting process.

This plan will guide Forest Service programs on the Ochoco National Forest beginning in fiscal year 1990 (Oct. 1, 1989). It will ordinarily be revised on a ten-year cycle, but at least every 15 years. The Plan may be amended or revised at any time if the Forest Supervisor determines that conditions in the area covered by the Plan have changed significantly, or if project level environmental analysis demonstrates the need to make a change.

Relationship of the Forest Plan to Other Documents

Relationship to the Environmental Impact Statement and the Record of Decision

This Forest Plan sets forth the preferred alternative for managing the land and resources of the Ochoco National Forest. The Plan results from extensive analysis and considerations addressed in the Environmental Impact Statement (EIS) and the Record of Decision (ROD). The planning process and the analysis procedures used to develop this Plan are described or referred to in the EIS. The EIS also describes other alternatives considered in the planning process.

Specific activities and projects will be planned and implemented to carry out the direction in this Plan. The Forest will perform environmental analysis on these projects and activities. This subsequent environmental analysis will be tiered to the EIS and Plan.

Relationship to the Regional Guide

The Regional Guide for the Pacific Northwest Region, as amended December 8, 1988, provides direction for National Forest Plans. It includes standards and guidelines addressing the major issues and management concerns considered at the Regional level to facilitate Forest planning.

2. Regional Regional Guide.

4. Project Site or project specific plans, generally at Ranger District level. Tiered to Forest Plan.

Relationship to Other Plans

This Forest Plan serves as the single land management plan for the Ochoco National Forest. All other land management plans are replaced or superseded by the direction in this plan, or will be made consistent with it; see Chapter 5 for a listing of existing plans that this Forest Plan supersedes.

Management alternatives for the Ochoco National Forest and the Crooked River National Grassland Land and Resource Management Plans are described in the EIS. The Ochoco National Forest retains administrative and management responsibility for both the Forest and Grassland. Required planning, programming, and management activities for both plans will be integrated at the Supervisor’s Office level for efficiency in implementation.

PLAN STRUCTURE

The Forest Plan is composed of five chapters, a glossary, and appendices. Chapter 1 provides planning background and a summary of the types of management decisions made. Chapter 2 summarizes the current situation, and the supply and demand of significant market and nonmarket goods and services on the Forest. Chapter 3 shows the Plan’s response to the major public issues, management concerns, and resource opportunities identified during the planning process.

Chapter 4 is the heart of the Forest Plan. It sets the management direction for the Forest for the next 10 to 15 years. It presents goals, objectives, and desired future conditions directing resource management on the Forest. Desired future condition sections describe what the Forest should look like after the implementation of the management direction. Chapter 4 also presents prescriptions for each of the 28 management areas, Forest-wide standards and guidelines, and management area standards and guidelines. Forest-wide standards and guidelines state the constraints within which all practices are to be carried out in implementing the Forest Plan.

Chapter 5 explains how management direction will be implemented, how activities will be monitored, and how the plan will be kept current with changing conditions or other findings. The appendices provide detailed, supplemental information needed to explain portions of the Plan. The Glossary, contained in the FEIS, lists and defines technical terms used in the Plan. An index is provided to assist readers in locating subjects of interest.

FOREST DESCRIPTION

Located near the geographic center of Oregon, the Ochoco National Forest consists of 845,498 acres of land. The Forest is subdivided into four Ranger Districts: Big Summit, Paulina, Prineville, and Snow Mountain. The Forest is headquartered in Prineville.

The Forest administers lands in the Maury and Ochoco mountains, southward extensions of the Blue Mountain physiographic province. Most of the Forest is drained by the Crooked and Deschutes Rivers. Part of the north slope of the Ochoco Mountains drains into the John Day River. The Snow Mountain District drains into three systems: the Crooked River, the John Day River, and Malheur and Harney Lakes.

Vegetative types found on the Forest are diverse.
Lower elevations of the Forest where annual precipitation is less than 10 inches per year are vegetated with juniper, sagebrush, and grasses. Higher up, stands of ponderosa pine dominate southern and western aspects and compose the largest single forest type found on the Forest. Mixed conifer stands, made up of Douglas-fir, ponderosa pine, white fir, and western larch, grow at higher elevations on the cooler northern and eastern aspects. Scattered stands of lodgepole pine cover less than one percent of the Forest.

The Forest is managed to produce both commodity and noncommodity resources. Timber produced on the Forest is a major component of the local economy. Summer forage for livestock available on the Forest is important to local ranchers. These commodity resources are managed with consideration for recreation, wildlife, soil, and water. Major recreational pursuits include big game hunting and rockhounding. Both of these attractions draw visitors from well beyond the local area.
Chapter 2

Summary of the Analysis of the Management Situation
Chapter 2

Summary of the Analysis of the Management Situation

Introduction

This chapter summarizes the supply and demand situation for the key market and nonmarket goods and services associated with the Forest. Included is a summary containing:

- resource supply and demand conditions for the Resources Planning Act (RPA) periods,
- production levels attainable under both the current management direction (Alternative A) and Forest Plan direction (Alternative I),
- and a list of information that would be desirable to have prior to the preparation of the next Ochoco National Forest Land and Resource Management Plan.

Resource and Economic Potentials

Benchmarks were developed to help define the resource and economic potentials of the Forest, and the range of outputs from which alternatives could be developed.

Most of the benchmarks were developed to explore the potential of the Forest to produce the maximum of a particular issue-related resource; e.g. timber, range, recreation, or big game. Two benchmarks were developed to determine the mix of resources that produced the maximum present net value (PNV) of the Forest: one using market values only and the other using market and assigned values. Market priced outputs include timber, minerals, livestock, grazing, and developed recreation. Outputs with assigned values are dispersed recreation, including wilderness, and fish and wildlife use. (See Appendix B of the FEIS for dollar values.)

One benchmark estimates the minimum costs to retain the Forest in Federal ownership with no outputs of goods and services other than those that would occur incidentally, such as dispersed recreation.

While benchmarks must be realistic, they could not serve as alternatives because they do not address the issues, concerns, or opportunities (ICO’s). Rather, they were used to define the minimum and maximum parameters within which alternatives might be developed.

All benchmarks and alternatives were required to meet management requirements (Regional Direction 1920, 11/10/83). The major management requirements (MR’s) addressed are:

- size and dispersion of timber harvest units,
- soil and water conservation;
- riparian areas; and
- minimum habitat requirements for old growth dependent species and primary cavity nesters. A more detailed discussion of benchmarks and opportunity costs for MR’s is in the FEIS Appendix B and Appendix F.
Resource Description and Supply/Demand Projections For Selected Resources

Introduction
Following is a brief discussion of the current situation of each of the major Forest resources (see FEIS Chapter 3 for more detailed discussions), and the anticipated supply and demand for goods and services associated with these resources. The supply figures were developed from benchmarks and independent estimates. Demand figures were estimated independently and the source is included in Table 2-1. Economists consider “demand” to be a schedule of quantities of an output that users are willing to consume within a price range, at a given time, and under certain conditions of sale. The term “demand,” as used in this section, identifies a certain level of consumption at a particular point in time. Although demand estimates are projected over several decades, long-term projections are expected to be less accurate than those for the near future.

Forage

Current Situation:
The Forest provides summer forage for approximately 11,300 cattle and 2,500 sheep annually (58,000 AUM’s), involving 55 permittees in 4 counties. These numbers have been relatively stable in the recent past, and adjustments in the numbers of livestock or season of use have not been common.

Supply:
While there appears to be adequate forage to increase the number of AUM’s on the Forest, the main limiting factor is distribution of forage use in order to keep some places (primarily riparian areas) from being over-grazed before other areas receive use. Water developments can draw livestock to other areas thereby making forage available that otherwise may not get used. Increasing the grazing to the maximum potential shown in Table 2-1 would require a substantial number of water developments. The construction of 290 water developments could increase the grazing capacity of the Forest by an estimated 9,900 AUM’s. Due to potential conflicts with riparian management and other resources, it is not expected that this increase will be realized in the near future.

Demand:
Ranchers regard the Forest as desirable summer range because of the high quality of forage and availability of water. As a result, allotments are usually fully occupied. When an allotment becomes available, it is usually filled, indicating a constant demand for available forage. In addition, there is interest in increasing livestock numbers and the season of use.

The demand figures in Table 2-1 are from the Forest Service 1980 RPA Program, and reflect the Forest’s apportioned share of the national demand for forage.

Fuelwood

Current Situation:
Local residents point out that the quality of firewood continues to lower, and travel distances increase. The Forest has sold an average of 10,000 cords of personal use fuelwood in the past 5 years.

Supply:
Availability of firewood on the Forest is proportional to the volume of the timber harvest; increased timber harvests increases residues available for firewood. As shown in Table 2-1, the maximum supply of firewood that could be produced in the first decade is 15,000 cords annually. Wind-thrown trees and juniper make up a small portion of the total supply.
Analysis of the Management Situation

Firewood is also available from other sources, including other nearby National Forests, BLM lands, private lands, and sawmills.

Demand:
Numerous factors influence demand for firewood from the Forest, including accessibility, size and species, availability from other sources, and the price of other forms of energy. These factors make demand difficult to estimate. The total demand for firewood used in homes in Burns, Hines, Redmond, Prineville, Madras, Mitchell, Dayville, and adjacent unincorporated areas is estimated to be 37,000 cords per year.

The proportion of the 37,000 cords that would come from the Forest is estimated to be approximately 18,000 cords annually. The total demand cannot be met by the Forest alone.

Minerals and Energy

Current Situation:
Approximately 140,000 acres of Forest land are under lease for oil and gas. There are no geothermal leases on the Forest. About 8,000 acres of the Forest have been staked as mining claims. There are 350 mineral material sources (quarries or pits) in operation.

Supply:
On the Forest, 807,521 acres are available for oil, gas or geothermal leasing. All of this area is classified as being favorable for the discovery of thermal water of sufficient temperature for direct heat application. Of the acres available, 718,370 acres are classified as being tentatively valuable for the discovery of oil and gas and 804,510 acres are available for the location of mining claims. Of this amount, 81,460 acres are classified as having moderate or high potential for mercury or gold. Reserves of common variety materials (sand, gravel, etc.) are estimated at over 5 million cubic yards.

Demand:
The demand for oil, gas, gold and mercury is directly related to international production and price. An increase in the price of any of these commodities will result in increased exploration on the Forest, and the discovery of a valuable deposit may result in the production of that commodity. The largest number of acres ever leased for oil and gas on the Forest was 670,000 acres in the early 1980’s. There is no known demand for direct heat applications of geothermal energy on the Forest. The demand for mineral materials is generated by the construction, reconstruction and maintenance of roads on and near the Forest. Approximately 850,000 cubic yards of mineral material will be produced on the Forest each decade if historic trends continue.

Old Growth

Current Situation:
Timber harvesting has significantly reduced the amount of old growth on the Forest; about 94,000 acres remain. What remains has a less than optimum distribution for wildlife that rely on old growth habitat. The Forest managed 32,000 acres of old growth for wildlife habitat under the 1979 Forest Plan. Approximately 20,000 acres are dedicated under this Plan. However, only about one third of these acres will exist in old growth at any given time.

Old growth areas are a valuable component of the Forest, providing habitat for over 100 wildlife species. They also provide cover for big game, provide attractive scenery, help provide diversity, and are a tree gene pool source. Twenty-one thousand acres are identified as the minimum amount of old growth needed to maintain viable populations of dependent wildlife species.

Supply:
The Forest Plan would resuce the available old growth to about 55,000 acres in fifty years. This is about ten percent of the total forested lands. See Table 2-8 in the FEIS for more details. This acreage of old growth would continue at this level until the
Plan was changed or a catastrophic event destroyed some of the existing old growth. The planned management strategy of uneven-aged managed and rotation ages that would provide 18-inch DBH trees will provide for stands that could be allowed to grow into an old growth condition in 20 to 50 years. These stands are identified as successional Stage V in Table 2-8 in the FEIS, and it is estimated that there would be about 230,000 acres in this condition in fifty years. The acres in this class would fluctuate from year to year but should never be less 100,000 acres. These stands would also provide additional habitat for some of the species normally found in old growth areas.

Recreation

Current Situation:
The Ochoco National Forest provides a wide range of outdoor recreation opportunities. Gentle terrain, high value timber, and good livestock forage encouraged early commercial use of the Forest and development of an extensive road system. As a result, 89 percent of the lands have been roaded for various management activities. Approximately 11 percent, located mostly on the north slope of the Ochoco Mountains or in isolated tracts of rough terrain elsewhere, currently offer opportunities for semiprimitive recreation use.

The Forest estimates use of 350,000 recreation visitor days (RVD's) annually. Much of the recreation use is tied to the road system. Camping, motorized travel, picnicking, and hunting are estimated to comprise 77 percent of the use. Activities associated with certain streams and the few available lakes are popular.

Current direction emphasizes dispersed rather than developed recreation. There are 767 inventoried dispersed sites. There may be over 400 additional dispersed sites which have not been inventoried. Most have no facilities. There are 38 developed (having facilities) recreation sites with a total capacity of 1902 people at one time (PAOT).

The existing trail system is a remnant of a formerly extensive system which has largely been replaced by roads. The Forest currently maintains 96 miles of nonmotorized summer trails. There are 9 miles of cross-country ski trails and 75 miles of snowmobile trails. Twin Pillars and Round Mountain trails are National Recreation Trails.

Supply:
Developed recreation capacity could be increased to support an additional 925 PAOT. This increase in PAOT's would be accomplished by increasing site capacity of existing sites and the construction of several new sites. As much of the Forest is currently roaded, the dispersed roaded recreation opportunities far exceed the demand.

The current inventory of roadless areas on the Forest (not including wilderness) totals 45,893 acres: Lookout Mountain, 16,594 acres; Rock Creek, 9,336 acres; Cottonwood, 9,737 acres; Silver Creek, 3,226 acres, and Green Mountain, 7,000 acres.

Demand:
Overall recreation demand is correlated with the population increase of approximately 1% per year. Demand for recreational vehicle camping, hiking, and interpretation is increasing at a higher rate than many other recreational activities. Hiking demand is highest in the semiprimitive natural setting. The latest information in the State-wide Comprehensive Outdoor Recreation Plan (SCORP) indicates that although more use actually occurs in roaded modified settings, the predominant preference is for primitive and semiprimitive nonmotorized settings.

The demand for roadless recreation expressed in RVD's is shown in Table 2-1. If all of the inventoried roadless areas were managed as semiprimitive nonmotorized (SPNM), the Forest could meet the demand for roadless recreation for 50 years and beyond.

The demand for future management of roadless is summarized as follows:

Lookout Mountain was the most controversial area. The majority of people who commented
on the Draft Plan favored continued management of the area for nonmotorized recreation, while others wanted a motorized access route to the top.

There was general support for managing Silver Creek, Rock Creek, and Cottonwood as roadless areas.

There was little support for managing Green Mountain for nonmotorized recreation.

Social and Economic

Current Situation:
In Crook and Harney Counties, over 80% of the forested land is in public ownership, most of which is administered by the Forest Service. The surrounding communities are significantly affected both socially and economically by resource management on the Forest. County revenues from the Forest exceed 30% of some local counties’ total annual receipts. Timber industry and government agency employment accounts for approximately half of the economic base. Livestock grazing on the Forest is vital to some local ranchers and important to the communities’ social character. The Forest also provides numerous recreational opportunities.

Supply:
The Forest has the ability to supply more outputs which influence jobs and payment to counties than current levels. Higher levels of these outputs (timber and domestic livestock) generally mean less opportunities for leisure activities such as hunting and roadless recreation.

Demand:
The Forest will continue to be relied upon for outputs that affect the social and economic character of the local communities. As the demand for all outputs and opportunities continue to grow, it is unlikely that the Forest will be able to provide for all aspects that influence the social and economic character of the local communities.

Timber

Current Situation:
Timber production from the Forest contributes significantly to the local economy and to the regional timber supply. The level of harvest directly affects income, employment, and county revenues in the Forest’s six-county general zone of influence, and particularly in Crook and Harney counties, the Forest’s primary zone of influence.

The average annual sale volume between 1979 and 1988 was 137 MMBF for all species, including 109 MMBF of ponderosa pine. The average annual cut, during this period, was 111 MMBF for all species, which included 87 MMBF of ponderosa pine.

Growth and inventory of forest stands is measured in units of cubic foot volume because it is independent of numerous product requirements occurring within a locale, region or the nation as a whole. Board foot volume measurement varies with size of trees and is designed for certain product specifications and current technology. Young stands that have been regenerated cannot be measured in board foot or equivalent units of measurement; attempting to do so would underestimate the biological potential of timber producing lands and make future growth projections impossible. It is Forest Service Policy (FSM 1922.15) to use cubic foot volume as a measurement of long-term sustained yield, as well as regulate the amount of timber to be offered and sold as specified by the allowable timber sale quantity (ASQ), in order to respond to changing technology and product requirements projected for the future (RFA, ’85).

Supply:
The maximum volume of timber that could be harvested annually on a sustained yield from the Forest, subject to legal requirements, is 23.3 MMCF - 10 percent higher than the current harvest. The maximum long-run sustained yield is 22.8 MMCF.

Measured in board feet, the maximum potential yield declines to two percent below the present harvest by the fifth decade (2026-2035). This is because
the smaller diameter trees produced in the future will saw into fewer board feet relative to cubic feet than the large diameter trees being harvested now. Due to past rates of harvest, the supply of large diameter ponderosa pine has been declining, resulting in smaller diameter trees and less ponderosa pine being produced in the future.

In the short term, the harvest could be increased by departing from nondeclining even flow. This would result in more timber available in the near future, but less thereafter.

The species mix will likely change in the future. While there is still a substantial volume of ponderosa pine standing on the Forest, future harvests will likely include greater percentages of Douglas-fir, western larch, and white fir than in the past.

**Demand:**
The Forest does not have the capability to meet local demand for timber as indicated by the installed mill capacity. The installed mill capacity in Crook and Harney counties is 400 MMBF annually. In 1987, the mills processed 280 MMBF - 70% of capacity. In 1982, they processed 87 MMBF, which was 25% of capacity at that time.

The mills are set up primarily to process large diameter ponderosa pine logs, and the greatest demand is for ponderosa pine. The change in tree size and species in the future will require the mills to continue retooling to process this change of materials. Industry is demanding not just that an adequate volume of timber be offered for sale in the future, but that a good share of it be large diameter ponderosa pine.

The Forest Service Pacific Northwest Region apportioned the RPA targets to the 19 Forests in the Region. The Ochoco National Forest was assigned a goal of 25 MMCF (150 MMBF) annually, for the years 1986 through 1995. This level of harvest would be maintained into the future. The demand figures are shown in Table 2-1.

In 1980, the Oregon State Forestry Department issued its "Forestry Program for Oregon." Within this report, output levels were assigned to various land owners: state, federal, private, and industrial. The outputs assigned to the Ochoco National Forest are shown in Table 2-1. In summary, the State calls for increasing the harvest on the Forest by over 20 percent in the 1980 to 1990 period.

The maximum supply could meet the state demand for the next 50 years, but could meet the RPA demand for only 20 years.

**Wildlife**

**Current Situation:**
There are over 375 different species of reptiles, amphibians, birds, and mammals known or expected to inhabit the Forest; 15 species of game fish, and numerous nongame fish species are in the area's reservoirs, lakes, and streams. Deer, elk and antelope are big game animals hunted on the Forest. Anadromous (steelhead) fish spawning occurs in some streams.

Habitat is known or expected to exist for the following species classified by state or federal wildlife agencies as endangered, threatened, or sensitive: peregrine falcon, bald eagle, Swainson's hawk, western sage grouse, greater sandhill crane, long-billed curlew, common loon, Malheurs spotted sculpin, wolverine, and redband trout.

**Supply:**
The Forest has potential habitat to support 4,040 elk by the year 2030. The current elk population is estimated at 2,300. The primary factors influencing big game habitat are: the amount of timber harvest, selection of silvicultural systems, and the extent and use of the road system.

The Oregon Department of Fish and Wildlife (ODFW) has a current planning benchmark of 2600 elk.

The deer population is estimated at 18,300, which is the ODFW management objective. The habitat could support a larger population.

MM$ - Million Dollars
M Cords - Thousand Cords
MAUM - Thousand Animal Unit Months
MRVD - Thousand Recreation Visitor Days
MMCF - Million Cubic Feet
ASQ - Allowable Sale Quantity
The Forest has the potential habitat to support larger populations of deer and elk than is required by the ODFW's management objectives.

Demand:
The primary demand for wildlife on the Forest is for populations of deer and elk large enough to be hunted. Hunting license sales are expected to grow two percent annually between 1986 and 1995, and one percent annually thereafter.

Although the demand for hunting opportunities is expected to increase in the future, big game population levels are ultimately limited by the capacity of the environment to support them. Control through hunting is a means of regulating big game populations at levels compatible with their habitat capacity. The authority for establishing hunting seasons and regulating populations rests with the State.

Habitat for Wildlife Species Dependent upon Snags

Current Situation:
The number of snags (standing dead trees) across the Forest is quite variable. In the mixed conifer stands on the north slopes, snags are fairly abundant. On the southern slopes, where ponderosa pine stands predominate, snags are relatively scarce because of timber harvesting and firewood cutting.

Snags provide habitat for many species of wildlife. Snags and down logs are used for nesting and/or shelter by at least 39 species of birds and 23 species of mammals. The number of snags is usually the limiting factor controlling the population of birds that nest in snags.

Supply:
The Forest is presently providing about 47 percent of the potential population level of cavity nesting species. A 40 percent level is dictated in General Forest, General Forest Winter Range, and Winter Range management areas. Other management areas do not have any level dictated but predominantly end up with higher than the 40 percent level due to other resource management constraints. Forest-wide, we will be managing for 49 percent of the potential population level of cavity nesting species by the end of the second decade, and 54 percent by the fifth decade.

Demand:
Demand for snag habitat is difficult to determine. The management requirement level (MR) is 20 percent of the potential population level. This is the level needed to maintain viable populations of cavity nesting species. Regional guidance is to provide for 40 percent of potential population on General Forest, General Forest Winter Range, and Winter Range management areas. Most of the other management areas have a higher than 40 percent level because of other resource constraints. Overall, the Forest will be averaging between 47-54 percent of potential population over the five decade planning horizon.

Information Needs

This section lists possible information, inventory and research needs for the Ochoco National Forest. Gaps in data or scientific knowledge that would be desirable to fill prior to preparation of the next Forest land and resource management plan are recognized. Organization and development of these needs is based on the biological, physical and social ecosystems which are the foundation for the planning process.

This ecosystem perspective has been used to develop a comprehensive framework for identifying and organizing information, inventory, and research needs. This framework is intended to encourage integrated research approaches that address interdisciplinary needs rather than traditional functional approaches.

The ecosystem approach should meet planning needs, as well as help the public understand information needs.
Several situations were identified as having particular current importance in forest planning. Old growth, riparian/aquatic, upper slope ecosystems, and human interactions within the forest environment, are examples of areas where more information would be desirable in order to test present planning assumptions as plans are implemented.

Information needed to address potential concerns fall into the five general categories: interactions/processes, long-term productivity, cumulative effects, social and economic analysis, and wildland/community relations.

**Interactions/Processes**

This category includes information leading to a better understanding of the interactions of ecosystems, and the physical, biological, social, and political processes that influence these ecosystems.

Refine recreation carrying capacity estimates by development of predictive model figures for dispersed recreation.

Determine the relationships between recreational settings, use, and opportunities and other resource uses.

Survey streams for native fish. Determine occurrence, distribution, and status.

Improve knowledge of the distribution and habitat requirements of wildlife associated with old growth forests.

Understand the relationships between old growth characteristics and ecological and visual diversity, associated plant and wildlife species, and the maintenance of natural gene pools.

Assess the effects of landscape patterns of timber harvest and road construction on biological diversity (including management indicator species) and stability of special habitat areas such as Research Natural Areas.

Determine the effects of vertebrate species on other ecosystem components (e.g., effects of big game on plantations, and effects of insectivorous birds on forest insect populations).

Assess effects of stream segmentation by barriers caused by road crossings, debris, etc., on fish production potential.

Assess fish productivity of various stream and lake habitats, and the effects of management activities on fisheries potential. Determine sediment types and levels that affect fish habitat components.

Assess the results of stream rehabilitation projects on fish population dynamics.

Develop effective methods of uneven-aged management to produce maximized resource benefits.

Evaluate the relationship of uneven-aged management with fuels treatment, long-term site productivity, designated skid trails, and reforestation needs.

Develop strategies (rotation length, stocking levels) for producing higher quality wood.

Develop strategies that minimize soil disturbance and compaction during harvesting, and post harvest activities.

Identify specific sites and situations where natural regeneration can be a successful management option.

Evaluate the costs and benefits (both monetary and nonmonetary) of alternative logging residue treatments.

Develop data base (inventory) and analysis techniques to identify sites that are uneconomical to manage for timber production given the anticipated variation in production costs and price.

Increase knowledge of site/moisture relationships in harvested areas (micro-watersheds).

Develop a predictive methodology for sediment production and soil productivity for use in project-level planning.

Identify key soil chemical or physical factors which might be monitored to determine significant impairment of long-term productivity.

Improve total tree biomass information that is needed to evaluate whole-tree harvesting practices.

Evaluate the effects of stand treatment combinations on understory composition in managed stands.
Evaluation of the Management Situation

Evaluate the effects of fire (presence or absence) on the nutrient cycle in local stand types.

Develop a drainage-specific predictive model for fisheries and the effects of habitat modification.

Identify the effects of prescribed fire on old growth habitat components.

Determine the necessary size of an old growth habitat area to support a pair of pileated woodpeckers.

Develop an effective technique to regenerate mountain mahogany, bitterbrush and aspen.

Discover how seasonal vegetation changes affect pocket gopher utilization of their habitat.

Discover how elk use different timber stand conditions. Identify whether we are treating ponderosa pine in a way that precludes future elk use.

Determine the abundance and distribution of redband trout and Malheur mottled sculpin (sensitive species) in the Silver Creek Basin on Snow Mountain Ranger District.

Determine what good avian indicator species for monitoring riparian habitat are. Determine which monitoring techniques are relatively low cost, but provide a reasonable level of reliability.

Discover how big game, both deer and elk, are responding to prescribed fire that has been applied to Pine Spring Basin in order to improve their habitat.

Determine elk use relative to Habitat Effectiveness Index values.

Determine if elk use patterns change on summer and winter range after timber management activities.

Determine fidelity of elk to winter concentration areas in the Horse Heaven drainage relative to varying winter severity. Determine if use patterns vary relative to severity of winter.

Locate calving areas in the Horse Heaven/Lookout Mountain area south of Big Summit Prairie.

Improve knowledge of requirements necessary to support viable populations of indicator species.

Long-Term Productivity

This section includes studies leading to better understanding of ecosystem needs in order to maintain various aspects of long-term productivity.

Determine user (visitor) needs and expectations for recreational opportunities.

Inventory wildlife habitats: riparian, wetlands, old growth forests, snags, and lodgepole pine by biological, chemical, and physical characteristics.

Assess the importance of seral vegetation in maintaining long-term site productivity for dependant species.

Determine the amount and distribution of in-stream woody debris necessary to maintain the productivity of fish habitat.

Determine the effects of forest fragmentation on ecosystem integrity and function, including viability of vertebrate species.

Determine the effects of management practices on the incidence and severity of pathogens and insects as they affect the condition of the Forest over time.

Develop local yield studies for principal timber species growing in managed conditions.

Evaluate the effects of soil compaction on long-term productivity.

Assess the effects of harvest practices and residue treatments on long-term productivity.

Understand the role of fire in the nutrient cycles that maintain long-term productivity.

Identify which nutrients, if any, are limiting production on the Forest.

Identify the current productivity levels of resources such as timber, wildlife forage, and fish habitat to establish baseline levels of productivity.

Identify the mineral potential of the Forest.
Cumulative Effects

This section includes studies to examine the cumulative effects of naturally occurring and human-induced activities on various aspects of selected ecosystems and resources.

Develop indicators or criteria to predict when recreational user patterns may change as a result of intensive forestry practices.

Determine wildlife and fish species reactions to patterns of habitat created or altered by management and natural succession.

Develop a drainage-specific predictive model for fisheries and the effects of habitat modification.

Determine the effects of human disturbance and livestock competition on wildlife species.

Assess the potential effects of predation of management indicator species on each other in small fragmented habitat units.

Evaluate the effects of planting genetically-selected stock on stand growth and yield, pathogen and insect population dynamics, forage nutritional quality for wildlife, etc.

Determine the cumulative effects of timber management activities (timber harvest, road construction, and site preparation) on water quality and stream stability and fish habitat.

Develop threshold of sediment production for cumulative effects on the soil and water resource considering the value of the water and the uses associated with the water.

Evaluate the cumulative effects on soil productivity by ground-based timber harvest equipment under uneven-aged management strategies.

Evaluate the effects of fire exclusion on the structure and function of ecosystems.

Social and Economic Analyses

Additional studies are needed to increase our understanding of the economic and social effects of many planned wildland activities.

Measure and predict the effects of changes to wildland landscapes on recreational values, both in economic and social terms.

Understand the effects of long-term changes in site productivity for a range of resources on local and regional economies.

Evaluate the relative costs of strategies aimed at managing the effects of pathogens and insects on stand growth and yield, recreation values, water quality, etc.

Evaluate decision processes that can compare market and nonmarket benefits.

Identify Forest Service contributions to the local economy and the dependency of local communities on the Forest.

Determine the economics of pruning ponderosa pine.

Evaluate the quality (grade, species, size) of wood that will be needed by local industry in the future.

Wildland-Community Relations

The relations and interactions between wildlands and the human communities within and around them need to be better understood.

Evaluate the patterns of resource theft and develop techniques for reducing losses.

Develop vegetative strategies that reduce risk of wildfire and recognize adjacent community values and concerns.
Chapter 3

Response to Issues, Concerns, and Opportunities
Chapter 3

Response to Issues, Concerns, and Opportunities

Overview

The Ochoco National Forest initiated its public involvement process in 1980 to prepare for the Draft Plan and Environmental Impact Statement (EIS). There has been a major effort throughout the process to capture and incorporate public and agency ideas so that the Final Ochoco National Forest Plan can be responsive to concerns and new information. This has been a continuing effort. The Plan is intended to be dynamic in its ability to respond to new ideas, issues or information as circumstances may require.

Issues Display and Discussion in the Final EIS

A discussion of the changes in issues from the Draft to the Final and how the Plan will address the issues follows.

Issue #1, Timber Supply and Forest Management, continued to be a major concern. Subissues relating to timber supply and forest management have been identified and are treated separately.

Timber Supply and Sustained Even-Flow Yield: Timber industry and dependent publics continued to offer support for sustained yield of 137 MMBF annually. Local economic stability and jobs were strongly related to high harvest levels by timber industry and dependent publics. At the other end of the spectrum, conservationists favored a much more conservative harvest level of 75 to 90 MMBF annually.

Between 1990 and 2000, the average annual harvest will be 19.0 MMCF (ASQ) (115 MMBF), slightly below the current harvest level. The volume of ponderosa pine offered annually will average 85 MMBF. This represents a considerable decrease from pine volume sold between 1980 and 1988, which averaged 109 MMBF annually.

The long-term sustained yield for this Plan is 19.0 MMCF. This is 82 percent of the potential estimated in the Maximum Timber Benchmark (23.5 MMCF).

The timber harvest will be modified in some areas to protect other resources. In old growth and roadless areas, harvest will be prohibited. In riparian areas and scenic corridors, rotation time will be lengthened. In big game areas, thinning practices will be altered.

Ponderosa Pine Management: There was significant support for the production of large diameter pine (at least 20 inches in DBH) and a timber supply scenario to sustain large diameter pine production over time to maintain the present industry base in Prineville and surrounding communities. The importance of large diameter pine to wildlife and as a visual resource was noted by other interest groups.
The strong interest in maintaining large diameter ponderosa pine over time has been incorporated into the Final Plan with even-aged silvicultural systems designed to provide an average tree of 18 inches DBH, and uneven-aged silvicultural systems designed to provide ponderosa pine greater than or equal to 20 inches DBH. Special management areas in the Final Plan will also provide large ponderosa pine greater than 20 inches DBH with some, such as Old Growth, providing old growth pine of diameters up to their biological potential in some cases.

Uneven-aged vs. Even-aged Silviculture: The timber industry and other groups noted some advantages and expressed general interest in the Forest exploring uneven-age management strategies on all or portions of the Ponderosa pine stands available for timber management. Industry sees this as a means to allow the continuation of high harvest levels in pine while providing a quality log. Conservation groups and other publics sensitive to even-age management systems see this as a means to limit clearcutting, reduce harvest levels and preserve a forested appearance over time.

In the first decade, 62,200 acres of forest land will be managed through uneven-aged timber harvest prescriptions. Even-aged timber harvest prescriptions (clearcuts, shelterwoods, and overstory removals) will be applied to 82,900 acres.

Departure: The preferred alternative in the Draft Plan proposed a departure from sustained yield to maintain high timber supplies for the first decade. There was essentially no support for this departure. Industry predicted that the departure option would result in an unstable timber supply which would negatively affect business and community stability. Conservationists suggested that the departure option was merely an euphemism for the rapid liquidation of old growth forest.

The timber harvest is scheduled to maintain a non-declining yield. The objective will be to maximize timber production within the constraints of the Plan, and maintain a sustained timber supply over time.

Clearcutting: There was almost unanimous opposition to clearcutting. Many opposed it as a waste of younger stock and potential crop trees. Others cited the adverse effects of clearcutting on other resources. Industry expressed some acceptance of clearcutting in mixed conifer stands, but regarded the clearcutting of Ponderosa Pine as unacceptable.

In the first decade, there will be 8,700 acres of clearcuts in mixed conifer stands. Root rot and other insect and disease problems, plus slash disposal needs, make any type of partial removal impractical for most of the mixed conifer stands. Ponderosa pine will be harvested with overstory removals, as appropriate. Clearcuts are used to harvest ponderosa pine only rarely when insects or disease preclude other harvest methods.

Issue #2, Social and Economic Wants and Needs of Local Communities, continued to receive the attention of the timber industry and dependent publics. These groups were adamant in demanding a high timber supply to maintain the local economy and jobs. Others called this viewpoint short-sighted and suggested that the rapid conversion to second growth/fiber management might not be positive in the long run. These respondents reasoned that old growth contributes more to the local economy even if harvest levels are significantly reduced, because old growth ponderosa pine has a much higher commercial value than second growth. This issue is interrelated with the departure, uneven-age, and ponderosa pine issues discussed in Issue #1.

Some comments noted the importance of grazing on local economies. These respondents expressed concern over the negative effect that reductions in grazing would have on Crook and Harney Counties. This issue is discussed in Issue #3, livestock grazing.

Local communities are dependent on forest-related jobs and income, and payments to counties in lieu of taxes. As a result, economics is the major factor in measuring the social and economic effect the Plan will have on these communities.

1These figures include the Crooked River National Grassland.
Using computer models (described in FEIS Appendix B), the economic effects of the Plans for the first decade were estimated.

- **Income**
  - Increase $1.737 million
- **Employment**
  - Increase 124 jobs
- **Payments to counties, average annual**
  - $4.9 million

Payments to counties will increase to $5.6 million in the second decade and then decrease to $5.4 million by the end of the fifth decade.

**Issue #3, Livestock Grazing or Grazing Allotments**, remained a major issue for the management of the Forest. In the public comments to the Draft, concern was expressed over the impact of grazing on riparian areas and big game habitat. Many felt livestock grazing numbers could not be increased while simultaneously improving riparian conditions. Others stated that the economies of Crook and Harney Counties are dependent on ranching, and that significant reductions in livestock numbers would have adverse effects on those economies.

Grazing will remain level or slightly decrease in the first decade and then slowly increase over time with improved management, improved riparian conditions and the installation of range improvements.

The use of riparian areas by livestock will decrease in the first decade. This will be offset by increasing forage production on transitory range, improved forage production resulting from nonstructural range improvements, and construction of water developments to distribute livestock into areas where forage is available, but natural water sources are not.

**Issue #4, Riparian Area Management**, received additional interest during the public comment period to the Draft. Generally, comments addressed the impacts of grazing, timber harvest and road building. As noted in the discussion for Issue #3, concern was expressed over the proposed increases in grazing numbers and how this might prevent the Forest and Grassland from improving riparian conditions.

All riparian areas on the Forest will be managed to achieve “excellent” condition. Fencing, log weir construction, rock structures, shrub plantings, and woody debris additions will be used to improve riparian conditions. These improvements will be completed in the first decade. However, it will be 20 to 60 years before all riparian areas have attained their full biological potential.

**Issue #5, Transportation System**, brought 1000 comments on the FEIS. Some commented that too many roads are constructed and that road standards are too high. These respondents expressed concern over the cost of road construction and maintenance.

Support was voiced for the physical closure of roads to protect water quality and sensitive areas. Both temporary and permanent road closures were recommended to protect wildlife habitat. This is different from the comments made at the first public meetings, which opposed the closure of areas to access by motorized equipment. This view was expressed in comments stressing the need for roads to provide recreation access for the elderly and handicapped.

A travel plan for the Forest will address road management concerns and will complement the objectives of the various management areas on the Forest and Grassland. Wildlife habitat effectiveness objectives will be partially met through road restrictions and closures. The number of miles of roads maintained open for public travel on the Forest will decrease nominally in the future as a result of these road restrictions and closures for big game habitat protection and erosion control and public safety.

In the first decade 840 miles of road will be maintained for passenger car travel, and 2,330 miles will be maintained for high clearance vehicles. By the fifth decade 850 miles will be maintained for passenger cars, and 2,270 miles for high clearance vehicles.

Roads will be closed to protect soil and water, prevent disturbance of big game, and limit investment loss. In the first decade, 1,160 miles of roads will be closed. In the fifth decade, 2,190 miles will be closed. Closures may be seasonal or year long.
Issue #6, Big Game Habitat, was second only to timber in the number of public comments on the Draft. The public continues to be very interested in the number of elk and deer on the Forest and Grassland. In particular, there was support voiced for population levels of elk higher than those proposed by the Draft Plan and the Oregon Department of Fish and Wildlife (ODFW). The public supported the management of big game winter range and the management of road systems to attain habitat effectiveness.

The Forest Plan will designate important areas of big game winter range in two management area classifications: Winter Range (64,130 acres) and General Forest Winter Range (107,360 acres). Management for big game habitat will be the primary emphasis in winter range. In addition, wildernesses, roadless areas, old growth areas, and Hammer Creek Wildlife/Recreation Area will provide important big game habitat.

The Final Plan will provide standards and guidelines for the management of cover and road management that will support elk numbers that meet the population objectives of ODFW. In these areas, road use and thermal cover will be managed to provide high quality big game habitat. Habitat will support 3,000 elk in the first decade, decreasing to 2,870 in the second decade, and to 2,620 by the fifth decade due to the effects of timber management. The ODFW’s current planning benchmark for elk on management units within the Forest is 2,600.

Issue #7, Roadless Areas and Wilderness Study Areas, generated the third highest number of comments on the DEIS. Public comments focused on Lookout Mountain and the Ochoco Canyons area of the Forest.

Lookout Mountain has received a lot of public interest from the beginning and continues to concern public groups and the Forest Service. Because of competing interests over available resources, the area has received special attention during the planning process.

Comments about Lookout Mountain involved access, recreation and multiple use. Commentors disagreed as to whether or not Lookout Mountain should be managed as a roadless area. Many supported a roadless designation, while others felt that the existing roads should be reopened to allow senior citizen, handicap or recreation access. There was also significant disagreement over the appropriate size of the area to be left roadless.

Other comments addressed timber management in this area. Some commentors felt that timber should be harvested, while others felt that management should stress recreation and wildlife.

Ochoco Canyons, Green Mountain, Silver Creek and the North Fork of the Crooked River also received comments. There was strong sentiment for the retention of existing roadless areas by some, while others objected to the single-use designation as precluding other uses. Some respondents recommended that roadless area management reflect a compromise between natural values and commodity production.

In the Final Plan, 15,660 acres at Lookout Mountain are allocated to remain unroaded. Cottonwood, most of Rock Creek, and a portion of Silver Creek, totaling 14,300 acres, will be retained as roadless areas and managed for semiprimitive nonmotorized recreation. Green Mountain will be managed as general forest. The Draft proposed semiprimitive motorized recreation which was determined not to be appropriate for the area and not supported by public comment.

The total wilderness, proposed wilderness, and unroaded acreage is 83,800 - about 10 percent of the Forest. Combined, unroaded areas and wilderness will meet the expected demand for semiprimitive recreation until the year 2025. A number of other special management areas which will also provide nonmotorized recreational opportunities have been designated. These are Summit National Historic Trail, Stein’s Pillar, Hammer Creek, Deep Creek and Round Mountain National Recreation Trail.
**Issue #8, Scenic or Visual Resources**, continued to receive public interest. Generally public comments to the DEIS concerned the retention of the scenic corridor along Highway 26.

Some comments supported increased emphasis on visual resources, while others supported less emphasis. Those favoring less emphasis expressed concern that an emphasis on visual resources would result in reduced harvest levels.

The Plan will provide for a number of scenic corridors where the primary emphasis will be to meet visual quality objectives in order to maintain and enhance key scenery. Travel corridors, including major roads, access roads to roadless areas, and a winter sports corridor on the Big Summit District, will be managed for scenic qualities. Scenic corridors will total 40,110 acres, 38 percent of the maximum potential of 106,700 acres. These scenic corridors will provide the public with views of large ponderosa pines in park-like settings.

Parts of the Summit National Historic Trail, roadless areas, dispersed and developed recreation areas, Bandit Springs, Stein’s Pillar, Hammer Creek, Deep Creek, and the North Fork Crooked River Scenic and Recreation Corridors will be managed to maintain a natural or near-natural appearance.

**Issue #9, Old Growth Forest**, generated over 1000 comments on the DEIS. A majority of the comments supported a larger allocation for old growth. In addition, there was interest in increasing the old growth management area size over that in the Draft Plan.

Approximately 47,890 acres will be managed for old growth: 19,990 acres specifically allocated to old growth management, and another 27,900 acres in wilderness and other special management areas (Wilderness Study Areas, Research Natural Areas, Summit National Historic Trail, roadless areas and facilities). This allocation includes 1,270 acres of timber stands which are mature, but not far enough along in succession to meet the definition of old growth. This represents 228 percent of the minimum level required by old growth dependent species (21,000 acres), and 51 percent of the maximum old growth available on the Forest (93,800 acres).

Refer to Table II-8 for acres of old growth by species.

The size and distribution of areas managed for old growth were designed to meet habitat requirements for the pileated woodpecker, a management indicator species. These areas will also provide habitat for other species dependent upon old growth.

The existing mature stands and designated old growth outside Old Growth, Wilderness, and other special management areas will be subject to timber harvest. By the year 2030, it is expected that only the following areas will contain stands of timber with trees up to 27 inch DBH: wildernesses, Research Natural Areas, old growth areas, Summit National Historic Trail, Rock Creek/Cottonwood Creek Roadless Area, Silver Creek Roadless Area, Lookout Mountain Recreation Area, eagle roosting areas, facilities, developed recreation areas, dispersed recreation areas, Bandit Springs, Highway 26 Visual Corridor, visual management corridors, Round Mountain National Recreation Trail, and Hammer Creek.

**Issue #10, Fuelwood Supply**, also generated over 1000 comments to the DEIS. The comments supported the continuation of fuelwood supplies into the future. This plan will continue to make firewood available to the public at levels commensurate with project activity and available access. A moderate amount of firewood will be available, approximately 13,000 cords annually, between 1990 and 2000.

Between 1984 and 1989, the annual demand for firewood on the Forest and Grassland has been less than 10,000 cords. Thus, it appears that demand will exceed supply.

**Issue #11, Snag Dependent Wildlife - Cavity Nesters**, continued to receive some interest. Although the number of comments was limited, they voiced support for the retention of snag habitat and concern that the Draft Plan did not adequately protect snag habitat.

Moderate (74 percent of potential) and fairly well distributed levels of habitat will be provided for cavity-dependent species. Snag levels will vary by management areas, ranging from 40 percent in intensively managed areas to 100 percent in wilderness areas.
and unroaded areas. Snags will not be allowed to remain in minor areas, such as developed recreation areas and facilities, for safety reasons.

**Issue #12, Winter Sports**, also received continued attention by segments of the public. The development of additional winter sports trails and snow park areas was widely supported. Some skiers supported the creation of separate use areas for skiers and snowmobilers.

Comments regarding conflicts between snowmobiles and cross-country skiers in the Lookout Mountain area were received. Opinions included eliminating snowmobile use, constructing separate cross-country and snowmobile trails, and allowing unrestricted snowmobile use.

Most of the Forest, except for Bandit Springs and Wilderness Areas, will be open to snowmobiling. Bandit Springs (1580 acres) will be limited to non-motorized winter sports, such as snowshoeing, cross-country skiing and sledding. Lookout Mountain Recreation Area will be open to snowmobiling.

**New Issues**

Public involvement, including comments on the DEIS, has resulted in the Forest adding four new issues to the twelve developed for the DEIS. Two of the issues are extensions of previous issues where it became evident that special attention would be appropriate in the FEIS to capture public concerns and allow full assessment of the issue in the development, analysis and selection of a final alternative for the Forest and Grassland Plans.

**Anadromous Fish**: Anadromous fish were not identified as an issue in the development of the DEIS and proposed Forest Plan. In the responses to the DEIS, anadromous fish were identified as a concern by several individuals and groups, including the Columbia River Inter-Tribal Fish Commission. Primary concerns included protection and enhancement of spawning habitat and the adequacy of the monitoring plan. Native American groups noted that treaties guarantee protection for anadromous fish habitat.

All riparian areas, including streams which support anadromous fish, will be managed for "excellent" condition. There will be 26 smolts per 100 square meters of streamed in the first decade, increasing to 126 smolts per 100 square meters in the fifth decade.

**Historic Trail Preservation**: It is Forest Service policy to identify and preserve cultural resources. The Ochoco National Forest has an old trail that was the major east-west travel route through the Forest for many years. The Summit Trail was originally constructed in the early 1900's as a pack trail, and continued to provide access as a trail system until the late 1930's. The significance of this trail was recognized by the Forest Service in January 1987, when it was nominated to the National Register of Historic Places. This action was subsequently followed by a Forest decision to protect and manage the trail corridor for its historical significance. Comments overwhelmingly favored the re-establishment and protection of this trail.

The Summit National Historic Trail is allocated to a management area in the Final Plan. This management area includes 170 acres of preservation, 5,600 acres of retention, and 3,790 acres of partial retention visual quality objectives. The outer boundary of the management area will generally not exceed 600 feet on either side of the trail.

**Off-Road Vehicle (ORV) Use**: This issue emerged during the issue/Final Plan validation phase. Most respondents desired a reduction in ORV use on the Forest and Grassland. Some favored a total ban on ORV's, while others felt use should be prohibited in sensitive areas. Damage to the environment and noise levels were the reasons given for restriction or prohibition.

In contrast, some respondents requested additional areas for ORV use. They felt that the Forest and Grassland have enough nonmotorized opportunities and that motorized recreation opportunities are lacking.

Only trails historically established for exclusive ORV use are being designated at this time. Any others will be accomplished in the Plan implementation phase through site-specific analysis and further planning.
Round Mountain: In its response to the Draft Plan, the Oregon Hunters Association (along with a number of other sponsors, such as the Oregon Natural Resources Council) asked that a recreation unit be established for the Round Mountain area. This was brought up again by one individual in the validation process. The individual suggested that the Round Mountain area could provide the opportunity, through a specific allocation, to demonstrate some management emphasis for a working forest with special provisions for recreation, scenic, and wildlife resources.

The Plan does not create a special management area for Round Mountain. A portion of the Round Mountain area is allocated to old growth, and the Round Mountain National Recreation Trail is treated as a separate management area. The rest of the area is allocated to General Forest.

Forest Management Direction

Section 1

Forest Management Goals, Objectives, and Desired Future Condition
Chapter 4

Forest Management Direction

Section 1

Forest Management Goals, Objectives, and Desired Future Condition

Goals are generalized statements that provide broad direction for future management of the Forest. The primary goal of the Ochoco National Forest is to manage under the principles of “Caring for the Land and Serving People.” Multiple use and sustained-yield management of all forest resources are an integral part of these principles. Specific resource goals are in support of these principles and are presented in this chapter.

Objectives represent projected, potential outputs in support of overall goals. They are based on available inventory data and assumptions, subject to annual budgets. Objectives for key forest resources are displayed as average annual outputs, or totals per decade for the next five decades. They do not infer a commitment on the part of the agency to supply the appropriate resource on a regular basis, but do state the maximum output available, subject to the broad discretion of the Forest Service.

Desired future conditions summarize the anticipated physical changes that are likely to occur as a result of carrying out planned management practices over time. These descriptions are provided at ten years, and fifty years and beyond, for the Forest.
The information presented in this section provides goals, objectives, and desired future conditions for each of the key Forest resources. Resources are presented in alphabetical order. They are:

- AIR QUALITY
- BIOLOGICAL DIVERSITY
- CULTURAL RESOURCES
- FACILITIES
- FIRE
- FORAGE AND LIVESTOCK USE
- FOREST HEALTH
- FOREST RESIDUES
- FUELWOOD
- LANDS
- MINERALS AND ENERGY
- OLD GROWTH
- RECREATION
- SCENIC RESOURCES
- SOCIAL AND ECONOMIC
- SOIL
- TIMBER
- TRANSPORTATION SYSTEM
- WATER
- WILDLIFE AND FISH

Air Quality

Goal(s)

Maintain air quality at a level adequate for the protection and use of the Ochoco National Forest resources, and which meets or exceeds applicable Federal and State standards and regulations (Clean Air Act, as amended, and Oregon State Implementation Plan for Protection of Visibility in Class I Areas).

Objectives

Use the best available technology and management techniques to minimize smoke production from prescribed burning activities. Table 4-1 shows the estimate of total suspended particulates (TSP) generated in smoke from both natural and activity residue treatments.
### Air Quality

#### Biological Diversity

**Resource/Activity**

<td>TSP Generation by Prescribed Fire</td>
<td>M Tons/Yr.</td>
<td>13.2</td>
<td>12.7</td>
<td>11.5</td>
<td>7.4</td>
</tr>
</tbody>
</table>

#### Desired Future Condition

**In Ten Years**

Smoke emissions are projected to decrease over time, as shown in Table 4-1. This will result in a similar percentage decrease in visibility impairment (see Fire, Prescribed Burning Objectives, this section).

**Fifty Years and Beyond**

Emissions will decline to stable levels by the fifth decade: about 7 to 10 thousand tons per year. Improvement in visibility over the long run is primarily the result of the timber harvest schedule and an anticipated 20-40 percent reduction in the amount of excess residues in the managed stand condition.

#### Biological Diversity

**Goal(s)**

Maintain native, historic, and desirable introduced plant and animal species and communities, including those that may be threatened, endangered, or sensitive.

Maintain or enhance ecosystem functions to provide long-term productivity of forest resources and biological communities.

**Objectives**

Provide for all seral stages of terrestrial and aquatic plant associations existing and/or desirable for the Forest, with a distribution that is ecologically sound and ensures continued reproduction of the specie(s). For the Ochoco National Forest, the following diversity elements (Table 4-2) serve as objectives for defining biological diversity for both plants and animals. Values are displayed as totals, rather than average annual outputs.

Stage IV=Young (40-79 years)
Stage V=Mature (80-159 years)
Stage VI=Old Growth (160 + years)
Desired Future Condition

In Ten Years
Forest-wide, biological diversity of plant and animal communities and species will be different in ten years.

Riparian areas, which serve as critical habitat for more than 75 percent of the Forest's wildlife species, will be improved over today's conditions, as a result of specific management actions. Connective habitat, of which riparian areas are a major factor, will be available in varying degrees across the Forest to provide linkage or extensions between forested habitats for wildlife species. Some riparian areas have been purposely widened in identified areas to accommodate movement of old growth dependent species (pileated woodpecker) between primary reproductive habitats (see Section 3, Management Area Standards and Guidelines for Wildlife and Fish).

Snag habitat for cavity nesters will be at about 47 percent of potential, but will be more evenly distributed as areas currently deficient in snags are improved due to natural mortality, or created through management action.

About 94 thousand acres of old growth will exist across the Forest, with large contiguous acreages concentrated mostly in wilderness, roadless areas and Research Natural Areas. Old growth specifically allocated for dependent wildlife species (along with equal acreages of supplemental feeding habitat) will exist in a somewhat evenly distributed pattern across the remainder of the Forest in order to ensure viable populations. In addition, other old growth will exist in areas allocated for various levels of vegetative manipulation (i.e. General Forest and other management areas), but will be declining over time.

Out of a total of 572 thousand acres of forested vegetation, all successional stages are expected to be present, though they will not necessarily be evenly distributed geographically. Pole/sapling, young stands, and mature stands (Stages III-V, respectively) will comprise the largest acreage, especially across intensively managed areas of the Forest. These will be represented both vertically (uneven-aged stands) and horizontally (even-aged stands). Grass/forb and shrub/seedling stages will be increasing, primarily in mixed conifer stands, as even-aged management is implemented. Old growth (Stage VI) will be decreased, both in total acreage as well as overall distribution.

In non-forest plant communities, species dominance may change as a result of forage enhancement for wildlife and livestock, and juniper thinning or removal for watershed improvement. No planned management practices are intensive to the point that they will actually result in a change from one plant community to another for non-forest vegetation types.

Even though not specifically stated as an objective above, habitat for existing threatened, endangered, and sensitive species of plants and animals will be available as needs are identified over time. Current conditions include habitat for bald eagles, as stated in specific management area prescriptions (see Section 2,
Management Area Prescriptions for Eagle Roosting Areas; also see Threatened, Endangered, and Sensitive Plants and Animals List, Appendix C).

Fifty Years and Beyond
Forest-wide, biological diversity of plant and animal communities and species will be substantially different.

Most of the riparian areas on the Forest will be in "excellent condition" as a result of specific management actions. Connective habitat will be available in varying degrees across the Forest in order to provide linkage or extensions between forested habitats for wildlife species, but may not be as effective as today, because most timber stands in these areas will have been placed under some level of management.

Snag habitat for cavity nesters will be at about 54 percent of potential, and as evenly distributed as possible. No areas of the Forest (other than those managed for safety concerns, i.e. administrative areas) will be below 40 percent of potential.

About 55 thousand acres of old growth will exist across the Forest, but will be concentrated mostly in wilderness, roadless areas and Research Natural Areas. In order to ensure viable populations, old growth specifically allocated for dependent wildlife species (along with equal acreages of supplemental feeding habitat) will still exist in a somewhat evenly distributed pattern across the remainder of the Forest. Very little old growth will exist in areas allocated for various levels of vegetation manipulation (i.e. General Forest and other management areas), as most of these areas will have been treated.

On forested land, all successional stages should be present, though they will not necessarily be evenly distributed geographically. Young and mature stands (Stages IV & V) will comprise the largest acreage, especially across intensively managed areas of the Forest. These will be represented both vertically (uneven-aged stands) and horizontally (even-aged stands). Grass/forb and shrub/seedling stages (Stages I & II) will be approaching an acreage indicative of a fully managed forest condition, meaning that similar acreages will be represented indefinitely. Old growth (Stage VI) will be about 55 thousand acres, and most will be concentrated in wilderness, roadless areas and Research Natural Areas. The remaining acreages will be in somewhat isolated stands reserved for dependent wildlife species across the Forest, with a small acreage still available in General Forest and other management areas.

No significant change in acre distribution of non-forest plant communities is projected at this time.

Habitat for threatened, endangered, and sensitive plant and animal species will be available as needs are identified in accordance with Federal Law.
Cultural Resources

Goal(s)
Locate, evaluate, protect, and mitigate if necessary, significant historic and archaeological sites. Enhance and interpret selected sites for public enjoyment, education and interpretation after public involvement with American Indian Tribes, historical societies, and local interest and professional groups. Promote opportunities for research, and traditional Native American cultural practices, writing, and photography.

Objectives
Complete “broad-area” cultural resource inventories and documentation prior to ground-disturbing activities on the Forest (see standards and guidelines, Section 3, this chapter). Identify Native American traditional food and religious use areas, in compliance with Public Law 95-341 (American Indian Religious Freedom Act) and the Treaty of 1855, with the assistance of the Warm Springs Confederated Tribes and the Burns Paiute Tribe.

Numbers shown in Table 4-3 represent estimates of site documentation, site enhancement or interpretation, and nominations to the National Historic Register for future decades, based on past experience.

</tbody>
</table>

Desired Future Condition
In Ten Years
In ten years, 60-70 percent of the Forest will have been surveyed for cultural resources. As the demand for timber harvest and other resources in previously avoided areas increases, many significant cultural resource sites will be mitigated. This will benefit the public as well as the academic community by increasing the body of knowledge about the prehistory and history of the Forest. Accurate, meaningful interpretation of a greater number of sites will result. Similarly, greater knowledge will enable the Forest to more efficiently manage the resource.
Management plans and allocations for site and thematic site classes may have been recognized, through amendment of the Forest Plan and involvement with appropriate individuals, groups and public agencies. Traditional Native American use of sites and areas will be recognized and considered during land and resource management activities. Site enhancement and interpretation will have been performed on specific sites and thematic classes. Stabilization of threatened cultural resource sites will have been performed within or adjacent to existing public recreation and use areas.

Fifty Years and Beyond
The accumulated knowledge of historic, cultural and prehistoric site types and implementation of management plans and allocation strategies for cultural resources will reduce the need to inventory certain portions of the Forest. Information on the prehistoric, historic, and Native American cultural use of the Forest will have increased to a level that management of the resource will be efficient and precise. Advances in archaeological methods, historic research, sampling site stabilization and thematic evaluation will affect changes in management and result in more accurate interpretation of the resource. A large body of protected sites and data from mitigation projects will provide the basis for ongoing interpretive programs and facilities.

Enhancement and interpretation will begin to dominate the cultural resource program. Local citizens, groups and professional organizations will be involved in site preservation and interpretation. Native Americans will make greater use of the Forest for traditional food gathering and religious practices; they will be involved in the management and treatment of prehistoric sites and burials, and the Forest in general.

Facilities

Goal(s)
Plan, construct, maintain, and manage Forest facilities to provide maximum economy, investment protection, user safety, and resource protection.

Objectives
Facilities relate to administrative sites located across the Forest. These include ranger stations, campground facilities, work centers, lookouts and electronic sites. Future facilities construction or improvements are provided as totals (first decade only), instead of average annual outputs. See Table 4-4.

#### Desired Future Condition

**In Ten Years**

Forest facilities will be attractive to users and reflect favorably on the Forest Service. Marginal facilities will have been removed or upgraded based on need and planned life expectancy.

**Fifty Years and Beyond**

No drastic changes in location or design of Forest facilities are predicted, even though some changes may occur as a result of an aging population.

### Fire

**Goal(s)**

Control wildfire aggressively (particularly in urban-Forest interface areas), and in a cost-effective manner (minimize suppression cost plus loss).

Provide for the ecologically sound use of prescribed fire as a cost-effective management tool for achieving resource management objectives.

**Objectives**

**Wildfire Management**

Provide a cost-efficient fire management organization as determined by the National Fire management Analysis System. The Wildfire Effectiveness Index figures shown in Table 4-5 represent average annual program cost plus wildfire loss per thousand acres protected.
Table 4-5

Prescribed Burning
Reduce wildfire intensities to support a cost-efficient fire protection organization.

Emulate the natural role of fire in maintaining environmental diversity and site productivity. Maintain or improve wildlife and range habitat.

Table 4-6 provides estimates of average prescribed fire acres. It is anticipated that there may be large variations above and below these averages in any one year due to variations in available burning conditions, funding, personnel, and timber harvest schedule.

Table 4-6

</tr>
</tbody>
</table>

Desired Future Condition

In Ten Years
It is expected that about 750 acres per year will burn as wildfires, based on planned suppression organization. The Wildfire Effectiveness Index will be about $715 per 1000 acres protected.

About 25,000 acres will have been prescribed burned per year, resulting in 246,000 acres burned at the end of the first decade.

In Fifty Years
No dramatic changes in the number of acres burned by wildfire are expected. Much of the Forest will have reached a near stable mosaic of residue levels, as a direct result of managed timber stands and appropriate use of prescribed fire.
Forage and Livestock Use

Goal(s)

Provide forage for wildlife and domestic livestock in a manner consistent with other resource objectives and environmental constraints, while maintaining or improving ecological condition and plant community stability.

Objectives

Present permitted use by domestic livestock is 58,000 Animal Unit Months (AUM's). The Forest objective is to improve all range conditions to good or excellent by intensifying management. In the long run, present AUM's can probably be maintained or increased; but short-term (within this planning period) reductions in AUM's are predicted, particularly for improving riparian conditions. Average annual production for the first decade will not be substantially different from today, due to increases in upland forage production, resulting primarily from timber harvest.

Structural and nonstructural improvements play a large role in achieving overall forage management objectives. As shown in Table 4-7, improvements are planned to increase over the next decade, and then decrease to a maintenance level thereafter.

Wild horses are found on particular areas of the Big Summit Ranger District. The number of wild horses is currently estimated at 60 and is expected to be maintained at that level indefinitely (see Appendix I, Management of Wild Horses).

</tbody>
</table>

\(^1\) AUM fluctuations are due primarily to acres of transitory range made available by timber harvest type, amount and location.
Desired Future Condition

In Ten Years
Most allotments will be managed under more intensive grazing systems than present. Management changes and the resulting structural improvements necessary to improve riparian conditions to excellent will have been installed. Predicted reductions in available AUM's due to riparian exclosures and other riparian improvement practices, completed during the first decade, will generally have been offset by increases in transitory range made available through timber harvest and additional water developments installed in the uplands.

Fifty Years and Beyond
Range conditions will be good and forage production will be higher than at present due to improved range conditions. All necessary range improvements (structural and non-structural) will be completed, and the range improvement program will consist primarily of reconstruction and maintenance. Most riparian areas will be in excellent condition.

Forest Health

Goal(s)
Maintain the health of the Forest for present and future uses, within management's ability to do so. Forest health is defined as "a condition where biotic and abiotic influences on the Forest (i.e., insects, diseases, atmospheric deposition, silvicultural treatments, harvesting practices) do not threaten management objectives either now or in the future."

Objectives
Utilize Integrated Pest management (IPM) strategies to maintain forest health. Prevention and control of damage to forest resources, caused by insects, diseases, and noxious weeds will be accomplished through a number of practices. Resource activities to control pests will depend on site specific analysis and may vary greatly from year to year. Emphasis will be on prevention rather than control. When control is necessary, the method with the least impact on the environment will be used. Best estimates of activities for the next five decades are shown in Table 4-8. These do not represent target acres of accomplishment.

Note: These acres do not include scheduled activities for resource management, such as precommercial thinning.

\( v \) Includes 25 acres of noxious weed control

\( ^2 \) Primarily related to control of spruce budworm and other defoliators, using Bacillus thuringiensis (B t ), or other suitable biological agents

**Desired Future Condition**

**In Ten Years**
Integration of pest management strategies in all activities will be practiced. Some of the most important activities are:

- Accelerated precommercial and commercial thinning in overstocked ponderosa pine and lodgepole pine where this can be done within management area and economic limitations.

- Attempts to identify severe root rot pockets and to treat these stands as soon as practical.

- Stands being regenerated, including selection cutting, emphasizing treatments that will favor early seral species. This will be done by a combination of prescribed fire, planting, site preparation for naturals, and seed tree selection.

**Fifty Years and Beyond**
Continued practice of standards and guidelines for Forest Health should provide stands with manageable levels of most root rots, dwarf mistletoe, and bark beetles. Care will be needed when planning projects around the boundaries of old growth or wilderness areas to prevent encroachment of diseases. Forest managers will need to be on the alert for insects and diseases in the younger stands as these become more common.
Forest Residues

Goal(s)

Manage forest residues (woody biomass), resulting from either natural or man-caused processes, as a separate resource. Provide this resource for the benefit of resources such as soil, water, wildlife, and timber, as well as for the social and economic benefits associated with firewood gathering and other family oriented endeavors centered around residues.

Objectives

Provide for natural levels of forest residues consistent with the access, vegetation community, stage of stand development, on-site nutrient cycling, diversity, and forest protection needs. Desired residue profiles for common vegetation types around the Forest are shown in Forest-wide Standards and Guidelines under Forest Residues. More specific profiles by management area are shown in Section 3, Management Area Standards and Guidelines. Approximately 12 tons per acre represents a weighted average residue condition across the Forest. This equates to about 10.4 million tons of minimum residue requirements for the whole Forest (See Minimum Site Requirements, Table 4-9.)

Remove residues that exceed minimum site requirements. Attempt to use excess residues to reduce the impacts of alternate disposal methods (machinery operations and/or emissions from prescribed fire).

Table 4-9 shows how the amount of forest residues change over time. Units represent total amount of residues available on the Forest at any one time, and not an average annual output.

<td>13.7</td>
<td>13.1</td>
</tr>
</tbody>
</table>
Desired Future Condition

In Ten Years
The Forest will continue to develop and implement its residue management program to assure the proper retention, use, and disposal of forest residues.

Compared to today, residues (activity slash, etc.) remaining after projects will gradually increase as implementation progresses. A more natural mosaic of residues will provide for greater habitat variety, increased nutrient capital onsite, improved visual variety, and cost-efficient wildfire protection opportunities.

Fifty Years and Beyond
The Forest will have a fully operational residue management program integrated into the project planning and implementation process.

Much of the Forest will have a natural appearing mosaic of residues managed to provide for biological diversity, appropriate nutrient cycling regimes, aesthetics, and a reasonable level of wildfire protection.

Fuelwood

Goal(s)
Provide fuelwood for personal and commercial use, consistent with other resource objectives and environmental constraints.

Objectives
The output of fuelwood shown in Table 4-10 declines over time, primarily as a result of the declining timber harvest. Other fuelwood sources will be increasing (thinning removals, etc.), but will not make up for the difference in lost timber sale slash.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1st</td>
</tr>
<tr>
<td>Fuelwood</td>
<td>M Cords/Yr</td>
<td>13</td>
</tr>
</tbody>
</table>
Desired Future Condition

In Ten years
The availability of dead lodgepole will be much less than today. Greater distances will need to be driven to find quality large material.

The supply of firewood in general will be about 13 thousand cords per year until 1995, and then will decline to about 11 thousand cords per year. If present demand continues, it will not be met with the quality and accessibility currently available.

Fifty Years and Beyond
Cull sawlogs that are commonly available for wood cutting today will be very scarce. There will still be tops and limb wood, and thinning size trees four to seven inches DBH. Many people will find gathering this size of wood too time consuming and will elect to buy firewood from commercial cutters. Demand and value of smaller logs for firewood will likely exceed the value for sawlogs, therefore much of firewood needs will be supplied by commercial sales. Opportunities to allow individuals to thin younger stands and use the resulting material for firewood will be available.

Lands

Goal(s)
Permit special land uses that have been evaluated in relationship to land management objectives, that are compatible with other resource objectives and environmental considerations, and that are in the public interest.

Achieve a pattern of land ownership that best supports resource goals, improves the efficiency of resource management, and demonstrates effective forest management.

Objectives
Table 4-11 shows the number of special uses that are projected to increase in the first two decades and then level off.

<table>
<thead>

<td>1st</td>
</tr>
<tr>
<td>Special Use Permits</td>
<td>Number [^v])</td>
<td>48</td>
</tr>
</tbody>
</table>

\[^v]\) At any one time.
Desired Future Condition

In Ten Years
Permits for special recreational events will increase. The National Recreation Strategy will result in additional permits for recreational facilities and activities. The number of permits for electrical and telephone permits will also increase as parcels of private land scattered throughout the Forest are developed for recreational purposes.

Fifty Years and Beyond
The land exchange program will have achieved a more efficient land ownership pattern. Isolated blocks of Forest Service land will have been exchanged for private inholdings; however, inholdings with high recreation and/or real estate values will remain in private ownership.

The number of acres of land in National Forest ownership will remain approximately the same. Land exchanges will result in the acquisition of some private inholdings and the disposal of some isolated parcels of National Forest land.

Minerals and Energy

Goal(s)
Provide for and facilitate the exploration, development, and production of mineral and energy resources in coordination with other resource objectives, environmental considerations, and mining and leasing laws.

Objectives

Oil and Gas
The Forest will respond to industry demand for oil and gas leasing. On the Forest, 807,521 acres (96 percent of the Forest) are available for leasing. Of these acres, 718,370 (85 percent of the Forest) are classified as prospectively valuable for oil and gas. This is assumed to be the maximum acreage that would be leased. Presently, approximately 140,000 acres of Forest land are under lease. Approximately 670,000 acres have been under lease historically.

Domestic demand for oil and gas leasing is directly related to International production and prices. Increases in the cost of imported oil trigger increased domestic exploration and production, and probably an increase in leasing on the Forest. However, a competitive bidding system for the sale of leases could result
in higher lease costs, and thus, fewer acres of land leased. Changes in the International situation, changes in technology, failure to discover a valuable deposit, or depletion of deposits would then result in a decline in the acres listed. Table 4-12 shows projected estimates of future leased acres.

\[v\] At any one time.

Geothermal
The Oregon Department of Geology and Mineral Industries (DOGAMI) has classified the entire Forest as “favorable for the discovery at shallow depth (less than 1,000 meters) of thermal water of sufficient temperature for direct heat applications.” However, approximately three-quarters of the state is given this classification, and DOGAMI states “it is probable that only small areas of this region are truly underlain by such thermal water.” For the purposes of this Plan, it is assumed that geothermal exploration in Oregon during the next five decades will be concentrated in those areas where it is now occurring, and the Forest will not issue any geothermal leases, as illustrated in Table 4-13.

</tbody>
</table>

Locatable Minerals
The Forest will encourage and facilitate responsible mining exploration and development in a manner consistent with other resource objectives. On the Forest 804,510 acres (95 percent of the Forest) are open to mineral entry. Of this amount, 81,460 acres are classified as having either high or moderate potential for gold or mercury. Gold exploration activity has increased during this decade. The discovery of a valuable gold deposit would result in increased development and exploration activities. Conversely, the failure to make a valuable discovery could result in a decrease in mining interest (and therefore mining claims) on the Forest. Table 4-14 shows projected estimates of future claims.

<td>85</td>
<td>85</td>
<td>85</td>
<td>85</td>
</tr>
</tbody>
</table>

Desired Future Condition

In Ten Years

Exploration and development of locatable (hard rock) and leaseable (oil and gas) minerals will be allowed on the Forest, except in locations specifically withdrawn from mineral entry (see Standards and Guidelines, Section 3). The actual amount of exploration and development is expected to remain at existing levels throughout the first decade, then rise rapidly for oil and gas exploration due to an expected increase in the nation's demand. Up to 80 percent of the Forest may be leased for oil and gas exploration, if this occurs. If a large, valuable deposit is discovered, mining activity could result in a significant increase in both exploration and development (but is not predicted at this time). Extraction of saleable (common variety) minerals will be limited to existing pits or new locations that have approved operating plans, and is not expected to increase significantly during the first decade.

Fifty Years and Beyond

Oil and gas exploration is expected to rise nearly four-fold after the first decade due to an increase in the nation's demand. It is predicted that this will level off to a somewhat lower level thereafter, and remain constant past fifty years. Geothermal exploration is zero now, and no increases are expected for the next five decades. No substantial increase in mining activity is projected, and it will
remain at about constant levels throughout the next fifty years, barring the discovery of a large, valuable deposit. Extraction of common variety minerals is expected to remain relatively constant for the next five decades and beyond.

Old Growth

Goal(s)

Provide stands of old growth throughout the Forest for wildlife habitat, ecosystem diversity, and aesthetic diversity.

Objectives

Old growth stands will be present in various areas of the Forest, even though total acres will be declining over time. Table 4-16 displays how total acres of existing old growth will slowly decline over the next five decades. Units are expressed as totals, rather than as an average annual output.

<table>

</tbody>
</table>

M = Thousand

¥ This does not include an additional 1,270 acres that have been allocated for old growth dependent wildlife species. These acres currently are not “suitable” old growth, they are currently “capable” and are expected to become suitable in the future.

¥ This includes visual and other unique areas like Deep Creek management Area, where management will include extended rotations (150 years plus).

¥ This includes General Forest, Big Game Winter Range, and the portion of Rock Creek/Cottonwood Creek Unroaded Helicopter Area.
Desired Future Condition

In Ten Years
Approximately 15 percent of the total forested acres on the Forest will be in an old growth condition. The majority will still exist in the General Forest areas, which are available for intensive timber management. Old growth stands allocated for old growth dependent wildlife species (18 thousand acres) will become more isolated as adjacent stands are harvested and placed in a managed condition. Barring a natural catastrophe, old growth found in wilderness, roadless and Research Natural Areas, will be maintained at current levels (about 30 thousand acres), and may even increase as younger stands develop old growth conditions. Stands with old growth characteristics will continue to be found at relatively high levels in visual corridors and other management areas which will be converted to managed stands at a relatively slow rate.

Fifty Years and Beyond
Approximately nine percent of the total forested acres on the Forest will be in an old growth condition. The majority will be found in wilderness, roadless areas and Research Natural Areas (approximately 30 thousand acres). Only two thousand acres of old growth will exist in areas available for intensive timber management, but another 18 thousand acres allocated for old growth dependent wildlife species will be distributed throughout these areas and the Forest as a whole. Stands with old growth characteristics will still be found at relatively high levels in visual corridors and special management areas (about five thousand acres).
Recreation

Goal(s)
Emphasize the National Recreation Strategy.
Provide for a variety of recreational experiences across all areas of the Ochoco National Forest, in a manner consistent with other resource objectives and environmental constraints.
Protect unique natural and recreational features.

Objectives

Developed Recreation
Manage, improve, modernize, and expand the developed recreation sites based on use and needs.

The total supply of developed sites, as well as the projected use expressed in MRVD’s (Thousand Recreation Visitor Days), are shown in Table 4-17.

<table>

Off-Road Vehicles (ORV's)
ORV use, and trail construction and reconstruction, will be allowed where they are not in conflict with other resource objectives. Routes will be identified on the Forest to encourage use in specific areas by offering a variety of challenges and terrain. No numerical estimates are presently available.

Trails
A managed trail system will be provided for a variety of uses, including hiking, horseback riding, mountain biking, all terrain vehicles (ATV’s), cross-country skiing, and snowmobiles.

There are currently 96.8 miles of summer use trails. About 186.9 miles of new construction and 13.0 miles of reconstruction are planned for nonmotorized use in the first decade, along with 95 miles of ATV trail construction, providing a
total of 378.7 miles of summer trails. In the second decade, a similar amount of construction and reconstruction is planned, providing a total of 563.6 miles of summer use trails.

There are currently 84 miles of winter use trails. Of that, 75 miles are designated snowmobile trails and nine miles are cross-country. In the first decade, 100 miles of construction and reconstruction of cross-country trails are planned, providing a total cross-country system of 109 miles. About 210 miles of construction are planned for snowmobile trails in the first decade, providing a total of 285 miles in the snowmobile trail system. Total winter trails will be 394 miles at that time. Construction and reconstruction of winter use trails in the second decade will be less than half of that for the first decade, providing a total winter system of 474 miles. See Table 4-20.

**Desired Future Condition**

**In Ten Years**

A variety of recreational opportunities will be available, focusing on dispersed recreation, backcountry recreation, and developed recreation across the Forest.
Recreation

The existing campgrounds, picnic areas, and boat ramps will be maintained in the future; in the next 10 years additional camping facilities will be added at Falls, Delinment Lake, and Antelope Reservoir, Ochoco Forest Camp, Ochoco Divide, Sugar Creek, and several horse camps at various locations across the Forest.

Opportunities for nonmotorized recreation will continue to be provided in three wildernesses (Black Canyon, Mill Creek, and Bridge Creek), and three roadless areas (Lookout Mountain, Rock Creek/Cottonwood Creek, and Silver Creek).

Most of the Forest will continue to be open to off-road vehicle (ORV) use, but use will be directed to and encouraged on designated routes that will be developed. Some areas or routes will be closed and are designated on the travel plan map (map packet). ORV use will be managed and monitored to provide for resource protection.

A complex trail system will be available, providing extensive opportunities for both summer and winter use. Some trails will connect to the East-West Intertie, a trail joining the Pacific Crest Trail with the Desert Trail. Thirty-eight miles of existing trails in wilderness will be maintained. Some relocation and reconstruction of trails in Black Canyon will be necessary to reduce sedimentation caused by existing locations in creek crossings and boggy areas.

ATV and mountain bike routes will be available, offering a wide variety of terrain and experience levels. An extensive, marked snowmobile route system and cross-country ski trail system will also be available for winter time use.

Even though the majority of the Forest will be open to snowmobiles in the winter, some areas will be closed in order to emphasize other resource amenities (See Management Area Standards and Guidelines, Recreation, Section 3, this chapter).

Fifty Years and Beyond

Opportunities for dispersed recreation will have increased substantially over today’s conditions. A much larger trail system will be in place and most trails will show substantial use. New trailheads, functional for more user types, will be in place. Loop trails, designated for day hikes (in such areas as Stein’s Pillar Recreation Area) will include interpretive features.

Most developed recreation sites will have completed construction and reconstruction, and will be under a fee structure with maintenance costs being recovered.

Semiprimitive nonmotorized and semiprimitive motorized areas will be maintained to retain their recreational opportunities as planned today. No permanent road intrusions will have occurred in the three major roadless areas on the Forest, i.e. Rock Creek/Cottonwood Creek, Lookout Mountain (Prescription Area A), and Silver Creek.
Scenic Resources

Goal(s)
Integrate visual quality management into all resource activities which have potential negative impacts on scenery.

Provide natural appearing scenery along major travel ways, at developed and dispersed recreation sites, and in management areas where recreation is emphasized.

Participate in the “National Forest Scenic Byways” program, through nomination of other forest roads that exhibit exceptional qualities and meet national selection criteria.

Objectives
Table 4-21 lists the acres projected for scenic resources by Visual Quality Objective (VQO). In addition to specific road corridors, this includes a number of other management areas, e.g. Bandit Springs Recreation Area, that will be managed with scenic resources as either a primary or secondary objective. See Standards and Guidelines, Section 3, this chapter, for listing of VQO’s by Management Area.

Desired Future Condition

In Ten Years
The figures shown in Table 4-21 represent a management allocation, but they do not accurately reflect what the Forest will look like in ten years. In reality, a large percentage of the Forest acres will continue to appear natural, as management prescriptions will not have been completely implemented. Timber management schedules for the General Forest areas will still maintain some degree of higher scenic values than Modification or Maximum Modification, even though activities will have occurred on many of the acres, and will continue to do so at a relatively high rate.
Along major travel routes, the Forest will appear as natural as possible, providing a variety of landscapes, and emphasizing natural features. The major recreation sites will be as natural as possible and facilities will be designed and placed to fit into the natural surroundings. A number of management areas emphasizing recreation will exhibit similar visual qualities in order to meet resource objectives.

In timber stands existing in areas with both partial retention and retention visual quality objectives, the Forest visitor will be able to view large, open park-like stands of ponderosa pine, as well as uneven-aged stands with a variety of age classes. Mixed conifer stands will exhibit a variety of size and age classes, with a focus on species such as larch and aspen, to give seasonal variety.

Fifty Years and Beyond
In fifty years, the figures shown by VQO in Table 4-21 should be reflected on the ground, as the majority of the management area prescriptions have been implemented. Primary scenery will be concentrated along travel routes and in management areas. But, General Forest areas will still appear somewhat natural due to use of uneven-aged management and other management techniques designed to reduce the negative viewing intensity of project activities. Size and color variety will be less in General Forest areas than in management areas allocated for higher Visual Quality Objectives.

Social and Economic

Goal(s)
Manage the Forest to lend support to the social and economic viability of local communities, as well as to the nation as a whole.

Provide equal opportunities to people regardless of race, color, creed, sex, marital status, age, handicap, religion, or national origin.

Maximize net public benefits (36 CFR 219.3).

Objectives
Maximize the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not, in a manner consistent with the principles of multiple-use and sustained yield.

**Desired Future Condition**

**In Ten Years**

The management of forest resources will be accomplished in an economically efficient manner. Investments in timber management or timber culture will take into account site productivity, product value and marginal rates of return. Resources with market value - special uses, minerals, grazing and timber - which contribute to country receipts and the local economy, nonmarket-unroaded recreation, wildlife habitat, and unspoiled scenery - will experience increasing competition. Urban population values and demands for the latter values from the National Forest will increasingly conflict with local utilitarian views and lifestyles. The Forest Service caught in this conflicting dichotomy will continue to seek to balance use, retain options, and to form public partnerships.

**Fifty Years and Beyond**

The dichotomy and competition for resources, and the purposes of the National Forests, will be politically and legislatively addressed and the questions of today resolved, although new issues will arise. Greater uniformity and clarity will exist in how publics view the National Forest, their purpose, and management. The present method of payment to counties, which encourages conflict, will be changed to something other than that requiring local governments to emphasize resource extraction from the National Forests in order to maximize county receipts.
Goal(s)

Manage soil to maintain, restore, or improve its natural productive potential. Strive to reduce soil compaction and displacement to get as close to 90 percent of any activity area (including permanent, rocked, and nonsurface roads) in a noncompacted or nondisplaced condition (as is realistically possible) within one year of the projects completion.

Objectives

Land disturbing management activities, such as logging, road building, grazing, and certain recreational uses have potential for dramatic decreases in soil productivity if not managed or mitigated correctly. Soil erosion and compaction are conditions most seriously affected by activities on the Forest. It is the objective of the Ochoco National Forest to prevent or correct long-term soil damage in all activity areas that result in productivity loss on lands dedicated to plant and water production. The following parameters have been established and serve as objectives to measure the affects of activities on the soil resource.

Soil loss (erosion) results primarily from road building and timber harvesting, but also reflects the overall condition of watersheds on the Forest which may be the combined effect of all activities, including recreation and grazing. Watershed condition objectives have been established for the Forest, and are found under “Water,” this section, this chapter. The tons of soil loss shown in Table 4-23 assume that watershed condition objectives will be met, and reflect what will be lost over time, despite proper management and mitigation, over the entire Forest.

Soil compaction results primarily from timber harvest and related activities (such as slash disposal). There is an estimated 102 thousand acres of forested soils in a compacted condition today, as a result of past and ongoing activities. In order to meet management requirements for soil, the acres of tillage shown in Table 4-23 (to relieve compaction at the 20 percent level) are planned over the next five decades. There are currently about 1,500 acres of tillage completed annually. Depending on annual management objectives and budgetary constraints, additional acres of tillage (at the 10 percent level) should also be considered.

</tbody>
</table>

**Desired Future Condition**

**In Ten Years**

As more of the Forest acres are affected by vegetation management activities, soil erosion will increase. These activities are mitigated in part by adherence to standards and guidelines. Soil loss is estimated to be limited to 1.7 thousand tons per year Forest-wide.

As areas with compacted soils are re-entered with timber sales or other projects, significant achievements in prevention and rehabilitation of compacted soils will be observed. The Forest will be moving closer to achieving a long-term goal of having no more than 10 percent of the managed acres in an unproductive condition.

**Fifty Years and Beyond**

Most available acres will be under some type of vegetative management, particularly for timber production. Fluctuations in soil loss will vary from year to year, and decade to decade, as a direct result of fluctuations in these activities. With adherence to standards and guidelines, soil loss should be limited to 1.9 thousand tons per year, based on current modeling.

During or near the end of the fifth decade, the Forest will have re-entered most acres of ground previously compacted, and rehabilitated these soils through tillage or other appropriate means, at least 80 percent of the total acres will be in a fully productive condition.
Timber

Goal(s)

Provide for the production of quality wood products, in a manner consistent with other resource objectives, environmental constraints, and economic efficiency.

Objectives

Table 4-24 provides a summary of major timber-related data for five decades in terms of average annual outputs. More detailed data concerning land suitability, comparisons with previous plans, and harvest schedules by management area are contained in Appendix A. These figures are projections of potential timber outputs based on available inventory data and assumptions, subject to annual budgets. All units are based on an average annual output. (MM=Million, M=Thousand.)

Desired Future Condition

In Ten Years
Forest stands will provide the raw material for industry as well as the setting for a variety of recreational experiences, and habitat for native wildlife species. Most of the harvest will still be coming from mature stands, but second growth stands will be providing small amounts, mainly from ponderosa pine. Many of the existing two-story stands (predominately ponderosa pine) will have had selection cutting. Clearcuts will be more common on mixed conifer (predominately fir species), and more young plantations will be visible. Sufficient acres of habitat for defoliators will be existing and will maintain the risk of an epidemic of spruce budworm or tussock moth. Commercial thinning in immature pine stands will be increasing, with an emphasis on prevention of bark beetle damage, but the risk of damage from mountain pine beetle will be reaching a peak in overstocked stands across the Forest. Ripping or cultivation may be needed to reduce soil compaction in existing stands.

Fifty Years and Beyond
Nearly all existing mature or two-story pine stands in the MA-F22 General Forest area will have had selection cuts or an overstory removal, and possibly a commercial thinning. Timber harvest will be coming from remaining mature stands and early commercial thinnings; the only overmature stands will be in wilderness and roadless areas, research natural areas, designated old growth habitat stands, portions of riparian areas, and portions of visual corridors. Most stands in General Forest will be under 130 years old and will be in a managed even-aged or uneven-aged condition. Ponderosa pine will be the major species, followed by western larch, lodgepole pine, Douglas-fir, white fir, and Engleman spruce. Except for pine climax types, nearly all stands will have a mixture of species. Hardwoods such as cottonwood, aspen, alder and willow will be more common than today along streams, meadows and wet areas. Most stands that are presently sapling or pole size will have had one or more commercial thinning, and some will be approaching a final harvest. Two-thirds of the mixed conifer stands will be in a managed even-aged condition from 0 to 60 years of age. All managed stands will be near optimum stocking level for the given management area; risk of damage from most insects and diseases will be reduced below today's level. Cultural activities, such as planting, thinning, and possibly pruning and fertilization, may be seen throughout much of the Forest. The Forest tree improvement program will have identified families best adapted to specific sites and conditions, seedlings from these families will be used in most plantations. A designated skid trail and landing system will be in place and used for most logging operations. Desired levels of snags and down woody material will exist on all timber stands. Soil compaction and disturbance will be within established guidelines.
Transportation System

Goal(s)

Plan, design, operate and maintain a safe and economical transportation system that provides efficient access for the movement of people and materials involved in the use and protection of the National Forest lands.

Objectives

Improve, expand, and maintain the road system to support other resource objectives in accordance with road management objectives, available funding to achieve economy, user safety, and resource protection.

New roads will be constructed to support timber management; some existing roads will be closed on a seasonal or yearlong basis due to structural limitations of the road, safety, or other resource considerations (such as those to meet wildlife needs or off-road vehicle (ORV) travel management needs). Ultimately, the road system will total 5478 miles, an increase of 20 percent over present mileage. By the year 2015, 63 percent of the new mileage will be completed; 81 percent will be completed by the year 2035. Roads will be constructed in roadless areas released from roadless management. Others will replace present low standard roads that are unsafe, causing resource damage, or that do not meet resource management needs. Unneeded roads will be obliterated and revegetated. The majority of the arterial and collector system is established; however, dollars will be allocated annually to maintain, restore to original design capacity, or increase the design capacity of the existing system. See Appendix A11 for proposed road construction and reconstruction schedule.

The miles of road open to passenger vehicles (Maintenance Level 3-5) and high clearance vehicles (Maintenance Level 2), and the miles closed seasonally or yearlong are shown in Table 4-25 and in Appendix D. At the end of the first decade, 67 percent of the Forest development road system will be open and unrestricted for passenger car or high clearance vehicle use, decreasing to 59 percent by the end of the fifth decade as additional road miles are closed on a seasonal or yearlong basis.

</table>

**Desired Future Condition**

**In Ten Years**

The principal access roads will be readily identifiable; they will have paved or gravel surfaces and will be suitable for passenger car use. Signs will assist the traveler in finding their destination. The other roads will appear rough or primitive, but most will be available for use by the more experienced traveler. Some will be closed with gates or signs.

**Fifty Years and Beyond**

Most of the principal road systems will be completed and have paved or improved surfaces. A few may have State Highway designations. Most other roads will be either closed, restricted, or visually inviting to only the high ground clearance type vehicles used by the more seasoned forest traveler.
Goal(s)

Maintain or improve water quality, quantity, and timing of run-off.
Comply with the objectives of the “Clean Water Act” and Oregon State water quality standards.
Provide water of consistently high quality to users and dependent resources.

Objectives

Maintenance or improvement of water quality can best be achieved through proper management of entire watersheds at all times, with special attention given to riparian areas.

Threshold values have been established to disperse harvest activities optimally over the Forest land base (see Soil and Water Standards and Guidelines, Section 3, this chapter). They also serve as benchmarks against which to measure the risk of experiencing a major climatic event in conjunction with a watershed condition or sensitivity that has the potential to result in long-term impacts to stream channels and therefore, to water quality. In Table 4-26, threshold values for individual watersheds have been combined into one average value for the Forest, which is 30.1 percent. No increases in the amount of disturbance above this threshold value have been predicted over the next five decades. More detailed analysis at the individual watershed level has indicated that threshold values may be exceeded on some watersheds, a situation that can be corrected by rescheduling or relocating harvest activities within other watersheds.

A long-term Forest objective is to maintain or improve all riparian areas to “excellent condition.” Currently, 9,100 acres (roughly half) of the Forest riparian areas are in excellent condition. The remaining areas are scheduled for improvement over time. As can be seen in Table 4-26, a large portion of the needed improvement work will be completed in the first decade, even though recovery to full biological potential may require 20 to 60 years. See Section 2, Management Area Prescriptions, this chapter, for desired future condition of Management Area F15, Riparian Areas, and Appendices A12 and A15 for schedules of activities to achieve riparian area objectives.

Water quantity outputs shown in Table 4-26 are not the result of any specific proposals to increase run-off, but reflect instead the surface water leaving the Forest as a result of natural run-off, and any increased run-off expected to result from the manipulation of vegetation (mainly timber harvesting). Year to year variations in precipitation are likely to obscure any increase or decrease in run-off resulting from management activities.
### Desired Future Condition

**In Ten Years**

Individual watersheds on the Forest that are currently in excellent condition are expected to remain so. Activities will be monitored and those watersheds not presently in good condition are scheduled for first priority improvements, but it may take decades before the entire watershed and riparian areas are fully functional again (as intended). The chances of a major storm event causing severe impacts will be even less than today. No significant increases in run-off for the Forest are expected.

**Fifty Years and Beyond**

It is expected that 90 to 95 percent of the riparian areas on the Forest will be in "excellent condition" by the end of the fifth decade. Additional research and monitoring of watersheds will have resulted in a situation where outputs of Forest resources (mainly timber) may be produced at levels explicitly tied to watershed condition, accounting for yearly and decadal variations in weather patterns and major storm events. Run-off of water is limited by total Forest acres and no significant increases are anticipated.
Wildlife and Fish

Goal(s)

Identify existing populations of any threatened, endangered, or sensitive species and maintain or improve their habitats.

Provide, manage and improve fish and wildlife habitats to maintain viable populations of existing native and desired non-native vertebrate species, including threatened, endangered, and sensitive species.

Objectives

Population management objectives as established by the Oregon Department of Fish and Wildlife (ODFW) are 18,300 for deer and 2,600 for elk on the Forest. The Ochoco National Forest objective is to manage the habitat to meet these population objectives to the extent practical. Populations of deer and elk are limited by habitat capability, which changes over time in response to vegetation manipulation and open road density (see Wildlife and Fish, Forest-wide Standards and Guidelines, for discussion on Habitat Models).

Wildlife habitat improvement will include items such as: prescribed burning, road closures, snag replacement, seeding, planting, mechanical treatment of woody browse species, grasses to improve summer and winter ranges for big game, and protection and improvement of special habitats such as springs, wet meadows, riparian, and aspen communities.

Fish habitat improvements will include rock and log weir installation, large woody debris and boulder placement, juniper rip-rap, riparian fencing, and planting shrubs and trees to restore shade and provide bank protection and stabilization.

Projections for anadromous fish production are derived from smolt habitat production estimates. Fish habitat is a function of both instream condition, and overall condition of the particular watershed.

Habitat for old growth dependent wildlife species is provided in mostly contiguous, allocated stands of old growth ponderosa pine and mixed conifer across the Forest, as well as that provided in wilderness, roadless areas and research natural areas. Other old growth which exists across General Forest and other special management areas, is not generally considered suitable habitat for major indicator species (pileated woodpecker), mainly because of stand size requirements. Even though the total acres of existing old growth will decline over the five decade planning horizon, a long-term allocation of 19,250 acres, as well as 30,300 unallocated acres in wilderness, research natural areas and unroaded areas will ensure maintenance of suitable habitat for the species. In addition, 19,250 acres of supplemental feeding areas surrounding each old growth block will be provided. See Table 4-27 and Table 4-16, with footnote 1/.
### Desired Future Condition

**In Ten Years**

In ten years, habitat capability on the Forest will continue to exceed that needed to meet Oregon Department of Fish and Wildlife objectives for both deer and elk, based on current modeling procedures and assumptions. Cover is expected to become the limiting habitat factor for big game, especially elk, and will be

---

*Shown as acres, but is actually a combination of acres and numbers of structural improvements.  
*These occur in wilderness, roadless and research natural areas  
*Assumes 60 percent occupancy by dependent species, which may or may not occur at any one time
declining over time, but decreased open road density and increases in habitat enhancement in winter range and general forest areas are expected to compensate for the cover loss.

As a result of fish habitat improvement and watershed/riparian restoration (see objectives for Water), relatively high populations of both anadromous and resident fish are expected to be available after ten years (as shown in Table 4-27).

The amount of snag habitat across the Forest will remain at current levels Forest-wide. The amount will vary by management area, ranging between 40 and 100 percent of the number needed to support the potential populations of primary cavity excavators. Forest-wide, snag habitat will average about 47 percent in ten years.

In ten years, approximately 68,900 acres of habitat will be available for old growth dependent wildlife species (pileated woodpecker). This includes 19,250 acres of old growth allocated across the Forest, plus 30,300 acres unallocated but available in wilderness, roadless areas, and research natural areas. Supplemental feeding areas (also 19,250 acres), not specifically meeting old growth definitions, will also be available in close proximity to actual, allocated old growth stands.

Fifty Years and Beyond

It is less certain that current ODFW objectives for both deer and elk can be met, due to expected decreases in overall cover across the Forest. It must be noted however, that ongoing research on habitat needs will provide management with better data than is currently available to project population estimates and to balance overall resource objectives. The estimates shown in Table 4-27 for fifty years and beyond are based on current models which are considered insufficient to predict accurate numbers of big game. These models are the best available at the present time.

As a result of fish habitat capability improvement (including watershed/riparian restoration), both anadromous and resident fish numbers are expected to increase in fifty years (as shown in Table 4-27).

The number of snags will actually increase Forest-wide, to an average of about 54 percent of potential. The estimated large acreage of ponderosa pine stands that are currently snag deficient, will be managed to provide levels of 40 percent or greater, along with other management areas at even higher rates.

Barring a major natural catastrophe, habitat for old growth dependent wildlife species will remain about the same as is available today (68,900 acres). Species using these areas will be more limited in terms of movement and selection; a large portion of the habitat will be in isolated stands scattered across the Forest.

Chapter 4

Forest Management Direction

Section 2
Management Area Prescriptions
Chapter 4

Section 2

Management Area Prescriptions

A management area is composed of lands with similar capabilities or characteristics, and is allocated to emphasize a particular resource or mix of resources. The lands may or may not be contiguous.

All areas of the Ochoco National Forest are managed under the Forest-wide standards and guidelines described in Section 3, and by broader multiple use principles directed by laws, regulations, and policies.

Within this broad multiple use guidance, each management area emphasizes a specific resource or mix of resources. For example, in the Winter Range Management Area (MA-F20), production of big game wildlife species will be emphasized, even though a variety of other compatible uses can occur.

In this section of Chapter 4, 28 management areas are presented to provide the reader with the physical description, management emphasis, and desired future condition of each area. Management area standards and guidelines are described in conjunction with Forest-wide standards and guidelines in Section 3.

Table 4-29 contains a list of the 28 Management Areas for the Alternative I (Preferred). Also shown are the acres allocated to each area; acres are mutually exclusive—management areas do not overlap. Locations of the management areas are displayed on the map for Alternative I (Preferred). Individual maps for each management area are located at the end of this section of Chapter 4.

Modifying Management Areas or Prescriptions

The appropriate setting for each management area is determined by the management goals, objectives, desired conditions, and suitability of the area to achieve these conditions. When a project would result in conditions that do not meet these criteria, the need to modify the management area allocation should be addressed (see Chapter 5, Implementation of the Forest Plan). Evaluation of factors including activity extent, duration of impact, season of operation, sight or sound impacts, or feasibility of rehabilitation would be necessary. Cumulative modifications of management areas should not exceed those described in Chapter 5, Implementation of the Forest Plan.

During implementation, it may be discovered that a management area boundary was inaccurately or inappropriately mapped. In such a case procedures for adjusting boundaries will also follow direction in Chapter 5, Implementation of the Forest Plan (Amendment and Revision Process). Final boundary adjustments will be documented and integrated into the Forest database by the initiating party.
MA-F1 Black Canyon Wilderness

13,400 acres, 2 percent of the Ochoco National Forest

Description

Black Canyon Wilderness contains approximately 13,400 acres and is located on the Paulina Ranger District. Black Canyon Creek drains into the South Fork of the John Day River and falls from 6,000 feet to 2,800 feet in elevation. It is characterized by steep sides and numerous north-south ridges with rolling to flat benches on the edges. Wolf Mountain and Dry Corner are on the south side. Bearskull Mountain is on the north side. The north facing slopes are covered with mixed conifers. The south facing slopes are predominantly ponderosa pine and juniper. The water produced by the watershed is used by livestock, wildlife, anadromous fish, and irrigation from the John Day River.

Emphasis

Protect the Wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

Desired Condition

The Black Canyon Wilderness will be as natural as is possible with reduced or little evidence of human activity. The area will be a place of natural settings with opportunities for solitude. Present road access and hunter caches and camps will
be rehabilitated to the point that their presence is no longer a dominant land feature. Recreational improvements, such as trailheads and access trails, will be evident where they are necessary to control use in order to preserve wilderness qualities. Livestock use will be evident but the successful application of allotment management requirements will also be evident.

Old growth stands will be evident within the management area along with those wildlife species in the Ochoco National Forest which are dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resultant of past spruce budworm and other endemic insects and diseases, will be evident, along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning starts occur. (See Appendix H - Wilderness Plans.)
MA-F2 Bridge Creek Wilderness

5,400 acres, less than one percent of the Ochoco National Forest

Description

The Bridge Creek Wilderness, established as a result of the Oregon Wilderness Act of 1984, is managed by the Big Summit Ranger District, Ochoco National Forest. The 5,400 acre wilderness is located in the north central portion of the District.

The topography is benchy, with densely forested slopes, open meadows and some scab flats. Elevations range from 4,700 feet to 6,600 feet. North Point at 6,607 feet is one of the higher peaks on the Ochoco National Forest and provides an outstanding viewpoint. Five springs lie within the area: Thompson, Pisgah, Masterson, Nelson and Maxwell. Bridge Creek and Maxwell Creek flow through the area. A historic diversion and ditch system will continue to exist and be maintained until the permittee no longer needs this to maintain the preexisting water rights.

Vegetation includes lodgepole pine, ponderosa pine, white fir, Douglas-Fir, western larch, sagebrush, snowberry, and other brush species.
Emphasis
Protect the Wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude. The area will be managed as a nontrailed wilderness where people can use their orientation skills.

Desired Condition
The Bridge Creek Wilderness area will be as natural as possible, with reduced or little evidence of human activity. The area will be a place of natural settings where solitude may be sought. Existing roads will be rehabilitated so that its presence is no longer a dominant land feature. Recreational improvements, such as trailheads and access trails, will not be evident, but entry points will be signed where necessary to control use and to preserve wilderness qualities.

Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures.

Old growth stands will be evident within the management area along with those wildlife species in the Ochoco National Forest dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

Tree mortality resultant of past Mountain Pine Beetle infestations, and other endemic insects and diseases, will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning starts occur. (See Appendix H - Wilderness Plans.)
MA-F3 Mill Creek Wilderness

17,400 acres, two percent of the Ochoco National Forest

Description

On June 26, 1984, President Reagan signed the Oregon Wilderness Act, and the 17,400 acre Mill Creek Wilderness was created; it is now managed by the Prineville Ranger District. The area is represented by all exposures but is predominately southern. Elevations range from 3,725 feet to 6,240 feet above sea level. The terrain varies from the rugged, rocky cliffs of Desolation Canyon to the flat meadows of Bingham Prairie. Spectacular rock outcrops are present at Twin Pillars and Whistler Point. The Wilderness is within the southwestern extension of the Blue Mountains physiographic unit. Bedrock consists predominantly of older volcanic basalts and pyroclastic sediments. Formations consist of flows, domes, and breccia. Hard basalt forms the steep slopes, ridges, and domes while softer rock dominates the toeslopes, basins, and benches.

Emphasis

Protect the Wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

Desired Condition

The Mill Creek Wilderness area will be as natural as is possible with reduced or little evidence of human activity. The area will be a place of natural settings where solitude may be sought. Any existing road will be rehabilitated to the point that its presence is no longer a dominant land feature. Recreation improvements such as trail heads and access trails will be evident where necessary to control use in order to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident.

Old growth stands will be evident within the management area along with those wildlife species dependent on old growth habitat in the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

Tree mortality resultant of past mountain pine beetle and other endemic insects and diseases will be evident along with associated changes in fuel loadings and plant succession. Fuel loadings will become very significant along the south side of Forest Road 27 within the Wilderness and will pose a serious fire risk. Fire occurrence will be evident where natural lightning and human-caused starts occur. There may be planned ignitions to achieve wilderness objectives.
Minerals activities on valid mining claims will be evident along with authorized access under approved plans of operation. (See Appendix H - Wilderness Plans.)
MA-F4 North Fork Crooked River Wilderness Study Area

1,125 acres, less than one percent of the Ochoco National Forest
18 percent forested, 82 percent nonforested

Description

The North Fork of the Crooked River Wilderness Study Area includes areas centered on Indian Trail Creek and Fox Canyon Creek which abut BLM land along the North Fork of the Crooked River.

The majority of the area is covered in scabland, although there are islands and stringers of ponderosa pine and juniper stands located along streams on favorable aspects (north facing slopes), and where there are deeper soils than is typical of the area. Part of the area (approximately 300 acres) has been allocated as old growth for dependent species.

Primary recreational uses of the area are dispersed camping, hunting, and fishing.

Emphasis

Management will maintain the existing conditions of the area for potential wilderness designation pending a decision by Congress, or until released from further consideration.
**Desired Condition**

The wilderness study area will be as natural as possible with reduced evidence of human activity. The area will be a place of natural settings where solitude may be sought. Existing roads and hunter caches and camps will be rehabilitated. Recreation improvements, such as trail heads and access trails, will be evident where necessary, to control use in order to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures.

Old growth stands will be evident within the management area along with those wildlife species in the Ochoco National Forest dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

The Final Environmental Impact Statement for Wilderness by the BLM is scheduled to be published during the spring of 1989. If these areas are not designated wilderness by Congress, then for the remainder of this planning period, these areas will be managed under old growth, riparian, and general forest standards and guidelines.
MA-F5 Research Natural Areas

4,400 acres, less than one percent of the Ochoco National Forest
83 percent forested, 17 percent nonforested

Description

This management area includes the Ochoco Divide, Dry Mountain, Silver Creek, and Stinger Creek Research Natural Areas (RNA's). RNA's represent both common and unique forest and rangeland ecosystems in a natural state or as close to undisturbed as possible. The RNA's were designated to be large enough to protect features of interest from management activities on adjacent land.

The Ochoco Divide RNA is 2,035 acres in size and is located on the Big Summit District. It is forested with ponderosa pine, western larch, Douglas-fir, and grand fir in associations typical of the Ochoco National Forest. Approximately 880 acres are ponderosa pine forest, 880 acres are mixed conifer, 190 acres are meadows and grasslands, and 85 acres are juniper/mountain mahogany scabs. There are three drainages which run to the north, south and west. The Ochoco Divide RNA (established in 1935) is fenced to exclude cattle. A nonmaintained historic trail passes through this RNA.

Dry Mountain is approximately 1,187 acres in size and is located on the Snow Mountain Ranger District, 27 miles northwest of Burns/Hines. It includes approximately 679 acres of ponderosa pine forest and 508 acres of nonforest and noncommercial woodland (juniper, mountain mahogany). This area is currently grazed.

Silver Creek is approximately 844 acres in size and is located on the Snow Mountain District, 26 miles northwest of Burns. It includes 758 acres of ponderosa pine forest, and 86 acres of dry to wet associated meadow land. Silver Creek is currently grazed.

Stinger Creek is approximately 453 acres in size and is located on the Snow Mountain District, approximately 24 miles northwest of Burns. It includes 355 acres of ponderosa pine forest and 98 acres of nonforest land. This area is currently grazed.

Emphasis

Allow natural processes to occur for research purposes and education. These processes will provide: baselines against which other activities may be measured, sites for study of natural processes in undisturbed ecosystems, and gene pool preserves for both plant and animal species.
**Desired Condition**

Natural conditions will be observed. Any management activities within the RNA’s will be directed at maintaining the natural conditions of the area. Human-caused changes to the ecosystem will not be readily evident. Continuing baseline studies may be occasionally visible in terms of equipment, instruments, and related activities.

Fire occurrence will be evident where natural and human-caused fire starts occur.

There is a high probability that grazing will not be evident, but this is still to be determined through the official designation (RNA) process.
MA-F6 Old Growth

19,250 acres, two percent of the Ochoco National Forest.
81 percent forested, 19 percent nonforested

Description

Approximately 19,250 acres of old growth are located across the Forest (outside of wilderness and research natural areas) in stands of mixed conifer and ponderosa pine, averaging 300 acres in size. An additional 19,250 acres of “feeding areas,” averaging 300 acres in size, are to be located in areas adjacent to the old growth stands. In combination, these two systems comprise a “habitat area.”

Most of the old growth stands show very few signs of past management and represent uninterrupted succession for major plant community types on the Forest. Due to distributional needs, less than seven percent of the allocated acres are in a “capable” condition, i.e. they are in a younger vegetational stage and are not currently “suitable” as old growth habitat. A multilayered canopy with shaded conditions and a large number of dead snags per acre is considered “optimum” for old growth habitat.

The surrounding feeding habitats provide supplemental snags at relatively high levels (about 90 percent), but are continuous 300 acre areas. These will be located within a 1,000 acre area surrounding each allocated old growth area.

Emphasis

Provide habitat for wildlife species dependent on old growth stands.

Desired Condition

Stands of old growth are not expected to change significantly over the next ten to fifty years, barring a natural catastrophe. They will continue to provide habitat for a number of dependent wildlife species, such as the pileated woodpecker, flying squirrel, white-headed woodpecker, as well as other nondependent species such as deer and elk. This habitat may become more extensively used by these species as the majority of the forest moves towards a “managed condition.” High levels of snag habitat will continue as individual trees within the stands die of old age, as well as from periodic infestations by insects and diseases. Management activities and roads will generally not be evident. Fire occurrence will be evident where natural and human-caused starts occur. Prescribed fire may be evident if natural fuels accumulate to dangerous levels, threatening the existence of the old growth stand, or where vegetation manipulation is needed to maintain stand structure and species composition. Grazing by livestock, as well as by big game wildlife species, may or may not be evident.
MA-F7 Summit National Historic Trail

9,560 acres, one percent of the Ochoco National Forest

- 170 acres - Preservation
- 5,600 acres - Retention
- 3,790 acres - Partial Retention

67 percent forested, 33 percent nonforested

Description

The Summit Trail is approximately 74 miles long and traverses the Ochoco National Forest through the Prineville, Big Summit and Paulina Ranger Districts. It was constructed as a pack trail by the U.S. Forest Service in the early 1900's, and was the primary east-west travel route in the Ochoco Mountains until the late 1930's. In the 1920's, lengthy segments of the original trail were widened for motor-vehicles, and subsequent alterations through road building and timber harvest have occurred. Despite this, the entire route of the Summit Trail can still be traveled via a combination of foot, horseback, bicycle or motor vehicle.

The Summit Trail is considered a historic resource and was found eligible for nomination to the National Register of Historic Places in January 1987. The Summit Trail Report, a comprehensive survey and evaluation of the trail completed in 1986, also recommended combining this resource with the proposed East-West Intertie Trail (Forest Service, 1986) and/or the proposed New Oregon Recreational Trail (Sullivan, 1986). On January 15, 1988, a Decision
Notice and Finding of No Significant Impact for the Summit Trail was signed by the Ochoco National Forest Supervisor, and established the initial protection and management guidance for this area.

**Emphasis**

Protect the existing integrity of the Summit Trail. Enhance and interpret significant segments for public enjoyment and education. Pristine segments will be managed to protect, interpret, and preserve their historic qualities.

**Desired Condition**

The Summit Trail will be a place where Forest visitors can enjoy the cultural and recreational resources offered in a visually pleasing environment. The majority of the trail route is along developed roads and will provide pleasurable travel by highway vehicle, as well as by mountain bike and horse. Vegetation may appear manipulated in widely dispersed areas in order to enhance cultural and recreational resources, but will generally not dominate the landscape. Interpretive facilities such as signs and landmarks may be visible in unique, culturally significant areas.

The outer boundary of the management area will generally not exceed 600 feet on either side of the trail.
MA-F8 Rock Creek/Cottonwood Creek Area

11,820 acres, one percent of the Ochoco National Forest
65 percent forested, 35 percent nonforested

Description

These areas contain mature and old growth ponderosa pine and mixed conifer stands with a predominance of western larch and lodgepole pine. The stand ages and size classes are largely a function of past fires; these areas have had very little direct human-caused disturbance from timber harvest, mineral and energy development, or intensive grazing. Slopes are generally steeper than 40 percent. In the Rock Creek drainage, there are extensive areas of scabland on steep slopes which result in some natural sheet erosion.

The area contains several important tributaries to the John Day River. Birch Creek and Rock Creek support significant trout and spawning steelhead populations.

The areas are generally summer and transitional range for deer and elk. There is an abundance of cover and consequently less than optimum forage distribution. Because of the relative inaccessibility of the area, it supports a higher proportion of trophy sized animals than in roaded areas to the south and north.

The area supports cattle and sheep allotments

There are several existing and proposed recreational trails, as well as cultural sites associated with early mining that occurred to the north of the Forest.
Recreational use of the area is currently light, consisting largely of hunting, fishing, horseback riding and hiking, and is presently limited by the existing access.

**Emphasis**

Provide protection of soil, water, and fisheries, and provide opportunities for nonmotorized recreational use and enjoyment. Maintain vegetation on steep slopes to prevent erosion, and to protect water quality and the anadromous fishery.

**Desired Condition**

Recreationists will see natural appearing areas free from motorized vehicle use. Recreational use, livestock grazing, prescribed fire and wildfire will occur, but the area will appear natural. These activities, along with any desired recreational improvements such as trails, will be the only visible impacts of direct human activities.

Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the management area along with those wildlife species in the Ochoco National Forest which are dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Structures may be constructed, or other work may be done to maintain or improve habitat for the anadromous fishery. The area will remain one where there are above average numbers of trophy sized elk and deer. Tree mortality, resultant of past spruce budworm infestations, and other endemic insects and diseases, will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural and human-caused starts occur.
MA-F9 Rock Creek/Cottonwood Creek Unroaded-Helicopter Area

2,480 acres, less than one percent of the Ochoco National Forest
70 percent forested, 30 percent nonforested

Description

This is a roadless area adjacent to Rock Creek/Cottonwood Creek Roadless Area. It includes those areas within Cottonwood, Birch and Payten Creeks which can be harvested by helicopter logging. This area has not been harvested except for incidental amounts removed from along the Forest boundary on the north slope. This area is generally heavily forested with mixed conifer or ponderosa pine community types. The steep slopes generally exceed 40 percent.

This area is tributary to the John Day River with Cottonwood and Birch Creeks supporting significant resident trout and anadromous fisheries. It also provides summer and transitional range for elk. There is an abundance of cover and consequently less than optimum forage distribution. Due to the relative inaccessibility of the area, it supports a higher proportion of trophy sized animals than in the roaded areas to the south and north.

The area is part of a sheep and cattle allotment in which most of the forage removed is by herded sheep.

Recreational use of the area is currently light, consisting of hunting, fishing, horseback riding and hiking.

Emphasis

Allow timber harvest while protecting the anadromous fishery, sensitive soils on steep slopes, and big game habitat.

Desired Condition

The area will be unroaded with evidence of timber harvest and associated activities using helicopter systems. Prescribed fire use will also be evident in some areas where its use is desirable to attain management objectives. The area will remain unroaded with landings located outside the management area. Visible harvest impacts will generally be limited to vegetation modification with little soil or other surface disturbance.

Recreational improvements such as trailheads and access trails will be evident where necessary to enhance access. Livestock use may be evident, but the successful application of allotment management requirements will show accept-
able grazing practices. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the management area along with those wildlife species dependent on old growth habitat on the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality resultant of spruce budworm and other endemic insects and diseases will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural and human-caused starts occur.
MA-F10 Silver Creek Roadless Area

3,110 acres, less than one percent of the Ochoco National Forest
64 percent forested, 36 percent nonforested

Description

The Silver Creek area lies within the canyon rims of Silver Creek. The area is one fourth to one mile wide from rim to rim, and ranges in elevation from 4,600 feet at its south boundary to 5,200 feet at the northern end. The area is dominated by open grown ponderosa pine forests and juniper woodlands. It contributes 574 AUM’s to five permittees within two allotments. It supports a yearlong mule deer population, and a resident elk and antelope herd. The bottom land and riparian areas show evidence of heavy overgrazing.

The Silver Creek roadless area contains sections of Silver, Delintment, Short, and Dodson Creeks. There is a resident rainbow trout fishery in Silver Creek which receives light fishing pressure. Recreational use is generally light. Primary recreational activities are fishing, hunting, hiking and horseback riding.
Emphasis

Protect and enhance the roadless qualities and provide nonmotorized recreational use.

Desired Condition

Recreationists will see natural appearing areas free from motorized vehicle use. Recreational use, livestock grazing, prescribed fire and wildfire will be evident. These activities, along with any desired recreational improvements such as trails, will be the only visible impacts of human activities within the management area.

Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the management area along with those wildlife species dependent on old growth habitat in the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality resultant of past spruce budworm and other endemic insects and diseases will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural and human caused starts occur.
MA-F11 Lookout Mountain Recreation Area

15,660 acres, two percent of the Ochoco National Forest
72 percent forested, 28 percent nonforested

Description

Lookout Mountain is located on the Big Summit Ranger District, about 25 miles east of Prineville. It rises above the surrounding topography, and can be seen from many points along Highway 26 as well as from other nearby mountains. Approximately 90 percent is forested. Elevations range from 3,793 feet to 6,926 feet. Most plant communities associated with the Blue Mountains are found in the area. Lookout Mountain is well-known for its scenery, big game habitat, and recreational opportunities.

The forest composition is white fir and Douglas-fir, which generally replace seral species ponderosa pine and western larch. At lower elevations, especially on southern exposures, open stands of ponderosa pine occur. Scattered western larch, evident during the fall, are interspersed in the mixed conifer stands, but are gradually decreasing with time due to plant succession. Steep slopes occur in drainage heads; the west side of the mountain drops off with a precipitous scarp. Above 6,000 feet in elevation, nonforested grasslands, subalpine meadows, and basalt rock outcrops dominate the landscape.

The subalpine, and more gentle, open pine areas, in particular, provide an excellent setting for a variety of recreational activities, including snowmobiling, cross-country skiing, hiking and hunting.

The Lookout Mountain Recreation Area is a roadless area managed to provide big game habitat and semiprimitive recreational opportunities within a natural setting. It has twice been considered for wilderness designation, but was left with Congressional advice to “examine the feasibility of continuing the current use in the National Forest Plan and determine the land allocation in the Forest Plan.”

Emphasis

Maintain a natural setting; provide continued opportunities for high quality, semiprimitive recreational activities, and wildlife habitat; while maintaining healthy forests.

Desired Condition

General

The Lookout Mountain Management Area will become a well known area for year-round recreation activities, and will provide excellent habitat for big game.
Prescription Area A

This area will comprise approximately 7,550 acres of forest land in a semiprimitive state with no vegetation manipulation planned. The recreational user and sightseer will experience a highly diverse, natural landscape with interspersed stands of trees, openings, rock outcrops, and talus. A tree species mix to include early successional species such as ponderosa pine, western larch and lodgepole pine will be seen across the lower elevations of the landscape, and lodgepole pine, sub-alpine fir, white fir and Douglas-fir will dominate at the higher elevations. Pockets of mixed conifer old growth will be an integral part of the vegetation mosaic. Natural tree mortality will be evident.

Big game habitat will be excellent due to the secluded nature of the area, high elevation moist meadows, and good year-round springs with heavy dense cover. Elk wallows will be numerous and big game use will be evident.

The area will be roadless, with currently existing roadbeds exhibiting evidence of rehabilitation activities, and eventually revegetation. Man-made improvements will be subordinate to the natural landscape and will be present to enhance recreational use of the area. Typical improvements apparent to the recreational user may include trails, trailheads, signing, trail shelters, livestock fencing, and possible wildlife habitat enhancement projects.

Prescription Area B

This area will comprise about 8,110 acres in a relatively natural appearing condition.

A variety of trails, roads, trail shelters, signs and other improvements for the benefit of recreational users may exist, but will be designed and managed to be subordinate to the natural landscape. Approximately one mile of Forest Road 4205 and one mile of Forest Road 4200-250 will remain open for motorized travel to dispersed campsites and mining activities associated with them.

Vegetation may appear manipulated in widely dispersed places in order to enhance recreational opportunities and wildlife habitat resources, but will not dominate the landscape, nor generally be evident to the casual Forest visitor. Various vegetation manipulation techniques will be used to promote healthy forested stands that are more resistant to catastrophic events that may detract from big game habitat or a recreational experience. As a result of these limited entries, ponderosa pine and western larch, which are tree species valued for their appearance to recreationists, will be maintained and/or become more abundant over time. These species will be interspersed in a mosaic of other mixed conifer species of various size and age classes, including stands of old growth mixed conifer and ponderosa pine.

Minimum standard roads designed for specific projects will exist in low densities on the more gentle ground. Road use will be restricted to project activities and roads will be closed upon completion of each project. Roadbeds and banks will be seeded with mixtures of legumes and grasses to improve wildlife habitat. Activities occurring at any one time will be limited by duration and amount.
MA-F12 Eagle Roosting Areas

570 acres, less than one percent of the Ochoco National Forest
60 percent forested, 40 percent nonforested

Description

This management area includes existing roosting areas for bald and golden eagles. The bald eagle in Oregon is classified as a threatened species under the Endangered Species Act of 1973, and therefore protection of habitat is required by law. On the Ochoco National Forest, the eagle habitat of concern is winter roosting areas. Eagle roosting areas are generally stands with large open crown trees adjacent to feeding areas. Common food sources include large game and livestock carrion, fish, waterfowl and ground squirrels. Consequently, creeks and meadows are typical feeding areas. Preferred trees are often large ponderosa pine and Douglas-fir, although other species such as cottonwood may be used.

Emphasis

Provide winter roosting habitat for migrating bald eagles annually during the period December through April.

Desired Condition

The areas will have uneven-aged stands which contain large trees at least 22 inches DBH, and a few trees which are 36-40 inches DBH. Roost trees generally are at least 22 inches DBH and have an open structure allowing eagles to land easily. Roost trees actively in use will be preserved, along with replacement trees that will be located in the same vicinity to the degree possible.

The area will be free of potentially disturbing human activity in the vicinity of roosting areas from December 1 to May 1. When roosting areas overlap with areas which have more restrictive prescriptions, the area will be managed under the most restrictive prescription as long as roost trees are maintained. This management prescription will also apply to any roosting sites discovered in the future.
MA-F13 Developed Recreation

1,810 acres, less than one percent of the Ochoco National Forest
62 percent forested, 38 percent nonforested

Description

This management area applies to sites currently developed or planned for camping, boating, trailhead parking, and other developed recreational activities. Developed recreation sites are located throughout the Forest and provide a variety of recreational experiences.

This management area includes the developed site and a visual influence area that surrounds each site. The visual influence area is variable in size depending on the topography.

Emphasis

Provides safe, healthful, and aesthetic facilities for people to utilize while they are pursuing a variety of recreational experiences within a relatively natural outdoor setting.

Desired Condition

Developed recreation areas will be natural appearing areas, but with obvious man-made controls and structures to direct users, provide for comfort and sanitation, and protect the natural resources while providing a variety of outdoor recreational opportunities. Developed sites will be provided for a broad range of recreational opportunities.

New and upgraded sites will incorporate a barrier-free design in order to accessible to the handicapped.

Timber activities will normally not be visually evident, but may be used for safety and visual enhancement. Scenic views may be enhanced through harvest or thinning but will appear natural.

Facilities, roads, and trails will have a well maintained appearance and provide a safe recreational environment. Public use may be prohibited, or discouraged on a seasonal basis, depending on management objectives.
MA-F14 Dispersed Recreation

1,970 acres, less than one percent of the Ochoco National Forest
76 percent forested, 24 percent nonforested

Description

This prescription applies to dispersed recreation sites located throughout the Forest. These sites generally occur along roads, and many are concentrated near riparian areas and stream courses. The prescription applies to the actual site and the influence area immediately around it.

Emphasis

Provide and maintain a near-natural setting for people to utilize while pursuing outdoor recreation experiences.
Desired Condition

The dispersed site will exhibit a relatively natural appearance, even though management activities (such as timber harvest) may be highly visible nearby. Primitive, user-constructed structures or facilities, consistent with the site's use, may be seen. Sites will be managed so that users tend to feel relatively isolated from the sights and sounds of civilization. A strategy will be developed that encourages individuals or groups to “find their own place.”

Livestock grazing may be evident but the successful application of allotment management requirements will also be evident.
MA-F15 Riparian

18,130 acres, two percent of the Ochoco National Forest
90 percent forested, 10 percent nonforested

Description
Riparian areas include land adjacent to water, where plants that are dependent on a perpetual source of water occur. They normally have high water tables and soils which exhibit characteristics of wetness. On the Ochoco National Forest, riparian areas exist along 800 miles of designated streams (see Riparian Area Map). They often contain stands of ponderosa pine and mixed conifer, as well as water-loving plant species such as sedges, alder, and willow; and they are among the most productive places on the Forest. Because of this, they are often the most intensively and extensively used areas on the Forest. Signs of past or current management can be seen in most riparian areas across the Forest, and the majority of the Forest road system lies near or adjacent to these areas. Camping, grazing, recreation, and timber harvest are all established uses within streamside areas.

Riparian areas are among the most critical wildlife habitats on the Forest. Over 75 percent of the Forest wildlife species are directly dependent on riparian zones or utilize them more than other habitat areas. Wildlife use streamsides as “connectors,” or travel lanes between forested habitats.

Fully functional riparian areas are essential for the maintenance of viable fish populations on the Forest. Riparian areas provide food, cover, and a source of large woody material for aquatic insects, fish and land animals. The vegetation of streamside areas filter sediment and shade the water surface to help maintain stable stream temperatures.

Significant investments have been made to rehabilitate or enhance primary streams on the Forest, and restrictions have been placed on uses which have historically had a negative impact on water resources within these areas.

Emphasis
Manage streamside vegetation and habitat to maintain or improve water quality. Meet temperature and turbidity levels as required by state standards under the Clean Water Act (see Forest-wide Standards and Guidelines, Water, and Best Management Practices (BMP’S), FEIS Appendix G).

Desired Condition
Riparian areas will exhibit a low, but apparent level of management. Vegetation
may or may not appear manipulated, depending on the condition of the stream. Suitable amounts of large woody material will be apparent within the riparian area to provide streambank stability and habitat. An abundance of wildlife species should be evident as a result of restrictions on management activities and level of habitat provided. Due to management restrictions and the low risk associated with these areas, the signs of natural or man-caused fire will be infrequent.

For management purposes, a special protection area (100 feet from the edges of perennial bodies of water) will be apparent. In addition, the streams listed below will receive extra protection to 200 feet from the stream edge to provide “connective habitat” for a variety of wildlife species on the Forest:

<table>

</tr>
<tr>
<td></td>
<td>West Fork Bridge Creek</td>
<td></td>
</tr>
</tbody>
</table>

Roads not planned for future use, through and across riparian areas, will be obliterated and revegetated to a natural or near natural condition.

Within the limits of ecological potential, a shady, brushy condition with a canopy of alder, willow, aspen, or other deciduous vegetation will exist.

Where coniferous evergreens are a natural component of the ecosystem, a variety of size classes will exist to perpetuate the supply of shade and woody debris over time. Sites unable to support a canopy of deciduous or evergreen species will be characterized by vigorous stands of forbs, grasses, and grass-like riparian species.

Bank slopes containing high plant densities, thick root masses, embedded angular boulders, and old logs will also characterize these areas. Extensive scouring of streambanks will be an uncommon occurrence as will soil deposition outside the norm for the individual stream system. Streambeds will be commonly covered by native aquatic growth on assorted sizes of rocks and boulders.

Where cobble and gravel bars are prominent, they will become covered by sandy loam soils as riparian vegetation filters and traps stream sediments. As stream banks are re-built and cutbanks stabilized, a narrower, deeper channel will gradually develop.

Springs and wet meadows are not specifically included in this management area prescription, but should receive appropriate protection as stated in Forest-wide Standards and Guidelines for Water, Section 3, this chapter.
MA-F16 Bandit Springs Recreation Area

1,580 acres, less than one percent of the Forest
97 percent forested, three percent nonforested

Description

The Bandit Springs Recreation Area is between the Mill Creek Wilderness and U.S. Highway 26, on the Big Summit and Prineville Ranger Districts. It has become a popular cross-country ski area due to its normally satisfactory snowpack and easy access. The area (Ochoco Divide) also has an Oregon State Rest Area and a nearby National Forest developed campground and sled hill. Scenic resources are created by mature stands of ponderosa pine and mixed conifer. Recreational development consists of several miles of established cross-country ski trails.

Emphasis

Provide dispersed, nonmotorized recreational opportunities within a setting where most management activities (timber harvest) are generally not evident to the casual observer. Expand the recreational activities and opportunities beyond winter recreation to year-round activities. Provide hubs of more developed facilities to reach a broader recreation audience.
Desired Condition

The Bandit Springs Recreation Area is expected to become an important winter sports use area on the Forest, as well as a setting for other year-round recreational activities, including: environmental education, mountain bike riding, day hiking, hunting, and horseback riding. Developments to accommodate a broad spectrum of nonmotorized recreationists’ needs will be built to enhance their experience. Emphasis will be on enjoying the natural scenery, with interpretation aiding the casual visitor. Developments may include: trail shelters, maintained trails, horse unloading ramps, toilets, information areas, parking, picnic areas, and signs.

Periodic manipulation of vegetation to meet recreational and visual objectives for the area will be apparent to the user. Timber stands will be managed to develop and maintain resistance to catastrophic events that would detract from the recreational experience. Both uneven- and even-aged silvicultural practices will be used. A road system will be visible, but secondary to the natural setting. Livestock use will also be evident.
MA-F17 Stein’s Pillar Recreation Area

1,070 acres, less than one percent of the Ochoco National Forest.
94 percent forested, six percent nonforested

Description

Located about 20 miles northeast of Prineville, the Stein’s Pillar Management Area has forested, rugged terrain with scattered juniper plateaus. There are volcanic plugs and unique geologic formations that offer contrast and interesting views. Stein’s Pillar, 300 feet in height, is the most prominent volcanic plug in the area.

The unroaded, conifer forest is dissected by streams running into Mill Creek. The ponderosa pine stands have a dense Douglas-fir understory and are beginning to lose their natural open character. The stands of white fir and Douglas-fir are very dense. Some of the forest is old growth, with large trees, as well as various-aged trees and snags. The entire area is important winter range for deer and elk, which also use it in the summer.

There are no structures in the area, few signs, and one trailhead and trail. A rustic trail accesses Stein’s Pillar. The main access to the area is provided by Forest Road 3300-500 along the southern part of the area, and leads to the Stein’s Pillar Trailhead. Forest Road 3350 accesses the northern boundary. Forest Road 3300 offers panoramic views of Stein’s Pillar.

Current recreational activities are mostly day-use, nonmotorized activities. These activities include hiking, sightseeing, rockclimbing, horseback riding, and some group activities. Both individuals and families enjoy the quiet, natural setting close to Prineville. They have the opportunity to see Stein’s Pillar and views of the Ochoco and Cascade Mountains. Many people picnic, as well as participate in the above-mentioned activities in this area.

Emphasis

Maintain a scenic, natural or natural-appearing setting associated with unique geologic formations, particularly Stein’s Pillar. Provide roadless nonmotorized recreation, with various opportunities to enjoy nature.

Desired Condition

The area will be a natural or natural-appearing place with a variety of volcanic plugs, topography, plant communities, and wildlife where recreationists can enjoy nonmotorized recreation.
Ponderosa pine stands will have large, yellow-bark trees, particularly along the Stein’s Pillar Trail. There will be a mosaic of these large-tree, open pine stands interspersed with juniper scab flats and fir stands. Created openings will blend with the natural appearance of the area. Scenic views will be created, but most management activities (timber harvest) will not be evident to the casual observer.

The area will offer scenic views of Stein’s Pillar and other volcanic plugs, as well as the Ochoco and Cascade Mountains. Recreationists will enjoy closeness to nature in their nonmotorized activities, including hiking, picnicking, rockclimbing, sightseeing, horseback riding, and group activities. These activities will mostly be day use.

Nonmotorized recreation opportunities and facilities will be provided. A rustic trail, designed and maintained for family day walks, will access Stein’s Pillar. There will be an associated trailhead and access route. The trail system may be extended to the north to tie to the Benefield Road. Also, a safe way to the base of the pillars will be constructed to allow easier access for climbers and others. Interpretive facilities will highlight geological, recreational, historical, old growth, and wildlife features, and the nearby wilderness.

Streamsides will be extremely shady and brushy with an abundance of tall overstory conifer trees and/or shorter hardwoods of alder, willow, and aspen, meeting the Riparian Management Area objectives.

Deer and elk may use the area for winter cover, feed, and security. Deer and elk may summer throughout the area. A 300-acre Old Growth Management Area will be available for wildlife, such as the goshawk and pileated woodpecker. Snags will occur naturally, providing habitat for woodpeckers, nuthatches, owls, and other cavity nesters.

Livestock use will be evident but the successful application of allotment management requirements will also be evident.
MA-F18 Hammer Creek Wildlife/Recreation Area

2,560 acres, less than one percent of the Ochoco National Forest
44 percent forested, 56 percent nonforested

Description

Located in the western Maury Mountains, the Hammer Creek Management Area is a mixture of conifer forest on mostly north-facing slopes, old growth in steep stream drainages, and large juniper plateaus. Existing stands are primarily composed of an overstory of large size ponderosa pine with an understory of Douglas-fir, although stands containing only pine and Douglas-fir are also found within the area. Hammer Creek flows through the northern part of the area and Sherwood Creek bounds the area's western edge. The area is the largest block of land in the Maury Mountains that has not had intensive timber management activities. The area has evidence of a few primitive roads.

The main access to the area is provided by Forest Road 16, which follows the area's western boundary. The area can also be reached by Forest Road 1750 and the Hammer Creek Trail from the south.

The Hammer Creek Area provides habitat diversity not found in the rest of the Maury Mountains. This diversity combined with minimal access makes the area valuable habitat for a wide variety of animal species.

Emphasis

Provide and maintain habitat diversity for a variety of wildlife species where open road density is minimal; and provide a scenic, seminatural or natural-appearing setting for nonmotorized recreational opportunities.

Desired Condition

Forested areas of ponderosa pine will be seen as a wide variety of size/age classes with a major component of large, yellow-barked pine. Mixed conifer areas will be a mosaic of open and closed canopy stands of various size classes to provide an optimum forage and cover mix for big game. Nonforested areas will generally appear natural in character, but with periodic evidence of livestock grazing. Riparian areas will be shady and have an appearance of consisting of a mixture of trees and shrubs. Management activities will remain visually subordinate to the characteristic landscape.

Developed facilities such as trailheads, picnic/camp areas, and associated access routes will be evident on the periphery of the unit. Interpretive facilities will be available to highlight historical, recreational, and wildlife features.

Access roads to trailheads will be open. All other roads will be closed to motorized use and rehabilitated after management projects are completed.
MA-F19 Deep Creek Recreation Area

770 acres, less than one percent of the Ochoco National Forest
66 percent forested, 34 percent nonforested

Description

The Deep Creek Recreation Area is located on the Paulina Ranger District, near the boundary with the Big Summit Ranger District. The area is located along Deep Creek and follows Forest Road 4250 from the junction with Forest Road 42 north to Forest Road 4256. The boundary for this management area is located on the slope break on either side of the Deep Creek drainage.

This area is popular year-round, for fishing, dispersed camping, hunting and sightseeing. Several dispersed recreation sites are located in the area. Forest Road 4250 is used heavily for commercial, public, and administrative traffic.

Conifer vegetation in the area consists of a mixture of Douglas-fir, western larch, ponderosa pine, and lodgepole pine. Some exceptional stands of old growth western larch occur on the north slopes of the drainage. Ponderosa pine occurs more on the south facing slopes. Lodgepole pine occurs primarily in the drainage bottom. Riparian vegetation is present along the creek, and alder is a common occurrence. An old growth area is located contiguous with the boundary of this management area.

Emphasis

Provide a near natural setting for recreational pursuits within the area where management activities are not visually evident.

Desired Condition

Forested areas will contain large size class trees of larch and ponderosa pine. Nonforested areas will generally appear natural in character with little immediate evidence of management activities. The riparian area will contain abundant alder and other riparian hardwood species, where naturally occurring.

Dispersed recreational areas will be protected. Opportunities for camping in developed sites will be provided at Deep Creek Campground.

Trails may be developed that provide day hiking or interpretive recreational opportunities.

Management activities including timber harvest and prescribed burning will not be evident to the casual observer. Livestock use will be evident but the successful application of allotment management requirements will also be evident.
MAF-20 Winter Range

64,130 acres, seven percent of the Ochoco National Forest
45 percent forested, 55 percent nonforested

Description

These sites are typically located along the exterior boundaries of the Forest. They are among the lowest elevation sites on the Forest. Ponderosa pine, occasionally associated with Douglas-fir and white fir, functions as the primary cover. Juniper woodlands, wet and dry meadows, sagebrush-grassland and other shrubland, as well as scabland types, provide species that furnish forage.

Several major arterial and collector roads go through designated winter range areas. Many of the arterials are used as snowmobile and winter sports routes to higher elevation areas.

There are both developed campgrounds and dispersed campsites within designated winter range areas.

There are several actual bald eagle winter roost sites within the winter range, in addition, several old growth areas are located within the management area. Most of the winter range management areas incorporate grazing allotments which are utilized during the summer months.
Emphasis
Manage for big game winter range habitat.

Desired Condition
Big game use on winter range will be seen as the primary activity with other management activities and human intervention restricted, from December 1 to May 1. Habitat effectiveness for big game will be improving over time, due to increases in both quality and quantity of thermal cover, and reductions in open road density. Road and trail use will be limited to one mile of open access per section, from December 1 to May 1, a greater density of trail and road access will be available during the remainder of the year, up to three miles per section.

Vegetation cover types, key species condition, big game use, and domestic livestock grazing will be inventoried and mapped. Treatment units will be identified; treatments will be prescribed on a scheduled basis to maintain key forage and browse species. Treatments will be monitored to assure appropriate forage and browse allocations for big game.

Management, including vegetation manipulation, structures, and prescribed fire to maintain or improve winter range, may be apparent. Livestock use of forage is planned, but will be conducted in harmony with big game winter range habitat needs.

Tree mortality, resultant of past spruce budworm and other endemic insects and diseases, may be evident in areas reserved for big game cover, along with associated changes in fuel loadings and plant succession.
MA-F21 General Forest Winter Range

107,360 acres, 12 percent of the Ochoco National Forest
58 percent forested, 42 percent nonforested

Description

These sites are typically located along the exterior boundaries of the Forest, and they are among the lowest elevation sites on the Forest. Ponderosa pine, occasionally associated with Douglas-fir and white fir, function as cover. Juniper woodlands, wet and dry meadows, and scablands furnish forage. These sites are in addition to those designated as MA-F20 Winter Range.

Several major arterial and collector roads go through designated winter range areas. Many of the arterials are used as snowmobile and winter sports routes to higher elevation areas.

Both developed campgrounds and dispersed campsites are within designated winter range areas.

There are several bald eagle winter roost sites designated as separate management areas within the general forest winter range; several old growth management areas are also located within this area.

Most of the general forest winter range management areas incorporate grazing allotments which receive use during the summer months.
Emphasis

Manage for timber production with management activities designed and implemented to recognize big game habitat needs.

Desired Condition

Big game use on winter range from December 1 to May 1 will be the primary activity, with other management activities and human intervention restricted. Habitat effectiveness will be slowly decreasing in this area, mainly due to future reductions in quality and quantity of thermal cover. This decrease will not be as rapid as in MA-F22 General Forest due to specified road closures and other incidental wildlife improvements. Road and trail use will be limited to one mile of open access per section during December 1 to May 1, but a greater density of trail and road access will be available during the remainder of the year, up to three miles per section.

Fire occurrence will be visible where natural and human-caused starts occur, and where prescribed fire was applied.

Management activities will take into account vegetation types and successional responses of those types in order to apply prescriptions which have beneficial results for habitat. Areas of particular importance as big game habitat will be identified and management activities modified to complement, protect, or improve habitat. Livestock use of forage is planned, but will be conducted in harmony with big game winter range habitat needs.

Tree mortality, resultant of past spruce budworm and other endemic insects and diseases, may be evident in areas reserved for big game cover, along with associated changes in fuel loadings and plant succession.
MA-F22 General Forest

496,850 acres, 59 percent of the Ochoco National Forest
72 percent forested, 28 percent nonforested

Description

The areas of the Forest where this management area is applied contain a wide variety of land types and vegetative cover. Most of the area has some type of tree cover, including ponderosa pine, mixed conifer and juniper. The area also contains scablands, meadows, rock outcrops, seeps and springs.

Emphasis

Produce timber and forage while meeting the Forest-wide standards and guidelines for all resources. In ponderosa pine stands, management will emphasize production of high value (quality) timber.
Desired Condition

Many ponderosa pine stands on slopes less than 30 percent, and some mixed conifer stands on slopes less than 30 percent, will exhibit the application of uneven-aged management. Trees up to 20 inches DBH will be seen in these stands; the evidence of trees managed for high quality lumber where the first log is relatively free of limbs will be noted.

Except in seedling and sapling stages, most mixed conifer timber stands, all stands on slopes greater than 30 percent, and some pine stands not suitable for uneven-aged management, will be even-aged with trees somewhat evenly spaced and fully occupying the site. Regenerated stands will generally be 20 to 40 acres in size. A mix of species with emphasis on the seral species such as pine and larch will be evident where conditions permit. The largest trees will generally be 18 to 22 inches DBH, but occasional larger ones may be found where left for snag replacements or other resource reasons. Trees will have full crowns and be relatively free of defect. Snags will be apparent over the area as the cavity nesters requirement will be at the 40 percent level.

A variety of native grasses, sedges and forbs will be available for grazing animals. Competition from nonforage species such as sagebrush and juniper will not be a major problem. Most of the forested range lands will be in fair and good forage condition class. Forage use will be apparent, and improvements installed to facilitate stock distribution and effective use of available forage will be evident.

Following use for timber haul, local access routes with planned future use will generally be open to high clearance access (maintenance level 2), and for Forest visitor and administrative use, unless there are significant reasons to do otherwise. Access routes/trails will be developed to offer a variety of terrain and experience levels for ATV’s, and users will be restricted to these areas. Recreational off-road, motorized use will be allowed, but user’s will be encouraged to use designated routes in order to protect forest resources such as soils and water quality.

The area will have dispersed sites scattered throughout which will be maintained in as natural a condition as possible.

Fire occurrence will be visible where natural or human-caused starts occur, and where prescribed fire was applied.
MA-F23 North Fork Crooked River Recreation Corridor

1,830 acres, less than one percent of the Ochoco National Forest
52 percent forested, 48 percent nonforested

Description

This management area contains a segment of the North Fork of the Crooked River which extends from the source at Williams Prairie to Big Summit Prairie, and from Big Summit Prairie to Deep Creek Campground. This has been designated as a Recreational River segment in the National Wild and Scenic Rivers System.

The upper-most segments of this river flow through open grassland flats with little riparian vegetation along the banks. Evidence of heavy grazing occurs here. This is a spring fishing stream, but generally flows are too low and temperatures too high to support fish populations during the summer months.

Forest Road 42, a major arterial on the Ochoco National Forest, parallels the lower North Fork of the Crooked River recreation segment along the length of this segment, generally staying within 200 to 600 feet of the river bank. It carries considerable amounts of industrial, administrative, and recreational traffic during late spring, summer, and fall.

There has been some timber harvesting along the north shore of the river. Generally the trees were selected for harvesting on a sanitation-salvage basis.
The majority of the stands on the south side of the river have never been harvested; part of the area is designated as old growth management. The area is grazed by cattle.

Primary recreational uses of the area are camping, fishing, and hunting. There is a developed campground called Deep Creek Campground at the eastern end and several dispersed camping sites along the river. Water flows are generally low during late summer and fall, and are unable to support fish during these times because water temperatures are too high.

**Emphasis**

Management will maintain the appearance of a natural landscape in the foreground view from Forest Road 42 to enhance recreational and scenic values. Management activities will protect and enhance public use and enjoyment of the river segment. Further planning for this management area will be forthcoming, as required by the Omnibus Oregon Wild and Scenic Rivers Act of 1988.

**Desired Condition**

This segment of the North Fork of the Crooked River will be a free-flowing river whose shorelines may be accessible by roads. The immediate river environment (up to one-quarter mile from the river) will appear natural, though there may be evidence of past and ongoing timber harvest, as well as grazing. Developed and dispersed campsites and interpretive signing will be seen throughout the area to assist in its enjoyment and protection. The use of prescribed fire may be evident where used to enhance the retention of featured tree species in viewing areas, such as old growth ponderosa pine or western larch.
MA-F24 North Fork Crooked River Scenic Corridor

830 acres, less than one percent of the Ochoco National Forest
46 percent forested, 54 percent nonforested

Description

This management area includes the segment of the North Fork of the Crooked River which extends from Deep Creek Campground south to the Forest boundary. It has been included in the National Wild and Scenic Rivers System, designated as a Scenic River segment.

The area is accessed by Forest Road 4260-230 on the east side of the river. Though there can be a considerable amount of industrial traffic on Forest Road 4260; the traffic on Forest Road 4260-230 is recreational and administrative. Access on the west side occurs by Forest Road 4240. This route actually fords the river just above the upper falls on private land.

Part of the area has been designated for old growth; the area is grazed by cattle.

Primary recreational uses of the area are dispersed camping, hunting, fishing, and for a short time in the spring, white-water rafting. Deep Creek Campground borders the north end of the unit, and there are several dispersed campgrounds.

Steep canyon walls, large old growth ponderosa pine, and perennial water make this unit a visually striking area.
Emphasis

Management will maintain and enhance the natural appearing landscape and protect the scenic river designation.

Several stands have been designated for old growth within the scenic river corridor. Where old growth restrictions are more restrictive than scenic river restrictions, the old growth prescriptions will apply. Further planning for this management area will be forthcoming, as required by the Omnibus Oregon Wild and Scenic Rivers Act of 1988.

Desired Condition

This segment of the North Fork of the Crooked River will be seen as a free-flowing river whose shoreline is accessed by a road. The immediate river environment (up to one-quarter mile from the river) will have an overall natural appearance, though there may be evidence of past timber harvest. Other management activities will be evident, including developments such as dispersed campsites and interpretive signing to enhance the public’s use of the area while protecting resources. A low standard trail will be developed that will require wading or rock-to-rock natural crossings to cross through the river corridor. Prescribed burning will be apparent where used to enhance the retention of featured tree species such as large old growth ponderosa pine and western larch.
MA-F25 U.S. Highway 26 Visual Corridor

6,850 acres, less than one percent of the Ochoco National Forest
85 percent forested, 15 percent nonforest

Description

This visual corridor includes foreground viewing areas classified as “retention” adjacent to 13 miles of U.S. Highway 26, which traverses the Ochoco National Forest through the Big Summit and Prineville Ranger Districts. It lies within two major drainages, Marks Creek to the south and West Branch Bridge Creek to the north; this is the primary visual corridor on the Forest. The highway constitutes a major east-west route through Oregon and is a designated “National Bike Trail.”

In April 1985, a fifty year implementation plan was developed and approved for the area, and is incorporated here to provide specific direction for long-term management.

The corridor contains outstanding stands of old growth ponderosa pine, some of which have been maintained in an open park-like condition through management activities. Other features of the corridor include mixed conifer stands of various ages and visual character, ungrazed meadows, occasional aspen stands, and unique geologic features such as basalt cliffs along Marks Creek. Marks Creek is a Class I stream that supports native trout populations and has received major investments for stream habitat improvement.
**Emphasis**

Maintain and enhance the scenery for travelers along U.S. Highway 26.

**Desired Condition**

The U.S. Highway 26 Corridor will be managed to maintain the big tree appearance; primary management activities will not be evident to the casual Forest visitor. Vegetation will be manipulated in order to provide a variety of size and age classes of timbered stands - from open park-like stands of old growth ponderosa pine, to dense, shaded stands of mixed conifer, to small openings with planted and natural tree seedlings. Both uneven- and even-aged stand conditions will exist over time.

An established road system will be in place, but will have been designed to minimize the visual effect on the landscape. Prescribed livestock grazing is planned. Pastoral scenes will add to visual variety. Prescriptive grazing will be designed to be in concert with the visual quality objectives of the area.

Wildlife may be viewed in the corridor. This might include big game, a variety of bird species, and fish. The affects of fire will be periodically evident, as a result of natural and prescribed burning.

Dispersed recreation sites will be abundant throughout the corridor for year-round use. Camping will be encouraged, except where restricted for other resource reasons, such as streamside management areas along Mark's Creek. Snowparks for winter recreation will be constructed to blend into the surroundings.
MA-F26 Visual Management Corridors

(This includes all visual management areas outside of other special management areas, i.e. Highway 26, Summit Trail, etc.)

33,260 acres, four percent of the Ochoco National Forest

9,300 acres - Retention

23,960 acres - Partial Retention

70 percent forested, 30 percent nonforested

Description

This management area includes all foreground areas that are adjacent to approximately 260 miles of roads across the Forest that serve as significant travel ways for the visiting public. In most cases these roads provide recreational access to specific destinations, such as Walton Lake Campground and the Black Canyon Wilderness.

Vegetation in these corridors are of primary importance to the scenic landscape as they represent “The National Forest” to the majority of the visiting public. At lower elevations, a mosaic of juniper, grasslands and ponderosa pine gives an impression of a semi-arid, almost desert environment. As one travels deeper into the Forest, this character gradually disappears and is replaced with stands of large, old ponderosa pine interspersed with nonforested grasslands and occasional rock outcrops. Continuing to most higher elevations within the Forest, one will experience a much more diverse and heavily forested setting, with stands of mixed conifer dominating a more subdued area of old growth ponderosa pine, aspen and high mountain meadows. As most of these corridors are located in
drainage bottoms along major streams, the chances of a Forest visitor viewing a number of wildlife species are good.

**Emphasis**

Maintain the natural appearing character of the Forest along major travel routes, where management activities are usually not evident or are visually subordinate to the surrounding landscape.

**Desired Condition**

**Prescription Area A**

This area will encompass about 86 miles of Forest roads and include approximately 9,300 acres of associated landscape. The outer boundary of the management area will generally not exceed 600 feet on each side the road. Retention will be the visual quality objective, which will result in long-term management where primary activities are not visually evident to the casual observer. Forest visitors will encounter a landscape which is diverse, and reflects ecosystems where management activities appear as a natural condition.

Vegetation will be manipulated, but will reflect a natural forest setting where stands of trees exist in multiple age classes, from young seedlings to mature old growth in both uneven- and even-aged conditions. Unique characteristics of the landscape, such as rock bluffs and aspen clones, will appear highlighted, where they are currently hidden from view due to existing vegetation.

**Prescription Area B**

This area will encompass about 174 miles of Forest roads and include approximately 23,960 acres of associated landscape. The outer boundary of the management area will generally not exceed 600 feet on each side the road. Partial retention will be the visual quality objective, which will result in long-term management where activities may be evident but are visually subordinate to the characteristic landscape. Forest visitors will encounter a near-natural scenic view, with a diverse ecosystem reflecting a low level of management.

Vegetation will appear manipulated and reflect a forest setting where stands of trees exist in multiple age classes in both uneven- and even-aged conditions, set in a more subdued background of rock outcrops, aspen clones and native grass communities.

**Prescription Areas A and B**

An established road system will be in place, but will have been designed to minimize the visual effect on the landscape. Grazing by livestock may or may not be visible immediately adjacent to these roads, but will be an acceptable resource use within the area.

As a consequence of visual management, an abundance of wildlife may be viewed in the corridor, this might include big game, a variety of bird species, and fish. The affects of fire will be periodically evident as a result of natural and prescribed burning.
MA-F27 Round Mountain National Recreational Trail

1,000 acres, less than one percent of the Ochoco National Forest
71 percent forested, 29 percent nonforested

Description

Round Mountain trail goes from the 148 spur of Forest Road 22 at its north end to Forest Road 4205 at its south end. It connects the Walton Lake Campground area on the north, to Forest Road 42, the main access route from the west to Big Summit Prairie. Total trail length is 7.5 miles. It is of low to moderate difficulty, and open to hikers, horseback riding, and mountain bikes. It is also used by cross country skiers and snowmobilers during the winter, and portions of the trail location have been signed for winter use.

From Spur 148 at an elevation of 5,200 feet, the trail is a gradual climb to the base of Round Mountain. At that point, the trail becomes considerably steeper switchbacking to reach the summit of Round Mountain at 6,750 feet. South from the summit of Round Mountain, the trail gradually descends to the 5,500 foot elevation.

The trail goes through ponderosa pine and mixed conifer stands, as well as an existing rock pit. There is no water along the trail except Scissor Springs. The trail goes through a sheep allotment. Wild horses may be observed from the trail.

The view from the summit of Round Mountain includes Big Summit Prairie to the east, Lookout Mountain to the south, and Prineville and the Cascade Range to the west.

Emphasis

Protect and manage for scenic qualities which make the trail corridor an attractive recreational setting. Rehabilitate trail sites where management activities conflict with National Recreation Trail objectives.

Desired Condition

The visitor will note a natural appearing forest along the majority of the trail route (visual quality objective of retention). The outer boundary of the management area will generally not exceed 600 feet on either side of the trail. The Round Mountain National Recreation Trail will be linked to trails on Lookout Mountain and the access road to the Summit of Round Mountain, as well as Walton Lake Campground, through appropriate signing. Recreational improvements will be evident in locations necessary to protect the land, for public safety, and to enhance the public's enjoyment of the area.
Old growth stands will be seen within the management area. Fire occurrence will be evident where natural and human-caused starts occur. Rehabilitation will be done in areas visually impacted by past management activity along the trail route.

MA-F28 Facilities

460 acres, less than one percent of the Ochoco National Forest
26 percent forested, 74 percent nonforested

Description

This prescription applies to administrative sites located on the Forest. These include ranger stations, work centers, lookouts, and electronic sites.

This prescription does not include the Forest Road System (approximately one percent of the total Forest acres).

Emphasis

Provide a safe, efficient, and healthful working environment where structure design and layout of the site blend with the surrounding area.

Desired Condition

Sites will be efficiently designed work areas consistent with type and intensity of use. Employee wellness and public safety will be the primary design criteria. Color and design of structures and facilities will appear to blend with the surrounding environment.

Traffic controls and signing will be apparent and designed to provide a safe driving environment. Roads and trails will be planned, designed, operated and maintained to levels sufficient to provide safe use for the intended traveler and use period.

The historical significance of buildings and structures will be considered during any modifications to sites.

Employee residential areas will be designed to fulfill employee needs for housing and recreation.

Management activities, such as timber harvest, thinnings, and fuel treatments for the protection of facilities from wildfire, may be visually apparent on a short-term basis.

Forest Management
Direction

Section 3
Forest-Wide and
Management Area
Standards and Guidelines
Standards and guidelines state the bounds or constraints within which all practices are to be carried out in achieving the planned goals, objectives and desired future condition. They are intended to supplement, but do not replace, policy direction found in Forest Service Manuals and Handbooks, and the Regional Guide for the Pacific Northwest Region. They also must comply with applicable State and Federal laws and regulations.

Forest-wide and management area standards and guidelines are grouped together by resource (or functional area), so that the user will have the total management direction available in one package. Management area standards and guidelines are more site-specific than Forest-wide standards and guidelines, and must be in compliance with them (Forest-wide) as well as higher order policy, regulation and law.

Some resource direction is only applicable on a Forest-wide basis and does not vary by management area. Hence, no management area standards and guidelines are presented for the following resources: Air Quality, Biological Diversity, Old Growth, and Social and Economic.
Air Quality

Forest-Wide Standards and Guidelines

Comply with regulations of the Clean Air Act, as amended, and coordinate activities with the Oregon State Department of Environmental Quality and the Oregon State Department of Forestry.

Demonstrate reasonable progress in reducing total suspended particulate (TSP) emissions from prescribed burning. The starting point for this reduction has been established as 9,200 tons per year for the Forest. Monitor particulate emissions originating from Forest activities as outlined in Chapter 5, Implementation of the Forest Plan.

Conduct prescribed burning in accordance with State smoke management plans.

Follow Regional standards and guidelines for smoke emissions as stated in Regional Vegetation Management Final Environmental Impact Statement.

Use the best available predictive methods and models and most cost-efficient technologies to minimize the impact of prescribed burning on designated smoke sensitive areas and Class I areas. Comply with regulations of the Oregon State Implementation Plan for Protection of Visibility in Class I Areas.

Protect the Forest air resources against pollution sources outside the Forest boundaries through application of the Prevention of Significant Deterioration (PSD) regulations contained in the Clean Air Act. Take appropriate action to contact the Oregon State Department of Environmental Quality when outside air pollution sources, in particular those originating on a regular seasonal basis from the Madras basin and the Willamette Valley, exceed Forest standards.

Biological Diversity

Forest-Wide Standards and Guidelines

Protect Research Natural Areas (RNA's) from influences which detract from their purposes. Monitor vegetation to insure that all major vegetative types and unique plant communities are preserved for future knowledge and gene pool diversity.

Manage and protect wildernesses in a manner that allows ecological processes, succession, fire, and similar influences to play a natural role, while protecting resources outside the areas from unnecessary risk of catastrophic fire.

Maintain viable populations of all threatened, endangered, and sensitive plant and animal species (see Standards and Guidelines for Wildlife and Fish).
A minimum of two percent of the Forest, in addition to areas in wilderness and some RNA's, will be managed for old growth, representing climax or near climax forest stand conditions.

Identify and protect unique ecological situations, through the Forest implementation and monitoring process. Examples of these include: eagle roosting, anadromous fish spawning, representative examples of old growth forest, aspen clones, river canyons, riparian areas and important connective habitat.

Disperse created openings and limit their size(s) to that described under the timber management guidelines.

Maintain soil productivity through management practices which reduce erosion and the application of guidelines that limit use of heavy equipment and skid road densities.

Incorporate plant association information (Hall, 1973 and 1989; Hopkins, et al, 1983) and their management implications, into project design and implementation.

Protect fragile sites such as shallow soil areas (scablands) and natural meadows.

Incorporate and design habitat-specific species requirements--such as those for cavity excavators--into guidelines and prescriptions for individual projects.

Monitor plant communities/associations to determine conditions and trends. Encourage recovery or prevent deterioration where activities may be leading to poor conditions, downward trends, the displacement of native plants or plant communities by undesirable weedy, annual or noxious vegetation, or where cover is unusually low for the particular plant associations (see Hall, 1973 and Hopkins et al, 1983). Manage aspen stands to produce a vigorous population, Forest-wide.

Limit the frequency of underburning of plant communities to the natural fire cycle, or less frequently, until research is completed on ecological effects of burning.

Cultural Resources

Forest-Wide Standards and Guidelines

Update the existing Cultural Resource Overview each decade to incorporate all known cultural resource information on each District. The Overview will provide a framework for evaluating cultural resources located through survey efforts, will assist in the development of a Forest Inventory Plan approved by the Oregon State Historic Preservation Office (SHPO), and will help to identify opportunities for site interpretation.
Conduct cultural resource surveys (inventories) in advance of all ground-disturbing actions. Accomplish this through the implementation of the Interim Inventory Design (Dyrden, 1988) or Forest Inventory Plan (when formally approved). Survey both project and non-project areas during the earliest stages of the planning (NEPA) process. Submit project Cultural Resource Reports for SHPO review and Section 106 (National Historic Preservation Act, as amended) compliance prior to issuance of the Decision Notice and Environmental Assessment or Environmental Impact Statement.

Evaluate cultural resource properties located during inventory to determine their eligibility to the National Register of Historic Places. This will be accom-
plished through the Lithic Scatter Programmatic Memorandum of Agreement (PMOA), individual site and thematic Determinations of Eligibility. Develop contexts and themes from which to evaluate all classes of sites through thematic Determinations of Eligibility. Develop management plans, Memorandums of Agreement (MOA's), and PMOA's in cooperation with the State Historic Preservation Office, the Advisory Council on Historic Preservation, and other interested publics (Native Americans, local historical societies, groups and professional organizations) to facilitate cultural resource treatment and future management.

Document through the NEPA process the results of cultural resource surveys for all proposed ground-disturbing projects (Federal, Federally-funded or permitted) or projects determined to have an effect upon cultural resource sites or values.

Prepare a Determination of Effect for all projects and submit for Oregon SHPO review and consultation (i.e. No Effect, No Adverse Effect, or Adverse Effect).

Mitigate adverse effects to eligible and significant sites under consultation with the Oregon SHPO, Advisory Council on Historic Preservation, and interested publics. In ranked order of preference, the following treatment options will be considered:

- Avoidance through project design modification or abandonment (No Effect).
- Combination of project modification and scientific data recovery under an approved data recovery plan (No Adverse Effect or Mitigation of Adverse Effect).
- Data recovery and analysis such that cultural resource values are protected and preserved in forms useful to various scientific, government, ethnic and local groups (Mitigation of Adverse Effect).

Cultural resource sites, districts and thematic classes of such will be nominated to the National Register of Historic Places. Schedule nominations incrementally until the Forest-wide inventory of cultural resources is completed. Protect significant sites from degradation due to public use or natural deterioration. Protection methods may include, but are not limited to, scientific study and collection, the use of fences or barriers, prudent use of signs, site stabilization, closure orders, site monitoring, area patrolling, and restriction of access to site locational information as provided for under the provisions of the Freedom of Information Act.

Interpret and enhance selected sites for the education and enjoyment of the general public. A priority will be given to sites within or adjacent to public use areas, and which are being degraded through natural or human impacts. Produce scientifically accurate and culturally sensitive displays, brochures, posters, tours, lectures, etc. Support the distribution of scientific reports, monographs, video tapes, and books for the benefit of interested members of the public. Promote
public-private partnerships which will benefit Forest visitors through enhancing and interpreting sites.

Burial Sites
Treat historic or prehistoric burial remains as follows:

- Evaluate the site to determine if the skeletal material is human and to what time period or ethnic group it may be ascribed.
- Contact local authorities, Native American Tribal Group(s), other ethnic groups and County Historical Societies where appropriate.
- For Native American burials, reinter in-place with involvement by the appropriate representatives of a federally recognized Tribe or Native American group. Project planning for management activities in the site vicinity shall consider burial location in planning decisions and if necessary modify implementation so as to avoid direct and indirect impacts to the burial site.
- Where reinterment in-place is not feasible or prudent, alternative locations for reinterment will be reviewed and selected in consultation with the appropriate Indian Tribal representatives. In situations where a direct link cannot be made to an existing Federally recognized Tribe, this consultation shall take place with the nearest tribe or confederation.

Religious Freedom
Meet all requirements of the American Indian Religious Freedom Act (AIRFA). This law makes it the policy of the Federal government “to protect and preserve for American Indians their inherent right of freedom to believe, express, and exercise [their] traditional religions.” This protection includes, but is not limited to, access to sites, use and possession of sacred objects, and the enactment of ceremonies and traditional rites. Related activities include the gathering and processing of plants for food, medicinal, or craft uses; the construction of sweat lodges, or “vision quest” structures, and the like.

AIRFA addresses the religious freedom of all Native Americans without regard for Federal tribal recognition, but does not convey exclusive use of areas or free use of Forest products. In considering access to properties or sites within its boundaries, the Forest will examine other potential or existing uses and activities. Publicly owned properties, sites, objects of antiquity, etc. remain the property of the United States government. Activities which may effect such properties, sites, or objects are subject to existing laws, regulations and treaties.

Treaty Rights
Honor the rights reserved by the Confederated Tribes of Warm Springs Indians for lands ceded to the Federal Government through the Treaty of 1855.

On the ceded lands, the Tribes have the right to take fish in streams running through and bordering the Reservation and at all other usual and accustomed stations in common with the citizens of the United States.
The right of hunting, gathering roots and berries, and pasturing stock on unclaimed lands in common with citizens was also secured within the ceded lands.

Management Area Standards and Guidelines

Resource - Cultural Resources

Practice
Enhancement and Interpretation

Standard and Guideline
On-site interpretation and enhancement of cultural resources will not be done. Off-site interpretation and enhancement is permissible.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas

Standard and Guideline
Enhancement and interpretation of cultural resources will not be emphasized. Significant cultural resource sites and features may be enhanced and interpreted if the action does not detract from the management area objectives.

Applicable Management Area
MA-F6 Old Growth
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Area(A)

Standard and Guideline
Selectively enhance and interpret cultural resources, with priority on identifying sites that will complement the management emphasis of the specific areas.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F12 Eagle Roosting Areas
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian Areas
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F22 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
MA-F25 Highway 26 Visual Corridor
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities

**Standard and Guideline**
Enhance and interpret cultural resources while meeting Forest-wide standards and guidelines.

**Applicable Management Area**
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F11 Lookout Mountain Area(B)
MA-F20 Winter Range
MA-F21 General Forest Winter Range
MA-F22 General Forest
MA-F26 Visual Management Corridors

---

**Practice**
Structures

**Standard and Guideline**
Structures, such as old fences, that do not qualify for the National Register of Historic Places, will be removed or allowed to deteriorate naturally.

**Applicable Management Area**
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas
Facilities

Forest-Wide Standards and Guidelines

Buildings, utility systems and related facilities should be planned, developed, maintained and operated for safe use, support of Forest resource programs, and cost effectiveness. Historic buildings will be managed in accordance with the Programmatic Memorandum of Understanding (PMOA) for Depression-Era Administrative Buildings.

Construction of new buildings, or additions to existing buildings and utility systems, shall comply with approved site development plan.

Provide and manage administrative facilities in a manner sufficient to accomplish land and resource management and protection objectives of the Forest. Prepare administrative site development plans for all Forest administrative sites. Long-term development and maintenance costs will be a consideration in facilities planning.

Management Area Standards and Guidelines

Resource - Facilities

Practice
Construction, Reconstruction and Maintenance of Administrative Buildings and Structures

Standard and Guideline
No administrative buildings or structures allowed.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas

Standard and Guideline
Allow no administrative facilities within floodplains unless no feasible alternative sites exist. (Executive Order 11988).

Applicable Management Area
MA-F15 Riparian Areas
Standard and Guideline
Locate and design facilities to blend into the natural terrain as much as possible; properly use the site; and provide for traffic control, sanitation, public safety, site protection, and use distribution. New and upgraded facilities will incorporate a barrier-free design in order to be accessible to the physically handicapped.

Applicable Management Area
MA-F13 Developed Recreation

Standard and Guideline
Primitive structures will be allowed when they are consistent with management area objectives and are not damaging to resources.

Applicable Management Area
MA-F14 Dispersed Recreation

Practice
Nonconforming Structures

Standard and Guideline
Remove, eliminate, or disguise all nonconforming structures. Retain existing bridges until unusable, then remove without any replacement structures.

Applicable Management Area
MA-F3 Mill Creek Wilderness

Standard and Guideline
Except for facilities necessary to protect fragile resources, limit nonconforming structures to trail shelters, and as needed for sanitary and safety needs. All should be of simple design, and of native, rustic materials. Site modifications for facilities should be very minimal to none.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
Fire

Forest-Wide Standards and Guidelines

Fire Management

Planning
Use the National Fire Management Analysis System to determine the most cost-efficient fire protection organization. Reevaluate organization as conditions change and better information is developed. Due to the nature of intermixed land ownerships, including a number of wildland subdivisions, interagency cooperation must be considered in the planning process.

Prevention
Monitor current and recent fire reports to target specific risks. Coordinate activities through the Central Oregon Fire Prevention Cooperative (or its equivalent).

Detection
Periodically review the mix of aerial and ground detection activities to maintain the most cost-effective combination.

Initial Attack
Apply aggressive suppression action to wildfires that threaten life, private property, public safety, improvements, or investments.
Where wildfires do not threaten to exceed acceptable sizes and intensities, apply the lowest cost suppression option.

If a wildfire escapes initial action and threatens to exceed established limits, prepare an escaped fire situation analysis. Weigh the cost of suppression against the resource potential losses. Suppression costs should be commensurate with the values threatened.

**Secondary Attack Forces**
Provide equipment and training for Forest Service employees outside of the fire management organization to assist in initial attack.

**Fuel Treatments**
Burn excess residues from management activities or natural events only after an interdisciplinary team evaluation of site needs and appropriate utilization efforts have been considered. The Ochoco National Forest Residue Management Plan, 3/89, will be used as a guide for identifying site-specific treatment selections. All treatments will comply with Forest-wide and Management Area Standards and Guidelines for Forest Residues.

A desired “protection” residues profile will be identified using an economic efficiency model, such as the Fuels Analysis Process recently developed by Region 6. This will be a guide for developing the appropriate share of cost in helping meet the overall desired residue profile(s) described in Forest-wide and Management Area Standards and Guidelines for Forest Residues.

**Prescribed Fire**
All planned prescribed fires will have prescriptions approved by the appropriate line officer.

Unplanned ignitions may be used as prescribed fires if:

1) a prescribed fire plan has been prepared and approved,

2) the fire is burning within prescription, and

3) there are enough personnel and equipment available to provide the staffing necessary to carry out the existing prescribed fire plan.

Conduct prescribed burns within existing Federal and State regulations affecting the timing, duration, and dispersal of emissions. Coordination with adjacent local smoke management groups and local agency offices will be required.

Construct water diversions on firelines in hilly or steep terrain to drain water into areas with sufficient vegetation or other protection to avoid erosion.

Provide for a protective strip of undisturbed surface between the prescribed burn area and perennial water courses, considering local topographic, vegetation, and soil characteristics.

Avoid intense prescribed fires on soils that are highly erodible and/or are subject to the development of hydrophobic (nonwettable) conditions.
Fuelbreaks
Use existing transportation and topographic features as much as possible for planned fuel breaks.

Use fuelbreaks only where risk analysis indicates this to be the most economically viable alternative treatment, and where doing so meets the objectives of management area prescriptions, listed in Section 2, this chapter.

Piling and Burning
Locate piles outside of the normal high water flow area of natural and man-made drainages or water courses.

Burn slash piles located within mapped floodplains within one year after piling.

Remove slash created within the normal high water zone of a stream, unless needed for soil protection purposes.

Slash will not be piles on scablands unless there is no other feasible location, i.e. under circumstances dictated by topography or at a skyline landing (See Soils Standards and Guidelines).

Chipping, Burning, Lopping Scattering
Dispose of material so it will not reach stream courses.

Disperse material over a wide area when practical.

Management Area Standards and Guidelines
Resource - Fire

Practice
Fire Suppression (P04)

Standard and Guideline
Confine and contain will be the principle suppression strategies on most natural ignition (lightning) fires. Control strategy will be invoked when lightning fires threaten to escape the Wilderness Areas or pose unacceptable risks to life or wilderness values. Use the "light hand on the land" techniques.

Suppression activities should minimize disturbances of the land surface.

Use of chainsaws, helicopters, air tankers, or pumps must be approved by the Forest Supervisor. Allow no helispot construction for initial attack.

Crawler tractors will not be used without prior approval from the Regional Forester.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
Standard and Guideline
Fire encroaching on research natural areas should be suppressed as quickly as possible. Confine and contain will be the principle suppression strategies on most natural ignition (lightning) fires.

Ground disturbing activity to suppress fires will be avoided if possible, and only water will be used as fire retardant.

Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
Wildfires within or threatening designated old growth areas will be suppressed with emphasis on the tactical strategy of "contain." The objective is to minimize the acreage affected by wildfire. Minimize damage from suppression activities.

Applicable Management Area
MA-F6 Old Growth

Standard and Guideline
The confine, contain and control strategies may be considered as per preattack block economic efficiency analysis. However, confine and contain will receive emphasis. Emphasize minimum physical disturbance by suppression activities.
Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Area (A and B)
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor

Standard and Guideline
Suppression activities in these prescriptions should emphasize minimum physical disturbance. Confine, contain or control strategies are to be considered and utilized as directed in preattack block economic efficiency analyses.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
Strategy is to control all wildfires. Suppression should emphasize minimum physical disturbance.

Applicable Management Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F28 Facilities

Standard and Guideline
Suppression activities should be very limited within the riparian zone. The objective is to minimize soil and vegetation disturbance. Confine and contain are the principle strategies.

Applicable Management Area
MA-F15 Riparian Areas

Standard and Guideline
All three suppression strategies (confine, contain, or control) will be utilized in accordance with the economic efficiency analysis for each preattack block.
Applicable Management Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F12 Eagle Roosting Areas
MA-F20 Winter Range
MA-F21 General Forest Winter Range
MA-F22 General Forest

Maximum acceptable individual wildfire size by Fire Intensity Level, and total area by decade can be found in Fire Management Direction Table, in Appendix A3, for all management areas.

Practice
Treatment of Activity Fuels (P11)

Standard and Guideline
Fuel treatment (particularly mechanical treatments) should be very limited within riparian areas. In particular, activities which reduce the shading potential or woody debris sources of the site should be avoided. Greater levels of wildfire risk are acceptable in these areas.

Nonmechanized treatments will receive preference. When mechanized treatments are necessary they shall be carefully managed to meet the objectives of the management area.

Applicable Management Area
MA-F15 Riparian Areas
Standard and Guideline
Slash treatment should be completed currently with project work and should not be visible for more than one season. Avoid total slash clean up that removes all native vegetative cover. Prescribed burn areas should not exceed 250 acres.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
Projects will meet retention visual objectives and emphasis will be on non-mechanized treatments.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area (A & B)
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein’s Pillar Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F23 NFCR Recreation Corridor
MA-F24 NFCR Scenic Corridor

Standard and Guideline
Fuels usable by recreationists should be stacked or piled in convenient locations. Unusable fuels should be piled and burned.

Applicable Management Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F28 Facilities

Standard and Guideline
Meet Forest-wide Standards and Guidelines.

Applicable Management Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F12 Eagle Roosting Areas
MA-F20 Winter Range
MA-F21 General Forest Winter Range
MA-F22 General Forest
Practice
Treatment of Natural Fuels (P12)

**Standard and Guideline**
With the consent of PNW Station Director, manage prescribed fire in natural fuels to perpetuate conditions that the RNA represents, but with prudent measures to avoid catastrophic fire within, and outside the RNA.

**Applicable Management Area**
MA-F5 Research Natural Areas

---

**Standard and Guideline**
Naturally caused ignitions may be allowed to burn if they meet conditions in an approved prescribed burn plan, and funds and necessary staffing are available. Planned ignitions may be used within wilderness areas if that is the best way of returning fire to its natural role and thus reducing the fuels profile to natural levels and lessening the risk of damaging the wilderness resource. Planned ignitions within the Wilderness are also permitted if there is no other practical and economic way to lessen the likelihood of the escape of damaging wildfire from the Wilderness.

**Applicable Management Area**
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area

---

**Standard and Guideline**
No prescribed burning allowed.

**Applicable Management Area**
MA-F6 Old Growth

---

**Standard and Guideline**
Fuel treatment (particularly mechanized treatments) should be very limited within riparian areas. In particular, activities which would reduce the shading potential or woody debris sources of the site should be avoided. Greater levels of wildfire risk are acceptable in these areas.

**Applicable Management Area**
MA-F15 Riparian
Standard and Guideline
Maintain a vegetative type similar to natural conditions as identified through fire history and to meet specific visual resource management objectives on each corridor plan. Planned ignition prescribed burns will be scheduled as follows:

<table>
<thead>
<tr>
<th>Years</th>
<th>Ponderosa pine</th>
<th>Noncommercial</th>
<th>Grassland</th>
<th>Mixed Conifer</th>
<th>Tree shrub</th>
</tr>
</thead>
</table>

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Historic Trail

Standard and Guideline
Maintain a vegetation type similar to natural conditions as identified in the desired residue photos. Prescribed burns should be scheduled as follows:

<table>
<thead>
<tr>
<th>Years</th>
<th>Ponderosa pine</th>
<th>Noncommercial</th>
<th>Grassland</th>
<th>Mixed Conifer</th>
<th>Tree shrub</th>
</tr>
</thead>
</table>

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area (A & B)
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Management Area
MA-F19 Deep Creek Recreation Area
MA-F23 NFCR Recreation Corridor
MA-F24 NFCR Scenic Corridor

Standard and Guideline
Natural fuels on managed stands may be treated by prescribed fire where stand age is 25 years or more when necessary to maintain desired protection residue.
profile if this activity is consistent with other management objectives. Emphasis is placed on consideration of cover objectives.

**Applicable Management Area**
MA-F20 Winter Range

---

**Standard and Guideline**
Natural fuels on managed stands may be treated by prescribed fire where stand age is 25 years or more, when necessary to maintain desired protection residue profile if this activity is consistent with other management objectives.

**Applicable Management Area**
MA-F9 Rock Creek/Cottonwood Creek Unroaded-Helicopter Area
MA-F12 Eagle Roosting Areas
MA-F21 General Forest Winter Range
MA-F22 General Forest

---

**Practice**
**Fuel Break Construction and Maintenance (P13, P14)**

**Standard and Guideline**
Limited shaded fuelbreak segments may be constructed along boundaries to take advantage of logical natural terrain features aiding in the prevention of fire spread across management area boundaries. The majority of such fuel break systems will be outside of the area.

**Applicable Management Area**
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area
MA-F5 Research Natural Areas
MA-F6 Old Growth
MA-F15 Riparian

---

**Standard and Guideline**
Use fuel breaks only where they do not conflict with management area emphasis. Also, see Forest-wide Standards & Guidelines.

**Applicable Management Area**
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter
MA-F10 Silver Creek Area
Forage and Livestock

Forest-Wide Standards and Guidelines

Forage Utilization
Utilization tables have been developed for “Primary Range” (Table 4-30) and “Riparian” (Table 4-31). In addition, special seasonal restrictions (for fall green-up) have been directed for individual management areas. See Management Area Standards and Guidelines for detailed information.

Administration and Grazing Systems
Identify allotments with riparian areas in less than satisfactory condition.

Range allotment management plans will include a strategy for managing riparian areas to meet the emphasis and desired future condition stated in management area prescriptions (See Management Area #15-Riparian, Section 2, this Chapter). The process recommended in Managing Riparian Ecosystems (Zones) for Fish and Wildlife in Eastern Oregon and Eastern Washington, 1979, was used in establishing these conditions. Management objectives in grazing allotment plans should follow these. When the current riparian condition is less than that described, allotment objectives will include a schedule for improvement. Measurable objectives will be set for key parameters, such as stream surface shaded, streambank stability, and shrub cover. Allotment plans will address monitoring needed to determine if the desired rate of improvement is occurring. Those
plans currently not consistent with this direction will be developed or revised on a priority basis under a schedule established by the Forest Supervisor.

Develop and maintain allotment management plans to incorporate and reflect other Forest Plan direction (tiering).

Administer lands available and suitable for domestic livestock grazing according to the Forest Service grazing permit system.

Use intensive grazing management systems where feasible.

Coordinate transitory range management with timber management.

Encourage demonstration projects that are compatible with other standards and guidelines.

Grazing on scablands will occur through planned use of other plant communities within an allotment. As a result, scablands will contribute some forage; however, they will not be considered or mapped as primary range in an allotment. The installation of structural improvements, or various types of livestock management will be designed specifically not to concentrate livestock use on scablands.

Wild Horse Management
The Big Summit Ranger District wild horse territory will be managed for a base herd of 60 horses, as is outlined in the Wild Horse Management Plan, Appendix I.
### TABLE 4-30
RIPARIAN FORAGE UTILIZATION
Allowable Use of Available Forage 1/

<table>
<thead>
<tr>
<th>Range Resource Management Level</th>

<td></td>
</tr>
</tbody>
</table>

1/ This will be incorporated in annual operating plans and Allotment Management Plans. Allotment Management Plans may include utilization standards which are either higher or lower than associated with intensive grazing systems and specific vegetation management objectives which will meet objectives for the riparian dependent resources. Includes cumulative annual use by big game livestock.

2/ Utilization based on percent of total annual forage production removed by weight.

3/ Utilization based on percent of the current years growth removed. Example: measure length of current years growth of browsed and unbrowsed leaders and determine incidence of use. Calculate percent of current years growth removed.

* For satisfactory and unsatisfactory condition see Glossary in FER

### TABLE 4-31

MA-F24 North Fork Crooked River Scenic Corridor
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities

Standard and Guideline
Fall green-up after the regularly scheduled grazing season will be reserved for big game. Grazing extensions will generally not be permitted.

Applicable Management Area
MA-F18 Hammer Creek Wildlife Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
Increased forage production due to vegetation management activities will not be programmed for livestock use. The forage will be allocated for wildlife use.

Applicable Management Area
MA-F11 Lookout Mountain Recreation Area

Practice
Nonstructural Improvements

Standard and Guideline
Nonstructural improvements are not allowed, except in connection with approved research projects.

Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
Seeding for forage improvement prohibited.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
Standard and Guideline
Allow nonstructural improvements such as seeding and burning unless they conflict with the management emphasis for the area.

Applicable Management Area
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area

Practice
Structural Improvements

Standard and Guideline
Allow construction and maintenance of structures to exclude livestock from the research area only, except in connection with approved research projects.

Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
Encourage developments to disperse livestock away from riparian areas.

Applicable Management Area
MA-F15 Riparian
Standard and Guideline
Maintain existing developments. New developments can be constructed only to protect the wilderness resource or to alleviate problems or conflicts, and only with the approval of the Regional Forester. Use of power equipment for maintaining range improvements will be for exceptional needs only, and approved on a case-by-case basis by the Forest Supervisor (for chainsaws, etc.), and Regional Forester for mechanized equipment (tractors, backhoes, etc.). Use native or natural-appearing materials and design improvements to blend into the surrounding landscape.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area

Standard and Guideline
Maintain existing developments. New developments may be constructed to alleviate resource problems or to enhance public enjoyment. Fences within view from the river banks should be constructed of native or natural-appearing materials. Exterior boundary fences may be constructed of barbed wire.

Applicable Management Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
Standard and Guideline
Allow new developments unless they conflict with the management emphasis for the specific management areas.

Applicable Management Area
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area

Practice
Use of Motorized Equipment for Improvements and Maintenance

Standard and Guideline
Require permittees to maintain improvements with nonmotorized equipment except where requests to use motorized equipment (chainsaws, etc.) have been approved by the Forest Supervisor, or mechanized equipment (tractors, backhoes, etc.) by the Regional Forester, on a case-by-case basis.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
Standard and Guideline
Use of motorized equipment prohibited, except in connection with approved research projects.

Applicable Management Area
MA-F5 Research Natural Areas
MA-F6 Old Growth

Standard and Guideline
Allow use of motorized equipment with District Ranger approval only.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area

Standard and Guideline
Use of motorized equipment prohibited from December 1 to May 1.

Applicable Management Area
MA-F12 Eagle Roosting Areas

Standard and Guideline
Use of motorized equipment restricted to open roads from December 1 to May 1.

Applicable Management Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range
All other management areas within the boundary of winter range or general forest winter range.

Standard and Guideline
No special restrictions.

Applicable Management Area
MA-F22 General Forest
Forest Health

Forest-Wide Standards and Guidelines

Use Integrated Pest Management (IPM) strategies to manage pests within the constraints of laws and regulations, and meet Forest management objectives. IPM strategies include manual, mechanical, cultural, biological, chemical, prescribed fire, and regulatory means. Select strategy through the environmental analysis process, and in compliance with the Regional Vegetation Management, Environmental Impact Statement, 1988.

Coordinate strategies with the Agricultural Pest Health Inspection Service (APHIS) when proposing major Forest-wide control projects.

Pesticide application, if used, will conform with EPA regulations, label restrictions, and the Regional Environmental Impact Statement on chemical applications.

Use the integrated pest management strategies on forested types, as displayed in Table 4-32. Exceptions for individual management areas are discussed in management area standards and guidelines for Forest Health.

Noxious Weeds

Control noxious weeds and invader plants to prevent threats to adjacent agricultural lands or to prevent unacceptable loss of range productivity.

<th>Pest</th>
<th>Conditions Favoring Damage</th>
<th>Management Strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root Diseases** (Laminated root rot, Armillaria root disease, and annosus root disease)</td>
<td>Stands with major true fir/Douglas-fir components where inoculum is present</td>
<td>Remove all costs in root disease centers and 50 foot buffers. Regenerate these areas with tolerant or resistant tree species. For laminated root rot and Armillaria root disease, discriminate against white and Douglas-fir; favor pines and larch. For annosus root disease, discriminate against white fir, favor any other species. In areas where white fir management is desired, consider stump treatment with borax within 48 hours of cutting to prevent annosus infection.</td>
<td></td>
</tr>
<tr>
<td><strong>Douglas-fir Dwarf Mistletoe</strong></td>
<td>Multistoned host stands with already infected overstories</td>
<td>Alternative I—eliminate inoculum by regeneration harvest. If a seed tree system is employed and Douglas-fir regeneration is desired, remove infected seed trees before regeneration is 3 feet tall or 10 years old. Establish mistletoe-free unit boundaries. Alternative II—favor non-hosts (any species but Douglas-fir).</td>
<td></td>
</tr>
<tr>
<td><strong>Larch Dwarf Mistletoe</strong></td>
<td>Multistoned host stands with already infected overstories</td>
<td>Alternative I—eliminate inoculum by regeneration harvest. If a seed tree system is employed and western larch regeneration is to be managed, remove infected larch seed trees before regeneration is 3 feet tall or 10 years old. Establish mistletoe-free unit boundaries. Alternative II—favor non-hosts (any species but western larch and lodgepole pine).</td>
<td></td>
</tr>
<tr>
<td>White Fir Stem Decays (mainly Indian paint fungus)</td>
<td>Stands that contain a major component of white fir and have a history of tree suppression and wounding. Do not manage high risk understories. Eliminate and start over. Where white fir management is desired, keep rotations under 120 years and promote tree vigor throughout the life of the stand. Avoid wounding of white fir crop trees.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Mixed conifer stands on the Ochoco National Forest are composed of white fir, Douglas-fir, western larch, lodgepole pine, and ponderosa pine with Engelmann spruce at high elevations. Fire tend to dominate.*

**Fir engraver beetles and Douglas-fir beetles are common associates of root diseases. Management of the diseases will usually also minimize beetle damage.*
Management Area Standards and Guidelines

Resource - Forest Health

Maintenance of a healthy forest resource is important as it relates to the ability of forest stands to meet the objectives of each management area. A major factor in the overall health of the forest is the vigor of the trees and other forest vegetation. If the majority of the trees in a given area have reached or exceeded their pathological age, or have densities that result in stagnated stands, they become vulnerable to attack by insects and disease.

The Ochoco National Forest will use a combination of silvicultural practices and the concept of Integrated Pest Management to manage the health of the forest resource. Integrated Pest Management (IPM) is a process that incorporates all factors and strategies for evaluating and treating pest and host conditions to manage pest populations.

Stands of trees on the Ochoco National Forest will be managed according to the objectives of each management area. The health of the forest resource will be managed to meet the objectives, within the management constraints, for each management area. Some management areas will be more restrictive in treatment options, and may also accept more risk to the Forest from pest damage.

Table 4-33 will be used to guide forest health management practices for each management area. The table provides guidance for the identified major insects and diseases affecting the Ochoco National Forest.

Forest Residues

Forest-Wide Standards and Guidelines

Residue Management
Retain the kind and amount of residues needed on-site for the benefit of multiple resources (e.g. soil, water, wildlife).
If residues need to be removed, encourage the use of these residues for a mix of appropriate products.
Provide for individual firewood gathering and other family oriented endeavors centered around residue use.

Table 4-34 shows Forest-wide averages and ranges of acceptable residue combinations identified from the Photo Series for Natural Forest Residues in Common Vegetation Types of the Pacific Northwest. They provide target levels for average loadings in the stand size classes represented by the photos. These are arranged by stand types found on the Forest and provide general guidance on acceptable residue loads on both natural and managed stand conditions. The photo series can be consulted for specific breakdown into smaller size class combinations that are considered acceptable.

A series of desired residue profiles have been developed to meet the management emphasis for each of the 28 management areas on the Forest.

Management Area Standards and Guidelines

Resource - Forest Residues

Practice
Residue Management

Standard and Guideline
Manage residues through the natural processes of accumulation and decomposition (including natural fire). Activity fuel residues shall be treated to a level consistent with the immediate surroundings in the wilderness and which will protect wilderness values.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area
**Standard and Guideline**
Reduce fuel loading to natural conditions on 20 percent of the Wilderness (about 3,500 acres) each decade when feasible.

**Applicable Management Area**
MA-F3 Mill Creek Wilderness

---

**Standard and Guideline**
Manage residues through the natural processes of accumulation and decomposition (including natural fire regimes). Activity fuel residues shall be treated to a level consistent with the immediate surroundings. Vegetation and residue mosaic management guidelines may be developed for each area in the future. At that time a mix of desired residue profiles may be identified.

**Applicable Management Area**
* MA-F5 Research Natural Areas
  MA-F8 Rock Creek/Cottonwood Creek Area
  MA-F10 Silver Creek Area
  MA-F11 Lookout Mountain Recreation Area
  MA-F16 Bandit Springs Recreation Area
  MA-F17 Stein's Pillar Recreation Area
  MA-F19 Deep Creek Recreation Area
  MA-F23 North Fork Crooked River Recreation Corridor
  MA-F24 North Fork Crooked River Scenic Corridor

* Only with approval of PNW Station Director

---

**Standard and Guideline**
Manage residues to allow natural accumulations of dead and down woody debris. Reduce fuel load only if created or natural fuels accumulate to a level likely to result in a catastrophic fire. Fuel reductions should leave adequate downed material to meet the criteria for old growth. Desired residue profiles for this prescription area are approximated by the residue photos in Table 4-35.

**Applicable Management Area**
MA-F6 Old Growth

---

**Standard and Guideline**
Manage residues to allow natural accumulations of dead and down woody debris. A natural appearance consistent with riparian stand types is the goal of activity fuel treatments and vegetation management. Desired residue profiles for this management are approximated by the residue photos in Table 4-35.

1/ 3-LP-3 For discouraging livestock use
2/ 8-PP-4 For more open conditions
3/ All thinning photos contain too much slash
4/ Jackpot burn recommended if area is greater than 40 acres
5/ The fuel bed depth in this photo is too high. Lopping is needed to bring high particle intercept to less than 18°

These are found in "Photo Series for Quantifying Forest Residues," a cooperative publication by the Pacific Northwest Forest and Range Experiment Station, U S Department of Agriculture, Forest Service, Portland, Oregon (1976-1980). PNW 52, PNW 95, and PNW 105.
Applicable Management Area
MA-F15 Riparian Areas

Standard and Guideline
Allow natural accumulations of dead and down woody debris. Desired residue profiles for this management area are approximated by the residue photos in Table 4-35.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
Manage residues to allow light natural accumulations of dead and down woody debris. A natural appearance consistent with stand types is the goal of activity fuel treatments and vegetation management. Desired residue profiles for this prescription area are approximated by the residue photos in Table 4-35.

Applicable Management Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F28 Facilities

Standard and Guideline
Manage residues to maintain site productivity, protect wildlife habitat, and reduce the loss of thermal cover to wildfire. Desired residue profiles for this management area are approximated by the residue photos in Table 4-35.

Applicable Management Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
Manage residues to protect stand characteristics desirable for eagles. Residues shall be treated to minimize risk of stand destructive fires. Desired residue profiles for this management area are approximated by the residue photos in Table 4-35.
Applicable Management Area
MA-F12 Eagle Roosting Areas

Standard and Guideline
Manage residues to maintain site productivity, reduce the chance of wildfire damage to timber, enhance forage productivity and access, and provide for wildlife habitat needs. Desired residue profiles for this management area are approximated by the residue photos in Table 4-35.

Applicable Management Area
MA-F22 General Forest

Fuelwood

Forest-Wide Standards and Guidelines

General
The fuelwood program should be considered as a means to meet resource objectives in appropriate areas, such as low productivity lodgepole pine stands and bug-killed material in mixed conifer understory.

Fuelwood availability, as well as public demand, will be considered during preparation, administration, and post sale activities associated with timber sales.

Permit removal of standing dead or down lodgepole pine and juniper for firewood unless otherwise specified.

Sign wildlife trees, which are not to be cut, that are near roadsides or otherwise accessible to firewood cutters.

Commercial Firewood
Make commercial fuelwood sales available in areas less accessible to the general public, areas where National Forest funds are expended to make wood available, and areas where control is needed to meet environmental concerns. Examples are:

- Contract areas with concentrations of slash where heavy equipment may be required for removal (timber sales, backlog slash, thinning areas).
- More remote areas where hauling costs make large loads more economical to haul than small loads.
- Areas where timing or environmental constraints require special control. Beetle or insect infested low value green trees.
Personal Use
The following areas will be used for gathering personal firewood:

Areas with easy access (landings, extensive areas of dead trees, slash piles, forest fires, etc.).

Areas designated and reserved for fuelwood gathering.

Management Area Standards and Guidelines
Resource - Fuelwood

Practice
Commercial and Personal Gathering

Standard and Guideline
Commercial and personal use prohibited.

Applicable Management Area
MA-F5 Research Natural Areas
MA-F6 Old Growth
MA-F28 Facilities

Standard and Guideline
Commercial use prohibited, personal use of down material for on-site use only.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Wildlife & Recreation Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
MA-F27 Round Mountain National Recreation Trail
Fuelwood Lands

**Standard and Guideline**
Trees, downed logs, or other significant features will be “signed” to prohibit use as fuelwood, otherwise, fuelwood (commercial and personal) is allowed.

**Applicable Management Area**
MA-F7 Summit National Historic Trail

---

**Standard and Guideline**
All firewood gathering prohibited from December 1 to May 1.

**Applicable Management Area**
MA-F12 Eagle Roosting Areas

---

**Standard and Guideline**
All firewood gathering restricted to open roads and adjacent areas from December 1 to May 1.

**Applicable Management Area**
MA-F20 Winter Range
MA-F21 General Forest Winter Range

---

**Standard and Guideline**
Firewood gathering subject to permit regulations only.

**Applicable Management Area**
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F16 Bandit Springs Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F22 General Forest
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors

---

**Lands**

**Forest-Wide Standards and Guidelines**

**Special Uses**

**Utility Corridors**
Coordinate analysis of utility corridors with other Forests and land management agencies. Determine the lead agency and develop a study plan prior to the start of any analysis. Develop environmental analysis and documentation in compliance with this Plan, and with procedures set forth in the Regional Guide.
Determine the compatibility of each alternative with management areas affected.

Designation of corridors does not imply entitlement of use and environmental review must precede occupancy on a project-specific basis. Whenever possible, utility rights-of-way will be designated to allow joint use of the right-of-way.

**Electronic Sites**
Manage Round Mountain Electronic site in accordance with the approved site plan (Ochoco National Forest Analysis File). In accordance with Environmental Assessment Report “Selection of Sites for Electronic Communication Facility Development,” 1979, (also the Forest Analysis File), the following sites are designated as electronic sites:

- Drake Butte
- Dry Mountain (existing site)
- Mt. Pisgah
- Round Mountain (existing site)
- Wolf Mountain

**Other Sites**
Review applications for other uses through the NEPA process.

Issue special use permits through a prospectus process when a competitive interest has been identified.

**Recreational Special Uses**
Issue recreational special use permits only after a public need has been demonstrated that applies to a significant number of the recreating public, which may not necessarily include business opportunities.

The experience provided through the permit must be compatible with the Recreational Opportunity Spectrum (ROS) classification of the management area.

Limit the number of special use permits for a specific use, to the extent possible, in order to minimize administrative costs and to create economic conditions that provide a high quality public service.

Minimize the impact of special use permits on other users through the operating plans.

**Land Ownership Adjustment**
Acquire and dispose of lands in accordance with the Land Adjustment Map (Map Packet) and management area standards and guidelines.

Survey and mark property boundaries to prevent encroachments, protect present corners or references where the possibility of disturbance exists, and assist in administration of the Forest.
Management Area Standards and Guidelines
Resource - Lands

Practice
Special Uses

Standard and Guideline
Compatible uses, such as nondestructive research projects, may be permitted with Regional Forester approval. Land occupancy permits are prohibited. Terminate existing noncompatible permits as opportunities arise. Award outfitter guide permits only when it will meet management objectives to provide a needed wilderness opportunity.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area

Standard and Guideline
Compatible uses, such as nondestructive research projects and simple fish habitat improvement projects, may be permitted with consent of PNW Station Director. Land occupancy permits are prohibited. Terminate existing noncompatible permits as opportunities arise.

Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
Compatible uses, such as nondestructive research projects and simple fish habitat improvement projects, may be permitted with Line Officer approval. Land occupancy permits are prohibited. Terminate existing noncompatible permits as opportunities arise.

Applicable Management Area
MA-F6 Old Growth
MA-F10 Silver Creek Area
Standard and Guideline
Compatible uses are permitted. Terminate existing noncompatible permits as opportunities arise. Land occupancy permits are prohibited.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded-Helicopter Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F27 Round Mountain Recreation Trail
MA-F28 Facilities

Standard and Guideline
Compatible uses are permitted. Activities prohibited from December 1 to May 1.

Practice
Land Ownership and Adjustment (By Ownership Category)

**Standard and Guideline**
Category 1
Retain and acquire lands, or scenic easements, under Congressional direction, that are necessary to maintain or enhance the management emphasis of the specific areas.

**Applicable Management Area**
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F12 Eagle Roosting Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor

**Standard and Guideline**
Category 2
Retain and acquire lands that are necessary to maintain or enhance the management emphasis of the specific areas.

**Applicable Management Area**
MA-F5 Research Natural Areas
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein’s Pillar Recreation Area
MA-F18 Hammer Creek Wildlife Area
MA-F19 Deep Creek Recreation Area
MA-F20 Winter Range
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities
Standard and Guideline
Category 3
Retain and acquire lands where the primary objective is for commodity production (regardless of ownership). Federal lands may be used to acquire (exchange) lands in Categories 1 and 2. However, lands in this category will not be disposed of if that would result in a breach in a sold block of Federally-owned land. Private lands within this category may be acquired in order to consolidate Federal ownership.

Applicable Management Area
MA-F21 General Forest Winter Range
MA-F22 General Forest

Standard and Guideline
Category 4
Use small, isolated blocks of lands which do not contain special features, and which are expensive and difficult to manage, to acquire lands in Categories 1, 2, and 3. Disposal of Category 4 lands will have priority over the disposal of lands in Category 3.

Applicable Management Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
Category 5
More intensive study and planning are necessary to determine the optimum land ownership patterns.

Applicable Management Area
MA-F4 North Fork Crooked River Wilderness Study Area

Practice
Rights-of-Way Grants for Roads and Trails, and Cost-Share Agreements

Standard and Guideline
Grant no rights-of-way, enter into no cost-share agreements, except as prescribed by law.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
MA-F27 Round Mountain Recreation Trail

**Standard and Guideline**
Grant rights-of-way, and enter into cost-share agreements, only when no other reasonable alternatives exist to maintain the integrity of the management area.

**Applicable Management Area**
MA-F6 Old Growth
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F15 Riparian

**Standard and Guideline**
Grant rights-of-way, and enter into cost-share agreements, only when no other reasonable alternatives exist to maintain the integrity of the management area. Include stipulations to prohibit activities from December 1 to May 1.

**Applicable Management Area**
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

**Standard and Guideline**
Grant rights-of-way, and enter into cost-share agreements, that are compatible with the management areas emphasis.

**Applicable Management Area**
MA-F7 Summit National Historic Trail
MA-F14 Dispersed Recreation
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F20 General Forest
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F28 Facilities

4-167
Practice
Federal Energy Regulatory Commission Licenses and Permits

Standard and Guideline
Allow uses that are compatible with management emphasis for the specific areas.

Applicable Management Area
All Management Areas except Wildernesses and RNA's

Standard and Guideline
Stipulate additional restrictions to prohibit activities from December 1 to May 1.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F21 General Forest Winter Range
MA-F22 Winter Range

Practice
Utility and Transport Corridors

Standard and Guideline
Exclusion Areas for utility corridors; significant barriers in which legislation exists to preclude establishment and use.

Applicable Management Area
MA-F1 Black Canyon Wilderness Area
MA-F2 Bridge Creek Wilderness Area
MA-F3 Mill Creek Wilderness Area
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas

Standard and Guideline
Category 1 Avoidance Areas for utility corridors; establishment and use of corridors conflict with management objectives.

Applicable Management Area
MA-F6 Old Growth
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
Standard and Guideline
Category 2 Avoidance Areas for utility corridors, management areas with unique values that have been accorded specific and protected management status through legislative action.

Applicable Management Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
Establishment and use of utility corridors must be compatible with management emphasis for the specific areas. Additional stipulation to prohibit activities from December 1 to May 1.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
Establishment and use of utility corridors must be compatible with management emphasis of the specific areas.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F22 General Forest
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F28 Facilities
Minerals & Energy

Forest-Wide Standards and Guidelines

Leasing
Include stipulations needed to protect surface resources and/or meet management objectives in leases. Refer to management area standards and guides for specific guidance.

Issue leases with a stipulation stating "no surface occupancy" on slopes greater than 40 percent.

Evaluate surface-use plans of operation through the environmental analysis and documentation process.

Common Variety Minerals
Use existing sources instead of developing new sources, exceptions include:

- when existing sources are unable to economically supply the quantity and quality of material needed,
- when conflicts with other resource uses are found to be unacceptable.

Cinder, hardrock, and gravel sources which are available for use during the planning period are designated on the Material Source Map (Forest Supervisor's Office).

Evaluate the supply of gravel or aggregate on the Forest before selling to the private sector. Insure that the public interest is being maintained during this process.

Sell minor amounts of clay, sand, and stone to the public on a case-by-case basis.

Develop a management plan describing development and reclamation for each mineral material source to be developed or used during the planning period.

Proposals for capital investments and improvements on structures, which may occur on known material source deposits, should be analyzed within the context of management direction within this Plan. Do not unnecessarily reduce options for future removal of materials, by making significant investments on sources when equally viable options exist in other areas.

Mining Claim Administration
Administer appropriate laws and regulations relating to minerals in a reasonable and consistent manner.
Assure that operating plans include reasonable and operationally feasible requirements needed for timely and effective coordination with other resources.

Require that reclamation plans describe final management objectives for specific mined areas and detail reasonable procedures and time frames which will be followed to accomplish those objectives. Formulate reclamation bond amounts on actual reclamation costs.

Under the mining laws, claimants are entitled to access to their mining claims. Analyze access for exploration and development of locateable mineral resources through the environmental analysis process, and include reasonable provisions for access in operating plans.

Notify mining claimants of impending Forest Service actions that may affect their claims. When possible, protect claim corners and mine workings from disturbance resulting from Forest Service activities.

Recommend withdrawal from mineral entry when an established or anticipated use is not compatible and cannot be mitigated as part of the mineral entry.

Rockhounding

Rockhounding (hunting and collecting rocks and minerals as a hobby) on land under Forest Service jurisdiction will be allowed without a permit, providing: the activity does not conflict with existing rights, and specimens are used for personal, noncommercial use. Activities involving other than casual removal of small amounts of material with minimal surface disturbance are provided for under the mining laws or Materials Act.
Management Area Standards and Guidelines
Resource - Minerals and Energy

Practice
Oil And Gas Leasing

Standard and Guideline
Issue no leases.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area

Standard and Guideline
Issue leases with consent of PNW Station Director only. Include a "no surface occupancy” stipulation.

Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
Issue leases with a “no surface occupancy” stipulation.

Applicable Management Area
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F17 Stein’s Pillar Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
MA-F28 Facilities
Standard and Guideline
Issue leases with a seasonal use stipulation prohibiting exploration, drilling and other development activity from December 1 to May 1. This limitation does not apply to maintenance and operation of producing wells.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
Issue leases with a stipulation requiring drilling and storage facilities to be set back a specified distance from the area or feature.

Applicable Management Area
MA-F12 Eagle Roosting Areas (660 feet from roost trees)
MA-F15 Riparian (Outside of management area)

Standard and Guideline
Issue leases with a stipulation requiring drilling and storage facilities to be set back 100 feet from developed facilities and maintained trails.

Applicable Management Area
MA-F16 Bandit Springs Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area

Standard and Guideline
Issue leases with a stipulation requiring all permanent and semipermanent facilities to blend into the surrounding landscape or be located out of view.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
No special restrictions.

Applicable Management Area
MA-F20 General Forest
Standard and Guideline
The following areas are withdrawn from mineral entry under the mining laws. Prospecting will be allowed if conducted in a manner compatible with the wilderness environment.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness Area (except existing valid claims)

Standard and Guideline
The following areas are currently withdrawn from mineral entry under the mining laws.

Applicable Management Area
MA-F5 Research Natural Areas (Ochoco Divide only)
MA-F13 Developed Recreation (Delintment Lake and Walton Lake Campgrounds only)
MA-F25 Highway 26 Visual Corridor (600 ft. right-of-way corridor only)
MA-F28 Facilities (Ochoco Ranger Station and Rager Ranger Stations only)

Standard and Guideline
Recommend withdrawal from mineral entry.

Applicable Management Area
MA-F5 Research Natural Areas (Dry Mountain, Silver Creek and Stinger Creek)
MA-F28 Facilities (Allison Guard Station)

Standard and Guideline
Include reasonable measures in operating plans in order to meet management emphasis for the specific areas. Include stipulation to prohibit activity from December 1 to May 1.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range
Standard and Guideline
Include reasonable measures in operating plans in order to meet management emphasis for the specific areas.

Applicable Management Area
MA-F3 Mill Creek Wilderness (existing claims)
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F22 General Forest
MA-F23 North Fork Crooked River Recreation Corridor
MA-F24 North Fork Crooked River Scenic Corridor
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities

Practice
Common Variety Minerals

Standard and Guideline
Do not develop material sources.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F13 Developed Recreation
MA-F15 Riparian

4-175
MA-F16 Bandit Springs Recreation Area  
MA-F17 Stein's Pillar Recreation Area  
MA-F18 Hammer Creek Wildlife/Recreation Area  
MA-F19 Deep Creek Recreation Area  
MA-F23 North Fork Crooked River Recreation Corridor  
MA-F24 North Fork Crooked River Scenic Corridor  
MA-F25 Highway 26 Visual Corridor  
MA-F26 Visual Management Corridors  
MA-F27 Round Mountain National Recreation Trail  
MA-F28 Facilities

**Standard and Guideline**  
Do not remove material from sources from December 1 to May 1.

**Applicable Management Area**  
MA-F12 Eagle Roosting Areas  
MA-F18 Hammer Creek Wildlife/Recreation Area  
MA-F20 Winter Range  
*MA-F21 General Forest Winter Range  
  * Removal will be permissible with Line Officer approval on a case-by-case basis.

**Standard and Guideline**  
Material sources development allowed.

**Applicable Management Area**  
MA-F22 General Forest

---

**Old Growth**

**Forest-Wide Standards and Guidelines**

All old growth stands meeting the definition stated in the Regional Guide, 1984, will be periodically inventoried and monitored (see Monitoring Plan, Chapter 5, Implementation of the Forest Plan).

Specific allocations have been made to provide habitat for old growth dependent species, with the pileated woodpecker as the indicator species. A portion of these acres are included in wilderness, roadless areas, and Research Natural Areas due to the distributional needs of dependent species. See Management Area Prescription #4 (MA-F4) - Old Growth in Section 2 and management area
standards and guidelines for Wildlife and Fish.,

Other old growth, outside of that allocated for wildlife habitat, is also available throughout the Forest, but subject to less stringent standards and guidelines, depending on the management area in which it is found.

For example, old growth stands currently existing in visual management areas, or riparian areas are available for management and will decline over time.

Old growth in research natural areas, wilderness and roadless areas, but not included in the wildlife habitat allocation, are also subject to the standards and guidelines for the respective management areas (i.e. underburning in wilderness and research natural areas).

Recreation

Forest-Wide Standards and Guidelines

General
Recreational activities will be managed to prevent site deterioration within riparian areas.

Developed Sites
Prepare site plans prior to rehabilitation, expansion, or construction projects.

See the management area prescription for MA-F13 Developed Recreation, Section 2.

Dispersed Recreation
Provide facilities needed to protect public health and safety (e.g., portable toilets, campfire rings), and for environmental protection.

See the management area prescriptions for MA-F14 Dispersed Recreation, Section 2.

Off-Road Vehicles (ORV's)
ORV use varies by management area. See management area standards and guides for Transportation.

ORV use on scablands will be limited to over snow vehicles (also see Forest-wide Standards and Guidelines for Soils and Transportation System).

Trails
Construct and maintain the trail system to standards suitable for type and amounts of use. Maintain trails to prevent resource damage, protect the investment in the system and provide for user safety. In areas of concentrated
use, trails should be designed and maintained to minimize impacts on riparian communities.

Encourage volunteer groups or individuals to maintain or construct parts of the trail system.

Additional direction on trails is contained in specific management area prescriptions.

**Management Area Standards and Guidelines**

**Resource - Recreation**

### Practice

**Wilderness Recreation Spectrum (WRS)**

**Standard and Guideline**

Primitive and Semiprimitive.

**Applicable Management Area**

MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area

### Practice

**Recreation Opportunity Spectrum**

**Standard and Guideline**

Semiprimitive Nonmotorized.

**Applicable Management Area**

MA-F5 Research Natural Areas
MA-F6 Old Growth
MA-F24 North Fork Crooked River Scenic Corridor

**Standard and Guideline**

Semiprimitive Nonmotorized, except snowmobiles operating on an adequate snow base between December 1 and May 1.

**Applicable Management Area**

MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
Standard and Guideline
Roaded Natural.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F15 Riparian Areas
MA-F16 Bandit Springs Recreation Area
*MA-F17 Stein's Pillar Recreation Area
*MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F23 North Fork Crooked River Recreation Corridor
MA-F27 Round Mountain National Recreation Trail

* These areas will exhibit some semiprimitive characteristics, but will not meet ROS criterion for a Semiprimitive, Nonmotorized classification.

Standard and Guideline
Roaded Natural, Roaded Modified or Rural.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F20 Winter Range
MA-F21 General Forest Winter Range
MA-F22 General Forest
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F28 Facilities

Practice
Developed Recreation

Standard and Guideline
Develop no interpretive, demonstration, or recreational sites.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas
MA-F6 Old Growth
Standard and Guideline
Do not locate developed sites in floodplains unless no feasible alternative sites exist. (Executive Order 11988).
Activities within floodplains must meet water quality standards and goals.

Applicable Management Area
MA-F15 Riparian Areas

Standard and Guideline
Trails, trail heads and trail shelters may be built to facilitate nonmotorized recreation. Minimum site modifications are allowed. Some minor improvements at high use camp sites, such as fire pits, may be allowed.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F24 North Fork Crooked River Recreation Corridor

Standard and Guideline
Develop facilities to compliment recreational opportunities and protect resource values, in a manner consistent with management area emphasis and desired future condition. Developed fee campgrounds will not be provided in these areas during this planning period.

Pursue opportunities for interpreting natural resources, history, geology, scenic views, and management practices.

Design or modify improvements to blend with the natural landscape, using native, rustic materials.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F14 Dispersed Recreation
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F23 NFCR Recreation Corridor
MA-F24 NFCR Scenic Corridor
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
Use the State Rest Area as a snowpark during the winter months. Develop
additional snow parks to facilitate parking at the sled hill for snowmobiling at the old guard station. Coordinate with the State Highway Department concerning future plans for this area.

**Applicable Management Area**
MA-F16 Bandit Springs Recreation Area
MA-F25 Highway 26 Visual Corridor

---

**Standard and Guideline**
Developed camp sites may be opened to the public from May 1 to December 1. New or additional developed campgrounds must be analyzed in a site specific plan.

**Applicable Management Area**
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

---

**Standard and Guideline**
Prepare environmental analysis and documentation, and design narratives and site plans prior to rehabilitation, expansion, or construction of projects.

**Applicable Management Area**
MA-F13 Developed Recreation
Practice
Dispersed Recreation

Standard and Guideline
Discourage recreational activities and use, including overnight camping, and pack and saddle stock use.

Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
Manage to protect the naturalness of the areas. Use of the areas for nonmotorized recreation is acceptable, but should not be encouraged.

Applicable Management Area
MA-F6 Old Growth

Standard and Guideline
Where conflicts develop, riparian objectives will take precedence over dispersed recreational needs.

Applicable Management Area
MA-F16 Riparian Areas

Standard and Guideline
Protect the naturalness of the immediate area encompassing the dispersed campsites.

Applicable Management Area
MA-F14 Dispersed Recreation

Standard and Guideline
Promote driving for pleasure and mountain biking.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F19 Deep Creek Recreation Area
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
Standard and Guideline
Develop a variety of all-terrain vehicle (ATV) routes for a variety of terrain and experience levels.

Applicable Management Area
MA-F22 General Forest

Standard and Guideline
Promote backcountry recreational opportunities for hiking, horseback riding, and mountain biking.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F16 Bandit Springs Recreation Area
MA-F27 Round Mountain National Recreation Trail
Standard and Guideline

Camp Sites
Discourage development of “permanent” dispersed campsites or facilities. Disguise, obliterate, or rehabilitate such campsites when found.

Allow no caching of camping supplies.

No more than two campsites will be visible or audible from any other campsite (within 500 feet).

MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area

Encounters
Primitive Area, encounters per day 80% of the time:

7 or less MA-F1 Black Canyon Wilderness
7 or less MA-F2 Bridge Creek Wilderness
6 or less MA-F3 Mill Creek Wilderness
7 or less MA-F4 NFCR Wilderness Study Area

Semiprimitive Area, encounters per day 80% of the time:

10 or less MA-F2 Bridge Creek Wilderness
12 or less MA-F3 Mill Creek Wilderness

Group Size
Maximum permissible group size:

12 people MA-F1 Black Canyon Wilderness
10 people MA-F2 Bridge Creek Wilderness
12 people *MA-F3 Mill Creek Wilderness
12 people MA-F4 NFCR Wilderness Study Area

* In Mill Creek Wilderness, “12” includes people and livestock in any combination.

Camp Sites
No more than two camp sites should be visible or audible from any other camp site (within 500 feet).

Encounters
During all use periods there should be no more than 10 other groups encountered per day.

Group Size
The maximum permissible party size is 12 people with 18 head of livestock.

MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area

Camp Sites
Various types of camp sites, some allowing interaction with other camp sites. Other sites remote from any others.

Encounters
During all use periods, there should be no more than 10 other groups encountered per day.

Group Size
The maximum permissible party size is 12 people with 18 head of livestock.

MA-F24 NFCR Scenic Corridor

Standard and Guideline
Manage use to keep contacts between users low to moderate (15 encounters with groups per day). Utilize minimum on-site controls and restrictions necessary to protect resources and promote safe use of the area.

Applicable Management Area
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Wildlife Recreation Area

Standard and Guideline
Nonmotorized recreational opportunities will be emphasized. Limit motorized winter access to Forest Road 27 and trailheads from December 1 to March 30. Limit motorized access during other times of the year to designated existing roads.

Applicable Management Area
MA-F16 Bandit Springs Recreation Area

Standard and Guideline
Pursue necessary steps to officially designate the trail/motorway section of the Summit Trail as the East-West Intertie Trail and the New Oregon Recreation Trail. Vigorously promote the use of this cultural resource for recreation including: mountain biking, driving for pleasure, horseback riding, cross-country skiing, and backpacking.

Applicable Management Area
MA-F7 Summit National Historic Trail
Standard and Guideline
Close area to camping from December 1 to May 1 except within 300 feet of designated access roads.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F20 Winter Range
MA-F21 General Forest Winter Range

-------------------

Standard and Guideline
Utilize minimum on-site controls and restrictions to protect resources and promote safe use of the area.

Applicable Management Area
MA-F19 Deep Creek Recreation Area
MA-F23 NFCR Recreation Corridor
MA-F27 Round Mountain National Recreation Trail

-------------------

Standard and Guideline
Provide recreational improvements where needed to protect the resources or sites.

Sites receiving recurring use should be checked periodically for safety considerations (water sources, hazard trees).

Applicable Management Area
MA-F14 Dispersed Recreation
MA-F22 General Forest

-------------------

Standard and Guideline
Recommend the pack it out policy for garbage.

Promote leave no trace camping techniques.

Applicable Management Area
All Management Areas except
MA-F13 Developed Recreation

-------------------

Practice
Search and Rescue

Standard and Guideline
Use of motorized vehicles for search and rescue must be approved by the Forest
Supervisor.

**Applicable Management Area**
- MA-F1 Black Canyon Wilderness
- MA-F2 Bridge Creek Wilderness
- MA-F3 Mill Creek Wilderness
- MA-F4 NFCR Wilderness Study Area

---

**Standard and Guideline**
Use of motorized vehicles for search and rescue must be approved by the District Ranger.

**Applicable Management Area**
- MA-F10 Silver Creek Area
- MA-F11 Lookout Mountain Recreation Area
- MA-F17 Stein's Pillar Recreation Area
- MA-F18 Hammer Creek Wildlife/Recreation Area
- MA-F24 NFCR Scenic Corridor

---

**Practice**

**Signing**

**Standard and Guideline**
Use minimum natural appearing signing identifying destinations and trail names where needed, but not mileages.

**Applicable Management Area**
- MA-F1 Black Canyon Wilderness
- MA-F2 Bridge Creek Wilderness
- MA-F3 Mill Creek Wilderness
- MA-F4 NFCR Wilderness Study Area

---

**Standard and Guideline**
Signing for recreational purposes should comply with management area emphasis and desired future condition.

**Applicable Management Area**
All remaining management areas

---

**Practice**

**Trails**

**Standard and Guideline**
Emphasize these areas with a nontrailed objective.
Applicable Management Area
MA-F2 Bridge Creek Wilderness

Standard and Guideline
Coordinate trail and trailhead planning to disperse users and offer a range of challenges. Design trails to blend with landscape, and construct with native materials.

Applicable Management Area
MA-F1 Black Canyon Wilderness
*MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroadded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area
MA-F17 Stein's Pillar Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F24 NFCR Scenic Corridor

* No new trails will be developed in Mill Creek Wilderness.

Standard and Guideline
Trails that allow year-round use of the area will be developed. This will facilitate use of the area by horseback riders, mountain bikers, and hikers and cross-country skiers.

Applicable Management Area
MA-F11 Lookout Mountain Recreation Area
MA-F16 Bandit Springs Recreation Area

Standard and Guideline
No motorized or mechanized use allowed on trails.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area

Standard and Guideline
No motorized use allowed on trails.
Recreation

Applicable Management Area
MA-F6 Old Growth
MA-F17 Stein’s Pillar Recreation Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F24 NFCR Scenic Corridor

Standard and Guideline
No motorized use of trails, except snowmobiles operating on designated routes, and on an adequate snow base between December 1 and May 1.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
No motorized use of trails or roads during the period of December 1 to March 30, except for the designated route on Forest Road 27.

Applicable Management Area
MA-F16 Bandit Springs Recreation Area

Standard and Guideline
No motorized use of trails, except snowmobiles operating on an adequate snow base. In some cases, snowmobile routes may be designated.

Applicable Management Area
MA-F11 Lookout Mountain Recreation Area

Standard and Guideline
Motorized use on designated trail routes is allowed. Restrict motorized use to designated open roads during the period December 1 to May 1.

Applicable Management Area
MA-F12 Eagle Roosting Areas
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
No motorized use of trails except on designated routes for research purposes.
Applicable Management Area
MA-F5 Research Natural Areas

Standard and Guideline
No motorized use of trails except on designated routes.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian Areas
MA-F19 Deep Creek Recreation Area
MA-F23 NFCR Recreation Corridor
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities

Standard and Guideline
Motorized use of trails encouraged on designated routes. Off-trail use will be discouraged.

Applicable Management Area
MA-F22 General Forest
Scenic Resources

Forest-Wide Standards and Guidelines

Manage for the visual quality objectives (VQO's) listed for each management area. See management area standards and guidelines for SCENIC RESOURCES.

Where natural catastrophes such as large wildfires, insect epidemics, or windthrows occur, management activities may differ from stated visual quality objectives.

In areas of the Forest managed for a Visual Quality Objective of "modification" or "maximum modification," be sensitive to the needs of the viewing public. Use cost-effective visual management techniques while meeting the emphasis of the management area. Examples of these techniques may include:

- Leaving visually appealing seed-trees in regeneration units;
- Modifying harvest boundaries to eliminate "sharp line" effects; and
- Construction of facilities, roads and other physical structures, with native materials, where possible.
Management Area Standards and Guidelines

Resources - Scenic Resources

Practice
Visual Quality Objective (VQO)

Standard and Guideline
Preservation.

**Standard and Guideline**
Modification.

**Applicable Management Area**
MA-F12 Eagle Roosting Areas
MA-F15 Riparian Areas

**Standard and Guideline**
Maximum Modification.

**Applicable Management Area**
MA-F20 Winter Range
MA-F21 General Forest Winter Range
MA-F22 General Forest

*These areas will be managed within a general border of 600 feet on each side of the edge of the road or trail. Flexibility is encouraged to take advantage of natural topographic features and "special scenery" areas. The management intent is not to manage the areas to the full background viewing area, but rather to provide a natural setting within the most visible foreground.

---

**Social and Economic**

**Forest-Wide Standards and Guidelines**

**Human Resources**
Minimize social, cultural and administrative barriers to legitimate uses of the Forest, within the legal authority of the agency.
Maintain and implement an affirmative action plan.
Consider needs of the handicapped in the design of facilities and in other possible ways.
Conduct compliance reviews as required by the Title VI of the Civil Rights Action of 1964.

---

4-194
Inform the general public, including minorities and the underprivileged, of benefits they are eligible to receive from Forest programs. Use techniques and the media best suited to increase awareness and participation.

Protect and preserve for American Indians, access to, and use of traditional sites, possession of sacred objects, and the freedom to worship through ceremonials and traditional rites. Coordinate location and protection of these areas with representatives of the Confederated Tribes of the Warm Springs Indian Reservation and Burns Paiute tribes. Consider the plans and policies of other Federal, State, local, and American Indian tribal governments in plan implementation.

Consider and provide for the ceded land rights (treaty rights) of the Warm Springs Confederated Tribes in all Forest related management activities (cf. Middle Oregon Treaty of June 25, 1855).

Coordinate resource activities with the designated representatives of the Confederated Tribes of the Warm Springs Indian Reservation.

Soil

Forest-Wide Standards and Guidelines

General

The standards and guidelines stated below apply to all proposed activities occurring on the Ochoco National Forest. Other standards and guidelines are specific to certain types of activities, such as timber harvesting and road building, and are listed under those applicable sections in order to increase the ease and effectiveness of management direction.

Compaction, displacement, puddling, and severely burned soils are to be considered collectively, when assessing impacts.

Watershed Management

Even though watershed effects are the cumulative result of all activities occurring in a particular watershed (including road building, recreation, grazing, etc.), timber management has the greatest potential for detrimental impacts. Therefore, Forest-wide standards and guidelines have been established and designed in the appropriate context, towards timber harvest scheduling and dispersion (see Forest-wide Standards and Guidelines-Timber).
Soil Compaction and Displacement

The threshold level of detrimental compaction is defined as any bulk density increase of 15 percent or more, or any macro pore space reduction of 40 percent or below 15 percent. These values are critical changes over the natural state in the top 12 inches of soil.

In order to maintain site productivity, all project activities will be planned to reduce soil compaction and displacement to the lowest reasonable level. Strive to reduce compaction and displacement to get as close to 90 percent of the total activity area (including permanent, rocked, and non-surface roads) remaining in a non-compacted/non-displaced condition, as realistically possible, one year after any land management activity. The minimum will be 80 percent of the total activity area. Existing areas exceeding these standards will be scheduled for rehabilitation as soon as possible.

Surface Soil Erosion

Land management activities will be planned to achieve effective ground cover as defined by the following classes:

<table>
<thead>
<tr>
<th>Soil Resource Inventory</th>
<th>Minimum % Effective Ground Cover</th>
</tr>
</thead>
<tbody>
<tr>
<td>Erosion Hazard Class</td>
<td>First Year</td>
</tr>
<tr>
<td>Low</td>
<td>20-30</td>
</tr>
<tr>
<td>Moderate</td>
<td>30-40</td>
</tr>
<tr>
<td>Severe</td>
<td>50-60</td>
</tr>
<tr>
<td>Very Severe</td>
<td>60-75</td>
</tr>
</tbody>
</table>

Effective ground cover is defined as the basal area of perennial vegetation, plus litter and coarse fragments (greater than 2mm sizes), including tree crowns and shrubs that are in direct contact with the ground. Exceptions may occur where specific projects meet erosion control objectives without meeting the ground cover objectives stated above.

Soil Mass Wasting

When a project could result in an increased potential for mass wasting, which could cause significant soil loss or sedimentation, hazards to property, loss of fish habitat, or damage to other resource values, alternative project proposals will be evaluated and documented through the project's environmental analysis.

An activity area is the total area for which a ground-impacting activity is planned, for example, a unit for a timber sale, slash disposal project, or grazing allotment. The area would also include transportation systems within and directly adjacent to the project.
Fragile Areas
Recognize the sensitivity and potential of certain areas and/or situations to be adversely affected by management activities and plan accordingly to minimize those effects. Fragile areas include scablands (shallow soil areas), elk wallows, and other isolated soil areas which exhibit sensitivities that require special care.

Scablands
Scablands are recognized as among the most fragile ecosystems on the Ochoco National Forest. Damage to the soil and vegetation as a result of management activities is nearly impossible to mitigate. This is a result of their having very shallow soils which are subject to severe water saturation and frost heaving during winter, thus making revegetation virtually impossible. For this reason, all management activities will be analyzed as to their affect on scablands prior to implementation. Use *Plant Communities of the Blue Mountains in Eastern Oregon and Southwestern Washington*, Hall, 1973, to identify scabland plant communities.
Other standards and guidelines for scablands are specific to certain types of activities, such as timber harvesting, livestock grazing, and road building, and are listed under those applicable sections.

Management Area Standards and Guidelines
Resource - Soil

Practice
Soil Conditions

**Standard and Guidelines**
Limit displacement and erosion to a rate that approximates natural processes. Soil compaction should not exceed limits that prevent plant establishment except at some campsites and in designated trail tread.

Locate, relocate, or close campsites to prevent excess soil erosion and compaction when necessary.

Correct areas of human-caused soil instability which contribute to resource degradation, utilizing measures compatible with the Wilderness objectives.

**Applicable Management Area**
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 NFCR Wilderness Study Area

**Standard and Guidelines**
Allow activities that do not conflict with the objectives of RNA’s, such as special studies, monitoring, and research. Develop soil rehabilitation plans to implement in the event of soil disturbing activities such as fire suppression.

**Applicable Management Area**
MA-F5 Research Natural Areas

**Standard and Guidelines**
Limit erosion to a rate that approximates natural processes. Soil compaction should not exceed limits that prevent plant establishment.

**Applicable Management Area**
MA-F6 Old Growth
Practice
Soil Conditions

**Standard and Guidelines**
Limit erosion to a rate that approximates natural processes. Soil compaction should not exceed limits that prevent plant establishment except at some camp sites or on designated trails.

**Applicable Management Area**
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area

---

**Standard and Guidelines**
No more than 10 percent of an activity area can be compacted or displaced to a degree which degrades vegetative productivity.

**Applicable Management Area**
MA-F15 Riparian Areas

---

**Standard and Guidelines**
Comply with Forest-wide Standards and Guidelines only.

**Applicable Management Area**
MA-F7 Summit National Historic Trail
MA-F12 Eagle Roosting Areas
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein’s Pillar Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F23 NFCR Recreation Corridor
MA-F24 NFCR Scenic Corridor
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors (Retention Sections)
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities
**Timber**

**Forest-Wide Standards and Guidelines**

**Suitable Forest Land**
Regulated timber harvest will only be allowed on lands classified as available, capable, and suitable. Lands currently classified as suitable but found unsuitable in project analysis will be identified as such on planning maps and treated as unsuitable.

Where unmapped, unsuitable lands are found, project implementation will recognize these areas and plan mitigation measures to avoid adverse impacts. An example of this may be small slumps (unstable soil areas) where soil disturbing activities are avoided.

**Silviculture**
Prepare silvicultural prescriptions for all activities proposing the management of trees or timber stands to meet resource management objectives. Prescriptions will be recorded in analysis files and stand records.

All prescriptions will be prepared or approved by a Certified Silviculturist.

Elements required in a silvicultural prescription are documented in FSH 2470, the Silvicultural Examination and Prescription Handbook, and by Regional direction. No standardized format will be required, but all requirements must be addressed in the prescriptions or through project environmental analysis.

*Plant Communities of the Blue Mountains in Eastern Oregon and Southeastern Washington*, Hall, 1973, or any future accepted guide, will be used as a guide to site productivity of forest communities and for other applicable management considerations.

The silvicultural prescription should consider integrated pest management. Pests refer to any biotic or abiotic influence on the Forest, including insects, diseases, atmospheric deposition, silvicultural treatments, harvesting practices, and competing vegetation.

Develop site-specific prescriptions to provide for biological diversity and ecosystem function, including consideration for long-term productivity. Vegetation management should allow for all natural species to function. None should be eliminated from the site.

Silvicultural prescriptions must provide for snags, and trees for future snags, that will meet the habitat requirements for cavity nesting species, according to management area objectives (see Management Area Standards and Guidelines for Wildlife and Fish); exceptions could be fuelbreaks or situations where snags could cause a safety hazard. During preparation of marking guides, include provisions which specify that damaged, defective, or low value trees be used for replacement snags as much as possible, especially in commercial thinnings.
However, take precautions not to leave disease ridden trees that may spread infection to adjacent healthy trees.

Retain trees whose roots stabilize streambanks along Class III and IV streams, especially where fair to poor streambank stability conditions exist. Generally large mature trees provide bank stability for a distance of 5 to 10 times the diameter of the trunk, though this area of influence may be considerably larger. Understory trees and juniper play a role in bank stability in an area approximately equal to their crown diameter. Merchantable trees may be removed if sufficient trees remain to provide root strength for bank stability or if stream-bank stability is good or excellent.

Stand examinations and/or other data gathering processes will be used to verify or develop silvicultural prescriptions.

A regeneration system providing the desired establishment conditions will be selected. Leave trees per acre and leave basal area per acre for seed tree or shelterwood systems will be silviculturally prescribed on a site-specific basis.

Uneven-Aged Management
The application of uneven-aged management is characterized by stands which contain at least two well defined age classes. Even-aged aggregations of trees within these uneven-aged stands should be of a size such that regeneration never loses the protection of the adjacent older age classes. Regulation of the rate of harvest within uneven-aged stands requires the control and maintenance of a desired distribution of size classes.

Uneven-aged management can be applied using either individual tree or group selection silvicultural systems. The decision to apply either system should be based on actual stand and site conditions.

Uneven-aged management is applicable to immature, mature, and overmature stands of essentially pure ponderosa pine within the ponderosa pine community types. Uneven-aged management can be most readily applied to relatively vigorous pure stands of ponderosa pine which display an uneven or mixed stand structure.

Uneven-aged management is most applicable to the mature and overmature stands within the pine/associated community types, but only where silvicultural activities will result in stands dominated by early successional species including ponderosa pine and western larch. Dominance in these community types is established when stocking by early successional species can be maintained at or above 50 percent of the minimum stocking level basal area established in the silvicultural prescription, on 80 percent of the treated acres. As an objective, dominance by early successional species should assure long term stand health and vigor, as well as provide for the final harvest of preferred species as planned in the silvicultural prescription.

Stands which are severely understocked, overmature and single-storied, decaying, heart-rotted, or are producing little net growth are generally poor candidates for uneven-aged management.
Uneven-aged management is not recommended in lodgepole pine community types.

Uneven-aged management is applicable where there is reasonable assurance that natural regeneration of acceptable genetic quality and diversity will occur within 10 to 15 years. Planting or interplanting is also appropriate to maintain acceptable genetic quality and/or diversity, dominance by early successional species, or to assure timely regeneration under extremely harsh site conditions.

Uneven-aged management is most applicable on slopes less than 30 percent where tractors normally operate.

Uneven-aged management is most applicable where the total area impacted by detrimental soil compaction, erosion or displacement can be restricted to less than 20 percent of the stand.

Uneven-aged management is most applicable where stands are free from dwarf mistletoe. Where stands are lightly infected, uneven-aged management is applicable only where dwarf mistletoe can be confined to the lower half of the tree crowns and within a single canopy layer. The infection of lower canopy layers by upper canopy layers should be avoided. The objective is to maintain stand growth within 80 percent of its disease-free potential.

Uneven-aged management is most applicable where stands are free from root rots. Where stands are lightly infected, uneven-aged management is applicable only where root rot can be managed to maintain stand growth within 80 percent of its disease-free potential. Root rot centers should be managed using even-aged systems.
Silvicultural prescriptions should be designed to maintain or improve the existing size class diversity and uneven-aged structure. Emphasis should be given to managing the existing growing stock. The existing relationship between trees in all size classes, and the condition of those trees, should be considered first as a basis for developing marking guidelines, rather than the ultimately desired size class distribution or upper diameter limit.

Timber harvest and post sale activities should generally be planned on a 20-year entry cycle. All post sale activities should be completed within nine years following the harvest entry. Stands should not be salvage logged at other than the prescribed entry cycle except where wildfire, bark beetles, disease, or other conditions have created catastrophic mortality.

No minimum or maximum sized stand treatment units are specified where an uneven-aged structure can be maintained throughout the stand treatment unit. An average treatment unit of approximately 100 acres or larger is recommended to facilitate inventory and record keeping needs.

Timber marking guidelines should be developed which retain the most vigorous trees of best quality. First priority for leave trees are those with demonstrated good vigor. Second priority are those trees which will produce high value products in the future.

Following each commercial harvest entry, post sale activities should emphasize natural regeneration and stocking level control. Where natural regeneration is a planned objective, post sale activities should be closely coordinated to produce disturbance to the litter and vegetation as necessary for natural regeneration to occur.

Timber harvest, fuel treatment, and site preparation activities should strive to avoid damage to residual trees.

Treatment areas will be coordinated with wildlife habitat needs for cover. Silvicultural prescriptions will address the size, spacial arrangement, and opportunities presented by the existing vegetation within a treatment area.

Pruning may be done where it is economically efficient to produce clear, quality lumber.

Even-Aged Management

General
Size of units for intermediate treatments, over-wood removal treatments, and precommercial thinning will be determined through the interdisciplinary process during environmental analysis. Normally these units will not exceed 100 acres. Possible exceptions are stands which have a high susceptibility to insects and disease or where they are exhibiting retarded growth due to disease.

Vegetation diversity will be considered when preparing prescriptions and schedules for large homogenous areas that are generally the same age, in order to provide a mosaic of stands at different conditions and ages.
Rotation Age
The minimum rotation age (at which stands are scheduled for harvest) will be the age at which the mean annual increment (MAI) is equal to or greater than 95 percent of culmination of mean annual increment (CMAI). Harvesting may be at older stand ages to meet specific management objectives (see management area standards and guides for Timber).

Dispersion
The maximum size of a created opening will be 40 acres, except when openings up to 60 acres will be allowed:

- When larger created openings will reduce the disturbance to soil, water, fish, or riparian resources, and residual vegetation by: (1) allowing economically feasible logging systems that reduce landing and road construction; or (2) locating roads away from unstable soils, and (3) reducing soil and vegetation disturbance from dragging logs.

- Where groups of dwarf mistletoe or root rot disease infected trees need to be incorporated into the created opening to avoid infection, and their inclusion cannot be achieved by centering the created opening over the area of infection.

- Where the visual quality objectives require shaping and blending of openings to fit landforms.

- When natural catastrophic situations such as fires, windstorms, or insect and disease attacks occur.

- On an individual case basis, after a 60-day public notice and review by the Regional Forester.

A harvested area will no longer be considered a created opening when (a) trees are four and one half (4.5) feet tall, free to grow, and meet minimum stocking requirements, or (b) when the vegetation in the harvested area meets the management area objectives, emphasis and desired future condition as stated in Section 2, Management Area Prescriptions, this chapter.

Created openings will be separated by blocks of land generally not classed as created openings as described above. The blocks of land between created openings shall vary in size and contain one or more logical harvest units. These blocks of land shall be large enough and of a stand structure appropriate to meet resource requirements of the Forest Plan.

Openings to be created contiguous to natural openings should receive an exceptional level of attention during the analysis and prescription for treatment since natural openings are recognized as important or critical. The decision to create openings contiguous to natural openings shall be supported by prescriptions specific to individual natural openings or to a group of natural openings where their importance is diminished by more frequent occurrence. Created openings should generally not exceed 1/3 the size and/or be contiguous to more than 1/3 the edge of a natural opening where the natural opening exceeds 30 acres in size.
Limitations for created openings contiguous to natural openings less than 30 acres in size will be subject to the interdisciplinary decision-making process and its review of land management objectives.

Reforestation
Stocking
Forest stocking guides will be utilized to assess adequate stocking on all regeneration units prior to certifying them as being satisfactorily reforested. See below.

Standards are established for each of the three timber types (low site pine, ponderosa pine, and mixed conifer) and by logging method (tractor or cable). They are based on 4.5 feet tall crop trees (usually between five and ten years of age). Make allowances for expected mortality and natural fill in that will occur prior to crop trees reaching 4.5 feet, based on staked tree and/or stocking surveys of similar stands. If rework is necessary, the stocking should be brought to the recommended level.

Recommended range of stocking is that which will produce the yields predicted in the Forest Plan. A variety of harvesting and cultural activities are allowed for, so recommended stocking varies to cover this range.

Tree species used in planting harvest units should be based on the potential of the site as indicated by plant communities. Consideration should be given to regenerating and maintaining a mixture of species, where appropriate for the site.

The recommended stocking for each stand will be established by the silviculturist in the prescription, based on local conditions and objectives, with consideration given to meeting costs and outputs projected in the Forest Plan.

<table>
<thead>
<tr>
<th>STANDING STANDARDS AT 4.5 FEET</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Level</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Recommended</td>
</tr>
<tr>
<td>Minimum</td>
</tr>
</tbody>
</table>

$^1$ No reforestation work planned for cable ground on low site

$^2$ Overstory will not be removed if stocking is below this level

$^3$ Replanting or additional effort will be required if stocking is below this level. Area can not be certified as stocked, and will need to be reported as a failure.

Natural regeneration opportunities will be taken advantage of if acceptable genetic quality and diversity is likely to result. If artificial regeneration is necessary, the recommended method will be to plant.

Planting should generally not be prescribed for low site pine types.
In clearcut units, site preparation should normally be completed within two years of harvest. Planting shall occur within one year of site preparation. Exceptions can occur, but only for resource objectives that have been documented through environmental analysis. These units should be suitable and certified as satisfactorily reforested three years after planting.

Planting will be done with seed from selected trees for all ponderosa pine seedlings and for other species when available.

**Precommercial Thinning**

Precommercial thinning is recommended when:

- Existing overstocking will reduce future yields below predicted or planned levels (1973, op cit) which varies by Hall’s Community Types and management emphasis.

- The expected return from increased timber production and value exceeds the cost of precommercial thinning.

- It is consistent with management objectives.

Stands with an average DBH over six inches should not be precommercially thinned, except when threatened by insects and disease. Sanitation cutting may be done to control mistletoe, or to remove defective or damaged trees that will not make a merchantable product.
The maximum acceptable stocking for ponderosa pine is 450 trees per acre, and for mixed conifer is 500 trees per acre. If the DBH for the stand is under three inches (excluding trees planned for overstory removal, if any) include all trees. If DBH is three inches or larger, exclude seedlings under 4.5 feet high from the trees per acre calculations.

There needs to be at least minimum stocking in trees capable of responding to release. This includes a minimum of 30 percent with live crown ratio, and sufficiently free of disease (such as mistletoe) or damage, to make a merchantable product.

Consider economics, as well as stocking, mistletoe (disease), and management objectives as criteria before arriving at decisions to precommercially thin stands. Thinning must be determined to be economically viable and to meet management prescription objectives.

Thinnings should retain a diversity of species based on site potential.

**Harvest Schedule**

**Allowable Sale Quantity**

The allowable sale quantity (ASQ) is planned to remain constant over the next five decades and beyond (See Objectives for Timber, Section 1 of this Chapter). The ASQ represents projected, potential outputs based on available inventory and assumptions, and accountability is on a decade basis. The planned harvest does not infer a commitment on the part of the Forest to supply the stated level on a regular basis, but rather states the maximum output available, subject to budgetary constraints and the broad discretion of the agency.

**Salvage**

Salvage volume is standard sound material from dead trees, standing or down, that is calculated outside of the planned ASQ. Harvest levels will vary from decade to decade and from year to year within a decade depending on mortality, economics of harvesting, etc., but total timber sold (ASQ plus salvage) for the decade will not exceed planned level by more than five percent (10 MMCF or 62 MMBF). If a catastrophic event makes more salvage volume available, it will be substituted for ASQ volume to keep total sale volume within five percent per decade. The salvage program may be increased up to ten percent of ASQ (12 MMBF) to harvest timber killed by a catastrophic event. Any increase above this will require an equal reduction in the ASQ sell volume. The amount of salvage available may be constrained by snag habitat requirements for the Forest, in any one year (See Cavity Nester Habitat, Wildlife and Fish Standards and Guidelines, this section of this chapter).

**Harvest Levels by Forest Watershed**

Based on current conditions, the following equivalent harvest acres (EHA) guidelines will be in effect and will remain in effect until updated or changed in the Forest Plan. This guideline assumes that suitable dispersion of harvest within a given watershed is achieved as well (also use for meeting water quality objectives).
# Watershed Sensitivity

<table>

## Forest Watersheds by Sensitivity Class

### High
- John Day River
- Rock Creek
- Trout Creek
- Bridge Creek
- Deep Creek
- Wolf Creek
- Nicoll/Sawmill Creek (s)
- Badger Creek
- Bear Creek

### Moderate
- Marks Creek
- North Fork Crooked River
- Emigrant Creek
- McKay Creek
- Howard/Porter Creek (s)
- Ochoco Creek
- Mill Creek
- Silver Creek

### Low
- Middle Fork Crooked River
- Dry/Stinger Creek (s)
- Beaver Creek
- Bear/Camp Creek (s)
- Keeton Creek

If during project implementation, an alternative is selected that is predicted to exceed appropriate threshold values shown above, a Forest level interdisciplinary review will occur, with full public disclosure.
Logging Methods
Ground skidding and slash piling equipment will be avoided on slopes exceeding 35 percent, and on soil conditions with high compaction, erosion or displacement hazards, or wherever soil productivity standards cannot be met.

Designated skid trails will be confined to 20 percent or less of the activity area for all timber harvest practices (including disposal of slash), unless it can be demonstrated beyond a reasonable doubt, that particular circumstances or equipment exist which will not detrimentally impact soils as stated in Soils Forest-Wide Standards and Guidelines.

Locate skid trails and roads to avoid paralleling stream channels. New landings should not be placed in riparian areas. Existing landings within streamsides areas which are impacting or could impact water quality should be rehabilitated.

Scablands will not ordinarily be used for landings and skid trails. An exception to this would be in the case of skyline logging where a particular location would necessitate using a scab. Should this occur, the affected area will be erosion-proofed through use of rock or other appropriate methods.

Low Productivity Lands
On timbered lands where site productivity is expected to be less than 20 cu.ft./acre/year, the regeneration method will be natural regeneration. This will be accomplished under the shelterwood method. Overstory will not be removed until regeneration is securely established.

Christmas Trees
Consistent with other resource objectives, Christmas trees will be offered for sale. Emphasis will be placed on personal use by individuals. Special restrictions are to be applied to prevent indiscriminate cutting of trees.
## Management Area Standards and Guidelines

### Resource - Timber

MA-F10 Silver Creek Area  
MA-F11 Lookout Mountain Recreation Area (Prescription Area A)  
MA-F28 Facilities |

**MA-F11 (B) Lookout Mountain Recreation Area**

The following standards and guidelines apply to MA-F11(B), the lower portion of the Lookout Mountain Recreation Area. Emphasis is to provide a natural setting for high quality, semiprimitive recreational activities, while maintaining healthy forested conditions. Vegetative manipulation will occur to benefit wildlife and recreational opportunities. The Pacific Northwest Experiment Station may assist the Forest in development of strategies to meet management area objectives. No timber harvest is scheduled, but area-related planning activities, including public involvement and environmental analysis will be initiated during the first decade in preparation for nonscheduled harvest possibilities.

**Silvicultural Systems**

Both uneven- and even-aged silviculture may be applied in specific stands in order to meet recreational and wildlife objectives, but regeneration cutting should not exceed five percent of the total mixed conifer acreage, or four percent of the ponderosa pine acreage per decade.
Uneven-aged management systems will follow Forest-wide standards and guidelines.

Encourage large, ponderosa pine and larch as primary species, but maintain 20-30 percent other species for visual diversity.

Reforestation
Rely primarily on natural regeneration. Plant only where needed to meet recreation or wildlife objectives.

Prescriptions should encourage stocking by seral species (i.e. ponderosa pine and western larch). Managed stands should be 70 percent pine and larch, and 30 percent other species.

Precommercial Thinning
Thin stands at varied spacings to meet visual management objectives and to maintain health and vigor.

Commercial Thinning
May vary from zero to three entries.

Harvest
Cutting practices may be used that meet the following objectives.

<table>

1. Utilize seed-tree cuts where acceptable western larch and ponderosa pine exist. Strive to leave all existing western larch and ponderosa pine saplings.

2. Actual harvest entry cycle will be prescribed in a site-specific silvicultural prescription.

3. The indicated diameter is an average end point diameter at rotation age for even-aged stands. For uneven-aged stands, the indicated size is a target diameter.

4. Refers to regeneration openings. Does not apply to intermediate treatments such as commercial thinnings, or single tree selection.
Landing locations will be used as parking areas, trailheads or other recreational facilities.

Give preferential treatment to land and vegetation for a 300 foot radius surrounding elk wallows and calving areas.

MA-F17 Stein’s Pillar, MA-F19 Deep Creek, MA-F24 NFCR Scenic Corridor.
The following standards and guidelines allow limited scheduled harvest. Harvest treatments will meet the objectives of these management areas. The visual quality objective is retention. These areas also have unique qualities requiring additional consideration when planning timber harvest activities.

Silvicultural Systems
Emphasize uneven-aged systems to meet the objectives for the area. Even-aged systems may be used on a limited basis when needed to meet the area objectives. Emphasize maintenance of large, yellow bark ponderosa pine and western larch.

Uneven-aged management systems will follow Forest-wide standards and guidelines.

Cultural Treatments
Precommercial thinning and commercial thinning may be done to meet the visual quality objectives and maintain healthy stands.

Harvest
Cutting practices may be used that meet the following objectives.

<table>
<thead>
<tr>
<th>Unit Size (acres) 1/</th>

</tr>
</tbody>
</table>

1/ Pine types will be individual tree selection while mixed conifer types will be group selection
2/ The diameter shown is average for group selection and the target diameter for individual tree selection

Entry Cycle
An average entry cycle of 40 years is prescribed for stands in this management area. Actual harvest entry cycle may vary as prescribed in site specific silvicultural prescriptions.

Manage ponderosa pine to encourage large trees and open park-like stands. Manage mixed conifer for a mix of species with emphasis on maintaining western larch where possible. Provide views of scenic features such as aspen stands and rock outcroppings.
Restrictions on Harvest
For Stein's Pillar only, harvest activities should take place during the period from December 1 through May 1.

MA-F13 Developed Recreation

Developed Site Area

Harvest Scheduling
Harvest only for the purpose of maintaining safe and attractive recreational sites. No scheduled timber harvest.

Reforestation
Rely primarily on natural regeneration. Planting may be done to meet management area objectives.

Visual Influence Area

Silvicultural System
Both even- and uneven-aged silvicultural systems may be used. Emphasize maintenance of large, ponderosa pine and western larch.

Uneven-aged management systems will follow Forest-wide standards and guidelines.

Cultural Treatments
Precommercial thinning and commercial thinning may be done to meet the visual quality objectives and maintain healthy stands.

Harvest
Cutting practices may be used that meet the following objectives.

**Restrictions on Harvesting**

For Bandit Springs only, harvest activities are allowed from April 1 through December 1. Restrict harvest activities during times of high recreational use.

**MA-F12 Eagle Roosting Areas**

**Silvicultural Systems**

Harvest ponderosa pine on an uneven-aged management system. Timber stands will be treated over time to produce the optimum number and size trees (36 to 40 inches at DBH) while avoiding a high risk of insect attack or disease. There are no limitations on thinning trees below 20 inches at DBH and thinning to maintain the health and growth of roost trees and future roost trees is desirable.

Uneven-aged management systems will follow Forest-wide standards and guidelines.

**Restrictions on Harvesting**

Harvesting will only be allowed between May 1 and December 1. Actual and designated roost trees will not be designated for harvest nor will adjacent trees where falling might cause the loss of roost trees. Snags will be left where safely possible to do so.
A site-specific management plan will be written for each roosting area which will be designed to maintain existing roost trees and develop suitable future roost trees. Stand conditions will be modeled and results incorporated into a certified silvicultural prescription. This Plan will require consultation and final review by the U.S. Fish and Wildlife Service.

Precommercial Thinning
Consider desired size for future roost trees when thinning.

Commercial Thinning
Consider desired size of future roost trees when thinning.

MA-F15 Riparian Areas
Silvicultural System
Utilize both uneven-aged and even-aged systems where ecologically suitable for meeting riparian objectives. Emphasize stand health and long-term shade production.

Both even- and uneven-aged management systems will follow Forest-wide standards and guidelines.

Reforestation
Avoid mechanical site preparation, aerial herbicide application and fertilization.

Silviculturist will determine reforestation and intermediate treatment needs, based on meeting the following objectives:

Unit size will vary according to habitat requirements and silvicultural treatment. Created openings should be designed to optimize big game forage/cover ratios.

1/Actual harvest entry cycle will be prescribed in a site specific silvicultural prescription

2/The indicated diameter is an average end point diameter at rotation age for even-aged stands. For uneven-aged stands, the indicated size is a target diameter

3/Does not apply to intermediate treatments such as commercial thinnings, or single tree selection

MA-F20 Winter Range

Silvicultural Systems

Both even and uneven-aged management systems may be used. However, emphasis should be on using even-aged management to provide stand conditions for cover.

Reforestation

Practices may vary from natural regeneration to planting at normal or increased stocking. Utilize natural regeneration on lower productivity sites and where natural regeneration is likely to be successful.
Precommercial Thinning
In ponderosa pine-wheatgrass (CP-G1-11), ponderosa pine-fescue (CP-G1-11), ponderosa pine-bitterbrush-Ross sedge (CP-S2-21) plant communities, thin to obtain cover prior to commercial thinning or final removal. Additional thinning may be required if stand condition deteriorates to the point that there is substantial increasing mortality because of bark beetles. Precommercial thin plantations at earliest stage possible to produce a thick crowned tree for cover enhancement.

In all plant communities with higher productivity levels than those listed above, 50 percent of all stands on a watershed basis (within the Winter Range) should be thinned to 150-250 trees per acre until the first commercial thinning entry. The remaining 50 percent will either not be thinned or be thinned to 300-400 trees per acre. It is desirable that thinned and unthinned stands are 30 to 60 acres in size and evenly distributed.

Commercial Thinning
In ponderosa pine-wheatgrass, ponderosa pine-fescue, ponderosa pine-bitterbrush-Ross sedge, thin to develop a mix of size classes toward uneven-aged management, when not in conflict with cover objectives.

On higher sites, in stands which have been left unthinned, thinning may be delayed based on big game habitat requirements and stand health. Thinning should emphasize developing a mix of species, stand health, and 25-40 percent crown closure immediately after thinning.

Sanitation-Salvage Harvesting
While meeting snag levels, an active program of sanitation harvesting will be done to protect stand condition while meeting cover objectives.

Silviculturist will model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the following objectives:

<table>
<thead>
<tr>
<th>PP</th>
<th>MC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rotation Age (years)</td>

</tr>
<tr>
<td>Diameter</td>
<td>16&quot;</td>
</tr>
</tbody>
</table>

Unit size will vary according to habitat requirements and silvicultural treatment. Created openings should be designed to optimize big game forage/cover ratios.

Actual harvest entry cycle will be prescribed in a site specific silvicultural prescription.

The indicated diameter is an average end point diameter at rotation age for even-aged stands. For uneven-aged stands, the indicated is a target diameter.
MA-F9 Rock Creek/Cottonwood Creek Unroaded-Helicopter Area

Silvicultural Systems

Both even- and uneven-aged management systems may be used in appropriate stands to meet the objectives for the area. Uneven-aged systems may be applied to stands on slopes greater than 30 percent. Silvicultural treatments will be designed to improve stand conditions while protecting the anadromous fishery, soil stability, and big game habitat.

Uneven-aged management systems will follow Forest-wide standards and guidelines.

Reforestation

When site preparation is necessary, burning will generally be used. Natural regeneration may be practiced if it can result in successful seedling establishment. Otherwise regeneration units will be planted.

Silviculturist will model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the following objectives:

<table>
<thead>
<tr>
<th></th>
<th>PP</th>
<th>MC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rotation Age (years)</td>
<td></td>
<td></td>

<td>18&quot;</td>
<td>16&quot;</td>
</tr>
<tr>
<td>Uneven-aged</td>
<td>20&quot;</td>
<td></td>
</tr>
</tbody>
</table>

Unit size will vary according to habitat requirements and silvicultural treatment. Created openings should be designed to optimize big game forage/cover ratios.

1/Actual harvest entry cycle will be prescribed in a site specific silvicultural prescription.

2/The indicated diameter is an average end point diameter at rotation age for even-aged stands. For uneven-aged stands, the indicated size is a target diameter.

Logging Systems

Only helicopter yarding will be permitted. Locate landings outside the management area boundary.
MA-F21 General Forest Winter Range
Silvicultural Systems
Both even- and uneven-aged silvicultural systems may be used. However, uneven-aged management is the preferred system on low pine sites and will comply with Forest-wide standards and guidelines.

Cultural Treatments
Precommercial thin plantations at the earliest stage possible to produce a thick crowned tree for cover enhancement.

Thinnings, in ponderosa pine stands, will be to stocking levels that minimize the risk of bark beetle infestation. But, avoid thinning large continuous areas that may create stand conditions devoid of age and size diversity.

Pruning may also be done in ponderosa pine stands when determined to be economically efficient; preference is to wait until commercial thinnings, when future production of a merchantable log (17 feet or greater) can be reasonably assured.

Silviculturist will model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the following objectives.
### MA-F22 General Forest

**Silvicultural Systems**

Most mixed conifer stands and stands (all species) on slopes greater than 30 percent should be managed using even-aged systems. Ponderosa pine stands, on slopes less than 30 percent and with suitable age class distributions, should be managed using uneven-aged systems, when free of relevant insects and diseases.

Uneven-aged management systems will follow Forest-wide standards and guidelines.

Silviculturist should model stand conditions in order to determine reforestation and intermediate treatment needs, based on meeting the following objectives.

<table>
<thead>
<tr>
<th>Rotation Age (years)</th>
<th>PP</th>
<th>MC</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Even-aged</td>
<td>18&quot;</td>
<td>16&quot;</td>
</tr>
<tr>
<td>Uneven-aged</td>
<td>20&quot;</td>
<td></td>
</tr>
</tbody>
</table>

1/ Actual harvest entry cycle will be prescribed in a site specific silvicultural prescription.

2/ The indicated diameter is an average end point diameter at rotation age for even-aged stands. For uneven-aged stands, the indicated size is a target diameter.
Reforestation
Select the most productive and accessible sites for increased stocking. Utilize natural regeneration on lower productivity sites and where natural regeneration is likely to be successful.

Cultural Treatments
Precommercial and commercial thinnings will receive high priority in development of stand management activities, in order to meet objectives for stand health (especially resistance to bark beetles), economic efficiency, and production of high quality wood. But, avoid thinning large continuous areas that may create stand conditions devoid of age and size diversity. Silviculturist will develop stocking levels in thinning prescriptions to meet these objectives, based on specific site conditions. Timing of future commercial entries should be considered when prescribing these levels, so that additional intermediate thinnings (especially precommercial) are not unnecessarily required to maintain stand health. Pruning may also be done in ponderosa pine stands when determined to be economically efficient, preference is to wait until commercial thinnings when, future production of a merchantable log (17 feet or greater) can be reasonably assured.
Transportation System

Forest-Wide Standards and Guidelines

Planning
Transportation systems will be planned to support resource activities in the management areas and to serve multiple resource needs rather than individual project proposals.

Roads and trails will be at the lowest density which meets long-term resource needs. Where existing roads or trails are impacting water quality steps will be taken to mitigate the problem.

The planned transportation system will be constructed to the required standards to meet the needs of the planned resource activities of the area. This standard will be such that repeated reconstruction to upgrade any given section of the system will be minimized during the planning period.

Prepare and maintain road management objectives (RMO’s) for proposed and existing system roads and identify roads not needed for future maintenance.

Coordinate with the State and Counties on management of their roads to complement Forest uses.

Identify roads that require Forest Service jurisdiction to meet resource objectives.

Update the “Forest Sign Plan” annually to reflect road management objectives.

Traffic Management

General
The adequacy and safety of the transportation system will conform to the Forest Service Manuals and Handbooks. If a road does not exist at an adequate and safe standard for the traffic expected to use it, traffic can be restricted to a level where the existing road is adequate. This could eliminate the need to reconstruct the road.

Manage traffic as needed to control access due to structural limitations of the road, safety, or to meet resource objectives, such as those to meet wildlife needs or off-road vehicle (ORV) travel management needs.

Strategies for managing traffic will range from highly restrictive low impact, single user, short-term roads to unrestricted long-term roads.

Strategies for managing traffic could include prohibiting use on a seasonal or yearlong basis, or eliminating all standard vehicle use for more than one year.

Put sign traffic control devices (such as gates) to let users know why use is restricted and for what period of time.
No construction or logging equipment parking or turnarounds will be allowed on scablands except under landings.

**Commercial Hauling**
During commercial hauling activities, public access will generally be discouraged or prohibited on single user local access roads.

Generally, primary commercial haul routes are reconstructed, operated and maintained to permit low clearance (passenger car) traffic. However, some commercial haul routes may be maintained for high clearance vehicles, Maintenance Level 2.

**Recreation**
Encourage ORV use only on roads where all standard vehicle use has been eliminated, or on roads which have no current or planned future use, where appropriate with other resources.

Access routes to developed sites will generally be reconstructed, operated and maintained to permit low clearance (passenger car) traffic. However, public use may be seasonally discouraged, or restricted.

Local road access to historical dispersed recreation sites are generally graveled to prevent investment loss and resource damage during wet periods of the year.
Road access management strategies to the dispersed sites will generally be "accept" or "encourage" use by dispersed recreationists.

**Construction and Reconstruction**

Design, construct, and reconstruct roads according to standards based on the following criteria: resource management objectives, environmental constraints, safety, physical environmental factors, traffic requirements, traffic service levels, vehicle characteristics, road users, and economics.

Roads will not be constructed through the length of a riparian area. Roads crossing a riparian area will not alter stream or groundwater flow characteristics to a degree which will impact the riparian characteristics.

Road drainage will be designed and maintained to eliminate any influx of sediment road runoff directly into stream channels, to the extent possible.

Road construction activities will be managed to minimize the amount of unprotected soil surfaces when heavy rain or heavy surface runoff are most likely to occur.

Ensure that erosion control measures are completed prior to times of year when heavy rain or heavy runoff are normally expected.

Whenever practical, roads should be located on areas with the lowest erosion hazard.

Provide cost effective timber haul based on the various seasons of the year.

Ensure that temporary culverts or bridges are used where stream bottoms or banks would otherwise be damaged, and that these temporary structures are removed after use.

Roads which pass through high water table areas should be constructed in a manner which does not alter the flow characteristics of the groundwater.

**Stream Crossings**

Design and construct the transportation system to minimize the numbers of stream crossings.

Locate stream crossings and the approach alignment to minimize stream damage.

Bridge approach fills should be riprapped or protected by wing walls.

Ensure adequate sizing of culverts or bridges to accommodate anticipated high streamflows and to allow fish passage.

Schedule stream crossing construction during low streamflow and/or outside fish spawning periods.

Stream crossings should not change floodplain or streamflow characteristics.

Maintain existing riparian communities both upstream and downstream from the crossing.
Scablands
Road construction on scablands will be limited to long-term collector, arterial and local roads. Temporary or short-term roads or trails will not be constructed across scablands unless there is no other feasible alternative. Should a specific activity necessitate the construction of temporary access, the area affected will be completely erosion proofed through use of crushed rock and other appropriate methods.

Thoroughly analyze the long term need before establishing borrow pits on scablands.

Visuals
Include parking areas and view points in road plans and designs where appropriate.

Locate material stockpiles out of site of the main travel route.

Gravel pits, barrow areas, landings, etc. should meet visual objectives for the management area.

Avoid locating roads in the visual foreground other than at junctions. Design roads to fit the topography, minimizing cuts and fills. Roads should not dominate the natural pattern of line, form or color.

Necessary road closures in visual management areas should be designed and constructed to blend with the natural characteristics of the landscape.

Road Operations and Maintenance
Operate and maintain all roads within available financing according to maintenance levels established in Road Management objectives and standards defined as follows:

<table>
<thead>
<tr>
<th>Minimum Maintenance Level</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obliterated</td>
<td>No current or future use (36 CFR 261.5)</td>
</tr>
<tr>
<td>1 (Closed)</td>
<td>No current use, planned future use</td>
</tr>
<tr>
<td>2</td>
<td>High clearance vehicles</td>
</tr>
<tr>
<td>3,4,5</td>
<td>Low clearance vehicles</td>
</tr>
</tbody>
</table>

If funding is inadequate to maintain some roads at the intended maintenance level, maintain roads at a lower maintenance level, such as high clearance access (Level 2) to a closed level (Level 1).

Stabilize and re-establish vegetation on obliterated roads.

Ensure that necessary road and trail maintenance is performed on all runoff control and drainage structures (dips and culverts).

Provide for additional maintenance of road drainage and crossing structures during periods when unusual runoff is expected.

Ensure that appropriate traffic management is established to prevent the creation of pollution-generating conditions, such as deep wheel tracks in roads during wet weather.

Generally, access routes will be open subject to Forest-wide Standards and Guidelines.

Applicable Management Area
MA-F7 Summit National Historic Trail
MA-F22 General Forest
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors

Practice
Off-Road Use

Standard and Guideline
No motorized use allowed.
Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area
MA-F5 Research Natural Areas
MA-F6 Old Growth
MA-F13 Developed Recreation
MA-F27 Round Mountain National Recreation Trail

Standard and Guideline
Motorized use restricted to designated routes and prohibited from December 1 to May 1.

Applicable Management Area
MA-F12 Eagle Roosting Areas

Standard and Guideline
Motorized use restricted to over-snow use only, and from December 1 to May 1.

Applicable Management Area
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area

Standard and Guideline
Over-snow motorized use restricted to designated routes from December 1 to March 30.

Applicable Management Area
MA-F16 Bandit Springs Recreation Area

Standard and Guideline
Motorized use restricted to designated routes. Over-snow use prohibited from December 1 to May 1.

Applicable Management Area
MA-F18 Hammer Creek Wildlife/Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

**Standard and Guideline**
Motorized use encouraged on designated routes.

**Applicable Management Area**
MA-F14 Dispersed Recreation
MA-F22 General Forest

MA-F17 Stein's Pillar Recreation Area

**Standard and Guideline**
Motorized use prohibited except for over-snow use on designated routes.

**Applicable Management Area**
MA-F17 Stein's Pillar Recreation Area

**Standard and Guideline**
Motorized use restricted to designated routes.

**Applicable Management Area**
MA-F15 Riparian
MA-F23 NFCR Recreation Corridor
MA-F24 NFCR Scenic Corridor
MA-F28 Facilities

**Standard and Guideline**
Motorized use restricted to designated routes except snowmobiles over snow.

**Applicable Management Area**
MA-F7 Summit National Historic Trail
MA-F19 Deep Creek Recreation Area
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
Water

Forest-Wide Standards and Guidelines

Water Quality

In cooperation with the State of Oregon, the Forest will use the following process:

- Select and design BMP’s based on site-specific conditions, technical, economic, and institutional feasibility, and the water quality standards for those waters potentially impacted.
- Implement and enforce BMP’s.
- Monitor to ensure that practices are correctly applied as designed.
- Monitor to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards.
- Evaluate monitoring results and mitigate where necessary to minimize impacts from activities where BMP’s do not perform as expected.
- Adjust BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level. Evaluate the appropriateness of water quality criteria for reasonably assuring protection of beneficial uses. Consider recommending adjustment of water quality standards.

Use the existing, agreed upon, process to implement the State Water Quality Management Plan on lands administered by the USFS as described in Memorandums of Understanding between the Oregon Department of Environmental Quality and U.S. Department of Agriculture, Forest Service (2/12/79 and 12/7/82). Also use “Attachments A and B” referred to in this MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest, 12/78, and Best Management Practices for Range and Grazing Activities on Federal lands, respectively).

Temperature
Crooked River, John Day River and Tributaries
Existing temperatures at or above 68° F. will not be increased. Temperatures at or below 66° F. may be raised a maximum of 2° F.
Where stream temperatures exceed 68° F., management activities will include objectives for reducing temperatures to levels that will improve fish habitat capability.

**Turbidity**
Stream channel cutbanks should not exceed an average of 20 percent for any given stream drainage.

**Waste Disposal**
Dispose of waste effluents (e.g. sanitary waste, fuels, solvents, and pesticides) in a manner that will prevent contamination of surface or subsurface water.

**Project Planning**
See Forest-wide Standards and Guidelines for Timber for direction on equivalent harvest acres (EHA) guidelines.

Plan for no management activities in and around Class III and Class IV streams that contribute to the deterioration of water quality below standards set for downstream Class I and II streams. Protection will be provided primarily through mitigation measures. Some short-term temperature and/or turbidity increases may be allowed, providing the standards for Class I and II streams continue to be met. Consider the potential for cumulative impacts. Provide suitable amounts of woody material based on specific characteristics of individual stream courses.

Develop specific objectives for the management of streams through the NEPA-process for all projects that could impact water quality.

**Floodplains, and Wetlands (including springs and wet meadows).**
Consider the presence of, and potential impacts to, any inventoried floodplain in project area environmental analysis.

Do not locate major structures, roads, or other facilities within floodplains unless no feasible alternative sites exist outside floodplains.

Allow projects causing short-term impacts on floodplain values only if specific mitigation measures designed to minimize the impacts are documented in the project environmental analysis. Restore natural floodplain characteristics after the activity has ceased.

See Management Area F15 Riparian (Section 2, this chapter) for emphasis and desired future condition of riparian as a management area prescription (not including springs and wet meadows), and management area standards and guidelines for desired resource areas, such as Fire, Timber, Transportation System, and Water.
Forest Plan
Chapter 4
Section 3

Management Area Standards and Guidelines
Resource - Water

**Practice**
Water Quality Improvement Projects

**Standard and Guideline**
Enhancement of riparian vegetation or other water related resources, is restricted to research purposes, unless authorized by PNW Station Director.

**Applicable Management Area**
MA-F5 Research Natural Areas

---

**Standard and Guideline**
Use of mechanized equipment for water improvement projects will be approved by the Regional Forester on a case-by-case basis. Power equipment such as chainsaws can be used with Forest Supervisor approval on a case-by-case basis.

**Applicable Management Area**
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Area
Standard and Guideline
Construction of structural improvements can be done with approval of the Chief of the Forest Service.

Applicable Management Area
MA-F1 Black Canyon Wilderness
MA-F2 Bridge Creek Wilderness
MA-F3 Mill Creek Wilderness
MA-F4 North Fork Crooked River Wilderness Study Area

Standard and Guideline
Use of mechanized equipment for maintaining existing improvements will be approved by the Regional Forester. Power equipment such as chainsaws can be used with Forest Supervisor approval on a case-by-case basis.

Applicable Management Area
MA-F2 Bridge Creek Wilderness

Standard and Guideline
Construction and maintenance for water improvement projects restricted from December 1 to May 1.
Applicable Management Area
MA-F11 Lookout Mountain Recreation Area (Prescription Area B)
MA-F12 Eagle Roosting Areas
MA-F18 Hammer Creek Wildlife Recreation Area
MA-F20 Winter Range
MA-F21 General Forest Winter Range

Standard and Guideline
Construction and maintenance for water improvement projects allowed, subject to Forest-wide Standards and Guidelines.

Applicable Management Area
MA-F6 Old Growth
MA-F7 Summit National Historic Trail
MA-F8 Rock Creek/Cottonwood Creek Area
MA-F9 Rock Creek/Cottonwood Creek Unroaded Helicopter Area
MA-F10 Silver Creek Area
MA-F11 Lookout Mountain Recreation Area (Prescription Area A)
MA-F13 Developed Recreation
MA-F14 Dispersed Recreation
MA-F15 Riparian
MA-F16 Bandit Springs Recreation Area
MA-F17 Stein’s Pillar Recreation Area
MA-F19 Deep Creek Recreation Area
MA-F22 General Forest
MA-F25 Highway 26 Visual Corridor
MA-F26 Visual Management Corridors
MA-F27 Round Mountain National Recreation Trail
MA-F28 Facilities

Practice
Temperature

Standard and Guideline
The requirements for shade along streams will generally correspond to provisions for more than 80 percent of the surface shaded. Where this can not be attained, 100 percent of the potential for shade is the standard.

Shade requirements may be reduced in cases where management is necessary to sustain a thrifty community of shade providing species over time, e.g., in the case of local infestation or disease, or for managing for future shade in a decadent stand, but activities may not result in an increase in temperatures above the limits specified.

Applicable Management Area
MA-F15 Riparian
Practice
Turbidity

Standard and Guideline
Allow no more than 10 percent cumulative increase in stream turbidity. Short-term (plus or minus 50 years) deviations from this standard to accommodate emergency or other legitimate activities will comply with state requirements for notification and approval.

Applicable Management Area
MA-F15 Riparian

Practice
Project Activities

Standard and Guideline
Riparian areas are a unique and biologically important system on the Forest. Special attention shall be given to land and vegetation for approximately 100 feet form the edges of all perennial streams, lakes, and other bodies of water. This area shall correspond to at least the recognizable area dominated by the riparian vegetation. No management practices causing detrimental changes in water temperature or chemical composition, blockages of water courses, or deposits of sediment which seriously and adversely affect water conditions or fish habitat shall be permitted within these areas. Topography, vegetation type, soil, climatic conditions, management objectives, and other factors shall be considered in determining what management practices may be performed within these areas, or the constraints to be placed upon their performance. (36 CFR 219.27e.)

Give preferential consideration to riparian-dependent resources over other resources in cases of unresolvable conflicts.

Provide suitable amounts of large woody material based on specific characteristics of riparian areas.

Discuss the presence of potential impacts to riparian areas in all project-level environmental documents.

Vegetation and ground cover requirements.

Where site potential and topographic factors permit, manage riparian areas to provide the shade necessary to meet stream temperature goals.

Maintain upper streambanks in a stable condition along at least 80 percent of the length of a stream.
Retain at least 80 percent of the potential ground cover in grass-forb riparian communities. Also, retain at least 80 percent of the potential tree or shrub cover in riparian areas dominated by trees or shrubs. In riparian areas with mixed layers, the cover requirement may be met by taking credit for the effective cover provided by all vegetative layers of the riparian community including shrubs, tree understories, and the dominant overstory. Consider the mitigating effect of stream size and orientation as well as surrounding topography when determining the amount of cover that may be removed.

Kovalachik's Riparian Plant Community guide will be used for determining site potential until more specific data is available.

Applicable Management Area
MA-F15 Riparian

Wildlife and Fish

Forest-Wide Standards and Guidelines
Coordinate activities that affect fish or wildlife resources with the Oregon Department of Fish and Wildlife, Columbia River Inter-tribal Council, Bureau of Land Management, and the U.S. Fish & Wildlife Service. The level at which coordination occurs will be based on the magnitude of proposed activities, and the species involved.

Structural improvements to provide water, or otherwise concentrate wildlife (big game) use will not be planned specifically for scablands (See Forest-wide Standards and Guidelines, Soils)

Management Indicator Species
Determine if the species’ use of the area is incidental or if it is essential habitat. If it is determined to be essential habitat (roosting sites, for example) protect it from adverse modification through curtailment of conflicting activities, modification of activities, seasonal restriction of activities, or avoiding the area. For bald eagles, request an informal consultation with the Endangered Species Branch of the Fish and Wildlife Service on proposed actions which may adversely affect the species.
For newly discovered essential habitat, conduct environmental analysis under the NEPA process to determine if it is necessary to designate the area as essential habitat. If so, the Forest Plan will be amended or supplemented where appropriate, and the essential habitat designation will supersede previous land allocations or can be substituted for other habitat allocated to threatened or sensitive species.

**Pileated Woodpecker**

Approximately 19,250 acres of old growth, and another 19,250 acres of supplemental feeding habitat have been allocated across the Forest (outside of wilderness and Research Natural Areas) to meet the needs of old growth dependent wildlife, with the pileated woodpecker as the major indicator species.

Another 2,100 acres of old growth within wilderness and Research Natural Areas are considered necessary to meet the distributional needs of the woodpecker, but have not been specifically allocated, due to legal precedence for these areas. Natural processes (natural fire ignitions, etc.) shall continue to occur in these stands and may circumvent management desires to maintain them for wildlife habitat. But, any planned management activities in wilderness and RNA’s (planned ignitions or research) should be done in such a way as to protect the integrity of these areas. See management area standards and guidelines for specific management direction. Also, see locations of old growth stands for habitat (both inside and outside wilderness and Research Natural Areas) on the Alternative I (preferred) map.

**Primary Cavity Excavators**

Primary cavity excavators create cavities for themselves and other cavity users. In addition to the ecological diversity provided by these species, they also play an economic role in the forest environment. These species, plus the secondary cavity nesters, consume insects that are destructive to forests. While these birds may not prevent epidemic populations from building, many authors have indicated a suppressive influence on insects at endemic levels. For these reasons, more than a minimum population of the primary excavators is desirable. Effective population levels of these excavators is believed to be above 40 percent of their potential population levels, as compared to a viable population of only 20 percent. See *Wildlife Habitats in Managed Forests, the Blue Mountains of Oregon and Washington*, Thomas, 1979, for further discussion of management of this specialized habitat.

Provide habitat to support populations of cavity nesters at various levels by management area in order to achieve a Forest-wide objective of 47 percent of maximum potential over the first decade (see management areas standards and guidelines, Wildlife and Fish).
Snag Distribution

Provide snags within areas that are generally no larger than normal harvest unit size (40 acres). These snags will be maintained through the full rotation on these areas by providing for green replacement trees that will become snags of adequate size when existing snags fall. It is not intended or possible that dead and defective tree habitat be uniformly distributed over every acre. But, do not (arbitrarily) combine areas with high concentrations of dead and defective tree habitat with non-adjacent areas devoid of dead and defective habitat to arrive at a prescribed average number per acre. Plan dead and defective tree habitat by units, such as project planning areas or subdrainages (3,000 to 5,000 acres maximum) where specific management levels can be monitored.

Where adequate snags are not currently available to meet the desired level (40%, etc), created snags should be used to meet the direction as nearly and as soon as possible.

If snags are not present and cannot be created, higher snag levels can be managed in adjacent areas and averaged with the low levels in deficient areas to meet management objectives. However, averaging should be done over as small an area as possible, and replacement snags should be planned for in the deficient areas to meet the distribution requirements as soon as possible.

In a forested setting (uneven-aged management or mid- to late-successional stages in even-aged management), either clumped or evenly distributed snags are acceptable.
In early successional stages (grass/forb, seedlings and saplings) of even-aged management areas (i.e. clearcut and overstory removal), it is more desirable to manage snags in patches because:

- Snag patches can provide foraging as well as nesting habitat;
- Snag patches are more likely to support species that won’t nest in the open than are single, uniformly distributed snags;
- It is operationally safer and more efficient to provide snags in patches rather than in single, uniformly distributed patterns, and
- Snag patches better provide opportunities for live trees that can become replacement snags through the rotation of a stand.

**Golden Eagle and Prairie Falcon**

Carefully evaluate activities having the potential to alter or disturb cliffs, talus, or cave habitats.

**Bald Eagle**
