Final Environmental Impact Statement

Land and Resource Management Plan

Ochoco National Forest and Crooked River National Grassland

Caring for the Land...
ABSTRACT

The Final Environmental Impact Statement documents, issues, data and information, analyses, processes for preparation, and potential environmental consequences of management alternatives are presented. The Plans for management of the 844,640-acre Ochoco National Forest and 111,510-acre Crooked River National Grassland are presented also.

Sixteen alternatives were analyzed in the process; six of these are described in detail in the FEIS. Each alternative responds differently to the issues and concerns identified:

- **Alternative NC, No Change**, continues management under the 1979 Timber Resource Plan without the full requirements of the National Forest Management Act of 1976 (NFMA).
- **Alternative A, No Action**, continues management of the Forest and Grassland under existing plans and policies, but has been updated to include NFMA requirements.
- **Alternative B-Modified** is the forest products industry's preferred alternative; it provides for the highest level of timber outputs of any alternative detailed in the FEIS.
- The environmentally preferred alternative is described by **Alternative C-Modified**; it emphasizes resources which do not have market prices (e.g., soil, water, wildlife, recreation, aesthetics).
- **Alternative E-Departure** was the Draft Preferred alternative; it featured a departure from even-flow to provide a relatively high level of timber output in the first decade, as well as a mix of other resources over time.
- **The Final Preferred, Alternative I** is represented by the planning documents issued with the FEIS, and is described in FEIS. Alternative I is the result of, and represents, an amalgamation of the public comments and suggestions received on the DEIS and the Supplement to the DEIS, the State of Oregon's involvement, incorporation of new information and legislation, and additional analyses conducted between Draft and Final. Alternative I attempts to deal with issues in a reasoned, comprehensive and equitable manner. Options are preserved, critical resources are identified and appropriately protected, and reasonable levels of commodity resources are provided. The Plans are amendable through the NEPA process if future requirements or changes are deemed necessary.

Summary
Summary

Final Environmental Impact Statement for the Land and Resource Management Plan

Ochoco National Forest and Crooked River National Grassland

Purpose and Need

This section is a general summary of the Environmental Impact Statement (EIS). It emphasizes the issues and concerns raised by the public and other local, state and federal agencies, including the Forest Service, regarding management of the Ochoco National Forest and Crooked River National Grassland. It briefly describes the themes of the alternatives and how they were developed, the unavoidable adverse impacts, the irreversible/irretrievable effects of implementation, and the major results of the planning process. The tables show management areas, land uses, and outputs and effects for each alternative.

The purpose of the Final Environmental Impact Statement (FEIS) is to describe alternative plans for managing the Ochoco National Forest and Crooked River National Grassland, including the Preferred Alternative I. The FEIS also describes the affected environment and addresses the consequences of implementing the Preferred and other alternatives considered. A Plan representing any of the alternatives would be in effect for 10 to 15 years, unless revised sooner.

In order to implement the forest planning provisions of the National Forest Management Act (NFMA) (36 CFR 219), preparation of an EIS disclosing a range of alternatives, identifying a preferred alternative and disclosing the environmental effects of the proposed action is required by the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality (CEQ), and NEPA Regulations as stated in Title 40 of the Code of Federal Regulations, Part 1500, (40 CFR 1500). For purposes of disclosure under NEPA, this EIS and the accompanying Forest and Grassland Plans are treated as a combined document.

Preparation of the Forest Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated National Forest System Land and Resource Planning Regulations (36 CFR219).

Forest Service planning is a continuous, interactive process (CFR 40 CFR 1508.28) tiered to and carried out on organizational levels within the National Forest System. These levels are:

2. Regional Regional Guide.
4. Project Site or project specific plans, generally at Ranger District level. Tiered to Forest Plan.

Public Participation

Issue Identification

In the autumn of 1980, the Forest began the task of identifying issues to be addressed in Forest planning. Six meetings with key interest group leaders and individuals were held. In the meetings, 125 preliminary issues, concerns and opportunities (ICO's) were identified. By an iterative process with the public, and through mailings, media, and meetings over the course of several months, these were consolidated into 12 major issues or "planning problems," which are:

1. Timber supply and Forest management
2. Social and economic wants and needs of local communities
3. Livestock grazing or grazing allotments
4. Riparian area management
5. Transportation planning
6. Big game habitat
7. Roadless areas (and Wilderness Study Areas)
8. Scenic resources
9. Old growth forest
10. Fuelwood supply
11. Snag dependent wildlife
12. Winter sports

Public Involvement on the Draft EIS/Plan

The Notice of Availability was published in the Federal Register on September 12, 1986. Over 1,000 copies of the documents were distributed. Each document package contained a "Reviewer's Guide" and "Summary." Over 50 newspaper articles were published, and 20 radio interviews and 39 meetings were conducted on the Draft. The forest products
industry, conservation groups, and snowmobile organizations conducted organized campaigns and information dissemination.

By the end of the 90-day review period, approximately 2,150 responses were received. All responses were acknowledged with reply cards. Over 20,000 comments were coded from the responses.

### Summary of Public Comment on the Supplement

The responses received on the Supplement to the DEIS were predominately local in origin. Ninety percent were form letters which came from local mills or mill owners. The form letters stated that they had "no major comments on the Supplement itself," but then went on to repeat the issues the mills and timber industry emphasized in the Draft - timber supply and jobs. Over 95% of the comments received on the Supplement did not respond to the issues addressed by the Supplement.

### Issue and Public Response Summary

#### Timber Supply and Forest Management

Major subissues relating to timber supply and forest management have been identified and are discussed separately.

#### Timber Supply and Sustained Even-flow Yield

Forest products manufacturing is the major industry of the area. Timber accounts for over 95 percent of the National Forest receipts. The Forest has 6.3 Million Board Feet (MMBF) of standing crop. Approximately 50 percent of which is comprised of mature ponderosa pine.

There are 533,177 acres of forest land tentatively identified as suitable for timber production. Of this, the Forest Plan allocates 496,850 acres to the general forest prescription, 92,200 acres to nontimber use such as wildernesses, roadless areas, and old growth, and 255,590 acres in other management areas.

Large fine-grained ponderosa pine is the most commercially valuable tree in Central Oregon. Open park-like stands of mature ponderosa pine are also what people identify the Ochoco National Forest with, and seek out for recreational purposes. Local mills are tooled for large material, although some modification has begun. Ponderosa pine may occur in relatively pure stands, generally on relatively low productivity sites, or associated with other conifer species. The latter are referred to as mixed conifer stands and generally occupy the better sites, but existing mixed conifer stands have a high incidence of insect and disease damage, which reduces value and silvicultural options.

The 1979 Forest Timber Resource Plan established a potential yield of 136.5 MMBF. The programmed harvest for the Forest, under that plan, has been 129.8 MMBF. The present planning effort developed alternative first decade allowable sale quantities in the DEIS ranging from 13.9 MMCF (82 MMBF) to 24.4 MMCF (146 MMBF). (The FEIS ASQ figures range from 15.6 MMCF to 21.9 MMCF.)

Three of the DEIS alternatives, including the draft preferred with an ASQ of 123 MMBF, plus an additional 5 MMBF in salvage sales, were departures. Yields or ASQ's exceeding 100 MMBF are not sustainable in board foot measure over time. Because FORPLAN yields were all calculated in cubic feet, the sustained yield in board feet beyond first decade is not readily available in a reliable estimate. The current net annual growth estimated in board feet for the Forest is about 80 MMBF. The harvest on the Forest has been at a historic high, - 153 MMBF in 1985. This high level of harvest was a result of the combination of timber availability and a strong market.

Mill capacity of Crook and Harney Counties alone is estimated to be 385 MMBF annually. Demand for timber currently exceeds supply. The Forest has sold an average of 137 MMBF per annum over the past decade, and cut 110 MMBF, of which 75 percent of
the cut volume was large ponderosa pine. Silvicultural systems applied have been predominately even-aged. Intensive timber management and resultant industrial activity on the Forest has potential to conflict with or impact other resources. Conversely, land allocations for other purposes compete with timber interests, and other management requirements can constrain timber management activities and reduce potential yields.

What the Respondents Said

Timber industry wanted an allowable sale quantity of 137 MMBF, which was the original 1979 Timber Resource Plan potential yield. They also asked for at least 100 MMBF of the ASQ to be in ponderosa pine. They attempted to show that the “commercial forest” land base had been decreased through the suitability determinations and other land allocations in the Draft Plan. Timber industry also wanted a larger salvage program. The conservation community, on the other hand, thought the ASQ for the Forest should be about 90 MMBF. Both industry and the conservationists agreed on the desirability of a sustained even-flow yield, but disagreed on the level of yield which was feasible on a sustained basis.

Ponderosa Pine Management

Large ponderosa pine trees are an important forest resource. They are more valuable and important than other species or second growth. Wood product remanufacturing has been increasing and relies on the high-quality lumber milled from the pine. This industry is dependent on large pine (20-inch DBH or larger) that is relatively free of knots. Large ponderosa pine is important to the economy of central Oregon. The majority of pine grows on relatively low productivity sites producing less than 58 cubic feet/acre/year. A quality versus quantity situation exists. Current forestry practices include rapid liquidation of old growth pine stands, even-aged management, and emphasis on fiber (quantity) production. Strategies in the DEIS were designed to produce either maximum cubic foot timber volume on available lands or maximum PNV. These strategies resulted in harvesting stands at 90 to 100 years and producing trees no larger than 14 to 16 inches DBH.

What the Respondents Said

Large ponderosa pine were viewed as a unique product of central Oregon. Small diameter second growth trees were not. The stumpage value of large ponderosa pine is many times greater than second growth. Some segments of the wood products industry would like to know what the supply of pine will be over time in order to plan their business operations. Both industry and other publics do not like even-aged management in ponderosa pine. Both want “selection” harvests, but for different reasons. Intensive management on low productivity pine sites is said not to be appropriate. It was thought that ponderosa pine, because of its uses and the sites involved, should be managed on a board foot (not cubic foot) basis. It was suggested ponderosa pine be inventoried and managed separately, with a separate ASQ established for pine.

Uneven-aged vs Even-aged Silviculture

The use of clearcutting as a silvicultural system on the Forest has increased in the past decade. This is due to implementation of the 1979 Timber Resource Management Plan and prescriptions in mixed conifer that favor more clearcutting and increases in harvest levels as the economy recovered from the recession of the early 1980’s. Overstory removal has been applied extensively in ponderosa pine. Clearcut acres under the Draft Plan would start increasing in the second decade as overstory removal opportunities continue to be reduced and management intensity increases.

The harvest methods employed in FORPLAN modeling and yield tables in the Draft Plan and alternatives were based on even-aged management. Uneven-aged management of ponderosa pine appears to be a viable alternative with offsetting advantages and disadvantages. Some limited uneven-aged management was programmed for certain management areas in the Draft Plan.

What the Respondents Said

There was strong support for uneven-aged management by the public and forest industry (albeit, for different reasons) and support for incorporation of uneven-aged management into the Plan. Some publics
see overstory removal as clearcutting. Uneven-aged management was perceived as a method to avoid clearcutting (see Clearcutting, this section) and to reduce conflicts with other resources.

**Departure**

This issue stems from the Plan (Alternative E - Departure) proposal for an ASQ of 123 MMBF in the first decade, declining to 118 MMBF in the second decade, and 89 MMBF by the fifth decade (20.6 MMCF to 16.1 MMCF). This amounts to a 25 percent reduction over 5 decades. The intent of the departure was to maintain a high timber supply to support community stability during the first decade. The issue, however, is more complex because none of the alternatives are sustainable in board feet over time. It is apparent that the current harvest level will decline over time and a decision as to the rate and to what level over time is needed, i.e. a “glide path” or “stepping down.”

**What the Respondents Said**

Neither forest industry nor conservationists liked the idea of departure. Industry said they needed a dependable (and higher) supply of timber, especially to encourage new business to Central Oregon. Conservationists said departure was a euphemism for rapid liquidation of old growth. The public, for the most part, asked for a “sustained yield” which they seem to equate with nondeclining even-flow. Some felt we were remiss in proposing anything but sustained yield (nondeclining even-flow).

**Clearcutting**

Of the approximately 35,000 to 40,000 acres currently under contract on the Forest, only about 15 percent are to be clearcut. However, the Forest program in near future years contains substantial acreages of clearcutting in mixed conifer stands. The Draft Plan proposed harvesting 1,444 acres (9 percent of total harvested acres), increasing to 2,208 acres (39 percent of total harvested acres) by the year 2030. Root rot and other insect and disease problems, plus slash disposal needs, make any type of partial removal impractical for most of the mixed conifer stands.

**What the Respondents Said**

There was almost unanimous opposition to clearcutting from industry, conservation groups, and members of the general public. Reasons cited included the adverse effects it has on other resources; the waste of fast-growing, younger stock and potential crop trees; and the destruction of advanced regeneration. The issue was posed as “clearcutting vs. selection.” Some publics perceived overstory removal as clearcutting. Clearcutting ponderosa pine was simply not considered appropriate. Acceptance for clearcutting in mixed conifer was conceded by industry. The uneven-aged issue is related to this issue.

**Social and Economic Wants and Needs of Local Communities**

Central Oregon’s economy is primarily based on its natural resources. Employment levels, community stability, ability to attract new industry and maintain the present, have been linked by some to timber supply levels. Our analyses show that the Forest cannot continue to concurrently provide the same amount of timber and amenities over time as is currently provided. As a result, there may be socio-economic conflict under any alternative.

The issue is greater than timber supply alone. Other factors, such as remanufacturing, material (log) transport into and out of the area, automation, market conditions, rate of liquidation of old growth, and ponderosa pine management affect jobs, employment levels, county receipts, community stability, and other businesses and industries that contribute significantly to the economic well-being of the communities.

**What the Respondents Said**

The forest products industry and many individuals were adamant in demanding a high timber supply to maintain the local economy and jobs. Others pointed out the shortsightedness of this viewpoint and suggested that the rapid conversion of old growth and shift to second growth/fiber management might not be positive in the long run. They collectively believe the important resource is large ponderosa pine.
Second growth is worth $40-60/MBF, old growth $100-300/MBF, so that even if the cut is significantly reduced in order to manage for larger pine, it would contribute more to the economy because of its value, remanufacturing potential, and in the future, possible scarcity. The issue is also interrelated with the departure, uneven-age, and ponderosa pine issues. Still others felt that the high harvest levels would result in the loss of amenity resources that are the reason many people choose to live, work, and recreate in Central Oregon. Nearly all thought that a departure was extremely short-sighted.

Livestock Grazing and Allotment Management

The Forest and Grassland provide summer grazing for about 14,000 cattle and 3,500 sheep, or 75,000 AUM's annually, involving 105 permittees. Changes in public perception about management of the Forest and Grassland in recent years have raised questions of possible conflict between livestock and big game, water quality, riparian conditions, fisheries recreationists and reforestation. Grazing permit administration is tied by law to allotment plans, not the Forest Plan.

What the Respondents Said

Strong criticism was expressed concerning our past performance in administering the grazing program. The public doubts that riparian conditions can be improved and livestock numbers increased simultaneously.

Some said that any significant reduction in livestock grazing would have an adverse effect on the socio-economic base of Crook, Harney, and Jefferson counties and eliminate currently viable ranching units. Still other respondents suggested that full utilization be made of all available forage.

Some respondents requested that additional data about current conditions be presented and that more detailed descriptions of the impacts of livestock use on other resources be provided.

Riparian Area Management

Approximately 20,040 acres, including 815 miles of streams, of the Forest and Grassland are considered the riparian influence zone. Riparian areas receive a disproportionate amount of recreation and grazing use. Our most productive timber sites also occur along stream bottoms. Approximately 6,650 acres of riparian area are considered to be in "poor" condition. Public attention for riparian area management and condition is increasing.

The Draft Plan proposed to manage 9,400 acres of streamside to achieve "excellent" conditions. Structural improvements were proposed to enhance these areas as follows: fencing, 255 miles; large woody debris placement, 14 miles; log weir construction, 300 acres, rock structures, 50 acres; and shrub plantings, 50 acres. The remaining 9,600 acres would be managed for "good" or "fair" condition.

What the Respondents Said

The public is concerned about the impact that grazing, timber harvest, and road building has on riparian areas. Of particular concern is the proposed increase in livestock use of forage and skepticism over the Forest's ability to adequately manage riparian vegetation. The view was presented that all riparian areas should be managed in "good" or better condition. There seemed to be a perception that if riparian areas were in "good condition," there would not be much concern over whether the vegetation was used by livestock or not. Some livestock users recommended that where fencing is employed to manage riparian vegetation, the fenced units should be large enough to be managed as riparian pastures; others wanted more specifics on the proposed riparian program.

Transportation System

The transportation system on the Forest and Grassland totaled 4,554 miles of roads in 1985. About 833 miles (18 percent) are maintained for passenger car use, with the remainder maintained for high clearance vehicles. In the past, roads were constructed to relatively high standards. Recently, economic pressures and more rigorous analysis led the Forest Service to adopt lower road standards.

Under the Draft Plan, the number of miles of road
maintained on the Forest and Grassland would decrease nominally in the future. Roads would be closed when needed to protect soil and water, prevent disturbance of big game, and limit investment loss. Closures could be seasonal or yearlong.

What the Respondents Said

There is strong opinion that the road standards and road density are too high. Seasonal road closures for protection of big game, and road closure after completion of timber sales are generally supported by the public.

The timber industry suggested that the conflicts between roads and big game result from roads being open to use, rather than roads per se. They contend that the needs of big game could be served as well by closing roads as by leaving areas roadless.

Big Game Habitat

The Oregon Department of Fish and Wildlife (ODFW) assigned planning benchmarks of 2,600 elk and 22,600 deer to the Forest and Grassland. The Forest and Grassland have potential habitat to support larger populations of big game than these objectives.

The Draft Plan proposed management for big game habitat would be the primary emphasis on 227,700 acres (approximately 25 percent) of the Forest and Grassland. In these areas, open road density and cover would be managed for high quality big game habitat.

What the Respondents Said

The public desired a larger big game population than what the Draft Plan allowed. They would like more seasonal and permanent road closures. They felt all of the big game winter range should be managed for that purpose, and an increase in the cover-forage ratios for general forest should be made.

Roadless Areas and Wildness Study Areas

The Draft Plan proposed managing Cottonwood Creek, most of Rock Creek, part of Silver Creek, and a small portion of Lookout Mountain for semi-primitive nonmotorized recreation (25,249 acres total). Green Mountain (7,000 acres) was proposed to be managed for semiprimitive motorized recreation.

The Oregon Wilderness Act of 1984 required the Forest Service to review the Deschutes Canyon-Steelhead Falls Wilderness Study Area (WSA) and make a wilderness recommendation in the Forest Plan. The Draft proposed a 5,200-acre wilderness (2,500 acres National Grassland, 2,660 BLM). The total WSA was 18,402 acres. Also, the portion of the Deschutes River flowing through the wilderness study area was being studied for classification under both state and federal wild and scenic river systems. The North Fork Crooked River WSA (1125 acres) was identified as being part of a larger area over which the BLM had the lead.

What the Respondents Said

Public response on this issue was very polarized. Many of those favoring maintaining areas as un-roaded on the Forest requested that acreage in each be increased over what was proposed in the Draft Plan. Lookout Mountain was most strongly supported to remain roadless, followed by "Ochoco Canyons," Rock Creek and Cottonwood Creek areas.

Those opposing roadless area management for recreation cited single-use management as the basis for their opposition, and grouped roadless areas with what they felt were other single-use areas, i.e. wilderness, research natural areas, and old growth.

Those commenting on the Deschutes Canyon-Steelhead Falls WSA favored expanding the wilderness to include more area if it was to be recommended as wilderness. There were few comments received on the North Fork Crooked River WSA.

Scenic or Visual Resources

The Draft Plan proposed managing 3,000 acres in the Bandit Springs area and a 7,000 acre area encompassing Crystal Creek, Walton Lake, Round Mountain, Lookout Mountain, Mount Pisgah, and East Point to protect the natural appearance of the landscape. Scenic corridors proposed totalled 52,000
acres, or about 50 percent of the potential roadside viewing of 106,700 acres.

What the Respondents Said

There were relatively few comments from the public on this issue. Most comments favored retaining Highway 26 as a scenic corridor. Some people felt that scenic corridors were just another means of reducing the timber base. The State of Oregon expressed strong concern about maintaining the visual character of the Ochoco Forest over time.

Old Growth Forest

The Draft Plan proposed to provide 26,400 acres specifically allocated (dedicated) to old growth management. Approximately 23,500 more acres of old growth were thought to be available in wilderness and unroaded areas.

The size and distribution of the areas managed for old growth habitat were designed to meet habitat requirements for the pileated woodpecker, a management indicator species.

What the Respondents Said

A great majority of those responding desired a larger allocation for old growth. Some also expressed interest in preserving old growth juniper habitat.

Fuelwood Supply

The Forest currently supplies about 10,000 cords of fuelwood per year. This is expected to decrease after a few decades as harvesting is done in younger stands. There is a large amount of material currently not used because of poor access (distance from road, distance from town) and because of small size. The availability and location of fuelwood is directly related to the timber sale program. Fuelwood gathering often conflicts with leaving adequate number of snags for wildlife.

What the Respondents Said

The people who use fuelwood for heating (which includes a majority of local residents) favored the continued availability or increase in availability of fuelwood.

Snag Dependent Wildlife

The Draft Plan proposed providing 55 percent of the potential snag habitat. Snag levels vary by management area, ranging from 40 percent in areas managed for timber production to 100 percent in wilderness and roadless areas. Fuelwood cutting and timber sales may not be leaving adequate supplies of snags.

What the Respondents Said

Most of the respondents on this issue wanted snags reserved for wildlife. There was concern that the Forest Plan did not adequately protect snag habitat and that too many snags would fall prey to woodcutters and commercial timber sales. Conversely, timber industry strongly requested an expanded salvage program, which could conflict with leaving snags or snag replacement efforts.

Winter Sports

At present, most of the Forest, except for the cross-country ski trails at Bandit Springs, is open to winter recreation, including snowmobiles. The Draft Plan proposed closing the summit of Lookout Mountain (3,000 acres) to snowmobiling.

The greatest limitation to winter recreation on the Forest is the lack of access, which at present is provided almost entirely by roads plowed to access timber sales.

What the Respondents Said

The proposal to close Lookout Mountain to snowmobiling was strongly opposed by snowmobilers. This appeared to be the major issue concerning winter sports that surfaced in the public comments. In contrast, there was little support by cross-country skiers for closing Lookout Mountain, or other areas of the Forest, to snowmobiling. Staff observations of winter use of Lookout Mountain indicate that the conflict between skiers and snowmobilers is normally minimal, and that at present use levels both uses can be accommodated in the area. One suggestion was that separate trails for skiers and snowmobilers to the top of Lookout Mountain be provided.
Additional Issues Not Identified in the Original ICO's

Anadromous Fish
Anadromous fish were not identified as an issue in development of the DEIS and Proposed Forest Plan. Anadromous fish were identified as a concern by several individuals and groups, including a lengthy, technical response from the Columbia River Inter-Tribal Fish Commission (CRITFC). Primary concerns included protection and enhancement of spawning habitat, and the adequacy of the monitoring schedule. Native American groups noted that treaties guarantee protection for anadromous fish habitat.

Historic Trail Preservation-Summit Trail
This management concern developed out of a separate study conducted during the interim between issuance of the DEIS/Plan and Final. The Forest coordinated with the State Historic Preservation Office (SHPO) on details contained in the Final. This trail has been related also to other groups’ proposals for an east-west intertie for a cross-state trail system.

Off-Road Vehicle (ORV) Use
This issue re-emerged during the issue validation phase for the Final Plans. It was not an issue of Forest-wide perspective in the Draft Plan phase. It was addressed in the Travel Plan.

Round Mountain
The Oregon Natural Resources Council in comment on the Draft Plan asked that a recreation unit be established for the Round Mountain area. This issue was brought up again by one individual in the validation process and addressed as part of the multiple use decisions.

Validation of Public Participation Process
Incorporation of public involvement into the decisions being reached in the final Forest and Grassland Plans has been an integral step in progressing from the Draft documents released in September 1986. Significant steps were taken during the last four months of final document preparation to insure that direction in the final plans responded accurately to comments received on the Draft. In response to public comment, new information, and legislation significant changes were made in the preferred alternative between Draft and Final. Concurrently, with the alternative modification, the Forest Service worked closely with the public in attempting to validate and/or seek “consent” for the Final Plan. During recent months, 39 meetings with more than 289 key individuals involving more than 70 interest groups or agencies were conducted. A video was developed on uneven-aged management in ponderosa pine and widely viewed and distributed. This networking and collaboration has laid a strong foundation for Plan implementation.

Summary of Changes Between the Draft and Final Preferred Alternative

1. The Forest and Grassland are treated in separate Plans.
2. The land and resource allocations are more refined - there are sixteen management areas in the Grassland Final, compared to eight in Draft; the Forest has twenty-eight in the Final, compared to fourteen in the Draft. (See Chapters 4, Forest and Grassland Plans.)
3. The additional management areas above primarily represent additional allocations for wildlife and recreation. (See Tables 2 and 3, this summary; and Chapter 4, Forest and Grassland Plans.)
4. Timber management in the Final is based on
5. The Draft was based primarily on even-aged silviculture, the Final incorporates 100,000 acres of uneven-aged management in ponderosa pine and in the general forest (MA-F22), and additional opportunities, for example, within visual corridors. (See Chapter 2 and Appendix E, FEIS. Also see Standards and Guidelines, Chapter 4, Forest Plan.)

6. Larger rotation diameters are established for ponderosa pine (18" even-age, 20" uneven-age vs. 14-16" in the Draft.) (See Standards and Guidelines, Chapter 4, Forest Plan.)

7. Updating of FORPLAN model with new prescriptions, yield streams, yield tables, and condition classes. (See Appendix B.)

8. Economic analysis revised to reflect new information, schedules, allocations, assumptions, and additional resources such as mineral leases and anadromous fish. (See Appendix B.)

9. Segments of North Fork Crooked River, Deschutes River and Crooked River formally classified under the Oregon Rivers Act, as compared to Draft where their eligibility was reported. An eligibility and suitability analysis has been completed for a 1,370 acre segment of Lower Squaw Creek from the Grassland boundary to its confluence with the Deschutes River. Alternatives B-Modified and I indicated that this segment of Lower Squaw Creek be recommended to Congress for designation as a "scenic river" in the Wild and Scenic River System. (See Chapter 4, Section 2, Forest Plan.)

10. A 5,200 acre wilderness area was proposed in the Draft for the Deschutes Canyon-Steelhead Falls Wilderness Study Area (WSA); in the Final no wilderness is recommended. Instead, a 7,840 acre semiprimitive nonmotorized area is established. Part of the WSA is included in the classified Deschutes Scenic River corridor. (See Chapter 4, Section 3, Forest Plan.)

11. The Draft recommended 38,710 acres of roadless area remain unroaded; the Final recommended 39,730 acres. Green Mountain was proposed for semiprimitive motorized recreation in Draft, and was allocated to multiple use (General Forest, MA-F22) in the Final. The Rock Creek/ Cottonwood Creek area to be managed as roadless in the Draft was decreased some. Silver Creek remained essentially the same. Lookup Mountain was planned for 2,930 acres to remain unroaded in the Draft, and is treated as a 15,660 acre management area emphasizing semiprimitive, nonmotorized recreation (7,550 acres) and recreation and wildlife (8,110 acres) with no scheduled timber harvest in the Final. (See Chapter 4, Forest Plan.)

12. Additional emphasis is placed on visual and scenic resources in the Final. An additional 18,080 acres are assigned the visual quality objective of partial retention or greater in the Final. (See Standards and Guidelines, Chapter 4, Forest Plan.)

13. Dispersed recreation sites are identified and recognized as an allocation in the Final; they were not in the Draft. (See Standards and Guidelines, Chapter 4, Forest Plan.)

14. Additional areas with special features or recreational attractions were allocated in the Final that were not in the Draft (e.g. Stein's Pillar, Deep Creek, Lookout Mountain). (See Chapters 4, Plans.)

15. Lookout Mountain (MA-F11) remains open to snowmobiles in the Final; in the Draft it was proposed to be closed. (See Chapter 4, Section 2, Forest Plan.)

16. Developed recreation sites, not included in the Draft, are incorporated into the Final (e.g. Cove Palisades, Haystack). (See Chapter 4, Section 2, Grassland Plan)

17. Areas emphasizing wildlife not included in the Draft are incorporated into the Final (e.g.,
18. The old growth allocations were changed between the Draft and Final. The old growth identified in the Final is comprised of 95 percent "suitable" stands, compared to 58 percent "suitable" in the Draft, although about 5,000 acres less are dedicated. Old growth juniper is allocated on the Grassland, it was not in the Draft. (See MA-F6, MA-G5, Chapters 4, Sections 2, Forest and Grassland Plans.)

19. The acreage of winter range allocated for big game stayed the same, with the exception of antelope winter range on the Grassland which was increased; improved spatial distribution of the winter range area was done in the Final. Another allocation representing potential winter range (MA-F21) was identified in the Final. (See Chapters 4, Section 2, Forest and Grassland Plans.)

20. No allocations were made for summer range in the Final, as compared to the Draft which allocated 154,100 acres for big game summer range. Habitat requirements for big game are considered throughout the Forest and Grassland management areas as specified in the standards and guidelines in Chapters 4.

21. Road density objectives are changed - in the Draft they were two mi/section on winter range and four mi/section in the timber/range emphasis; in the Final they range from one mi/section on winter range (seasonally) to three mi/section on general forest. (See Standards and Guidelines, Chapters 4, Forest and Grassland Plans.)

22. Cover guidelines for elk and deer were changed to reflect natural vegetation capabilities and patterns; more emphasis is placed on mixed conifer for cover. Modeling assumptions for calculating habitat effectiveness were changed. (See Appendix B, FEIS, and Standards and Guidelines, Chapter 4, Forest Plan.)

23. Forage utilization standards for domestic livestock grazing have been standardized by the Region in the Final. A system for prioritizing range allotment planning needs and riparian improvements is established specifically by grazing allotment in the Final, as compared to a general forest approach involving water developments in the Draft. (See Standards and Guidelines, Chapters 4; and Appendices A, Forest and Grassland Plans.)

24. All streamsides will be managed for excellent conditions, compared with the Draft which had two riparian prescriptions. A travel plan is developed in the Final reflecting the land allocations and management direction, compared to the Draft where all areas were open unless otherwise identified. (See Appendix D’s; MA-F15 and MA-G9, and Standards and Guidelines, Sections 2 and 3, Chapters 4, Forest and Grassland Plans.)

25. Utility corridors, minerals and land adjustments are addressed more specifically in the Final, than in the Draft. (See Chapters 4, Forest and Grassland Plans.)

26. A Summit National Historic Trail (MA-F7) has been identified and incorporated into all alternatives. Anadromous fish, ORV’s and Round Mountain are additional issues identified in the Final, not shown in the Draft. (See Chapter 2, FEIS; and Chapters 3, Forest and Grassland Plans.)

Affected Environment

The land administered by the Ochoco National Forest occupies 844,640 acres within Crook, Harney, Grant and Wheeler Counties. The Crooked River Grassland contains 111,510 acres in Jefferson County. Total population of a six county area, which includes those above plus Deschutes, is approximately 105,000. The area’s economy is highly dependent on forest related industry, government agencies, agriculture, recreation and tourism.

The Ochoco, which in the language of the Paiute Indian means “wind in the willow,” is characterized by park-like stands of old-growth ponderosa pine
intermingled with mountain meadows. The Ochoco and Maury Mountains, where the Forest occurs, range from 2,200 feet to over 7,000 feet in elevation. The Forest is drained by the Crooked and John Day Rivers. The National Grassland consists of high lava plains, canyons, and volcanic buttes and is drained by the Deschutes River.

For more detailed information the reader is referred to FEIS Chapter 3.

Alternatives Including the Proposed Action

Based on public issues, management concerns and the natural resources involved, the Forest formulated and analyzed 11 implementable alternatives, and eight benchmark alternatives in the DEIS. In addition, a “no change” alternative was presented in a Supplement to the DEIS. As a result of the public response to these alternatives, new information, and legislation, all but three of the above alternatives were dropped in the Final, two were modified, and a new alternative was created. The latter, Alternative I, is the preferred alternative. The status of the alternatives generated in the planning process is displayed in Table S-1. Thus a total of 15 alternatives were fully developed, analyzed and evaluated over the course of the planning process in arriving at the selection of the preferred final.

An analysis of the requirements of NFMA which are incorporated into alternatives was completed. Alternative ways of meeting the management requirements were analyzed and opportunity costs are given in Appendix F.

Preferred Alternative

The preferred Alternative I is represented by a combination of management areas (allocations) that reflect public comment, new information and recent legislation. The National Forest and Grassland are listed separately.

Management Area Allocations

The preferred alternative establishes land allocations which apply to specific uses, resource considerations, natural features or legislatively designated areas. The allocations are mapped as Management Areas (see Alternative I map) and have had preliminary ground truthing. Specific standards and guidelines (prescriptions) have been developed for each management area.

The management area allocations for the Forest and Grassland are summarized (by resource emphasis) in Tables S-2 and S-3, and they are presented in more detail in Tables S-4 and S-5. Objectives and desired future condition have been described by management area in Chapters 4, Forest and Grassland Plans.

The grouping of management areas for modeling and prescriptions is discussed in Appendix B and Chapter 2 of this FEIS, and summarized on page S-18.

1/ Includes 6 old growth units within wilderness, unroaded, and WSA
Summary of Management Area Groupings and Prescriptions for Modeling the Preferred Alternative

Management areas were grouped in the modeling (FORPLAN) process and prescriptions for forest management assigned as shown below.

**Group I**
92,200 Acres - 11%
No scheduled treatment

- MA-F1 Black Canyon Wilderness
- MA-F2 Bridge Creek Wilderness
- MA-F3 Mill Creek Wilderness
- MA-F4 N.F.C.R. Wilderness Study
- MA-F5 RNA's
- MA-F6 Old Growth
- MA-F7 Summit Trail (preservation)
- MA-F8 Rock Creek/Cottonwood Creek Unroaded
- MA-F10 Silver Creek Unroaded
- MA-F11 Lookout Mountain
- MA-F28 Facilities

**Group II**
18,130 Acres - 2%
Silviculture - Even- or uneven-aged
Rotation Age - 200 years
Diameter 20"+
Average annual cu.ft. volume - 0.2 MMCF

- MA-F15 Riparian

**Group III**
3,240 Acres - less than 1%
Silviculture - Even- or uneven-aged
Rotation age - 300 years
Diameter 30"
Average annual cu.ft. yield - <0.1 MMCF

- MA-F12 Eagle Roosting
- MA-F17 Stein's Pillar
- MA-F19 Deep Creek
- MA-F24 N.F.C.R. Scenic River

**Group IV**
28,110 Acres - 3%
Silviculture - Even- or uneven-aged
Rotation age - Pine 250 years, mixed conifer 200 years
Average annual cu.ft. yield - 0.6 MMCF

- MA-F7 Summit Trail (retention)
- MA-F13 Developed Recreation
- MA-F14 Dispersed Recreation
- MA-F16 Bandit Springs
- MA-F25 Hwy 26 Corridor
- MA-F26 Visual Management - retention
- MA-F27 Round Mountain National Recreation Trail

**Group V**
32,140 Acres - 4%
Silviculture - Even- or uneven-aged
Rotation age - Pine 200 years, mixed conifer 150 years
Diameter - Pine 27", mixed conifer 22"
Average annual cu.ft. yield - 0.7 MMCF

- MA-F7 Summit Trail (partial retention)
- MA-F18 Hammer Creek
- MA-F23 N.F.C.R. Recreation River
- MA-F26 Visual Management (partial retention)

**Group VI**
64,130 Acres - 8%
Silviculture - Even-aged
Rotation age - Pine 125 years, mixed conifer 90 years
Diameter - Pine 16", mixed conifer 15"
Average annual cu.ft. yield - 0.9 MMCF

- MA-F20 Winter Range

**Group VII**
606,690 Acres - 72%
Silviculture - Even- or uneven-aged
Rotation age - Pine 130 years, mixed conifer 90 years
Diameter - Pine 18", mixed conifer 16" (uneven-aged 20")
Average annual cu.ft. yield - 16.6 MMCF

- MA-F9 Rock Creek/Cottonwood Creek Helicopter
- MA-F21 General Forest Winter Range
- MA-F22 General Forest
Summary Description of Final Alternatives

Alternative NC - NO CHANGE
The “No Change” alternative has been developed as a no-action alternative representing current management plans. It provides for a level of goods and services as defined in unit plans and the 1979 Timber Resource Plan. The alternative does not comply with all provisions of the National Forest Management Act (NFMA), and could not be implemented or used in future management of the Forest without Congressional and/or Secretary of Agriculture action to change the law (see Supplement to the DEIS).

Alternative A - NO ACTION (Current Direction Benchmark in Table 1)
This is the “no action” alternative required by the National Environmental Policy Act. It would continue the present course of action established in plans and policies formulated and approved prior to passage of the NFMA and have been made consistent with present laws and regulations. Relatively high levels of timber production, combined with visual quality objectives, and moderate levels of fish and wildlife, are emphasized in this alternative. In the Draft this alternative was represented by the “Current Direction Benchmark with NFMA.”

Alternative B-Modified - FOREST PRODUCTS INDUSTRY PREFERRED
This is the alternative supported by the forest products industry. Alternative B-Modified evolved from Alternative B, B-plus post-Draft discussions and Alternative I. Alternative B-mod. was developed by industry by amalgamating selected aspects of Alternative I with Draft B. The intent is to provide a high level of timber output with some considerations for other resources.

Alternative C-Modified - HIGH AMENITY VALUES
Alternative C emphasizes resources associated with amenity values. For example, riparian areas, scenic corridors, retention of roadless areas, recreation and forest management designed to provide big game habitat. Old growth and snags would also be provided at high levels. Timber and range resources would be managed at comparatively low levels. This is generally the alternative supported by the conservation community.

Alternative E - Departure - DRAFT PREFERRED
Alternative E-Dep was the Draft preferred alternative. It emphasizes a combination of timber production, roadless recreation, and big game habitat. Timber is scheduled as a departure from nondeclining yield. In other respects, this alternative is based upon, and is the same as Draft Alt. E. Timber harvests are scheduled so that first decade volumes remain close to current levels, and then decline over the next 10 to 50 years. The departure is designed to maintain local economic conditions for the short term. All resources are managed or maintained at least at moderate levels.

Alternative I - FOREST SERVICE FINAL
This alternative represents a new alternative evolved from E-Dep., the Draft Preferred Alternative, in response to new information, recent legislation, and public comment. It is the agency's preferred final.
This alternative seeks to maintain a reasonably high level of commodity outputs on a sustained, non-declining flow. In a complimentary and equitable manner it has also attempted to provide wildlife habitat and recreation resources, as well as preserving the character or setting of the Forest and Grassland over time. Alternative I differs from the Draft preferred E-Departure as noted in the summary of changes between the Draft and Final discussion on pages S-11 through S-13.

Figures S-1 through S-12 and Tables S-6 through S-9 present summary comparisons between alternatives for resource allocations, outputs, and economics.

</table>

1/ RNA acreage totals are derived from the final management area mapping and A-2 data base acreage calculations. RNA boundaries were slightly modified from the DEIS to the FEIS and consequently the total acreage for the final does not exactly track with that from the DEIS and the discussion of RNA's in Chapter 3 of the FEIS.

2/ An eligibility and suitability evaluation has been made for Squaw Creek. A recommendation and interim management guidance for a Wild and Scenic River designation has been made in Alternative B Modified and I. For these alternatives, 1,370 of unroaded recreation emphasis has been deleted and added to the Wild and Scenic River emphasis.

</table>

1/ Note that due to different bases for calculation, these figures may not be directly comparable. However, they may be used to show changes in specific components for calculations over time. All calculations were done in cubic feet. The volumes in this table are estimates based on board foot/cubic foot ratio.

2/ Yield of lumber projected for the period of 1980 to 1989, as calculated for the 1980 Timber Management Plan and adjusted for 1984 Oregon wilderness bill. The Programmed Allowable Harvest (P A H) is sawtimber from green and salvage sales scheduled for harvest.

3/ Allowable sale quantity calculated for the current land and resource management plan direction, projected into the future using new scientific information, such as yield tables and suitability for timber harvest, and using FORPLAN analysis model.

4/ Estimated volume of ponderosa pine that is included in green sales volume.

5/ Average volume sold was not adjusted for "buy-back" volume.

6/ Reduction in all but E DEP is due to change in BF/CF ratio and estimated reductions in salvage volume as more stands become managed. Change in E DEP is mostly due to the planned departure from even flow.

7/ Actual firewood volume is based on years 1985 to 1988. Essentially all of this was sold as personal use. Planned volume is the estimated amount if firewood available. Typically less than half of this will be utilized.

S - 24
Environmental Consequences Summary

Effects on Resources that Vary by Alternative

Oregon State Air Quality Implementation Plan
The current Forest and Grassland prescribed fire program is producing 10 to 20 tons/year of total suspended particulates (TSP). This amount varies by alternative. Fugitive dust from construction activities and traffic also occurs.

Cultural Resources
Cultural and archaeological sites will be protected in all alternatives. However, the possibility of damage, vandalism, and discovery of sites will be greater in alternatives that emphasize commodity resources.

Developed Recreation
The Forest maintains 30 developed recreation sites; 96 miles of trail, 15.8 miles of which are designated "National Recreation Trail"; and seven small reservoirs. Alternatives consider the development of additional recreational facilities, including trails, campgrounds, and impoundments. The associated recreational activities can result in environmental effects of a local nature, such as vegetation loss, soil compaction, erosion, and conflicts with wildlife, timber harvest activities, and livestock grazing.

Dispersed Recreation
Over 445,000 visitor days of use are received annually, and recreation use continues to increase. This amount of dispersed recreational use calls for controls on off-road vehicle use to prevent noise pollution, damage to soil, vegetation, and aesthetics; and road closures to maintain habitat security for wildlife, to prevent damage to road surfaces, and to prevent conflicts with other resource management activities such as log hauling. The alternatives affect the amount of unroaded area available for semi-primitive and other dispersed recreational activities.

Energy Conservation
Activities on the Forest and Grassland which generally have a positive net energy balance are firewood harvesting and forage production. Generally, all other activities consume more energy than they produce. The average range that energy consumption from planned National Forest activities exceeds energy yields has been estimated to be in the magnitude of three to five billion BTU's/decade.

Fire and Fuels
There are an average 108 wildfire ignitions per year. Prescribed fire is being increasingly used as a management tool. Approximately 15 to 20 thousand acres of slash are treated with prescribed fire annually. Use of fire in management can have effects on soil erosion, short-term appearances, air quality, vegetation productivity, plant community, species composition, and fuels.

Floodplains and Wetlands
Considerations for floodplain management as required by Executive Order 11988, and protection of wetlands, Executive Order 11990, are incorporated into all alternatives.

Human Resource Programs and Civil Rights
The Forest and Grassland will continue to participate in these programs in accordance with the laws, administrative opportunities, and economic availability of programs. Minorities and economically disadvantaged groups will not be adversely affected by any of the alternatives.

Landscape Appearance
Emphasis on maintaining scenic quality within road corridors varies by alternative. Significant effects on landscape appearance are related to timber harvest practices; dispersion of cutting units, protection and
management of riparian areas; and road location, design, and densities, all of which are related to direction in the management prescriptions in Chapter 4 of the Plan.

**Livestock Grazing**
Livestock grazing is maintained at nearly current levels for most alternatives considered. Livestock grazing activities, if not carefully managed, can cause soil compaction, impact streamside vegetation, affect water quality of stream habitat for fisheries, compete with wildlife, affect plant community composition and productivity over time, and alter the appearance of natural settings. Water developments and salt intended for livestock also benefit wildlife.

**Minerals**
There is little real difference in the effects on mineral production or mineral leasing between alternatives. The effects on mining operations and mineral leasing would be reflected in operation plans and lease stipulations, for example alternatives proposing unroaded area management and research natural areas could result in attachment of no occupancy stipulations to specific leases. Mineral leasing provides returns to local governments in terms of receipts.

**Old Growth Habitat**
Old growth habitat is identified for protection and management for purposes of wildlife habitat and genetic diversity. The amount and dispersion varies by alternative. Protection of old growth habitat results in reduced timber harvest levels.

**Prime Farmlands, Forestlands, and Rangelands**
All the alternatives propose actions which are consistent with the intent of the Secretary of Agriculture direction for protecting and managing prime lands.

**Research Natural Areas**
Research Natural Areas (RNA’s) preserve places for the purpose of research and maintaining genetic diversity. The maximum increase in area proposed for RNA’s is 2,630 acres. The designation and protection of RNA’s can affect timber harvest level, mineral leasing, road system development and grazing activities. Because of the small acreage involved, these consequences are minimal regardless of alternative.

**Riparian**
Approximately 800 miles of streamside area, plus wet meadows and lake shores, have been identified on the Forest as riparian areas. While only an estimated two percent of the total Forest and Grassland area is considered riparian, it receives the most intensive and concentrated use of any land area. More than 50 percent of the recreational use occurs there, transportation corridors are located along stream bottoms, grazing in the past has been intense; important wildlife habitats are found there; streamside areas provide productive timber sites; fisheries habitat is dependent, in part, on the condition of streamside vegetation. Nearly all Forest activities have either direct or indirect effects on riparian areas and water quality. Protection and restoration of riparian areas can impact other activities over the short term.

**Roads and Off-Road Vehicles**
Over 4,550 miles of roads have been constructed on the Forest and Grassland. Management and maintenance of this transportation system requires closures and restrictions at times to protect road surfaces, other resources, and public safety. Travel planning for road and off-road vehicle use has placed more restrictions on vehicles and motorized use of the Forest and Grassland in order to protect resources.

**Social and Economic**
The Forest and Grassland directly influences a six County area which contains a population of about 110,000. Socio-economic consequences are related to economic stability of communities, livelihoods in terms of numbers and types of jobs, local government revenues, lifestyles, and community cohesion. Alternatives favoring timber and other commodity uses tend to impact livelihoods and lifestyles dependent on amenity values, and vice versa. On this
Forest, the production of net cash returns to the U.S. Treasury, levels of employment, and payments to counties are directly dependent upon the level of timber production. These benefits are less under alternatives that place more emphasis on nontimber issues, such as those associated with wilderness and roadless areas, high levels of scenic quality, and vegetative diversity. The benefits associated with minerals are similar for all alternatives.

Threatened and Endangered Species
The only Federally listed threatened or endangered species observed on the Forest/Grassland are the peregrine falcon and bald eagle. Neither is a known permanent resident. All Federal and State listed species are protected in all alternatives as provided for in the standards and guidelines in Chapter 4 of the Forest and Grassland Plans, or Appendix D of this FEIS.

Formal consultation with the Fish and Wildlife Service (FWS) was initiated through request by the Forest Service in October 1986. The resultant FWS consultation addressed the possible effects of selecting Alternative E-Departure in the DEIS. The consultation was limited to the bald eagle and the peregrine falcon, both federally classified as endangered. The biological opinion of the FWS is that the implementation of Alternative E-Departure in the DEIS would not jeopardize the continued existence of the bald eagle and peregrine falcon.

There has been continued informal consultation between the Ochoco National Forest and FWS since the DEIS. The Feis incorporates a number of changes that have resulted from both the formal and informal consultation. Among them are the allocation of 570 acres to an Eagle Roosting Management Area (MA-F12) for all the alternatives, specific monitoring requirements for threatened and endangered species, and the direction to develop site specific management plans for the roosting sites during implementation of the Forest and Grassland Plans.

Timber Management
Timber production and associated management, and cultural activities have the greatest influence locally on jobs and economics of any resource on the Forest. An array of alternatives ranging from 15.6 million cubic feet production per year to 21.9 million cubic feet is examined in the environmental impact statement. The alternatives considered emphasize utilization of appropriate silvicultural systems which may be either even- or uneven-age depending on field conditions and objectives. Timber management and associated activities such as road construction, reforestation, thinning, harvest, slash disposal, and various site treatments have a wide variety of effects on other resources, particularly soil, water, air, wildlife, fisheries, landscape, recreational experiences, and socio-economics. Practices and management requirements are applied that minimize adverse effects.

Toxic and Hazardous Materials
Activities that may occur on the Forest and Grassland involving the use or disposal of hazardous or toxic materials are required to meet all State and Federal laws and provisions. Therefore, provisions and procedures for dealing with any of these materials are the same for all alternatives.

Unroaded Areas
The areas remaining that have not been designated as wilderness or wild and scenic rivers, totaling 52,880 acres, are treated in the Plans.

The range of alternatives provides for varying degrees of development, or retention of roadless characteristics for semiprimitive recreation.

The most significant conflict of maintaining unroaded areas is with timber production. Approximately 38,430 acres will be managed in an unroaded condition for semiprimitive recreation under the preferred alternative.

Utility and Transportation Corridors
All alternatives recognize State and County road corridors. Utility corridors are also recognized and no alternatives result in any conflict with movement of power or energy throughout the area.
Wild and Scenic Rivers
An inventory conducted by the National Park Service under PL 88-29 and PL 90-252 identified segments of the Deschutes River, Crooked River, and North Fork Crooked River for study and potential classification under the Wild and Scenic Rivers Act. The Oregon Rivers Act of 1988 classified segments of these rivers. All alternatives provide for the protection of the rivers until required planning for their management is complete.

Eligibility and suitability determinations have been made for a portion of the Squaw Creek area. A 7.5 mile segment of the creek, 1,370 acres, from the Grassland boundary to the confluence with the Deschutes River would be managed as a "scenic river." In addition, it would be recommended for inclusion in the Wild and Scenic River System. This preliminary recommendation would receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. The Congress has reserved the authority to make final decisions on designations of rivers as part of the National Wild and Scenic Rivers System.

Wilderness Establishment
Three wilderness areas totaling 36,200 acres were established under the Oregon Wilderness Act of 1984 on the Ochoco National Forest. A range of options were considered for the Deschutes River-Steelhead Falls area which the Oregon Wilderness Act identified for further study. No wilderness is being recommended. A 7840-acre semiprimitive nonmotorized management area is being established which involves part of the WSA; some of the remaining portion is included in the classified Deschutes Scenic River. North Fork Crooked River area is addressed in a separate study by the BLM. The BLM recommended no wilderness in their draft EIS for this area.

Wildlife
Important game species habitat, namely deer and elk, is afforded some degree of protection in all alternatives, but its management is emphasized in certain ones. Snag and old growth forest habitat is provided at varying levels throughout a range of alternatives. Fish habitat protection is related to those alternatives emphasizing management of riparian areas. Management activities and uses on the Forest and Grassland directly and indirectly affect wildlife and fisheries habitat. Road construction, timber harvest, timber cultural practices, livestock grazing, recreation uses, prescribed fire, and firewood cutting are common activities on the Forest and Grassland which can affect wildlife and fisheries habitat. Alternatives, management requirements, standards and guidelines, and project design incorporate means to minimize impacts on wildlife and their habitat.

Probable Adverse Environmental Effects that cannot be Avoided
Soil displacement or erosion can be expected to result from planned management activities, such as vegetation removal; slash disposal; logskidding; prescribed fire, construction and maintenance of roads, trails, transmission facilities, recreation sites and others. Soil productivity would be maintained except for sites dedicated to roads, skid trails, log landings, recreation sites, and other facilities or uses that may compact the soil, alter soil profile, or deplete nutrients. An estimated one percent of the Forest and Grassland would be occupied by roads or facilities. Experience has shown that temporary road surfaces can be re-vegetated, but the productivity is reduced. Forest-wide an estimated 10 percent of cable-logged areas and 30 percent of tractor-logged areas would experience increases in soil bulk densities or compaction. These factors, in turn, have indirect effects relating to reduced wildlife habitat, vegetation productivity, occurrence and spread of noxious weeds, and increases in stream sedimentation.

Prescribed fire use may be expected to contribute to total suspended particulates (TSP) in the atmosphere, to periodic increases in haze, and may reduce visibility.
The general natural appearance of the landscape and forest would change overtime, with the natural and characteristic features as they exist today giving way to more domination in places by management activities and results of management.

Forest vegetation would be altered in respect to species composition, stand structure, and age. Existing mature forest “suitable” lands would be subject to management treatments. Where feasible, mixed conifer stands would be replaced with currently more economically or silviculturally desirable species (primarily ponderosa pine). Other management treatments include overstory removal of old-growth ponderosa pine from multi-storied stands, resulting in a reduction in basal area, and removal of less desirable species within densely forested areas by thinnings. Intensively managed or regulated forests may provide less habitat for species dependent on old growth forest, snags and down material, and provide less scenic settings, species diversity, and habitat diversity.

Average size of trees that are harvested would change over time to smaller material as old growth and existing mature forest are converted to younger stands. Over time this would have an affect on types of harvest equipment and wood processing, and machinery and manufacturing requirements; and likely will bring a shift towards cubic feet management rather than board feet.

Approximately 93,110 acres on the Forest and Grassland would remain roadless. With the exception of 36,200 acres designated as wilderness, 4030 acres designated as wild and scenic rivers, and 52,880 acres remaining available, opportunities for semiprimitive recreation may decrease over time.

Increased road densities, improvement in access, subsequent increases in human presence, and continuing expansion of management activities can result in reduction of wildlife habitat security, harassment of wildlife, increased road kills, physiological stress in wildlife species resulting in altered behavior and productivity, and changes in hunter attitudes and experiences over time. The preferred alternative provides for road management closures and restrictions which would reduce open road density over the next five decades.

Actions to improve riparian conditions may result in increased costs to grazing management; e.g., in installation of improvements (fencing and water developments), herding, and transport to control stock distribution and use, and possible temporary reductions in animal unit months.

Current procedures cannot insure that all cultural resource sites will be located. Some sites could be inadvertently destroyed or damaged. Such impacts are unavoidable pending advances in inventory techniques.

Forest users would encounter more controls and restrictions over time as management intensity, resource competition, and human populations increase.

**Short-Term Uses of the Environment and Maintenance of Long-Term Productivity**

From a perspective that each generation is trustee of the environment for succeeding generations, an objective of this Plan is to provide for the proper and continued development of resources in a manner that maintains economic viability, yet maintains local natural heritages, such as, wildlife habitat, outdoor recreation opportunities, water quality, scenic qualities, and livestock grazing. The preferred alternative emphasizes a balanced mix of uses and intensive commodity (timber, range) production on suitable places in order to help provide economic stability, but also attempts to provide for the protection of other resources (soil, water, wildlife habitat, aesthetics).

While the Plan involves harvest of mature timber, sustaining or improving long-term productivity is planned through intensive forest management practices (e.g., reforestation and thinnings). This may result in future utilization of smaller trees to maintain harvest levels over time. Lands were identified as “unsuitable” for sustained yield timber management due to regeneration difficulties. Dispersion of timber harvest activity, retention of old growth, and protection of riparian areas and big game habitat have all been planned to prevent impairment of long-term land and resource productivity.
Construction of roads, mechanical slash piling, and log skidding are short-term uses that can reduce long-term vegetation productivity.

Increases in road densities, improvement in access, subsequent increases in human presence, and continuing management activities have the potential in the near future to affect long-term productivity of wildlife habitats, aquatic systems, and local socio-economic aspects.

Irreversible or Irretrievable Commitment of Resources

This plan deals with both developed and undeveloped or roadless lands. Lands where road systems, plantations, thinnings, and structures are established represent a type of economic commitment that for all practical purposes commits the land to those activities. These investments represent “sunk funds” from an economic standpoint and are not retrievable, nor do they necessarily have any “liquidity,” over the planning period.

The specific acres (estimated to be one percent of the total Forest and Grassland area) upon which roads and facilities are constructed, represent a loss of soil and vegetation productivity and unaltered landscape.

Use of rock for road surfacing and construction purposes, estimated to be 200,000 tons annually on the Forest and Grassland, is an irreversible and irretrievable commitment of a resource, but is not considered critical because of the abundance of quality rock in this locale.

Undeveloped and roadless areas once allocated for development will, within a relatively short amount of time, become irretrievably unsuited for wilderness classification. In the case of lands already intensively developed by roading, a high degree of irreversibility exists; whereas, in the case of undeveloped lands, frequently a wide range of management options exist.

Dasmann, et al, in Ecological Principles for Economic Development, 1973 (pp. 22-23), recognized six broad development levels for lands, each representing progressively greater commitment of resources. The development levels are:

1) The land can be left in a completely natural state and reserved for scientific study, educational use, wilderness, watershed protection, and its contribution to landscape stability.

2) It can be used as a park, refuge, or reserve with the natural scene remaining largely undisturbed to serve as a setting for outdoor recreation and an attraction to tourism.

3) It can be used for limited harvest of its wild vegetation or animal life, but maintained for the most part in a wild state - serving to maintain landscape stability, support certain kinds of scientific or educational uses, provide for some recreation and tourism, and yield certain commodities from its wild populations.

4) It can be used for more intensive utilization of its wild products as in forest production, pasture for domestic stock (recreation), or intensive wildlife production. In this case, its value as a “wild” area for scientific study diminishes, but it gains usefulness for other kinds of scientific and educational uses. Its value for (some) tourism and outdoor recreation diminishes, but is not necessarily lost. Its role in landscape and watershed stability is changed, but may be maintained at a relatively high level.

5) The wild vegetation and animal life having been removed in part, it can be intensively utilized for the cultivation of planted tree crops, pastures, or farming crops.

6) The wild vegetation and animal life having been almost completely removed, it can be used for intensive urban, industrial, or transportation purposes.

So long as any of the first three choices are taken, the option remains open to change to any of the others. In the fourth choice, the options for restoring the land to any of the first three levels are reduced, but not eliminated. Lands allocated to development are likely to approach the fifth and sixth level over time.
This would largely prohibit any shift to other alternatives on those acres.

For Preferred Alternative I, with the resource allocations proposed herein, 19 percent of the lands are committed to categories of "low" or "moderate" irreversibility; about 80 percent of the land that is proposed for intensive timber culture, transportation systems, special uses, and rangeland management can be categorized as "moderately high." Another one percent would be considered "high" irreversibility of irretrievability for commitment of resources (Table S-10).

Mitigation

Mitigation measures are intended to minimize or eliminate potential conflicts or adverse effects of implementation. Mitigation measures have been developed through interdisciplinary efforts and incorporated into the alternatives at different levels in several different ways.

The standards and guidelines and management area prescriptions in Chapter 4 of the Plans are a fundamental and integral part of these measures, and as such they are a basic and essential part of the Plans.

The allocations play an important role in mitigation by the separation of incompatible uses, impacts and conflicts.

National Forest Management Act (NFMA) requirements were incorporated into the planning process and are reflected in the allocations and standards and guidelines (Chapter 4 of the Forest and Grassland Plans), and are discussed in Appendix B.

"General Water Quality Best Management Practices" (USDA Forest Service, Pacific Northwest Region, November 1988. 86p) are incorporated by reference under requirements of Section 319 of the Clean Water Act, are reflected in the standards and guidelines (Chapter 4 of the Forest and Grassland Plans), and are discussed in Appendix H.

Mitigation measures are developed at the site specific project level of planning, and projects are "tiered" to other planning level measures above.

Coordination with other Agencies

This planning effort involved coordination with major local, county, state, and federal agencies. The Preferred Alternative is not in substantial conflict with the plans of any other agency.

Chapter 1

Purpose and Need
Chapter 1

Purpose and Need

Introduction

The Forest and Grassland Plans are major Federal actions with significant effects on the quality of the human environment; therefore, an Environmental Impact Statement is required. The Notice of Intent to prepare an EIS was published in the Federal Register in 1980; the Notice of Availability of the Draft EIS (DEIS) was published in the Federal Register on Sept. 12, 1986. A Supplement to the DEIS was prepared to address timber industry concerns outlined in two appeals, and a Notice of Availability was published in the Federal Register in October, 1989.

This Final Environmental Impact Statement (FEIS) discusses six alternatives, including the actions described in the Forest and Grassland Plans. A reasonable range of alternatives has been explored with an initial look at eleven alternatives in the DEIS. The Supplement to the DEIS, discussed in Chapter 2 of this FEIS, added the No Change (NC) alternative to reflect the continued application of the existing Ochoco National Forest Timber Resource Plan. The public comment to the DEIS has resulted in the formulation of Alternative I, and the modification of Alternatives B and C for the Final. This FEIS also describes the affected environment and the environmental consequences of implementing the alternatives.

The alternatives represent different ways to: 1) address local, regional, and national issues, concerns, and opportunities; 2) provide the mix of uses representing “multiple use”; and 3) provide a flow of goods and services from the Ochoco National Forest and the Crooked River National Grassland. Each alternative generates a different mix of goods and services. Alternatives were evaluated to determine their potential to provide a sustained yield of goods and services in ways that maximize long-term public benefits in an environmentally acceptable manner. The proposed action, Alternative I, provides multiple-uses, goods, and services which maximize long-term net public benefits within the laws and regulations governing National Forests. The definition of “net public benefits,” as noted in 36 CFR 219.3, can be summarized as the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs).

The purpose of the FEIS is to document and disclose environmental outcomes to make a reasoned choice among alternatives. Equally important, the FEIS provides the environmental documentation for public review. The DEIS encouraged public participation and comment, and the FEIS reflects that participation and comment. The initial public involvement process and the resultant issues and concerns are discussed in Appendix A to this FEIS. The Forest responses to the public comments on the DEIS are displayed in Appendix I. The major changes between the draft preferred alternative in the DEIS and Preferred Alternative I in the FEIS are discussed in detail in this chapter.

The purpose of the Forest and Grassland Plans is to direct and guide all natural resource management activities on the National Forest and Grassland. The plans meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) as amended by the National Forest Management Act of 1976 (NFMA), plus the associated National Forest System Land and Resource Planning Regulations (36 CFR 219). The plan period covers the next 10 to 15 years. This period is defined by the NFMA regulations as one decade (36 CFR 219.3 (1982)), while the law permits a 15-year maximum (16 USC 1604 (f)(5)). In the Plan, conditions on the Forest will be evaluated every five years.
Under certain circumstances, the plan may be revised (36 CFR 219.10 (g)(1982), 16 USC 1604 (f)(5)). Chapters 5 of the Forest and Grassland Plans discuss implementation and the Plan amendment or revision process.

A Record of Decision (ROD) accompanies this FEIS and outlines the processes and decisions, and the rationale for the decision. The decision is represented by the two Plans outlined in the proposed action in this FEIS, which is Preferred Alternative I. Information in the FEIS provided the basis from which the Regional Forester made the decision to implement the Plans.

Implementation of the Forest and Grassland Plans will involve project level environmental analysis as discussed in Chapters 5 of the Plans. These analyses will deal with issues and management concerns relating to the specific projects and project areas, and will be in accord with the direction in the two Plans. Project analysis will be tiered to this FEIS.

This FEIS includes a list of acronyms and a glossary of terms to assist the reader. The FEIS and the two Plans each have a table of contents, a list of tables and figures, and an index to assist the reader in locating the various subject areas and discussions.

The approved Plans will not become effective until at least 30 days after the Notice of Availability of the FEIS is published in the Federal Register. See Planning Records, pg. 1-3. Additional information on Regional planning procedures is available from the Director of Planning at the USDA Forest Service, Pacific Northwest Region, 319 S.W. Pine St., P.O. Box 3623, Portland, Oregon 97208.

Planning Process

The Forest Service has a four-level, integrated planning process as required by RPA, NFMA, and the related implementing regulations.

4. Project Site or project specific plans, generally at Ranger District level. Tiered to Forest Plan.

At the national level, the RPA program establishes long range resource objectives based on the present and anticipated supply of, and demand for, various resources. Each of the nine Forest Service Regions is apportioned a share of the National objectives based on that Region’s resource capabilities and needs. The RPA assessment is an aggregation of the Region’s forest plans.

The Forest Service Pacific Northwest Region resource situation is addressed in the “Regional Guide.” This document apportions National objectives to each National Forest in the Pacific Northwest. In addition, the Regional Guide establishes certain management standards and guidelines.

The environmental analysis process, documented in this FEIS, has considered a reasonable range of alternatives. One of the alternatives consists of the current RPA Program resource objectives identified in the Regional Guide. Analysis of the alterna-
tive's outputs and effects in Forest planning provides valuable information for future Regional and National Assessments and programs. The planning process is iterative; the information from the Forest level flows up to the National level, is utilized in developing the RPA Program, and then is related back to Regional and Forest levels.

Planning at the RPA program level is used to assist Congress in the development, appropriation, and authorization of the agency's annual budget. Since the amount and allocations in the annual budget have a major effect on Forest management activities, many of the Forest's actual outputs and environmental effects are determined to a great degree by the annual budget. The annual budget planning is done at all agency levels in order to support programs on the National Forests.

Forest plans are prepared at the local level (at the applicable Forest headquarters). These plans provide allocations and standards and guidelines, and are generally programmatic in nature.

The planning process specified in the NFMA implementing regulations (36 CFR 219), and the environmental analysis process specified in the CEQ regulations (40 CFR 1500), were used in developing this FEIS and the Forest and Grassland Plans. The general planning steps employed are shown below.

Forest Planning Process Steps

1. Identification of Issues & Concerns
2. Development of Planning Criteria
3. Inventory Data & Information Collection
4. Analysis of the Management Situation
5. Formulation of Alternatives
6. Estimated Effects of Alternatives
7. Evaluation of Alternatives
8. Preferred Alternative Recommendation
9. Environmental Statement
10. Public Review
11. Plan Implementation
12. Monitoring & Evaluation

The chronology for the formulation of the Forest and Grassland plans is as follows:

On implementation, this FEIS will be a base to "tier" environmental analyses for proposed Forest management activities and projects. Tiering means that environmental analyses conducted for specific Forest projects will reference and be consistent with the direction in the FEIS and Forest or Grassland Plan, and associated documents rather than repeating them (40 CFR 1508.28). Environmental documents for specific projects will then concentrate only on issues unique to those projects. "Monitoring" will be a way to assure that activities are consistent with plan projections, and to determine if, and where changes to the plan may be necessary.
The Forest and Grassland Plans are intended to supersede and/or incorporate all previous land management and resource plans for the Ochoco National Forest and Crooked River National Grassland. On implementation, all activities affecting the Forest and Grassland, including budget proposals, will comply with the Forest and Grassland Plans. In addition, all permits, contracts, and other instruments for the management, use, or occupancy of the National Forest and Grassland will be required to be in conformance with the Plans. Chapters 5 of the two Plans address existing and required plans and their status in relation to the Forest and Grassland Plans.

Planning Records
All of the documents and files that chronicle the Ochoco National Forest and the Crooked River National Grassland's planning process are available for review at the Forest Supervisor's Office, 155 N. Court, P.O. Box 490, Prineville, Oregon 97754. These documents and files (planning records) contain the detailed information used in developing the FEIS and the two Plans. The FEIS, the appendices to the FEIS, and the two Plans reference the planning records.

Regional direction for some procedures, such as management requirements, are available at the USDA Forest Service, Pacific Northwest Region, 319 Southwest Pine St., P.O. Box 3623, Portland, Oregon 97208.

Forest Overview
Located near the geographic center of Oregon, the Ochoco National Forest is unique among its neighboring national forests; it administers the only national grassland in the Pacific Northwest Region. The combined area of the Forest and Crooked River national grassland equals 956,150 acres (net acres: 844,640 Forest acres; 111,510 Grassland acres). The Forest is subdivided into four ranger districts: Big Summit, Paulina, Prineville, and Snow Mountain. The Grassland is administered as a separate unit. The headquarters for both the Forest and Grassland are in Prineville (Figures 1-1 and 1-2).

The National Forest lies in a four county area which includes: Crook (population 13,400), Grant (8,230), Harney (7,350), and Wheeler (1,430). The National Grassland is contained in the boundaries of Jefferson County (12,150).

The National Forest and Grassland directly influence local community lifestyles, recreational activities, and economic well being in these counties. Local economies, like Burns, Hines, Madras, and Prineville, rely on forest products manufacturing and ranching.

The Forest occupies a southwestern extension of the Blue Mountain physiographic province (Franklin and Dyrness, 1973) known as the Ochoco and Maury Mountains. Elevations range from 2,200 feet to over 7,000 feet. The Crooked River National Grassland is a northern physiographic extension of high lava plains containing rolling range country interspersed with deep canyons, mesas, and volcanic buttes. The Deschutes River drains the Grassland. The Crooked River, which is a tributary to the Deschutes, is the largest river that originates from the northern portion of the Forest (Big Summit, Paulina, and Prineville Districts).

Water flowing from the Snow Mountain District enters three systems: the Crooked River, the John Day River, and the Malheur and Harney Lakes area. The area surrounding the Ochoco is referred to as the “High Desert” due to its relatively arid climate and cool average annual temperature. The Forest can be characterized as an island of green rising from within the high mountain desert.

The Ochoco, which in the language of the Paiute Indian means “Wind in the Willows,” is characterized by park-like stands of old-growth ponderosa pine intermingled with mountain meadows that are often fringed with aspen. A pastoral aspect is portrayed by cattle grazing the meadows and grassy forest understories. This impression is readily gained as one travels on U.S. Route 26, from Prineville northeast across the Forest to Ochoco Summit.
Figure 1-1

OCHOCO NATIONAL FOREST

VICINITY MAP
The Grassland, and approximately a third of the Forest, have vegetation characteristic of the surrounding high desert. Juniper, sagebrush, and grasses predominate as a result of low annual precipitation (less than 10 inches). As elevation increases, stands of ponderosa pines are encountered. The open, park-like pine stands are extensive and compose the largest single forest type found on the Ochoco National Forest. Mixed conifer stands occur on the northern and eastern aspects. These stands are made up of varying proportions of Douglas-fir, ponderosa pine, white fir, and western larch. The Forest also has scattered stands of lodgepole pine at higher elevations. These cover approximately one percent of the total land area, and have been subject to major mortality caused by mountain pine beetle.

The diversity of the vegetation, climate, and geology provides habitat for a wide variety of wildlife and fish species. There are over 375 different species of reptiles, amphibians, birds, and mammals known or expected to occur on the Forest and Grassland. The fisheries resource includes 15 species of game fish and numerous nongame fish species in the Forest and Grassland’s reservoirs, lakes, and streams. There are 45 miles of spawning streams used by anadromous fish.

Major recreational opportunities consist of rockhounding, water related recreation, and big game hunting. Agates and thundereggs are a national attraction for rockhounds. Antelope Reservoir, Delmtment Lake, Walton Lake, and numerous creeks and rivers provide camping, picnicking, and fishing opportunities. Passage of the Oregon Wilderness Act in 1984 further enhanced the Forest’s recreational opportunities by designating three Wildernesses: Black Canyon (13,400 acres), Mill Creek (17,400 acres), and Bridge Creek (5,400 acres). Big game and the Ochoco are synonymous to many hunters throughout the state. Hunting opportunities, provided by mule deer (22,600), Rocky Mountain elk (1750), and pronghorn antelope (750), are major attractions. Total recreational visitation averages 572,000 visitor days annually (see Table 2-8, FEIS Chapter 2); much of this is compressed into the 30-day period coinciding with the hunting seasons. There is one research natural area, with an additional five proposed.

The Forest has an estimated 6.3 billion board feet (MMBF) of standing timber and 533,177 acres classified as suitable for sustained yield timber production. About 137 MMBF of timber has been offered for sale by the Forest annually, with an average cut of 114 MMBF over the past decade. One hundred and five permittees use 75,000 AUM’s annually on 90 grazing allotments. Mineral resources include mercury and gold, semi-precious gemstones such as agates and jasper, leaseable potential oil and gas deposits, and potential geothermal resources.

Riparian areas include approximately 20,240 acres along 815 miles of streams. Average annual runoff from Forest watersheds is estimated at 574,000 acre feet. Maintaining or improving water quality, soil productivity, and riparian areas are important goals of Forest management activities.

Issues, Concerns and Opportunities

The Ochoco National Forest and Crooked River National Grassland contain varied and complex natural ecosystems which are managed and used by people within the local social and economic setting. The Forest and Grassland meet both local and national demands for resources, goods, and services, and provide opportunities for a diversity of land uses.

Individuals and interest groups have differing and often divergent ideas on how the Forest and Grassland should be managed. Because the resources, land uses, and environmental conditions of the Forest and Grassland are interconnected and finite, managing to emphasize particular resources can cause changes in others. Certain “tradeoffs” may result, and competition for some resources will undoubtedly occur. In short, there are practical and natural limits to what the National Forest and Grassland can provide.
An important planning task was determining what goods, services, uses, and environmental conditions people want (or do not want), and the different ways to manage the Forest and Grassland to meet those demands.

"Public issues" were determined and are defined as subjects or questions of widespread public interest relating to management of the National Forest and Grassland. Interests expressed by individuals and groups, and the physical, biological, and legal limits of Forest and Grassland management are incorporated into the public issues and management concerns identified, and used to guide the planning effort.

"Management concerns" are defined as issues, problems, or conditions which limit options or constrain management practices as generally perceived by the agency. These concerns are usually prompted by legal and regulatory requirements or actions necessary to protect or provide other resources at certain levels.

Lastly, "opportunities" were discovered or suggested by both the public and the Forest Service. Opportunities are often the basis for the issues or concerns identified. For example, the opportunity to preserve or develop resources to varying degrees on the National Forest and Grassland has been, and continues to be, the focus of many of the issues.

Identification of Ochoco National Forest and Crooked River National Grassland Issues, Concerns and Opportunities

The first step in the planning process was to identify the public issues, management concerns, and opportunities (ICO's). These ICO's were used to focus the planning effort; they ensured that the resulting Plans provided appropriate and effective management direction that addressed the ICO's.

In autumn of 1980, the Forest began to identify the principal issues to be addressed in the Forest Plan. The approach utilized "interest groups" as a starting point. Individuals representing key interests of conservationists, ranchers, recreationists, sportsmen, the timber industry, and government agencies worked with the Forest's Interdisciplinary Planning Team to establish a base group of issues. This interaction provided the Forest with a consolidated list of 60 issues which were submitted to the public for review.

Critique and comment was received at public meetings and through the mail. Using this information, the planning team again consolidated the issues into seventeen issue statements. These issues were again made available to the public to determine the degree of interest in each. Subsequently, the interdisciplinary team condensed the seventeen issues to twelve by combining related and compatible items (see below).

The DEIS was released for public comment in 1986. Over 2,150 responses were received. From these responses, 25,985 specific comments were identified through coding and analysis. These comments were grouped by similarity and subject, and were evaluated. This provided further clarification and refinement of the twelve ICO's to be addressed in the planning process.

In 1988, a Supplement to the DEIS was prepared and released to the public. It addressed some Forest Industry concerns about management requirements and disclosed opportunity costs associated with their application. It also portrayed a "no change" alternative based on the 1979 Timber Resource Plan and unit plans. The nearly 200 public responses to the Supplement were coded and analyzed similarly to the DEIS comments, grouped by resource or issue, and used to further refine the final ICO's.

Additional information on the formulation, evaluation, and selection of the ICO's is presented in Appendix A. The entire response, materials from the mailings, and the evaluation of public comments are available for review at the Forest Supervisor's Office in Prineville.

The final ICO's identified for the Ochoco National Forest and Crooked River Grassland are summarized as follows:
#1 What Should Be the Level of Timber Production?

Sustained Yield/Even-Flow and Departure
There was unanimous support for sustained yield and even-flow - a reaction to the proposed departure alternative, Alternative E-Departure, for the Ochoco National Forest. There was essentially no support for a departure from an even-flow to maintain high timber supplies for the first decade. Timber industry and dependent publics continued to offer support for sustained yield and an even-flow. Local economic stability and jobs were strongly related to high harvest levels by timber industry and dependent publics. At the other end of the spectrum, conservationists favored a much more conservative harvest level of 75 to 90 MMBF annually. The departure option was seen by industry as an unstable timber supply over time, and a negative influence on business development and stability over time. Conservationists suggested that the departure option was merely a euphemism for the rapid liquidation of old growth forest.

Uneven-aged Management
Timber industry and other groups noted some advantages, and expressed general interest in the Forest exploring uneven-aged management strategies on all or portions of the ponderosa pine stands available for timber management. Generally this silvicultural system is perceived as having the benefit of allowing harvest while providing for other resource needs. It is perceived by industry as means to allow the continuation of high harvest levels in pine while providing a quality log. Conservation groups, and other publics sensitive to even-aged management systems, see this as a means to limit clearcutting, reduce harvest levels, better manage for snag dependent wildlife species, and preserve a forested appearance over time.

Timber Supply/ASQ
Growth and inventory of forest stands is measured in units of cubic foot volume because it is independent of numerous product requirements occurring within a locale, region, or the nation as a whole. Board foot volume measurement varies with size of trees and is designed for certain product specifications and current technology. Young stands that have been regenerated cannot be measured in board foot or equivalent units of measurement; attempting to do so would underestimate the biological potential of timber producing lands and make future growth projections impossible. It is Forest Service Policy (FSM 1922.15) to use cubic foot volume as a measurement of long-term sustained yield, as well to regulate the amount of timber to be offered and sold as specified by the allowable timber sale quantity (ASQ), in order to respond to changing technology and product requirements projected for the future (RPA, 1985).

Between 1990 and 2000, the average annual harvest under the Forest Plan will be 19.0 million cubic feet (MMCF) (95 MMBF), slightly below the current harvest level. The volume of ponderosa pine offered annually for the first decade will average 17.0 MMCF (85 MMBF). This represents a considerable decrease from pine volume sold between 1979 and 1988, which averaged 109 MMBF annually.

The maximum level of timber volume that can be annually produced on a sustainable basis from the Forest is 23.5 MMCF (maximum timber benchmark). Competitive resources will have to be managed at or near minimum levels to sustain this level of timber harvest. This maximum level is 10 percent higher than the current Forest output. Changing the timber harvest level one way or another will probably affect other forms of resource management. The ability to resolve this issue is constrained by the trade-offs that are considered acceptable.

Within Crook and Harney Counties, over 80 percent of the forested land is in public ownership, most of which is administered by the Forest Service. Maximum mill capacity in these two counties, approximately 385 MMBF annually, substantially exceeds timber volumes processed in the past. Many factors have influenced the volume processed (including stumpage prices and expected market conditions), causing actual production to vary considerably from year to year. Recent estimates (1987)
indicate that approximately 280 MMBF (75 percent of maximum capacity) are currently milled annually in Crook and Harney counties. Lack of suitable timber supply from the Ochoco National Forest has been portrayed as the cause of higher stumpage prices, thus reducing the ability of local forest products firms to compete in the market place. Higher timber volumes sold from the Ochoco could be processed locally, possibly leading to lower stumpage prices.

Ponderosa Pine Supply and Tree Size
The species composition of the harvest has also become an element of this issue. Over the years, the majority of the Forest's timber harvest was composed of large ponderosa pine trees. As a result, local sawmills were set up to process large pine logs. While a substantial volume of ponderosa pine remains on the Forest, future harvests will include greater percentages of other species, such as Douglas-fir, western larch, and white fir. The average size of these trees is substantially smaller than the ponderosa pine trees harvested in the past. The change in tree size and species will require local mills to retool for efficient log handling. Other species do not presently have the secondary markets for remilling that pine has. The rate that these less profitable species become part of the Forest's harvest has become a source of concern to local sawmills.

#2 How can Activities on the Forest and Grassland Fulfill Social and Economic Wants and Needs of Local Communities?
The surrounding communities are significantly affected both socially and economically by the resource management carried out on the Forest and Grassland. County revenues from the Forest provide 30 percent of some local counties' total annual receipts. The timber industry and related government agencies account for approximately half of the local area's economic base. The harvest level provided by the Forest contributes a major economic return to the local economy. For example, greater harvest levels attained from the Forest will likely result in more local jobs and income. Additionally, twenty-five percent of the Forest's receipts are returned to the counties. Timber is the primary commodity output from the Ochoco National Forest and accounts for more than 90 percent of its receipts. Management of timber also significantly affects economic efficiency.

The large old growth ponderosa pine were particularly noted for their significant value to timber industry, with stumpage valued as much as 30 times greater than second growth timber. A significant amount of support exists for the sustaining the production of large diameter pine (at least 18 inches DBH) over time to maintain the present industry base in Prineville and surrounding communities.

Maintaining large diameter ponderosa pine over time has been incorporated into the Final Plan; even-aged silvicultural systems have been designed to provide an average tree of 18 inches diameter breast high (DBH), and uneven-aged silvicultural systems have been designed to provide ponderosa pine greater than, or equal to 20 inches DBH. Certain management areas in the Final Plan will also provide large ponderosa pine greater than 20 inches DBH, with some, such as the Old Growth Management Area, providing old growth pine with diameters up to their biological potential.

The residents of Central Oregon have expectations of the Forest and Grassland besides timber harvest. Summer livestock grazing on the Forest and Grassland is an essential component of ranching operations in the area. Economically viable ranches contribute to the local economy's tax base and to the social make-up of local communities. Big game hunting, fishing, wilderness use, and other recreational activities are also important to local citizens. By providing these opportunities, the Ochoco National Forest and Crooked River National Grassland supply both monetary and nonmonetary benefits while satisfying social needs. The predicted levels of these opportunities is also an issue.

The ability of the Forest and Grassland to respond to community wants and needs is constrained by the extent of the resources available, the level of public expectations, and the efficiency of resource management.
#3 What is the Appropriate Level of Livestock Grazing and Intensity of Range Management?

Livestock grazing, and the intensity of range management, remains as a major issue for the management of the Forest and Grassland. A primary concern expressed in the public comment on the DEIS is the past and present grazing impacts to the riparian areas and wildlife habitat on the Forest and Grassland. Some felt livestock grazing numbers could not be maintained or increased while simultaneously attaining riparian rehabilitation. Others believed that the economies of Crook, Harney, and Jefferson Counties are dependent on ranching, and that reductions in livestock numbers would have significant adverse effects. All grazing allotments are used and there is constant pressure to increase the numbers of livestock allowed, or to extend the season of pasture use. Permitted livestock numbers have not varied greatly in the past decade. Some increase has occurred as a result of improved range management practices, making more forage available.

Forage is generally not the limiting factor in managing the number and amount of livestock use. Water is usually the limiting factor. Forage far from water sources may be only lightly utilized, while forage near a water source may receive heavy use.

Conflicts generated by the present level of grazing arise from varied points of interest. Primary conflicts occur when grazing in a riparian area degrades water quality and fisheries habitat, when competition exists between livestock and big game for forage, and when livestock have damaged trees seedlings needed for reforestation. Additionally, livestock can have negative impacts on the aesthetics of recreation sites.

The Forest and Grassland will attempt to resolve these issues through adjustment of the animal unit months (AUM's) provided and the extent of the livestock management and range improvement practices conducted. Livestock management techniques, such as herding, fencing, salt and mineral block placement, and water development, minimize the impacts of grazing. Forage may be increased by prescribed burning, timber harvesting, and grass seeding. Under the proposed Forest and Grassland Plans, the number of livestock using riparian areas will be reduced, or subject to better controls, over time to provide for riparian area improvement. This will be offset by: 1) increasing forage production on transitory range, 2) improved forage production resulting from nonstructural range improvements, and 3) construction of 27 water developments to distribute livestock into areas where forage is available but natural water sources are not.

Currently, the Forest and Grassland provide 75 thousand AUM's annually. The Regional Guide for the Pacific Northwest Region has established a goal of 82 thousand AUM's for the Forest and Grassland to be attained in the next decade. The maximum capability of the Forest and Grassland to provide commercial livestock grazing has been estimated at 110 thousand AUM's annually (maximum livestock benchmark). Other resources will have to be managed at or near minimum levels to attain this level. Much of this potential depends on the construction of additional water developments and intensive management practices.

#4 How Should Riparian Areas be Managed to Meet Various Resource Needs?

Approximately 20,240 acres of the Forest and Grassland are within the riparian influence zone. The riparian area condition is poor along 402 miles of streams (about 50 percent of the riparian areas). Though occupying only two percent of the land base, riparian areas offer great potential for increased resource productivity. Riparian areas are very important as fish and wildlife habitats, and contribute significantly to species diversity. Stream margins frequently contain highly productive timber sites. Livestock utilize the vegetation in riparian areas more heavily than in other areas. Their relatively gentle topography makes riparian areas attractive for road locations. A majority of the Forest and Grassland's recreational use occurs in riparian areas; they are often very scenic and provide a refreshing contrast to the much drier surrounding areas.
Concentrated use in these areas has caused conflicts. Vegetation diversity along many riparian areas is presently low. There is an abundance of grass but a limited presence of trees and shrubs. This has negative implications for fisheries, wildlife, and recreational use of the areas. Some trees that once provided shade have been removed by timber harvests. The primary reason for the lack of vegetation diversity is livestock overgrazing the forage in riparian areas. Overgrazing has reduced water quality, eliminated streamside shrubs, caused soil compaction, accelerated erosion, and broken down stream banks. This conflict is particularly difficult to resolve because these areas are vital to livestock for water, provide palatable forage, and naturally provide relatively cool spots for livestock to congregate.

The present transportation system has also had impacts on riparian areas. Roads in riparian areas can be sources of soil erosion and tend to channel and accelerate water flows. A riparian area's ability to moderate water flows and filter out sediment can be decreased, and stream water quality degraded by sedimentation. Sedimentation and warmer water temperatures caused by lack of shade have caused the water in many streams to fall below State water quality standards.

Generally, the less disturbance that occurs in riparian areas, the better the area condition. However, resource use in riparian areas can be compatible with good riparian condition. The extent of each use, and the mitigation practices employed, largely determine the riparian area condition. Riparian areas are relatively resilient and respond to improvement measures. Rehabilitation efforts and the future management of these areas will be addressed. Presently, opinions differ concerning existing conditions and on the management needed to attain the best combination of riparian area use and future productivity.

#5 What Transportation System Should be Provided to Meet Public, Commercial, and Administrative Access Needs?

Forest and Grassland road system needs continue to be a high interest area - the Forest received 1000 comments on this subject on the DEIS. The comments voiced strong sentiments that road standards are too high and that the number of roads on the Forest is excessive. The comments offered support for the closure of roads following completion of projects, timber sales in particular. There was also support voiced for the closure of roads for the protection of big game, erosion control and reduced maintenance costs. This is a departure from the original comments which opposed the closure of roads and areas to access by motorized equipment. Timber industry observed that the number of roads was not the issue, but if the number of roads open to public travel and open road densities were reduced, other resource objectives could be still be attained.

Off-road vehicle use continues to be a growing concern. The roads issue has been expanded to address general access concerns which includes ORV uses of off road areas. A travel plan for the Forest and Grassland addresses road management concerns and will complement the objectives of the various management areas on the Forest and Grassland. Wildlife habitat effectiveness objectives will be partially met through road restrictions and closures. The number of miles of roads maintained open for public travel on the Forest will decrease nominally in the future as a result of these road restrictions and closures for big game habitat protection, erosion control, and public safety.

In the first decade, 840 miles of road will be maintained for passenger car travel and 2,330 miles will be maintained for high clearance vehicles.

By the fifth decade 850 miles will be maintained for passenger cars and 2,270 miles for high clearance vehicles.
Roads will be closed to protect the investment, to protect public safety, to minimize soil erosion and water quality degradation, and to maintain wildlife habitat effectiveness. In the first decade, 1,560 miles of roads would be closed. In the fifth decade, 2,190 miles would be closed. Closures may be seasonal or yearlong.

#6 Should Habitat be Provided for Increased Populations of Big Game?
Habitat for big game was second only to timber in the number of public comments on the Draft. The public continues to be very interested in the production of elk and deer on the Forest. In particular, there was support voiced for population levels of elk in excess of those proposed by the Draft Plan and Oregon Department of Fish and Wildlife (ODFW) goals. Along with outputs, there was expression of support for the management of big game winter range and the management of road systems to attain habitat effectiveness. The management of habitat for antelope is an issue on the Grassland.

The Forest and Grassland contain significant numbers of mule deer, pronghorn antelope, and Rocky Mountain elk. ODFW has identified the desired deer and elk population levels for the wildlife management units encompassed by the Forest and Grassland. There are approximately 2,300 elk on the Forest now, according to a recent census. ODFW's objective (planning benchmark) is for 2,600 Elk. The ODFW objective for deer and antelope populations has already been attained: approximately 23,000 deer and 750 antelope.

The Forest and Grassland Plans will designate important areas of big game range in four management area allocations on 171,490 acres of the Forest and 35,440 acres of the Grassland. Three of these management areas are big game winter ranges. The Plans provide standards and guidelines for the management of cover and road management that will support elk numbers that meet the population objectives. In these areas, road use and cover would be managed to provide high quality big game habitat. Habitat would support 3,000 elk in the first decade, increasing to 2,870 in the second decade, then declining to 2,690 by the fifth decade due to changes in cover and road access.

The Forest and Grassland have the potential to provide habitat for more elk than presently exist. Benchmark analyses indicate the maximum capability of the Forest and Grassland would produce and sustain 23,000 deer and 4,800 elk. It would take approximately 50 years to reach these levels for elk. The number of deer is about the same as current population estimates due to ODFW management of herd size. The primary factors limiting big game habitat are the quality and amount of big game cover and the extent and use of the road system.

Management for other resources or land uses can enhance big game habitat. Timber management and range improvement practices can improve an area's forage production. Measures intended to rehabilitate riparian areas benefit big game habitat. Lands managed for wilderness, roadless values, or old growth habitat generally provide better big game habitat than lands managed intensively for timber production.

#7 How much Roadless Recreation Opportunity Should be Provided?
Unroaded recreational opportunities generated the third highest number of comments on the DEIS. Public comments focused on Lookout Mountain and the Ochoco Canyons area of the Forest. There was strong sentiment for the retention of existing roadless areas by some, while others challenged the designation as limiting and precluding other uses.

When the issue was originally identified, there were ten areas on the Forest and Grassland that met roadless area criteria. Since then, the Oregon Wilderness Act of 1984 created three wilderness areas on the Forest (Bridge Creek, Mill Creek, and Black Canyon). The roadless area question posed by this issue still needs to be resolved for six other areas: Green Mountain, Rock Creek, Cottonwood Canyon, Silver Creek, Lookout Mountain, and Deschutes Canyon-Steelhead Falls. The remaining area, Broadway, was committed to timber harvest and road construction under existing plans in the interim.
Due to its status as a "further planning" area from the RARE II process, the Oregon Wilderness Act directed that a recommendation of non-wilderness be made for the Deschutes Canyon-Steelhead Falls area on the Grassland through the forest planning process.

Allocating areas for unroaded recreation limits the capability of these areas to produce some other benefits. Recreationists that rely on roads for access would not be served by these areas. Lack of immediate access hinders resource management activities and adds to the difficulty of controlling wildfires. Timber harvests are generally not permitted. This limitation results in decreased economic returns from the Forest. In some cases, the inability to manage the timber hinders development of big game habitat.

Lookout Mountain roadless area has received strong interest; specified treatment will be offered in the FEIS. The Rock Creek/Cottownwood Creek area will be dealt with in two management areas in the Forest Plan in order to address the interest in unroaded recreational opportunities, and the need to make some of these roadless areas available for other resource use opportunities. Cottonwood, most of Rock Creek, and a portion of Silver Creek will be retained as roadless areas and managed for semiprimitive nonmotorized recreation. Green Mountain will be managed as general forest. The Draft proposed semiprimitive motorized recreation which was determined not to be appropriate for the area, and not supported by public comment.

The total wilderness, wilderness study area, and unroaded acreage is 96,228, about 10 percent of the Forest and Grassland (does not include wild & scenic rivers). Combined, unroaded areas and wilderness will meet the expected demand for semiprimitive recreation until the year 2025. A number of other management areas have been designated, e.g. Stein's Pillar, which will also contribute recreational opportunities in response to this issue.

Recreation projections for the Ochoco indicate that the demand for unroaded recreation use is continuing to grow, and may exceed the Forest and Grassland's ability to supply such opportunities in the next ten to fifty years.

#8 How Should the Forest and Grassland Manage the Scenic Resources?

Scenic resources continued to receive interest by some publics. The State of Oregon and others expressed concern for maintaining the scenic character or setting over time. Generally the public comments to the DEIS concerned the retention of the scenic corridor along Highway 26. Travelers in the Ochocos often leave with a picture of open ponderosa pine stands interspersed with park-like openings. Other vegetative types are intermingled, but stands of large pine predominate in the primary travel corridors. scenic corridor management has retained most of these large trees. The extent of visual corridor management across the Forest has been questioned since the large old growth pine is preferred by the local mills, creating pressure to harvest the readily available trees along traveled Forest corridors.

This issue has not been limited to visual corridors. A number of individuals and groups recognize that the visual character of the Ochoco National Forest and the Crooked River National Grassland will change through management over time. Early harvest operations usually removed only scattered individual trees, leaving multistoried stands. More recently, clearcuts have been used to initiate even-aged timber management, while the multistoried stands people have grown accustomed to seeing are being converted to relatively single-storied stands.

The Forest and Grassland Plans will provide a number of scenic corridors where the primary emphasis will meet visual quality objectives to maintain and enhance key scenery. Travel corridors, including major roads, access roads to roadless areas, and a winter sports corridor on the Big Summit District, will be managed for scenic qualities. Scenic corridors will total approximately 40,110 acres, 38 percent of the maximum potential of 106,700 acres. In addition, all management areas for the Forest and Grassland have Forest-wide and management area standards and guidelines which provide guidance on the visual quality objectives (VQOs) and how these VQOs can be met.

3/ Includes designated wilderness, North Fork of the Crooked River Wilderness Study Area, and the total roadless area (using the criteria boundary roadless area figures from Appendix C) less the 650 acres allocated to wild and scenic river designation in Deschutes Canyon.
How Much Old Growth Habitat Should be Provided?

Old growth generated over 1000 comments on the DEIS. A majority of the comments supported a larger allocation for old growth. In addition, there was interest in seeing the individual old growth management area size increased over that in the Draft Plan.

A relatively small component of old growth habitat remains across the entire Forest (approximately 93,800 acres). Past logging practices have significantly reduced old growth ponderosa pine. The Forest's remaining old growth habitat is primarily mixed conifer. This imbalance between amounts of old growth habitat in the mixed conifer and pine types results in a poor geographic distribution of wildlife that rely on old growth habitat.

The retention and management of old growth is a significant issue with timber industry. Industry claims that the old growth resource is a critical part of the total short-run timber supply on the Ochoco National Forest. The allocation of existing old growth blocks to a management allocation for the retention and preservation of old stand conditions would reduce the available supply well below the demand. Timber management activities within the allocation would be limited to treatments which enhance or maintain the desired old growth stand structure. As these stands age, they become increasingly vulnerable to insects and disease. While the mortality of old growth trees provides additional wildlife habitat, the risk of loss from wildfire is increased as woody debris accumulates on the forest floor. These potential losses in old growth areas may or may not detract from their value as wildlife habitat, depending on the extent of stand mortality.

In spite of these risks, old growth areas are a valuable component of the Forest. They provide habitat for approximately 100 wildlife species on the Ochoco. These areas also contribute to big game cover requirements. Soil and water conditions in old growth areas are generally favorable due to the absence of disruptive activities. They are often attractive from a visual standpoint, particularly in the pine types, and may be incorporated as parts of scenic or riparian corridors. Old growth can provide unique habitats for certain species, serve as gene pools, and contribute to diversity.

The Forest has allocated 72 stands containing 21,650 acres of old growth to be managed on a "dedicated basis." Of this amount, 20,380 acres are determined to be "suitable" and 1270 acres "capable." Of the 72 stands, seven are within areas allocated to wilderness and RNA's, leaving 19,250 acres actually allocated as dedicated old growth. That old growth dedicated in the management areas for old growth, wilderness, and RNA's amounts to 103 percent of the minimum level estimated to be required by old growth dependent species (21,000 acres), and 23 percent of the maximum old growth available on the Forest (93,800 acres). Out of a total of 1200 acres of existing old growth juniper, the Grassland has 740 acres allocated.

Old growth for the Ochoco National Forest and Crooked River National Grassland has been defined using the Regional definition from the Regional Guide for the Northwest Region, 1984. The size and distribution of areas managed for old growth were designed to meet habitat requirements for the pileated woodpecker, a management indicator species. These areas will also provide habitat for other species dependent upon old growth.

The existing mature stands and designated old growth outside old growth, wilderness, and other special management areas, will be subject to timber harvest. By the year 2030, areas not allocated specifically to the referenced management areas are expected to lose their old growth characteristics.

To What Extent Should Firewood be Provided to meet Demand?

Fuelwood also generated over 1000 comments on the DEIS. A significant portion of this comment came as a form letter response sponsored by forest industry. These comments supported the continuation of fuelwood supplies into the future. The utilization of firewood from the Forest and Grassland has increased many fold in recent years. In years past acquiring firewood was merely a matter of driving out of town and gathering wood from downed logs. As competition for wood has increased, the firewood supply has declined.
Demand for firewood from the Forest and Grassland is difficult to estimate. Contributors to the overall supply in the areas using Forest and Grassland firewood include the Bureau of Land Management, Deschutes National Forest, Malheur National Forest, private lands, and sawmills that make unused residues available for firewood. Accessibility, size, species, and the price of other forms of energy are other factors influencing demand.

The amount of firewood collected on the Forest and Grassland varies annually. Based on the Forest’s firewood permit system, 10,482 cords were removed in 1984. In 1983, 14,137 cords were removed. Accurate estimates of firewood collected prior to 1983 are not available.

Firewood gathering from the Forest provides several benefits: the public gains in terms of reduced energy costs, many people consider firewood collecting a recreational experience, and the Forest benefits through reduced risk of wildfire loss.

Some conflicts relate to firewood gathering. Wildlife snags near roads, including snags left in cutting units, are often at risk from illegal firewood cutters. Similarly, valuable green trees are sometimes felled illegally for firewood. Use of vehicles to gather firewood has caused soil damage in some cases. Logs gathered for firewood means a loss of feeding, nesting, and reproduction sites for numerous wildlife species. Providing firewood after timber harvesting can cause modifications to planned slash treatments; conversely, prescribed burning of slash has been criticized as consuming potential firewood.

The Forest’s ability to provide firewood generally varies directly with the amount of timber harvest that takes place. Firewood gathering from other sources, such as wind-thrown trees and juniper, will still occur as a relatively small portion of the total. To meet a portion of the local demand, this plan will continue to make firewood available to the public at levels commensurate with project activity and available access. The Forest and Grassland alone cannot meet the total local demand, which is estimated at 18,000 cords annually.

#11 How Much Habitat Should be Provided for Wildlife Species Dependent on Snags?

The number of snags (standing dead trees) across the Forest is variable. Snags are fairly abundant in mixed conifer stands found mainly on the Forest’s north slopes. On the southern slopes, where ponderosa pine stands predominate, snags are relatively scarce. This scarcity is a result of past salvage harvesting and firewood cutting in the ponderosa pine type.

Snags and down logs are used for nesting and/or shelter by 39 species of birds and 23 species of mammals. The absence of suitable nest sites is usually the limiting factor controlling the population of birds that nest in snags. Where snag densities are low, populations of dependent animals are usually also low. When snags eventually fall they become habitat for ground dwelling wildlife and play an important role in the nutrient cycling process. When snags fall across streams they sometimes create small pools that benefit fisheries and riparian conditions.

Opinions vary on the number of snags the Forest needs to manage. Many woodcutters see them as the best possible source of firewood. Salvage operations aimed at converting solid snags into lumber are viable operations. From this perspective, some people feel that snags left for wildlife are a wasted resource.

The Forest and Grassland will be managed to provide snag habitat at levels appropriate for the management objectives for the respective management area. The overall snag level on the Forest and Grassland, 47 percent, is expected to increase over time, with management, to approximately 54 percent in the fifth decade. The snag level should not go below 40 percent for any of the management areas.

#12 To What Extent Should the Forest Provide for Winter Sports Activities?

The primary factor limiting winter sport opportunities on the Forest is access to higher elevations during the winter months. Use levels at accessible
areas are sometimes high and conflicts have occurred between recreationists. This has been particularly true on Lookout Mountain, a large, relatively flat-topped mountain currently managed as a roadless area. The mountaintop is a favored area by both snowmobile users and cross-country skiers. There is one major trail to the top and conflict between users sometimes results. The current management direction for the area states:

"No cross country two- or four-wheel motor vehicle travel will be allowed.

Snowmobile use will be permitted in designated areas, at times when it does not conflict with non-vehicle uses.

The primary emphasis will be placed on access by foot or horseback."

The Forest also has requests to manage the Bandit Springs Area for more cross-country skiing opportunities. The Bandit Springs area is located along Highway 26 and provides excellent winter access at the Bandit Springs Rest Area (maintained by the State Highway Division). Currently, a cross-country trail system is managed in the area (approximately 1000 acres in size). There is local interest to further develop the cross-country skiing opportunities in this area.

Additional Issues not Identified in the Original ICO's but Identified as Comments to the Draft or During the Development of Changes From the Draft to the Final

#1 Anadromous Fish
Anadromous fish were not identified as an issue in development of the DEIS and Proposed Forest Plan. Anadromous fish were identified as a concern by several individuals and groups, including a lengthy, technical response from the Columbia River Inter-Tribal Fish Commission (CRITFC). Primary concerns included protection and enhancement of spawning habitat, and the adequacy of the monitoring schedule. Native American groups noted that treaties guarantee protection for anadromous fish habitat.

#2 Historic Trail Preservation - Summit Trail
This issue arose out of a separate study conducted during the interim between issuance of the draft and final documents (Gowan, 1896). The Forest coordinated with the State Historic Preservation Office (SHPO) on details contained in the Final Plan. This trail has also been related to other groups' proposals for an east-west intertie in a cross-state trail system.

#3 Off-Road Vehicle (ORV, ATV, OHV) Use
The off-road issue was one of the 14 original planning issues identified in the scoping phase of the forest planning process. It was dropped as one of the final ICO's; the comments were limited to local problems on the Grassland which were not considered to be of significance to the generation of alternatives for management of the Forest and Grassland. Comments on the DEIS regarding access, both pro and con, concerned road closures. The off-road issue did emerge again during the issue/Final Plans validation phase. Comments were generally opposed to off-road use because of resource impacts and trespass from the National Forest onto private lands.

#4 Round Mountain
The Oregon Natural Resources Council, in comments on the DEIS, asked that a special recreation unit be established for the Round Mountain area. This issue was brought up again by one individual in the validation process.
Summary of Changes Between the Draft and the Final EIS and Plans

Public involvement has been incorporated into the decisions reached in the Final Forest and Grassland Plans; this has been an integral step since the draft documents were released in September 1986. Significant steps were taken during the months of final document preparation to validate that direction in the Final Plan’s response to comments received on the Draft. Meetings and contacts with selected groups, individuals, agencies and political leaders were made to:

1. Validate public responses received during the process;
2. Insure that we interpreted what was said appropriately; and
3. Insure that we did not miss something or overlook stumbling blocks towards successful implementation.

In response to the comments, new information, and legislation, and where it appeared appropriate, adjustments were made and changes were incorporated into the Final Plans. This was intended to strengthen the Plan decision and build a base of support for effective implementation.
Plan Structures

Draft

The Plan for the National Forest and National Grassland was incorporated into one document.

The National Grassland had 8 management areas in the Draft, and the National Forest had 14 management areas.

Final

Two separate Plans were developed—one for the National Grassland, one for the National Forest—and covered by one Environmental Statement.

In the Final, the Grassland has 16 management areas, and the Forest has 28 management areas.

NOTE: See National Forest Ownership, this section on page 1-37 for explanation of acreage changes from the Draft to the Final.

---

**Summary of Changes**

1. Separate plans for the National Grassland and the National Forest.
2. Refinement in management area allocations.
3. Changes in resource emphasis.
Reasons for Change

National Grassland management and direction was overshadowed by the National Forest. The public requested they be separated into two plans.

Additions and changes in management areas (allocations) result from responses to public comments, incorporation of new information, new policies, improved understanding of the processes related to implementation and congressionally designated rivers.

Forest Management and FORPLAN Modeling

**Draft**

Even-aged silvicultural system. General Forest rotation diameter 14-16". Rotation age 90-100 years. Departure (by vol. first decade).

<table>

FORPLAN Modeling

The changes from Draft to Final have resulted in differences in FORPLAN modeling. The changes in allocations and related management guidelines have resulted in the development of new yield streams for timber and other resources, silvicultural systems, rotation ages, and decade harvest limitations.

New Prescriptions and Yield Streams applied in FORPLAN Model

Uneven-aged timber management applied to ponderosa pine on general forest (20-inch target size).

Uneven-aged timber management applied to ponderosa pine in special areas with 30-inch DBH target size: Lookout Mountain, Stein’s Pillar, Deep Creek, North Fork Crooked River.

Uneven-aged timber management applied to mixed conifer in some special areas.

Extended rotation ages and new thinning cycles for ponderosa pine in general forest.

Extended rotation and stricter decade harvest limitations for special areas.

Changes in the percent cover for big game required by allocation.

More reliance on mixed conifer to produce cover vs. ponderosa pine.

Acres and Timber Yield Tables:

Acres - Condition classes (i.e. the amount of pine sawlogs, saplings, etc.) have been updated from the 1983 information used in the Draft to 1988. This was done to more accurately assess timber harvest scheduling and resultant associated outputs and effects.

Timber Yield Tables - Yield tables were updated to reflect the growth that has occurred in the last five years to more accurately determine outputs and effects.

Summary of Changes

1. Incorporation of uneven-aged management in ponderosa pine where stand structure, condition, and management objectives allow.
2. Larger tree at rotation; general forest ponderosa pine 18-20" versus 14"-16" (wood quality).
3. Sustained even-flow in cu.ft.vol. versus departure (on volume basis).
5. Large target diameters (27'-30+") for recreation, wildlife and visual emphasis management areas.

6. FORPLAN model yield tables, acres, prescriptions and assumptions changed to reflect updated information (see above).

Reasons for Change

Response to public comment for uneven-aged management, growing larger trees, maintaining historic harvest levels in ponderosa pine, sustained yield even-flow vs. departure, improved and updated information.

Economic Analysis

Changes in schedules, outputs, allocations, effects, assumptions and new information will result in different economic effects and outputs in the final documents.

Incorporation of additional resources into the economic analysis overlooked in the draft documents (mineral leases, anadromous fisheries).

Wilderness Study Area

Draft

Proposed recommending 5,200 acres (2,500 FS, 2,700 BLM) in the Deschutes Canyon-Steelhead Falls Wilderness Study Area for wilderness classification.

Final

No additional wilderness proposed. A 7,840-acre Squaw Creek management area emphasizing semiprimitive, nonmotorized recreation, protection of natural features, and vehicle access management incorporates the core of previously recommended wilderness; the majority of the remainder of the draft proposed wilderness was included in the Deschutes Scenic River Corridor classified by the Oregon Omnibus Wild and Scenic Rivers Act in 1988. An eligibility study for lower Squaw Creek for Wild and Scenic Rivers was completed and the potential identified and preserved.
Summary of Changes

The 5,200 acres recommended for wilderness which was centered on Squaw Creek and the Deschutes River Canyon, was changed to a 7,840-acre special management unit centered on Squaw Creek, classification of the Deschutes River and canyon portion under the Wild and Scenic Rivers Act.

Reasons for Change

The Deschutes Canyon-Steelhead Falls area was determined to be too small to be appropriate for and manageable under the Wilderness Act. The Deschutes River and canyon area was classified and protected under the Oregon Omnibus Wild and Scenic Rivers Act.

Public expressed interest for classification of Lower Squaw Creek under Wild and Scenic Rivers Act. A 1,370-acre segment from the Grassland boundary to the confluence with the Deschutes River has been determined to be suitable for designation as a "scenic river" under the Wild and Scenic River System.

Wild and Scenic Rivers

Draft

Segments of North Fork Crooked River, Crooked River, and Deschutes River eligibility studies completed and management units developed to preserve options for river classification.

Final

Segments of North Fork Crooked River, Crooked River, and Deschutes River classified as Recreational or Scenic Rivers under the Oregon Omnibus Wild and Scenic Rivers Act. Lower Squaw Creek eligibility and suitability determination completed. Recommended for designation as a "scenic river" in the Wild and Scenic River System in Alternatives B-Modified and I.

Summary of Changes

Rivers Designated by Congress.

Lower Squaw Creek evaluated and determined suitable for Wild and Scenic Rivers designation. Recommended for designation as a "scenic river" in Alternatives B-Modified and I.
Reasons for Change

Oregon Omnibus Wild and Scenic Rivers legislation. Lower Squaw Creek evaluation conducted based on public comment and legislative hearings related to above Act.

</tbody>
</table>

Summary of Changes

1. Green Mountain proposal for semiprimitive motorized recreation (the area remaining roadless) was dropped for reasons of no apparent public interest or support. Soil erodibility and slopes found not to be suitable for that use.

2. The Rock Creek/Cottonwood Creek area to be managed as unroaded was decreased. A portion of the area which was determined to be economical for timber management was allocated to general forest and unroaded helicopter. Steeper areas were reserved for roadless area management, or helicopter logging, to protect watershed, anadromous fisheries, recreation, and wildlife values.

3. Silver Creek area to remain roadless and adjusted to a more manageable boundary along canyon rim.
4. Lookout Mountain was originally designated as a management area in the Ochoco-Crooked River Land Management Plan - 16,581 acres. The original RARE II designation included 15,260 acres. These acreages were further adjusted to 14,273 acres (roadless criteria boundary acres) to reflect changes in management. In the DEIS, the area designated for unroaded recreation was limited to 2,950 acres. In the Final Plan, the Lookout Mountain area to remain unroaded increased from 2,950 acres to 7,550 acres. The area was remapped (see planning process records) to approximate the original unit plan boundary. The difference in acreage is attributable to the inclusion of two old growth patches and the scenic corridor along the Road 42.

Planning for stand treatments will begin in first decade, but no entry will be scheduled.

5. A portion of the Deschutes River Canyon-Steelhead Falls Wilderness Study Area and an additional area outside the WSA in Squaw Creek are combined to form a 7,840-acre management area emphasizing semiprimitive, nonmotorized recreational opportunities and wildlife habitat management. The 5,200-acre draft wilderness proposal was dropped.

Reasons for Change

Response to public comments. Efforts to address the resource values involved in a more specific manner. Implementation concerns.

Lookout Mountain

Draft

2,950 acres to be managed for semiprimitive nonmotorized recreation; 11,323 acres allocated to general forest, and remainder to old growth areas. The top of the mountain closed to snowmobiling.

Final

A 15,660-acre Lookout Mtn. area treated as one management area within which there is a 7,550-acre mountain top unit, and two old growth areas. The 8,110 acres remaining will be managed with emphasis on recreational and wildlife habitat values and maintaining the character of the Forest over time. No entry needs to be planned until site-specific planning is completed. Road access corridors (Brush Creek and independent mine roads) are incorporated into the management unit. The entire area is open to snowmobiles during specific periods.
Summary of Changes

1. Treatment of entire Lookout Mountain and access corridors as a management area.
2. No entry planned prior to completion of site-specific planning.
3. Increase in unroaded mountain top management area from 2,950 to 7,550 acres.
4. Lower part of the mountain also managed with recreation, wildlife, and forest health emphasis.
5. Open to snowmobiling during specified periods.

Reasons for Change

To respond to public comment, and to address resource values involved in a more specific/responsive manner.

Summary of Changes

1. Immediate/foreground viewing area around recreational developments (campgrounds) assigned a visual management objective.

2. The acreage with visual management objectives increased from 46,449 in the Draft EIS to 64,300 in the Final. The width of the viewing corridor used in calculations was changed from > 2,640 feet to 1,200 feet.

3. Entire Summit National Historic Trail corridor was assigned a visual management objective relative to cultural aspects of the particular trail segment.

4. Round Mountain National Recreation Trail management corridor reduced in width from > 2,640 feet to 1,200 feet.

5. Added 560 acres of viewing area from Lake Billy Chinook reservoir on the National Grassland.

6. No middle ground viewing areas allocated as management areas.

7. All management areas assigned a visual quality objective.

Reasons for Change

To incorporate visual management considerations in important foreground viewing areas in a more balanced manner. New information. Discussions with the State of Oregon.

Bandit Springs winter recreation sports area identified.

Bandit Springs recreation management unit (1,580 acres) allocated; deals with all-season recreational activities.

Restricted all motorized use on Lookout Mountain summit.

Lookout Mountain open to snowmobile use in winter.

No recognition of special features or recreational attractions (other than roadless areas, developed recreation, and wildernesses).

Allocation of additional areas emphasizing recreational features or attractions and dispersed recreational opportunities, Stein's Pillar (1,070 acres), Hammer Creek (2,560 acres), Deep Creek (770 acres), Lookout Mtn. (15,660 acres).

No identification of recreational attractions and developments on the National Grassland. Summit National Historic Trail would be interpreted for public enjoyment.

Identifies and allocates the Summit Trail National Historic Route, with 3 different levels of management intensity per various segments (9,560 acres). Management area allocations made for Haystack Reservoir, Rimrock Springs Wildlife Viewing Area, and Cove Palisades State Park.

Summary of Changes

1. Increased recognition of importance of dispersed recreational activities on the Forest and Grassland.
2. Incorporation of existing recreational attractions, developments, cultural resources and special features not allocated in the Draft.
3. Lookout Mtn. would remain open to snowmobiles.
Reasons for Change

Improved and more complete information, public comment, and national emphasis (recreation strategy).

Wildlife

Old Growth

Draft

26,400 acres allocated; approximately (58% “suitable,” 48% “capable”) on National Forest only.

Final

21,650 acres old growth allocated (approximately 95% “suitable,” 5% “capable”).

1,000 acres of riparian area is recognized as connective habitat between some old growth areas. The connective habitat is allocated in the riparian prescription.

740 acres of old growth juniper allocated on the Grassland.

</tr>
</tbody>
</table>

1/ Old Growth Management Areas F6 and G5 (includes capable acres)

2/ Wilderness, Wilderness Study Areas F1, F2, F3, F4

4/ Total Existing Old Growth from 1987-1999 Inventory. This does not include 1,070 acres allocated to old growth but not presently old growth and 1,200 acres of existing juniper old growth.
Winter Range

Draft

76,000 acres of big game winter range to meet Oregon Department of Fish and Wildlife management objectives.

Final

99,570 acres of big game (deer/elk) winter range allocated, but redistributed spatially across the Forest and Grassland.

Identified big game winter range that was not necessary to meet ODFW big game management objectives and therefore, not allocated as winter range, but recognized as a separate management situation called “general forest/winter range,” 107,360 acres.

Added 22,700 acres to area identified as antelope winter range on the Grassland.

Summer Range

Draft

154,100 acres were allocated to big game summer range with specified amounts and quality of cover for optimum big game habitat.

Final

No areas specifically allocated for big game summer range. Big game habitat requirements are treated throughout the general forest area.

Bug-proofing of some ponderosa pine stands, if done, would reduce big game habitat effectiveness due to the inability of those stands to provide cover.

Snags

Draft

Specific snag management levels were set by management area, which averaged out to an overall forest level of 55 percent of the potential population for snag dependent species.

Final

Specific snag management levels by management area average 47 percent of the potential population level in the first decade, and reach 54 percent by the fifth decade.
Eagle Roosts

**Draft**

Management direction provided to preserve the integrity of actual and potential bald eagle winter roost sites, but none were specifically identified.

**Final**

Eight bald eagle winter roosts are identified. Two are not shown on the map because they are included within old growth areas which have more restrictive management prescriptions.

Site specific management plans for each eagle roost area will be developed in fiscal year 1989 and 1990.

---

Hammer Creek

**Draft**

No special management designated in Hammer Creek except for an old growth area.

**Final**

A 2,560 acre management area is allocated for wildlife and recreation emphasis. It includes an old growth stand and includes a variety of habitat types.

---

Road Density

**Draft**

Road density averaged four miles per section in timber/range emphasis and two miles per section in big game emphasis.

**Final**

Road density averaged three miles per section in general forest and one mile per section seasonally in winter range.

---

Modeling Assumptions Habitat Effectiveness for Elk

**Draft**

Assumed potential is four elk per square mile in ponderosa pine types; 10 per square mile in mixed conifer; average six per square mile.

**Final**

Assumed potential is six elk per square mile in ponderosa pine types; 15 per square mile in mixed conifer, average nine per square mile.
Summary of Changes

1. Reduction of total area allocated to old growth, but increase in quality ("suitable" vs. "capable") of that dedicated, and distribution across the Forest and Grassland improved. Application of concept of "connective habitat." Increased recognition of importance of old growth occurring within other management areas (e.g. wilderness, Lookout Mtn., Stein's Pillar, Deep Creek, etc.).

2. Allocation of old growth juniper on the National Grassland.

3. Improved spatial distribution of winter range allocations.

4. Additional acres of antelope winter range area identified and allocated on the Grassland.

5. Allocation of general forest winter range, in addition to winter range resulting from improved habitat effectiveness.

6. Elimination of big game summer range allocation and consideration of big game habitat requirements in standards and guidelines for all management areas.

7. Snag management level increased on certain wildlife and recreation management areas created since the Draft, but an overall drop in potential population level due to big game summer range allocation change (noted above).

8. Specific identification and management direction for bald eagle winter roosts.

9. Allocation of a Hammer Creek Management Area with an emphasis on wildlife habitat management.

10. Modeling assumptions for habitat effectiveness changed based on new information from ODFW.

11. Emphasis on maintaining habitat with quality and quantity of cover and road density comprising the basis for rating habitat effectiveness.

Reasons for Change

Public comments. Consultation with Oregon Department of Fish and Wildlife. Improved information and intent to improve the ability to implement.
Grazing Management

Draft

Forage utility standards were broken out by slope class and meadows for each management area. They generally were the same, except for those in the Riparian Management Area which were more restrictive.

Final

Forage utilization standards developed by the Region for east-side Forests are used. There is one set of standards for riparian areas and another set for all other management areas not excluded from grazing. The standards are based on vegetation type, range condition, and Forest and Range Experiment Station (FRES) management strategies.

Draft

Allotment improvements were considered with emphasis on water developments across the Forest to improve utilization and distribution.

Final

A system for prioritizing range allotment planning needs and a program estimate for riparian improvements are established on an allotment by allotment basis.

Reasons for Change

Public comments. Provision of means to more effectively address the allotment-specific nature of concerns relating to grazing management, and to tier allotment management planning to the Forest and Grassland.

Travel/Transportation Planning

Draft

All areas on the Forest and Grassland would be open unless otherwise designated, as determined by other management objectives. The ORV opportunities and closures were outlined in the DEIS (pg. 156), and in the travel plan map published with the DEIS.
Final

Travel access routes and areas designated with respect to management unit objectives.

Two designated ORV trails established, one in the Henderson Flat area on the Grassland and one on the Prineville Ranger District.

Draft

Allocated an area on Green Mountain to semiprimitive motorized recreation.

See road densities discussion under wildlife, pg. 1-30

Final

Changed Draft proposal for semiprimitive motorized recreation on Green Mountain to General Forest.

Summary of Changes

1. More specificity on area closures and designation of routes or roads within management areas.
2. Refers ORV trail designation to project level implementation.
3. Additional emphasis on ORV management and control.
4. Increased emphasis on improved road management with resultant reduction in open road density.

Reasons for Change

Public comment. Coordination and attainment of other Forest management objectives, e.g. improvement of elk habitat effectiveness, reduction of visual and on-site impacts, and other special area objectives.

Riparian

Draft

Two allocations or prescriptions: "Acceptable" and "Excellent." The latter was assigned to all anadromous fish streams and other high value fish streams.
All streams will be managed under one prescription - "Excellent."

Analysis and scheduling of need for treatment is based on a recently updated (1987) stream condition inventory.

No "connective habitat" identified or allocated.

Riparian corridors on approximately 40 miles (1,000 acres) of high value streams have been expanded to offer additional protection to these streams and to enhance "connective wildlife habitat."

Summary of Changes

1. Provides a simplified and more direct approach - riparian area management planning and analysis will be made compatible with stream condition.
2. Allotment management planning will have more detailed direction and objectives.
3. Provides a system for prioritizing range allotment planning needs on the Forest.
4. Introduces the concept and value of connective habitat.

Reasons for Change

Clarity in communicating planning details. Responsive to public, agency and internal comment. Provides specific information on objectives and impacts affecting allotment management and planning.

Utility Corridors

Utility corridors are addressed in general terms in the Forest-wide Standards and Guidelines.
Existing utility corridors (rights-of-way) are designated as a management area, 460 acres, in the Grassland Plan. Incorporates Federal Power guidelines and requirements (Western Regional Corridor Study, 1986).

**Land Adjustment**

The land adjustment plan shows four categories of land.

A fifth category is added: areas where Congress has directed the Forest Service to acquire non-Federal lands for a designated purpose. The Deschutes Scenic River and the North Fork Crooked River Scenic Corridor fall into this category.

The land adjustment maps are more detailed and based on recent analysis. Lands are placed in adjustment categories according to management area and priority.

"Consolidate ownership of Cove-Palisades State Park area" is listed as a land adjustment priority.

The issue of ownership patterns for Cove-Palisades State Park is deferred and opportunities for recreation management “partnerships” explored.

**National Forest Ownership**

National Forest ownership totaled 955,100 acres: 843,721 acres of National Forest, and 111,379 acres of National Grassland.

National Forest ownership totals 956,150 acres: 844,640 acres of National Forest, and 111,510 acres of National Grassland, due to land exchanges which have occurred since the Draft was prepared.
Minerals and Energy

**Draft**

Oil and gas leasing activity planning was based on the Mineral Leasing Act of 1920 and the Mineral Leasing Act for Acquired Lands of 1947.

**Final**

The Federal Onshore Oil and Gas Leasing Reform Act of 1987 changes the way oil and gas leasing will be administered. Regulations governing leasing procedures are expected to be finalized in late 1989.

**Draft**

Outputs for minerals activities were not adequately addressed in the DEIS (Table IV-6).

**Final**

Outputs for oil and gas leasing, geothermal leasing, mining claim location and common variety mineral production are discussed in the FEIS.

**Draft**

The economic analysis does not include revenues from oil and gas leasing.

**Final**

The economic analysis has been updated to include oil and gas leasing revenues.

**Draft**

The issue of providing a mining mineral inventory was deferred for resolution outside the Forest Plan.

**Final**

A mineral potential map and mineral inventory were prepared.

**Draft**

Approximately 80 percent of the Forest and Grassland were leased for oil and gas.

**Final**

Forest and Grassland area available for leasing is similar, but only approximately 10 percent of the Forest and Grassland are under lease, due to changes in oil prices.
No leasing would be allowed on administrative sites.

Leases will be issued with a “no surface occupancy” stipulation on administrative sites.

Leases would be issued with some restrictive stipulations in old growth areas.

Leases will be issued with a “no surface occupancy” stipulation in old growth areas.

Approval for mining operations will be given when concerns are mitigated in a responsible and responsive manner.

Under the mining laws, claimants are entitled to access and develop their mining claims. Operating plans will include reasonable and operationally feasible requirements for timely and effective coordination with other resources.

Chapter 2

Alternatives, Including the Proposed Action

Introduction

This chapter is the heart of the Environmental Impact Statement (EIS). It presents alternative ways of managing the Ochoco National Forest and displays the resource outputs and environmental effects of those alternatives. It also describes how alternatives were developed, how they compare to each other, and how they compare to the way the Forest is currently being managed.

This chapter has three main parts. The first section summarizes the process used to develop the alternatives. A detailed presentation of this analysis is given in Appendix B, Description of the Analysis Process. In the second section, all the alternatives carried forward to the Final EIS are then described in terms of their purpose and management emphasis. In the third, the alternatives are compared to each other in terms of outputs, responsiveness to issues and concerns, emphasized resource outputs, environmental effects, and economic costs and benefits which would occur with each alternative. This information is displayed in tables within this chapter.

Summary of Changes Between the DEIS and FEIS

In this chapter, the changes from the DEIS to this FEIS include a number of alternatives being eliminated from further study, the modification of several draft alternatives, the addition of the “No Change” alternative and the formulation of a new alternative. The comparison of the alternatives almost exclusively concerns the issues, concerns, and opportunities (ICO's) and the indicators of responsiveness.

A more thorough discussion of the changes from the DEIS to this FEIS is presented in the Summary to this FEIS.

Alternatives

Forest management can vary by what is done, where it is done, and when it is done. These varying combinations of what (management activities), where (management areas), and when (activity schedules) result in different resource outputs and environmental conditions, while meeting the unique objectives of each alternative.

Each alternative is a unique combination of these three elements: management activities, management areas, and activity schedules. As a result, each alternative generates a different mix of goods and services for the public, and a different combination of resource outputs, land uses, and environmental effects.

The basis for alternatives are the public issues, management concerns, and resource use and development opportunities and the manner in which they respond to the ICO's. Laws and regulations also require that certain alternatives, which are based on national or regional issues and concerns, are included in the process. Given those alternatives required by law or regulation, and based on the issues,
concerns and opportunities identified in this planning process, an Interdisciplinary Team (IDT) formulated alternatives covering a broad range of possible actions. The alternatives represent a variety of ways to respond to the issues, concerns and opportunities.

This chapter also discusses "benchmarks." Benchmarks are calculations of the maximum potential output, production, or economic opportunities for the Forest. They are used to define the decision space and range of alternatives that can be developed for particular resources.

Eleven alternatives were developed for the DEIS based on the public involvement process described in Appendix A to this FEIS. Because of the appeals discussed later in this chapter (see pg. 2-21), an additional alternative, the No Change Alternative (Alternative NC) was developed in a Supplement to the DEIS, October 1988. This alternative represents management of the Forest according to the 1979 Timber Resource Plan and unit plans. This alternative used a different set of criteria for acres of land suitable for timber harvest.

An additional alternative was developed to reflect public comment and new information on the DEIS. This alternative is also a product of close coordination with the State of Oregon in the development of their proposed management strategy for the Forest and Grassland. Four of the alternatives in the DEIS were modified, updated and carried forward to this FEIS. Ten of the alternatives displayed in the DEIS were eliminated from further detailed analysis in this FEIS. The disposition of the alternatives is also illustrated in Table 2-1. In addition, further discussion of required, departure, the "No Change," and new alternatives, and also those alternatives eliminated from further discussion can be found on pages 2-18 through 2-21.

1/ Alternative B-Mod represents evolution and change of Alternative B-plus proposed by timber industry. Alternative B-Mod is a new industry alternative. It is different than B-Departure in the Draft, the latter of which was much the same as Alternative B.

2/ Preferred Alternative I

3/ Current Direction Benchmark with National Forest Management Act (NFMA), Alternative A in this FEIS.
Formulation of Alternatives - The Process

Overview

The purpose of forest planning is to formulate and select an alternative that most nearly maximizes net public benefits. Net public benefits are defined as the "...overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not...consistent with the principles of multiple use and sustained yield" (36CFR 219.3).

Forest planning and the National Environmental Policy Act (NEPA) are both issue-driven processes. Maximization of net public benefits and responding to issues are, therefore, related. Net public benefit is not to be confused with present net value (PNV), which is the difference between discounted costs and discounted benefits. The Preferred Alternative may not have the highest PNV but should have the highest net public benefit in the judgement of the responsible official.

Both priced and non-priced outputs and effects must be considered when addressing net public benefits. Priced outputs are those for which there is an established value. It may be a market value such as that assigned to timber, developed recreation, minerals, and range, or a non-market value such as that assigned to dispersed recreation, wildlife, wildlife related recreation, and wilderness recreation. Non-priced outputs are those which have no established value, such as scenic quality, cultural resources, and water quality. The formulation of a range of alternatives involves, therefore, an economic evaluation of priced outputs, and a subjective evaluation of the amenities the Forest offers, such as scenery, water quality, and recreation opportunities.

The planning regulation (36 CFR 219 12(e) and (f)) requires an analytic process, which includes an inspection of various minimum and maximum production levels and economic factors. In addition, the range of alternatives must respond to management concerns and include alternatives which reflect current and national programs, such as RPA.

Some alternatives represent management of the National Forest or Grassland to maximize the production of priced commodities such as timber and forage, whereas other alternatives could emphasize non-priced amenities, such as dispersed recreation, wildlife, and scenic qualities. One alternative, the No Action Alternative, reflects the objectives of the Forest Service National program. Some alternatives, departure alternatives, have an altered timber harvesting schedule to meet specific needs.

Alternatives must be responsive to public issues, management concerns, and resource opportunities. Finally, the alternatives must reflect resource capabilities, in terms of both limitations and potentials, of the many different areas of the Forest. The potential of the Forest to produce goods and services is compared to projected demand and supply potentials for those same goods and services in Central Oregon. The ability of the forest to supply goods and services in response to society's demands was determined in the Analysis of the Management Situation (1984) and is reflected in the range of alternatives in this FEIS. In summary, the Interdisciplinary Team formulated the alternatives using the issues and concerns as the starting point, considering the Forest's capabilities, and addressing both priced and non-priced resource outputs to create a range of alternatives.

From this range of alternatives, a preferred alternative is selected. The preferred alternative is the alternative which, in the opinion of the Regional Forester, comes closest to maximizing net public benefit as defined above and is responsive to public issues.
The process and chronology for the preparation of the Forest and Grassland Plans follows:

Resource Inventories

The physical inventory of the forest resources and their productive potential is a major part of the analysis process. Resource information was collected on a common map base, with different layers developed for various resources and inventory components. Inventories of the character, potentials and limitations of the Forest and Grassland were conducted. Areas of the Forest and Grassland were with similar physical and biological characteristics were stratified into "capability areas." These homogeneous areas are expected to have a somewhat uniform response to any particular management prescription. The inventory and the development of capability areas and their function in the analysis process is further discussed in Appendix B of this FEIS.

Public Issues, Management Concerns and Opportunities (ICO's)

Public issues, management concerns and opportunities are the beginning basis of forest planning. The ICO's drive the planning process. To develop alternative ways of managing the land and resources, it is necessary to determine what is important to the public who benefit from the Forest. In the Fall of 1980 the Forest began to identify the principal issues to be addressed in the draft Forest Plan. A decision was made to build on the previous issues identified for the existing unit plans. Interest groups were used as a starting point and were invited to identify preliminary issues that could be expanded or refined by a broader audience. These key interest groups met with the Forest Interdisciplinary Planning Team (IDT) at six meetings held during the fall, 1980. From the meetings, 125 preliminary issues, concerns, and opportunities (ICO'S) were identified. The IDT then consolidated these ICO's into 60 issues and submitted this list to the public along with a request for response. In addition, public involvement was requested through various news media. The interdisciplinary team also conducted six public meetings to gather additional public comment. The information that was gathered was used to consolidate the issues into resource and/or land use topics. Seventeen issues were developed from this exercise. Further consolidation resulted in twelve issues being displayed in the DEIS.

Since those meetings, the Forest has used a variety of methods to keep its employees and the local communities informed of the planning process. We published periodic articles and special editions in our Forest and Grassland report (we prepared and distributed a Forest Plan Report). During the sum-

2-4
mer and fall of 1985 we had multi-resource media coverage, providing information and education on Forest Management. Through a networking process, each Management Team member has been contacting key individuals in our local communities, informally discussing Forest management and the planning effort and validating our course of action for the final Forest and Grassland Plans.

Eleven alternatives were drafted for public review in the DEIS in September 1986. Alternative E-Degarure was selected as the preferred alternative. During the 90-day comment period, the Forest received over 2,150 responses, which included over 20,000 specific comments. The Forest considered this public input and modified the issues, modified some of the alternatives and created two new alternatives.

A Supplement to the DEIS was prepared in response to Forest Industry taking issue with some of the methods used in forest planning by National Forests in the Pacific Northwest. They were concerned with how the “No Action” Alternative was described, and the methods used to address Forest planning management requirements. The Supplement to the DEIS described a new alternative, Alternative NC, and analyzed alternative levels of management requirements. The Supplement was published in October 1988, and the 90-day public review period ended January 17, 1989. The Forest received nearly 200 letters in response to the Supplement. The results of the public response period for the Supplement are also discussed in Appendix I of this FEIS.

Significant steps were employed during the last 3 months of final document preparation to insure that direction in the Final Plan responded accurately to comments received on the Draft. Meetings were held, and contacts made with selected groups, individuals, agencies and political leaders in order to:

- Validate public responses received during the process;
- Insure that we correctly interpreted what was said;
- Insure that we did not miss something or overlook stumbling blocks towards successful implementa-

Set the stage for implementation of the Plan.

This networking followed our efforts in seeking broad public review of our draft documents. During this time, 39 meetings have been held with more than 289 citizens, and 69 interest groups or agencies. In response to this effort, when appropriate, adjustments were made to the final planning documents.

The details of the public involvement process and the development of the ICO’s is further discussed in Appendix A. The changes between the DEIS and FEIS are highlighted in the Summary and in the Record of Decision.

Analysis of the Management Situation (AMS)

The document titled “Analysis of the Management Situation,” Ochoco NF and Crooked River National Grasslands, Nov. 1984, provides a description of the Forest’s environment and an analysis of the Forest’s potential to provide both market and non-market resources and services (see Ochoco National Forest planning records).

Information from the AMS was used to further define the alternatives presented in the DEIS and this FEIS. Specifically, the AMS was used to:

- Define the maximum potential of the Forest to produce resource outputs for selected market and non-market goods.
- Evaluate the complementary and conflicting relationships between market and non-market goods the Forest could produce.
- Analyze the efficiency and implications of constraints placed on the alternatives to meet legal, policy, or resource management requirements.
- Identify the range within which alternatives could be developed.
- Determine if current management direction is satisfactory or if there is a need to change.

Summary of Supply and Demand

Projected supply and demand for selected resources is discussed in Chapters 2 of the Forest and Grassland Plans. This information is repeated in this chapter of the FEIS to supplement the comparison of alternatives and is also discussed again in Chapter 3 in this FEIS.

Identification of Alternative Themes and Objectives for the DEIS

Different “themes” and “objectives” were developed to help ensure a range of reasonable alternatives. Based on the minimum and maximum resource output levels (benchmarks) developed in the AMS, a number of output levels for each issue or concern were established. In some cases outputs represented production levels, such as volume of wood, and in other cases they represented conditions, such as acres of “old growth habitat.” The alternative themes and objectives were created by grouping that, in the planning team’s judgement, appeared to be compatible output levels for each issue or concern. Each output level for every issue or concern was incorporated into an alternative, in order to assure that the appropriate range of alternatives was considered.

In a second stage of alternative theme and objective evaluation every identified issue or concern was addressed to ensure that it was resolved in at least one alternative, and then tested to assure that the resulting alternative was significantly different from others. As a result of this step, some preliminary alternatives were consolidated and further refined, while others were eliminated.

The Regional Forester and his Directors reviewed the Ochoco AMS and proposed alternatives in December 1984. The alternative themes and objectives were approved with a few relatively minor refinements. It was decided that three of the eight alternatives should be evaluated and fully developed with timber harvest schedules that depart from nondeclining yield. Thus, a set of eleven alternatives were analyzed in the development of the Forest Plan DEIS.

Determination of Management Areas

Different ways of managing the Forest and Grassland were developed as “management prescriptions” during the AMS stage described earlier. “Management areas” are delineated by applying a management prescription to a particular piece of land. To a large degree it is the mix of management areas in an alternative that determines the levels of outputs and conditions that result.

Each potential management area was analyzed to develop trade-off information. The FORPLAN model was used to assist in this process. The next section in this chapter describes the Ochoco FORPLAN model in general, and Appendix B describes the model and analysis process in detail. Relative impacts on present net value (PNV), big game numbers, and timber outputs were assembled for each potential management area. Using this data and other information presented on the relative benefits of managing one area versus another under a given management prescription, an expanded Forest Management Team assigned priorities to management areas for each alternative. Using these priorities, and the alternative themes and objectives, final management area maps were developed for each alternative in the FEIS.
Management Activity
Scheduling, Cost Efficiency and Feasibility Testing

After management areas were defined for each alternative, the Forest scheduled management activities over time with cost efficiency, using FORPLAN. Each alternative was “run” with all specified resource objectives being treated as constraints. This then led to a cost efficient schedule of activities by maximizing present net value.

A series of “feasibility screens” were performed on the scheduling results for each alternative. Criteria considered included: 1) timber volume available in the Burns-Hines area over time, 2) timber species mix, 3) logging systems, 4) reforestation methods, and 5) ability to meet watershed protection requirements. Adjustments needed to produce realistic alternatives were made, and the alternatives were adopted for additional analysis and evaluation in the DEIS.

Refinement of Alternatives from the DEIS to the FEIS

The public responses to the DEIS and the supplement to the DEIS have been used to refine the ICO’s along with management concerns. The result has been the development of separate plans for the Forest and Grassland. The specific refinements of the alternatives carried forward in this FEIS are discussed for each alternative in the section on alternatives in this chapter (pp. 2-21 through 2-54). As has been noted, the changes from the Draft to the Final have also been discussed in the Summary to this FEIS.

Between the DEIS and the FEIS some data was changed, some processes were altered, and some additional analysis was performed. Those changes are summarized as follows:

New Prescriptions and Yield Streams Applied in the FORPLAN Model

- Uneven-aged timber management applied to ponderosa pine on general forest (20” target size).
- Uneven-aged timber management applied to ponderosa pine in special areas with 30-inch DBH target size: Lookout Mountain, Stein’s Pillar, Deep Creek, North Fork Crooked River.
- Uneven-aged timber management (group selection) applied to mixed conifer in some areas.
- Extended rotation ages and new thinning cycles for ponderosa pine in general forest.
- More reliance on mixed conifer to produce cover.

Acres and Timber Yield Tables

- Acres - Condition classes (i.e. the amount of pine sawlogs, saplings, etc.) have been updated from the 1983 information used in the DEIS. This was done to more accurately assess timber harvest scheduling and its associated outputs and effects.
- Timber Yield Tables - Yield tables were updated to reflect the growth that has occurred in the last five years in order to more accurately determine outputs and effects.

Other

- New elk coefficients.
- New Habitat Effectiveness model for elk.
- Standard view shed procedures eliminated in favor of set width (1200 ft.).
- New riparian analysis and scheduling based on updated stream condition inventory.
- Potential water developments for livestock and wildlife were re-evaluated. Existing old growth inventory was updated.
- Anadromous fisheries were identified, the analysis included resource production relationships and economic parameters.
Potential for mineral exploration and leasing, and the economic value of mineral leases incorporated.

Potential for capital investments concerning developed and dispersed recreation, including trails, was re-evaluated.

Some changes were made to the cost and values data between the DEIS and the FEIS. These changes are detailed in Appendix B, Section IV, Economic Efficiency Analysis. Generally the number of changes were limited in scope. They included addition of data for mineral leases and anadromous fisheries which were ignored in the Draft. A review of the individual resources and their potential to significantly affect present net value and the comparison of alternatives, and potentially the decision, became the primary decision criteria for making any changes.

FORPLAN and the Analysis Process

Description of FORPLAN

Alternative development and evaluation for an entire National Forest has proven to be a complex process during which an enormous amount of information must be considered. Because of this complexity, several interconnected computer models and analytical tools were utilized to help develop alternatives and to evaluate their associated outputs and effects. The central model for this analysis process is called FORPLAN (FORest PLANning Model). FORPLAN is a computerized linear programming model which allows a great deal of flexibility in formulating a mathematical representation of forest management interactions and activities. The major purpose of FORPLAN is to assist selection of the most efficient method of achieving goals and objectives, primarily timber management. Tens of thousands of management options, or combinations of options, can be considered simultaneously by FORPLAN. The FORPLAN model was designed and used to analyze the economic and output trade-offs associated with the different emphases provided by the ICOs. A brief discussion of the Ochoco FORPLAN model is contained in the following paragraphs. A detailed description can be found in Appendix B.

The first key step in the development of the FORPLAN Model was to identify the "analysis areas" for the Forest and Grassland. Analysis areas are tracts of land with similar ecological characteristics that result in similar costs, outputs, and effects in terms of the model. These units have significant physical, biological, and economic differences in the way they respond to alternative management prescriptions. For example, an analysis area on the Forest may be two-storied ponderosa pine stands, on steep slopes, contained in roadless areas located on the Big Summit Ranger District.

In the FORPLAN model analysis areas were assigned to "management prescriptions" to achieve resource management objectives for particular benchmarks or alternatives. The prescriptions are associated with particular management areas and contain sets of standards and guidelines describing how forest resources in that area are to be managed. Development of prescriptions was a major step in the modeling. Forest interdisciplinary teams designed prescriptions to achieve a range of goals and objectives based on the ICOs. From six to ten different management prescriptions were prepared for each analysis area depending on its resource capabilities.

The management prescriptions and associated standards and guidelines were represented in FORPLAN as "coefficients." In other words, the costs, outputs, and effects of applying a prescription to an analysis area had numerical values in the model. Such things as the dollars required, forage produced, timber
harvested, and effects on elk habitat made up the core of the model. Different timing patterns were also allowed. These specific options concerning how to manage a particular piece of land over time, then, served as the basis for choice in FORPLAN.

The prescriptions FORPLAN selected depended on the “objective function” and the set of “constraints” used to represent a particular benchmark or land management plan alternative. The objective function served as the overall driving force for the model and usually maximized present net value. Constraints designed to meet all of the multiple resource goals and objectives for a particular benchmark or alternative had to be met first. Once the model had determined that a feasible solution existed by satisfying all of the constraints, it would then search for the set of prescriptions which permitted it to optimize the results according to the specified objective function.

The Analysis Process

Guidance for analysis of alternatives is found in the NFMA regulations (36 CFR 219.12 (f)(8)) as stated below:

“Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in the alternative.”

This requirement was met through design of the FORPLAN model, use of the model to select and schedule prescriptions for each alternative, use of the model in sequential analyses to help design alternatives, and by conducting supplemental analyses. The following paragraphs summarize the types of analyses performed.

The Forest performed several types of analyses in the process of designing and building the FORPLAN model. The purpose of these analyses was to provide a wide range of choice in order to evaluate the significant aspects of cost-efficient prescription assignment.

Major examples of this type of analysis follow:

1. Development of Analysis Areas - Testing different combinations of land classifications leading to use of the analysis area data that appeared to most efficiently reflect economic and environmental factors (Forest Planning Records, 1920/7/83).

2. Cost Efficiency Analysis - Specific modeling prescriptions were developed, tested, and selected based to a large degree on cost efficiency analysis (Forest Planning Records, 1920 9/10/84).

3. Specific modeling procedures themselves were also analyzed for cost efficiency. For example, the Forest elected to manage and model old growth habitat with a dedicated stand system based in part on economic efficiency considerations (Forest Planning Records, 1920 6/21/84). Also, procedures for dispersion of harvest units were adopted to minimize the impacts on present net value (PNV) while meeting dispersion objectives (Forest Planning Records, 1920 6/13/85).

The resulting Ochoco FORPLAN model was used to determine cost efficient prescription assignment and scheduling for each alternative and benchmark.

A number of other different types of analyses were performed in conjunction with FORPLAN runs, both to evaluate different mixes of goals and objectives, and to evaluate choices not explicitly analyzed in FORPLAN. For example, an analysis in the latter category examined the relative cost efficiencies of different management prescriptions and the timing of initial entry, as applied to individual roadless areas. The FORPLAN model was not able to validly analyze these choices with a single model run, so sequential analyses were performed to provide the economic efficiency trade-off data.

Another similar type of analysis examined relative cost efficiencies of different management area locations on the Forest and Grassland as described in Appendix B. The AMS also documented a series of analyses performed to provide a framework for alternative development. In the AMS, different mixes of goals and objectives were examined to provide cost efficiency information relative to the maximum
PNV obtainable, competition between market and assigned values, and current management direction. Opportunity costs of economic assumptions, management requirements, and timber harvest policies were also determined.

Between the DEIS and FEIS, Alternatives B-Modified, C-Modified and E-Departure were updated, and Alternative I was developed for the Forest and Grassland Plans. Alternative A in this FEIS is the “current direction” benchmark from the DEIS. See Appendix B for more detail.

The FORPLAN model, however, is not able to deal with all types of planning questions. Significant situations were analyzed “outside the model” through supplementary analyses. For example, early in the planning process an opportunity to increase domestic livestock forage availability by constructing additional water developments was recognized. An economic analysis of the proposed investments was conducted and the results used in the various benchmarks and alternatives. Another example is the elk habitat effectiveness index (HEI). The HEI is developed from a model outside FORPLAN, which uses cover quantity, cover quality and road density to evaluate the quality of elk habitat. Forage availability is not a factor in this model. An analysis of forage availability for livestock and wildlife on the Forest and Grassland showed that forage availability is not a limiting factor for elk habitat on the Forest (this analysis is available in the planning records located at the Ochoco National Forest headquarters in Prineville, OR.). Forage availability will, however, be looked at on a project basis during implementation of the plans and the resultant allotment management plan revisions.

Land Allocations

Management of certain areas of the Forest remain constant in all alternatives due to existing legislative or administrative requirements. The Forest does not have the authority to change the management of these areas. Such places include Wildernesses and Wild and Scenic Rivers. Areas of the Forest not held constant because of legislative or administrative requirements are assigned to management areas. There are 28 management areas on the National Forest and 16 on the National Grassland in Alternative I. These are not contiguous areas, but rather, each area represents a different management emphasis. For example, Management Area 20 emphasizes management of winter range for big game and is found in various places across the Forest, as may be other management areas. The maps accompanying this FEIS display management emphasis. The management areas are actually aggregates of those emphases.

Land use allocations (management areas) are not displayed for Alternative NC. A discussion of land classification can be found in the 1979 Timber Resource Plan.

During the planning process, the Interdisciplinary Team developed management strategies, called management prescriptions, for each management area. Each management strategy emphasizes a particular resource or use, or it incorporates legislated allocations such as wilderness. All management strategies meet all management requirements (see discussion that follows). Each of the management strategies was represented in alternatives where the area allocated was capable of attaining the desired future condition.

Management Requirements

Many laws and regulations guide Forest Service activities. One law in particular, the National Forest Management Act of 1976 (NFMA), and its implementing regulations, provides direction for the forest planning process. The regulations for National Forest System Land and Resource Management Planning, in Section 36 of the Code of Federal Regulations, Part 219 (36 CFR 219) specify: 1) the minimum specific management requirements to be
met in accomplishing the goals and objectives of the National Forest System (36 CFR 219.27), and 2) the minimum requirements for integrating individual forest resource planning into the forest plan (36 CFR 219.14 through 219.26).

Some requirements are procedural and need not be addressed here. Some were analyzed and available for public review during the environmental analysis for the Regional Guide and are omitted as well. The management requirements treated in the supplement to the DEIS that required additional analysis were: size and dispersion of created openings, providing adequate habitat to maintain viable populations of existing native vertebrate species and water quality. A more thorough discussion of management requirements is presented in Appendix F.

The management requirements from the planning regulations (36 CFR 219.27) are legal requirements, and as such are ends that must be achieved on the ground when the forest plan is implemented. For example, the NFMA implementing regulations require that fish and wildlife habitat be managed to maintain viable populations of existing native vertebrate species and desired nonnative vertebrate species in the planning area. Whatever implementation methods are chosen, this—and all other management requirements—must, by law, be met.

Specifications or standards for achievement for each management requirement are established at the national level or through analysis at the regional level for most of the management requirements. These are listed in the regulations or as standards and guidelines in the Regional Guide. Additional specifications identified on the Forest are listed as standards and guidelines in the Forest and Grassland Plans and in the FEIS Appendix D.

Often, the pool of scientific knowledge is insufficient to provide the entire basis for defining the specific conditions or standards that will satisfy or meet a management requirement. When this happens it is necessary to rely on field experience, to use professional judgement of knowledgeable professionals and to establish monitoring and research that will provide better information for future planning efforts.

Implementation methods are the means or ways of meeting the ends (management requirements). Using the pileated woodpecker as an example, the end is to provide adequate habitat to maintain a viable population of pileated woodpeckers into the foreseeable future. The means of providing this habitat involves designing and implementing a set of practices that will assure that nesting and feeding areas meeting the needs of pileated woodpeckers are available in the future. These habitats are to be located closely enough together to allow woodpeckers occupying adjacent habitat areas the opportunity to interact, thus maintaining genetic diversity and viability of the species.

Unfortunately, the distinction between ends and means is not always clear. For example, the requirement regarding viable populations of vertebrate species, stated above, is well defined. In contrast, the size and dispersion of created openings management requirement (end) is rather general: NFMA specifies that maximum size limits for areas to be cut in one harvest operation be established for areas to be clearcut (SEC.6(G)(3)(F)(IV)), but does not specifically state the objective (end) to be accomplished by doing so. Nonetheless, the implementing regulations and the Regional Guide have specified maximum unit sizes and dispersion requirements.

Often there is more than one way of achieving a management requirement. Considering and analyzing different means (or ways) of meeting a specific management requirement are particularly important if there are potentially large opportunity costs involved. The Forest and Grassland, through analysis, identified three management requirements that had opportunity costs greater than or equal to two percent. The methods of implementing these three management requirements were also analyzed. Appendix F to this FEIS provides a detailed discussion of the management requirements used in the planning process, their opportunity costs and the alternative methods of implementing each of them, for the Forest and Grassland. In addition, the BMP’s for water quality (one of the MR's) are discussed in Appendix G.
Role and Use of Benchmarks

Benchmarks are calculations of the maximum output, production, or economic opportunities for a forest. They are similar to alternatives; they are a combination of management strategies, land capability, and activity schedules, the same “what, where, and when” considerations of alternatives discussed previously. Unlike alternatives, they are usually not capable of actually being implemented because they lack a consideration of specific geographic locations, environmental effects, compliance with management regulations, and generally do not respond to issues, concerns, and opportunities. They do provide significant information about the maximum biological and economic production potential. By showing potential, the benchmarks help to define the decision space within which alternatives could be developed.

Some benchmarks are economically based, while others indicate the maximum physical productivity of land for various resources. In benchmark analyses, each option must include meeting minimum management requirements of 36 CFR 219.27, such as protecting the productivity of the land and meeting minimum air and water quality standards. There are several benchmarks that are required by the regulations (36 CFR 219.12(e)) and National direction. They include:

Minimum Level: The minimum level benchmark displays outputs which would occur if management activities were reduced to levels necessary to keep the land in National Forest ownership, while meeting essential minimum environmental constraints and providing for the protection of life, health, and safety of incidental users. The Forest would be managed at a custodial level. Natural ecological succession would occur. Except for minimum administrative requirements and minerals and occupancy permits, there would be no man-made structures.

Maximum Present Net Value Based on Established Market Price: This benchmark specifies management of the Ochoco National Forest which would maximize the present net value of those outputs that have an established market price, such as timber and developed recreation. This benchmark manages timber subject to non-declining flow. Minimum timber rotations are based on utilization standards (7-inch diameter at breast height).

Maximum Present Net Value including Assigned Values: This benchmark specifies management which would maximize the present net value of priced outputs. Priced outputs include those that have a market price such as timber, and those that are non-market but have an “assigned” value based on what people would be willing to pay in the marketplace, such as dispersed recreation. This benchmark manages timber subject to non-declining even-flow and minimum timber rotations based on 95 percent of culmination of mean annual increment. Recreation and wildlife outputs are significant on the Forest. The difference in PNV between this benchmark and the previous one is primarily due to the added value of recreation and wildlife, with range having a smaller effect. Table 2-5 shows that timber, recreation, and wildlife are the major contributors to PNV on the Forest.

Current Level: This benchmark estimates the outputs and costs on the Forest subject to established management direction in current Multiple Use Plans, Land Management Plans, and specific resource plans. This benchmark was constrained to reflect existing budget levels. Timber is managed for at least 130-year rotations, and harvest is constrained to meet non-declining even-flow. Recreation and wildlife output values are low because low budgets preclude maintaining outputs at standard levels.

Maximum timber Benchmark: This benchmark estimates the maximum capability of the Forest to produce timber in the first decade. This benchmark manages timber to meet non-declining even-flow. Minimum timber rotations are based on 95 percent of culmination of mean annual increment.

Maximum Unroaded Recreation Benchmark: This benchmark estimates the maximum potential for unroaded recreation on the Forest. All inventoried RARE II areas are allocated to roadless manage-
ment providing the largest possible unroaded acreage that is available on the Forest. Timber is managed on remaining lands for minimum timber rotations of 130 years to improve the quality of the recreation experience. Timber harvest is constrained to meet non-declining even-flow.

Other benchmark analyses were conducted to determine opportunity costs of management requirements, the affect of restricting timber harvest rotations to the culmination of mean annual increment (CMAI), and the effect of non-declining flow (NDF) of timber harvest. Table 2-4 displays the required benchmarks done prior to the DEIS along with the selected outputs for each. Table 2-5 shows information on maximum outputs from benchmark analysis by resource compared with outputs for the alternatives.

Assumptions Common to All Alternatives

Some assumptions are common to all alternatives. Among them is requirement that the alternatives meet laws, regulations, and policies that are applicable to the management of the Forest and Grassland. Significant items are noted below.

The selection of harvest systems must conform with the criteria specified in the Regional Guide and the U.S. Department of Agriculture regulations. Additional discussion on the selection of harvest systems is presented in Appendix E to this FEIS.

The Region’s recent direction on vegetation management, “Managing Competing and Unwanted Vegetation” FEIS, Nov. 1988, guides vegetation management activities for the Forest and Grassland and interprets application of the standards found in 36 CFR 219.27(b).

The management requirements, discussed earlier in this chapter, are incorporated into all alternatives except Alternative NC in the Supplement to the DEIS. Only the No Change alternative is carried forward without them. Forest-wide Standards and Guidelines are generally designed to meet resource protection or mitigation required by laws, regulations, or policies. They are common to all alternatives. Resources treated in this manner are: air quality, cultural resources, soil and water, threatened and endangered plant and animal habitat, Native American rights and claims, and human resource programs (see Chapter 4 of the Forest Plan and FEIS Appendix D).

Best Management Practices (BMP’s) are specifically designed to protect water quality, as required by Section 208 of the Clean Water Act. General BMP’s will be selected and tailored for site-specific conditions to arrive at project-level BMP’s for the protection of water quality (see Appendix G).

Range of Alternatives

Overview

A range of alternatives was formulated according the requirements of NEPA and NFMA. The alternatives were designed to address the issues from the public involvement process and validation phase between the DEIS and this FEIS. Decision space for alternatives was defined through the analysis of the management situation and the benchmark analysis and evaluation previously discussed. Additional discussion of the formulation of alternatives is provided in Appendix B to this FEIS.
Required Alternatives

Information generated by the benchmark analyses was used by the Interdisciplinary Team to construct alternatives. Among the alternatives formulated were several required by regulation, and National as well as Regional direction. These alternatives were reviewed against the public comments to the DEIS and carried forward intact or with modifications, or they were eliminated from further consideration as listed and briefly described below:

Current Direction (No Action, Alternative A): This is the “No Action” alternative required by the Council on Environmental Quality (CEQ) regulations (40 CFR 1502.14). This alternative continues management of the Ochoco National Forest and Crooked River National Grassland according to direction in existing management plans. It is a continuation of existing policies, standards, and guidelines with current budget updated for changing costs over time. It approximates production of current levels and mixes of resource outputs. Current management emphasis is on a mix of timber, big game, and roadless recreation. Alternative ‘A’ represents the “No-Action” alternative herein.

Emphasis on the Current RPA Program (Alternative B-Modified): This alternative determines how the Current (1980) RPA Program attributed to the Ochoco National Forest through the Regional Guide might best be implemented. In the DEIS, Alternative B emphasized RPA timber and range goals, and alternative B-DEPARTURE combined RPA timber, range, and wildlife goals. Alternative B is car-

ried forward in this FEIS with modifications to incorporate both forest industry and other public concerns and data updates. It will be called Alternative B-Modified.

**Emphasis on Nonmarket Opportunities (Alternative C-Modified):** This alternative puts emphasis on water, fish and wildlife, recreation, and other amenity values. Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on amenity values. In the DEIS, Alternative C emphasized amenity values. It is carried forward here with modifications to incorporate public comment and data updates and continues as Alternative C-Modified.

**Emphasis on Nondevelopment and Intensified Management (DEIS Alternative F):** This alternative retains all roadless areas in an unroaded condition while increasing commodity production on those areas already roaded. Its purpose is to strive for high commodity outputs and high roadless recreation management, and intensified management on areas already developed. This alternative was considered in the DEIS but is not carried forward in this FEIS.

**Emphasis on Market Opportunities (DEIS Alternative H):** This alternative emphasized outputs that have an established market price (timber, domestic livestock use, developed recreation opportunities, and minerals) in the DEIS. Management for other resources was at economically and environmentally feasible levels consistent with market-oriented outputs. In the DEIS, Alternative H emphasized market opportunities for the Forest and Grassland. This alternative was considered in the DEIS but is not be carried forward in this FEIS.

**Emphasis on Economic Efficiency (DEIS Alternative H-Departure):**

This alternative emphasized management of outputs with market or assigned values at their most economically efficient levels. In the DEIS, Alternative H-DEPARTURE met this emphasis. This alternative was considered in the DEIS but is not be carried forward in this FEIS.

---

**Departure Alternatives**

Three “Departure” Alternatives (B-DEPARTURE, E-DEPARTURE, and H-DEPARTURE) had the same emphasis and management areas as the alternatives they are based on (B, E, and H respectively) in the DEIS. Their timber harvest schedule was modified to “depart” from a nondeclining flow of timber. Management under the departure alternatives would result in higher volumes of timber harvested in the “near future,” but have lower volumes of timber available for the “intermediate future.” Alternative E-Departure, the Draft preferred alternative, is carried forward here as a reference point. The other departure alternatives are eliminated based on public comments.

**No Change Alternative**

The No Change Alternative, Alternative NC, was developed in response to decisions made regarding appeal number 1588, brought by the Northwest Forest Resources Council on May 19, 1986. The appeal questioned the decision by the Regional Forester to “require inclusion of minimum requirements (MR’s) in the No Action Alternative for each forest plan.” The substance of the appeal was that a “true no-action alternative representing current management plans” was not included in the Forest Plan DEIS’s. The No Change alternative is designed to represent the existing 1979 Timber Resource Plan and unit plans, and consequently does not comply with all provisions of NFMA and regulations promulgated to implement NFMA.

New Alternatives/
Preferred Alternative

A thorough review of the public comment and continuing validation and dialogue with key publics has resulted in the Forest developing a new alternative. The new alternative separates plans for the Forest and the Grassland. It was developed through a complex process of combining publicly supported parts of the other alternatives with Alternative E-Departure. It incorporates new information since the DEIS, such as the passage of the Oregon Omnibus Wild & Scenic Rivers Act. This new alternative, Alternative I, is the preferred alternative.

Alternatives
Considered but
Eliminated From
Detailed Study

Eleven alternatives were developed to address the twelve ICOs identified for the DEIS. Analysis and evaluation of public comment and an administrative appeal resulted in the development of new alternatives (NC in the Supplement to the DEIS, and I in this FEIS), the modification of Alternatives B and C, the replacement of Alternative A to reflect the current situation benchmark, and E-Departure being carried forward as a reference point from the DEIS to the FEIS.

Alternative A in the DEIS has been replaced by the current direction benchmark which incorporates the NFMA requirements and makes the no action alternative one which could be implemented. Alternative A in this FEIS is the no action alternative.

Alternative B was modified by Timber Industry and provided as Alternative B+ between the DEIS and the FEIS. The Forest, in conjunction with Timber Industry representatives, refined B+ and refer to it as B-Modified to represent the Timber Industry proposal for the FEIS. With the exception of E-Departure, the other departure alternatives were eliminated based on the overwhelming public support for staying within sustained yield bounds for the Forest. Alternative C was modified to incorporate data updates and some management emphasis updates. Alternatives D, E, F, G, and H were not carried forward in this FEIS. Their further analysis was not considered necessary at this point, though they have contributed to the consideration of a reasonable range of alternatives in the development of the Forest and Grassland Plans. Based on a thorough review of the public comments and management concerns, it was determined that these alternatives could be eliminated at this point. The modified alternatives carried forward and the new alternatives respond to planning issues considered in the DEIS and offer a reasonable and appropriate range of choice for the decision on the Forest and Grassland Plans.

Alternatives
Considered and
Analyzed in Detail

Description of the Alternatives
Introduction

The alternatives treated, present a reasonable range of implementable approaches to managing the Forest and Grassland. Each is a combination of management activities, practices and schedules which results in a unique combination of resource outputs, land uses, and environmental conditions. They were formulated through an analysis process that explored a wide array of possibilities as shown by the benchmarks and alternatives discussion on pages 2-13 through 2-17.

Resource emphases by alternative are summarized in Table 2-6. Some of the management area allocations can be lumped into resource emphasis categories which summarize land allocations with very similar resource management emphasis.

Allocating lands on the Forest and Grassland into different management areas is a part of the alternative formulation process. For example, a given management area consists of the lands which emphasize a particular resource or combination of resources such as "old growth." Acreages allocated to different management areas vary from one alternative to another. Table 2-7 presents the actual acreage allocations by management area by alternative. Management area maps displaying the allocations are included with the Forest and Grassland Plans.

Management areas are managed according to specified standards and guidelines that provide direction on the types, amounts, and timing of activities. Resource coordination and mitigation are also provided for by the standards and guidelines. Some standards and guidelines were developed by the interdisciplinary team specifically for environmental conditions on this Forest and Grassland. Others were adopted from the Regional Guide. They are found in Chapter 4 of the respective Plans. For other alternatives, they are given in Appendix D of this FEIS.

Alternatives have different land uses being emphasized, different resource outputs, and as a result, different environmental effects. Some of the differences among the alternatives are a reflection of the specific objectives which are incorporated by design.

The land uses, environmental effects, and resource outputs by alternative are summarized in Table 2-8. The interrelationships between resource outputs and environmental effects are discussed in Chapter 4 of this FEIS, Environmental Consequences. Table 2-8 is intended to facilitate comparison of the alternatives.

Mitigation Measures Common to All Alternatives

Mitigation measures are intended to minimize or eliminate potential conflicts or adverse effects of implementation. Mitigation measures have been developed through interdisciplinary efforts and are incorporated into the Plans at different levels in several different ways:

- The standards and guidelines and management area prescriptions in Chapter 4 of the Plans are a fundamental and integral part of these measures, and as such they are a basic and essential part of the Plan.

- Additional mitigation measures in the Forest-wide standards and guidelines and mitigation measures specific to individual management areas are also contained in Appendix D for all alternatives other than I.

- The management area allocations play an important role in mitigation by the separation of incompatible uses, impacts, and conflicts.

- National Forest Management Act (NFMA) requirements were incorporated into the planning process and are reflected in the allocations and standards and guidelines (FEIS Appendices B and D, Plans Chapters 4).

- "General Water Quality Best Management Practices" (USDA Forest Service, Pacific Northwest Region, November 1988. 86p) are incorporated by reference under requirements of Section 319 of the Clean Water Act and are discussed in Appendix H.

- The monitoring plan, which includes provisions for monitoring the effectiveness of mitigation measures, is contained in the Proposed Forest

1/ RNA acreage totals are derived from the final management area mapping and R2 data base acreage calculations. RNA boundaries were slightly modified from the DEIS to the FEIS and consequently the total acreage for the final does not exactly track with that from the DEIS and the discussion of RNA's in Chapter 3 of the FEIS.

2/ An eligibility and suitability evaluation has been made for Squaw Creek. A recommendation and interim management guidance for a Wild and Scenic River designation has been made in Alternative 3-Modified and 1. For those alternatives, 1,375 of unroaded recreation emphasis has been deleted and added to the Wild and Scenic River emphasis.

</table>

* As opposed to the DEIS, the above acres include roads and administrative sites

1/ Entire acreage goes to Partial Retention

2/ Prescription Area A (top) only, remainder to go to General Forest

3/ Does not include connective habitat as in Alternative I

4/ Reduced from that shown in Draft to reflect NFCR Scenic Corridor designation and Deschutes River Scenic Corridor

5/ Reduced from that shown in Draft to reflect NFCR Recreation Corridor designation and Crooked River Recreation Corridor

6/ Reduced from that shown in Draft to reflect NFCR Wilderness Study Area

7/ There are no acres allocated to Semiprimitive Motorized for Alternatives B-MOD, I or A

8/ There are no acres allocated to Partial Retention Middleground for Alternatives B-MOD, I, A, or C

9/ Deschutes Canyon/Steelhead Falls - portions allocated to wilderness for E-DEP. All 10,000 acres allocated to wilderness - Alternative C. None to other alternatives

10/ A portion of the Squaw Creek Management Area is being recommended for inclusion in the Wild and Scenic River System, a total of 1,370 acres for Alternatives B-Modified and I.

</table>

1/ Management Indicator species (MIS) for snag dependent wildlife on the Forest and Grassland are the primary cavity excavators such as the Pileated woodpecker (also see Ch 3 pp 13-16)

2/ Acres are from the 1980 Timber Resource Plan and are adjusted for the Oregon Wilderness Act as per Timber Management Plan Amendment No 1

</table>

3/ Forage production as displayed is the "potential," based on estimates by allotment, that could be achieved with the proposed schedule of range and riparian improvements by alternative. These potentials may not be achieved and are at the minimum, directly dependent upon the implementation of the proposed improvements in the first decade. It is reasonable to expect that some or all allotments may experience up to a 10% reduction in AUM's during the first decade to allow the accomplishment of riparian management objectives.

4/ Steelhead Habitat Capability Index, thousands of small.

5/ Management Indicator Species (MIS) for Old Growth on the Forest is the Pileated woodpecker. The common flicker is the MIS for old growth juniper on the Grassland

6/ NA - Data not available

7/ That which does not currently meet the characteristics described for "suitable", but exists on a site "capable" of producing it some time in the future

8/ This was based on managing these stands with timber harvest with long rotations.

</table>

11/ For the NC alternative, these lands are the regulated commercial forest lands. These lands were not classified using the suitability criteria, but were arrived at using the 1972 land classification system provided for by Amendment #1 of the 1985 Timber Plan. These lands are the standard, special and marginal components of commercial forest lands.

12/ For the NC alternative, these lands are the standard component of the regulated commercial forest base.

13/ Potential yield applies only to the "No Change" alternative and comes from the Timber Resource Plan. The potential yield for the next ten years is the maximum harvest that could be planned to achieve the optimum perpetual sustained yield harvesting level attainable with intensive forestry on regulated areas considering the productivity of the land, conventional logging technology, standard cultural treatments, and interrelationships with other resource uses and the environment.

14/ See Appendix E, Selection of Harvest Cutting Methods.

16/ Old Growth in management areas with no programmed timber harvest.

17/ Toal Old Growth in management areas which is allocated. Old Growth in management areas not allocated but with no programmed timber harvest, and supplemental feeding areas.

** The outputs, effects, activities, and costs included in this table are estimates and projections based on available inventory data, use of various modeling techniques and analyses, professional judgement and are subject to the annual budgetary process.
Mitigation measures are developed at the site specific project level of planning, and projects are "tiered" to other planning level measures above. Management requirements established in accordance with Regional direction (1920, 2/9/83) are a major part of mitigation found in all alternatives. Requirements that may be termed mitigation having substantial influence on management are listed in Figure 2-1.

**Research Natural Areas**

The Ochoco National Forest presently has one established RNA, the Ochoco Divide Research Natural Area. In cooperation with the Federal Committee on Research Natural Areas, the Forest and Grassland has identified five additional areas that would meet the needs for RNA's representative of Central Oregon natural features. These areas have been identified for inclusion in the planning process for consideration in the final Forest and Grassland Plans. The direction for the identification and establishment of RNA's is specified in Forest Service Manual 4063. The RNA's acreages by management area are displayed in Tables 2-6 and 2-7. They are also discussed in Chapter 3, pp. 3-19 through 3-20.

**Alternatives**

This section describes the six alternatives analyzed in detail in this FEIS. For each alternative, the primary goals and objectives are presented along with a description of how the alternatives respond to the ICO's.

**Alternative NC**

**Goal and Purpose**

The "no change" alternative (Alternative NC), described below, was developed in response to the Northwest Forest Resource Council request that a "true" no action alternative representing current management plans be described and included in forest plans and environmental impact statements. Alternative NC is very similar to the no action alternative (Alternative A) described and analyzed in the Draft Environmental Impact Statement. Both do not include the National Forest Management Act (NFMA) requirements and were based on the 1979 Timber Resource Plan and the four unit plans: Ochoco-Crooked River (1979), Silvies-Malheur (1978), South Fork (1978) and Crooked River National Grassland (1980). The Timber Resource Plan and Unit Plans currently guide land and resource management on the Forest and Grassland.

Alternative NC presently differs from draft Alternative A in that it is based on a different computer model, timber inventory, and yield tables. Also, there are some differences in the way old growth and big game habitat are to be managed, resulting in potentially different environmental effects. A Current Direction—NFMA Benchmark, created originally by applying management requirements to Alternative A, is described in the DEIS. It allows outputs and costs attributable to NFMA requirements to be isolated and compared.
Since Alternative NC is based on the existing Timber Resource Plan, it does not incorporate requirements of the National Forest Management Act (NFMA), nor the implementing regulations (CFR 219 14-27, et al). For Alternative NC to be implemented, it would either have to be modified to meet NFMA requirements (as was done with Alternative A in this FEIS), or some NFMA requirements would have to be legislatively amended to allow current practices to be continued.

Management Direction
The following assumptions guided the development of the No Change Alternative:

1. Only NFMA requirements that are a part of current direction as established in current multiple use plans, unit plans, and timber resource plans will be followed.

2. Land allocations and management direction.

   Current plans will be used to fix the land allocation. An exception is where adjustments can be made to reflect updated, improved information on the suitability of land for timber production (this should include new inventory information, new land suitability classifications, etc.).

   Management direction in existing plans will be adhered to in setting the management strategy for management areas.

Yield Tables
Yield tables affect the calculation of long-term sustained yield. The yield tables used in the 1979 Timber Resource Plan (the basis for Alternative NC) were developed in 1975 for the entire Blue Mountain area without benefit of computer models. One set of yield tables was made for each timber type (Appendix D, Timber Resource Plan, 1979). While representing the state-of-the-art at the time they were developed, the predicted yields now appear to be overly optimistic when applied to the Ochoco National Forest because:

   Productivity on the Ochoco National Forest is below the average for the Blue Mountains, and Yields were based, in part, on the expectation that small material resulting from thinning would be merchantable, which, to date, has not happened.

The yield tables used for developing all alternatives except NC are based on prognosis models and adjusted to Ochoco National Forest conditions. Several different combinations of cultural treatments (e.g., planting, thinning, natural regeneration, extended rotation) were simulated and yields projected for each. Each alternative contains a combination of treatments that were selected by the FORPLAN model to best meet forest management objectives particular to each alternative.

Reconciling Unit Plans and the Timber Resource Plan with NFMA
The resource objectives of the unit plans and the Timber Resource Plan, the basis for Alternative NC, were not fully integrated and may not comply with current NFMA requirements. Taken a step further, the Current Direction with NFMA Benchmark, in the DEIS, shows the results of incorporating NFMA requirements into Alternative A. The result is Alternative A in this FEIS.

Modeling, Rotation Ages, and Timber Silvicultural Treatments
The amount of site preparation, planting, thinning, and other timber cultural work modeled in FORPLAN to achieve the resource objectives of Alternative A varies from that described for Alternative NC.

The Timber Resource Plan was modeled using Timber RAM (Resource Allocation Model), a linear program that is less sophisticated than the FORPLAN model used to develop the other alternatives. Timber RAM cannot consider economics or other resource constraints as FORPLAN does. For example, the potential yield in the Timber Resource Plan was based on the assumption that all available acres would be thinned. In reality, it is not economical to thin all stands, e.g., lodgepole stands on steep slopes. All calculations were based on application of shelterwood silvicultural system with planting, but the option of using other prescriptions was left open
(Timber Resource Plan, pp. 15-16) and in practice other methods were used on the Forest. In fact, overstory removal has been the most common silvicultural system applied on the Forest. Rotation age in the old model was fixed at 130 years, but the FORPLAN model can select a rotation age that best meets management objectives. This varies from 95 percent of culmination of mean annual increment (CMAI) to 150 years, resulting in 90 to 100 year rotations in many areas on this Forest.

Terminology
Some of the terms used in the Timber Resource Plan and units plans differ from those used in the DEIS, Supplement to the DEIS, FEIS and the proposed action. For example, "commercial forest," "standard component," "special component," "marginal component," "unregulated" and other old terms have either been redefined or replaced with new terms that have similar, but not identical, definitions. This makes comparing Alternative NC with the other alternatives difficult and confusing (see Glossary).

Timber Inventories
Alternative NC was based on the 1972 timber inventory. Alternative A (and all other alternatives) were based on the 1982 timber inventory. Both inventories were based on photo-typing, that is, delineating timber stands on aerial photographs. The 1982 inventory was field checked to a greater extent than the 1972 inventory.

A difficulty inherent in developing a timber inventory on the Ochoco is that the distinction between forested and nonforested land is not clear. For example, on parts of the Snow Mountain Ranger District and in the Maury Mountains, forested areas grade into the desert with no definable line separating the two. While this could result in acreage differences between the two inventories, the impact on volume would be minimal because the forest-desert transition is low productivity land.

The inventories were also structured differently. The 1972 inventory model was based on percent volume by species, while the 1982 inventory model was based on productivity by community types.

Timber Land Suitability
The method for determining timber land suitability in Alternative NC was different from the NFMA-mandated methods used for Alternative A (and all other alternatives).

The suitable timber base in Alternative NC was taken from the Timber Resource Plan. Land allocations from the unit plans were deducted from the timber base in the reserved or deferred categories, or included as commercial forest land in one of four categories: standard component, special component, marginal component, or unregulated. The commercial forest land in the Timber Resource Plan (adjusted for the Oregon Wilderness Act) is 535,253 acres.

In developing Alternative A (and all other alternatives), tentative timber land suitability was developed according NFMA regulations. The lands identified as tentatively suitable for timber management total 533,177 acres. Final suitability varies by alternative. In Alternative A, 533,177 acres would be available for timber harvesting. The deductions from the tentatively suitable base are primarily the result of land allocations for wilderness, wilderness study areas, RNA's, roadless areas and old growth.

Potential Yield
The potential yield in Alternative NC, represented by the Timber Resource Plan adjusted to reflect the Oregon Wilderness Act, would be 133.8 MMBF. Because these yields include gains assumed but not realized from earned harvest effects (see discussion below), it is questionable whether they could be sustained in the long-run.

The allowable sale quantity (ASQ) under Alternative A would be 19.3 MMCF, or 115 MMBF in the first decade. In addition, the Forest analyzed and displayed two alternatives in the DEIS (B and H) that would generate allowable sale quantities (ASQ) of 137 MMBF approximately the adjusted potential yield shown in the Timber Resource Plan. These alternatives were developed from the maximum timber benchmark and offered options for achieving
high timber harvest levels in the near decades while still meeting one alternative level of NFMA requirements. However, the harvest levels for the alternatives discussed above are sustainable in cubic feet as both models calculated yields and controlled flow in cubic feet but not board feet. Harvest volume in board feet would decrease because the smaller trees that will be harvested in the future will produce fewer board feet in proportion to cubic feet than the large trees being harvested at the present time.

Old Growth
The major difference in the acreage shown in the suitable timber land base between Alternatives A and NC (533,177 versus 552,300) results from the way old growth is proposed to be managed under each. In Alternative NC, the approximately 32,860 acres that would be managed for old growth dependent wildlife is included as commercial forest land in the special component, which means these lands could be harvested, but at 60 to 70 percent reductions in yields. Old growth stands would be about 300 acres each and uniformly distributed over the Forest. Stands would be managed on a long rotation to provide optimum habitat for non-adaptive species in at least one-third of the stands at any time. This would be accomplished by periodic harvesting on a group selection or larger area basis.

In Alternative A, approximately 36,970 acres (29,800 acres of suitable timber land) would be managed as “dedicated” old growth. Dedicated stands would not be harvested and are deducted from the suitable timber base. They would remain in old growth condition unless changed by fire or other natural disasters.

Earned Harvest Effect
In the 1979 Timber Resource Plan the potential yield was increased 7.3 MMBF based on the intent to plant genetically improved stock. This is called the earned harvest effect and it allows additional volume to be harvested today because of practices expected to increase forest growth and yields in the future. In the proposed programmed harvest level, only a 1.1 MMBF increase was claimed because only a small amount of genetically-improved stock was available for planting. Also, the primary silvicultural system used, overstory removal, has not required as much planting as was projected in the Timber Resource Plan.

In Alternative A, FORPLAN selected management practices that would maximize timber production, including thinning and planting genetically improved stock. Thus, the earned harvest effect influences Alternative A, but varies in amount and timing. This makes an exact comparison of the earned harvest effect between the NC Alternative and the other alternatives difficult.

Alternative A

Goal and Purpose
This alternative focuses on management under current direction. It is the “No Action” alternative required by NEPA, and can be used as a basis for comparison with other alternatives. The sources for present direction are:

1. Four “Unit Plans” (Ochoco - Crooked River, Silvies - Malheur, South Fork of the John Day, and the Crooked River National Grassland). These Plans contain specific land use allocations and provide management direction for those allocations.

2. The Timber Resource Plan that provides the basis for the timber management program and specifies allowable harvest levels.

3. Forest Service Manuals and policy memos. Where these sources may conflict, priority was given to the Unit Plans (as per Regional Direction 1920, 11/10/83). Present budget or funding, a type of Congressional emphasis, was considered to continue at current levels under this alternative.

Alternative A is the “Current Direction Benchmark” from the DEIS and not “A” as presented in the DEIS. This alternative does incorporate National Forest Management Act requirements.

This alternative in the FEIS uses eleven of the original 14 management area allocations from the DEIS. In addition, four new management areas
have been added to incorporate the new wild and scenic river allocations. Management under existing plans results in a blend of resource emphases, but the resources (timber, range, big game, roadless, scenic, riparian, and recreation) are all managed at a sustained level substantially greater than minimum and less than maximum potential.

Management Direction

Timber Supply and Forest Management
Timber harvest is scheduled on a nondeclining yield basis. Current direction is to intensively manage timbered stands to the degree consistent with other resource requirements identified in the Unit Plans. This involves planting harvested units with genetically superior seedlings, planting at increased stocking levels, precommercial thinning to control the spacing of trees, one to three commercial thinnings both to harvest trees early and concentrate growth on the remaining trees, and managing for a rotation age close to the point in time where average annual growth is highest. This type of management is planned for the majority of the Forest's acres. Other resource requirements for some lands may either prohibit timber harvesting (old growth and roadless recreation management), lengthen rotations (riparian areas and scenic corridors), or alter thinning practices (big game emphasis areas). The allowable sale quantity (ASQ) in the first decade that results from this mix of practices is 115 million board feet (19.5 million cubic feet).

Social and Economic Wants and Needs of Local Communities
Alternative A ranks fourth amongst the alternatives with a PNV of $421 million. Jobs and payments to the counties would not change significantly with implementation of this alternative. This alternative provides next to the least recreational opportunities and wildlife emphasis and would influence local leisure time opportunities accordingly. Community cohesion would remain about the same as would community stability.

Livestock Grazing and Allotment Management

Current direction is to make forage available for livestock use at levels that do not cause conflicts with other resources. Restrictions on dollars available to the Forest and Grassland limit construction and reconstruction of structural improvements (e.g., water developments and fences), which limits forage availability. Management in riparian areas to meet State Water Quality Standards may also restrict forage availability, particularly when budgetary constraints reduce management options. The forage utilization would be in concert with management practices to rehabilitate riparian areas. There is some likelihood that AUM's on some or all allotments may have up to 10 percent reductions in the first decade to meet riparian area management objectives.

Riparian Management
Current direction for riparian areas entails meeting State Water Quality Standards. This would require improving riparian area conditions from "poor" to "fair" on approximately 7,000 riparian acres. Riparian areas tributary to streams with anadromous fisheries would be managed to provide "excellent" riparian conditions (approximately 5,400 acres).

Transportation System
Eight hundred forty-four miles of road would be maintained for passenger car travel in the first decade. This is estimated to remain relatively constant through the fifth decade. There would be 3,236 miles of road maintained for high clearance vehicles in the first decade, declining to 2,736 miles by the fifth decade. Approximately 944 miles of road will be closed in the first decade, increasing to 1,734 miles in the fifth decade. Roads would be closed to protect the investment, to provide for public safety, to limit soil erosion and water quality degradation and to increase wildlife habitat effectiveness.

Big Game Habitat
Big game habitat receives primary management emphasis on 93,800 acres. On these areas, road use and thermal cover quantity, quality, and distribution would be controlled to provide high quality big game habitat. Three thousand three hundred-seventy elk could be supported through the first decade. This
number would decline steadily to 2,690 by the fifth decade. This alternative exceeds the ODFW management objective of 2,600 elk.

Roadless Areas and Wilderness Study Areas

Lookout Mountain, Deschutes Canyon-Steelhead Falls, and Silver Creek would be managed to maintain their roadless character. Green Mountain and the Rock Creek-Cottonwood Creek area would be managed as a general forest allocation. The North Fork of the Crooked River would be retained as a Wilderness Study Area, 1125 acres, until a decision is made on the pending BLM environmental analysis. The Deschutes Canyon-Steelhead Falls area would be recommended for wilderness in its entirety, 10,000 acres less the wild and scenic river allocation (MA-D8).

Segments of the North Fork Crooked River, Crooked River, and the Deschutes River were classified as Recreational or Scenic Rivers under the Oregon Omnibus Wild and Scenic Rivers Act. Four new management areas have been developed to incorporate these legislated areas into Alternative A equaling 4030 acres. These include MA-23 North Fork Crooked River Recreation Corridor, MA-24 North Fork Crooked River Scenic Corridor, MA-G6 Crooked River Recreation Corridor and MA-G7 Deschutes River Scenic Corridor.

A more detailed discussion of the existing roadless areas on the Forest and Grassland is presented in Appendix C.

Scenic or Visual Resources

Corridors along most of the principal roadways throughout the Forest and Grassland would be managed to attain or retain scenic qualities. This amounts to 83,450 acres.

Old Growth

Old growth would receive a comparatively high emphasis, with 36,970 acres dedicated as a management area. This represents 39 percent of the 93,800 acres remaining on the Forest and Grassland.

Fuelwood Supply

Personal use of firewood is provided for on both the Forest and Grassland. Generally, most of the firewood comes from timber harvest residues; some juniper cutting also occurs. Firewood volumes available for use total approximately 14,000 cords annually.

Snag Dependent Wildlife

Alternative A would provide 46 percent to 52 percent of the potential snag habitat an average from the first through the fifth decade across the Forest and Grassland.

Winter Sports

A majority of the Forest and Grassland, including Lookout Mountain and Bandit Springs, would be open to winter sports activities. A cross-country ski trail system is in place at the Bandit Springs area. Snowmobiles would be allowed to access all areas of the Forest except wilderness.

Anadromous Fish

Alternative A would provide for a gradual increase in the production of steelhead smolt over time (see Table 2-8). This increase would be primarily due to the improved riparian habitat gained through improved management practices and stream enhancement work.

Historic Trail Preservation

The Summit Historic Trail would be managed as specified in the Decision Notice issued for this trail in 1986. It would not be allocated as a management area but rather, the appropriate visual quality objectives (VQO's) would be applied and the integrity of the trail preserved.

Off-Road Vehicle (ORV) Use

No all-terrain vehicle (ATV) trail development would occur under this alternative.

Round Mountain

There would be no special management consideration for this area.
Alternative B-Modified (DEIS Alternative B modified to incorporate industry comments)

Goal and Purpose
The design of Alternative B in the DEIS was an attempt to meet the Regional Guide 1980 Renewable Resource Planning Act (RPA) timber and range program targets with a timber harvest schedule based on nondeclining yield. Some of the wildlife-related RPA goals conflicted with timber and range objectives and were not achievable under this alternative. Alternative B focused on intensive management to produce timber and range outputs.

Alternative B-Modified in the FEIS follows the basic philosophy of the original Alternative B but emphasizes other resource management where compatible with timber. For some resources (selected roadless areas, visual corridors, etc), timber volume was given up to provide for these resources. Also, Alternative B-Modified incorporates 39 of the management areas from Alternative I (23 from Forest Plan and 16 from Grassland Plan).

Management Direction
Timber Supply and Forest Management
Timber harvest is scheduled on a nondeclining yield basis. Many of the available timbered lands are managed intensively for timber production in this alternative. This involves planting harvested units with genetically superior seedlings, planting at increased stocking levels, precommercial thinning to control the spacing of trees, one to three commercial thinnings to harvest trees early and concentrate growth on the remaining trees, and managing for a rotation age close to the point in time where average annual growth is highest. The resulting allowable sale quantity is 21.8 million cubic feet (130 million board feet in the first decade). With additional volumes from anticipated salvage sales and firewood, the total cubic foot volume provides 88 percent of the RPA goal for the planning period through the fifth decade.

Social and Economic Wants and Needs of Local Communities
Alternative B-Modified ranks third among the alternatives with a PNV of $455 million. Jobs and returns to the counties would be higher than the current situation. This alternative would increase logging and sawmill industry employment by about four percent (39 jobs) and remanufacturing industry employment by about three percent (35 jobs). The support sector would see a modest increase also.

This alternative provides the least opportunity for leisure activity as it has the lowest level of recreational and wildlife management emphasis.

This alternative provides for high commodity outputs at the expense of amenities, and community cohesion may be affected by the resultant polarization that would surface. Community stability could be a problem if the timber or forage supply was disrupted because of the local economic dependence on the timber and range industries. This alternative would not stimulate the local communities to diversify.

Livestock Grazing and Allotment Management
Potential forage production could build toward and exceed the 1980 RPA program level by the fifth decade, as projected in Table 2-8. This would require construction of 138 acres of structural and 13,100 acres of non-structural improvements in the first decade. The forage utilization would be in concert with management practices to rehabilitate riparian areas. There is some likelihood that the AUM’s on some or all allotments may see up to 10 percent reductions in the first decade to meet riparian area management objectives.

Riparian Management
All riparian areas would be managed to meet State
Water Quality Standards. This would require improving riparian area conditions to “excellent” on 10,000 acres in the first decade, and on 17,500 acres by the fifth decade.

**Transportation System**

Eight hundred fifty miles of road will be maintained for passenger car travel in the first decade with an increase to 869 miles by the fifth decade. There would be 3,037 miles of road maintained for high clearance vehicles in the first decade, declining to 2,492 miles by the fifth decade.

There will be 913 miles of closed road in the first decade increasing to 2,123 miles in the fifth decade.

**Big Game Habitat**

Big game habitat would see some management emphasis on 171,490 acres of General Forest Winter Range on the Forest and an additional 35,440 acres on the Grassland. An average of 3,210 elk could be supported through the first decade. This number would decline steadily to 1,700 by the fifth decade. This alternative would fail to provide the ODFW planning benchmark of 2,600 elk in the fifth decade.

**Roadless Areas and Wilderness Study Areas**

Portions of Lookout Mountain, Deschutes Canyon-Steelhead Falls and Silver Creek would retain their roadless character with no scheduled timber harvest. A portion of the Deschutes Canyon-Steelhead Falls Wilderness Study Area (which was not made wilderness in the 1984 legislation), has been allocated to the Squaw Creek Management Area for unroaded recreation. The North Fork of the Crooked River Wilderness Study Area would be retained, 1,125 acres.

Segments of the North Fork Crooked River, Crooked River, and the Deschutes River were classified as Recreational or Scenic Rivers under the Oregon Omnibus Wild and Scenic Rivers Act. Four new management areas have been developed to incorporate these legislated areas into Alternative B-Modified (MA-F23 North Fork Crooked River Recreation Corridor, MA-F24 North Fork Crooked River Scenic Corridor, MA-G6 Crooked River Recreation Corridor and MA-G7 Deschutes River Scenic Corridor).

Eligibility and suitability determinations have been made for a portion of the Squaw Creek area. A 7.5 mile segment of the creek, 1,370 acres, from the Grassland boundary to the confluence with the Deschutes River would be managed as a “scenic river.” In addition, it would be recommended for inclusion into the Wild and Scenic River System. This would be a preliminary recommendation that would receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.

A more detailed discussion of roadless areas on the Forest and Grassland is presented in Appendix C.

**Scenic or Visual Resources**

Corridors along most of the principal roadways throughout the Forest and Grassland would be managed to retain scenic values. Approximately 34,400 acres would be allocated to management areas with visual resource emphasis. This would include visual management zones along certain travel corridors such as Highway 26.

**Old Growth**

Old growth would receive low emphasis under this alternative, with 18,740 acres dedicated as a management area allocation. This represents 20 percent of the 93,800 acres remaining on the Forest and Grassland. The remaining old growth on the Forest outside the allocation by the fifth decade would be approximately 42,400 acres, 45 percent of the existing 93,800 acres.

**Fuelwood Supply**

Personal use of firewood would continue to be provided on the Forest and Grassland. Generally, most firewood would come from timber harvest residues. In the first decade, 15,000 cords would be provided annually. This figure would decrease to 13,000 cords by the fifth decade.
Snag Dependent Wildlife
Alternative B-Modified would provide 43 percent to 33 percent of the potential snag habitat from the first decade through the fifth across the Forest and the Grassland. The decline over time would be the result of intensive timber management.

Winter Sports
A majority of the Forest and Grassland would be open to all users including Lookout Mountain. The Bandit Springs Area would be managed for cross-country skiing. Snowmobilers may access all areas of the Forest except for Bandit Springs and wilderness.

Anadromous Fish
Alternative B-Modified would provide a steadily increasing production of steelhead smolt over time (see Table 2-8). The increase is generally representative of the improved riparian area conditions over time through management practices and enhancement projects.

Historic Trail Preservation
The Summit Historic Trail would be managed to protect its historic qualities. It would not be allocated as a management area, nor would there be any special provisions. The appropriate VQO's would be applied to protect its scenic qualities.

Off-Road Vehicle (ORV) Use
Under this alternative, steps would be taken to construct, reconstruct and designate existing trails for ORV use. The schedule calls for 95 miles in the first decade, increasing to 190 miles by the third through fifth decade. Some area closures would also be implemented in conjunction with trail designations and the identification of resource impacts.

Round Mountain
The scenic qualities and recreational opportunities supplied by the Round Mountain Trail would be recognized under this alternative through the allocation of 1,000 acres as the Round Mountain Management Area.

Alternative C-Modified
Goals and Purpose
Alternative C-Modified emphasizes resources associated with amenity values, for example, riparian areas, visual corridors, roadless areas, recreation, and forest management designed to provide big game habitat. Old growth and snags would also be provided at high levels. Timber and range resources would be managed at relatively low levels.

This alternative in the FEIS uses 11 of the original 14 management area allocations from the DEIS. In addition, four management areas have been added to incorporate the new wild and scenic river allocations.

Management Direction
Timber Supply and Forest Management
Timber harvest is scheduled on a nondeclining yield basis. Timber management activities which are most economically efficient would be used while meeting other resource objectives. Other resource requirements for this alternative would either prohibit timber harvesting (old growth and roadless recreation management), lengthen rotations (riparian areas and scenic corridors), or alter thinning practices (big game emphasis areas). Approximately 170,000 acres of ponderosa pine stands with the appropriate characteristics would be managed under an uneven-aged management strategy. The allowable sale quantity in the first decade that would result from this mix of practices is 94 MMBF (15.6 MMCF).

Socio-Economic Analysis
Alternative C-Modified ranks fifth amongst the alternatives with a PNV of $395 million. Jobs would see a significant drop under this alternative. Employment in the logging and sawmill industries would decrease by about two percent (21 jobs) and in the remanufacturing industry by about four percent (55 jobs). Other segments of the economy would see a slight gain in employment through the diversification of the local economy that this alternative would stimulate. This alternative could enhance community stability in the long run, but the short-term effect would be destabilizing.
Returns to the counties would be the lowest of the alternatives discussed.

This alternative would provide the highest level of recreational, scenic and wildlife emphasis, and therefore would provide increased opportunities for leisure time pursuits. This heavy emphasis on amenities would disrupt community cohesion in the short run.

**Livestock Grazing and Allotment Management**

In the first decade forage would be made available for livestock use at levels slightly lower than is currently provided. Heavy emphasis on the improvement of riparian conditions and timber management designed to maintain dense timber stands for big game cover, account for the diminished level of forage for livestock use. As riparian conditions improve in the future more forage would likely be available. AUM’s are expected to increase only slightly from present levels (from 73,100 to 74,400 AUM’s).

**Riparian Management**

All major streams with existing or potentially significant fisheries will be managed to achieve an “excellent” condition. This will require improving 10,000 acres by the end of the first decade and a total of 17,500 acres by the end of the fifth decade.

**Transportation System**

Eight hundred forty miles of road will be maintained for passenger car travel in the first through fifth decades. There would be 2,384 miles of road maintained for high clearance vehicles in the first decade, a decrease of 26 percent compared to the current situation. By the fifth decade, this would decrease to 1123 miles.

An estimated 1,520 miles of road would be closed in the first decade, increasing to 3,224 miles in the fifth decade.

**Big Game Habitat**

Big game habitat receives primary management emphasis on 732,530 acres. In these areas road use and cover quantity, quality, and distribution would be controlled to provide high quality big game habitat. A population of 3,740 elk could be supported through the first decade, decreasing to 3,700 by the fifth decade. This alternative would exceed the ODFW planning benchmark of 2,600 elk.

**Roadless Areas and Wilderness Study Areas**

The Silver Creek, Rock Creek/Cottonwood Creek, and Lookout Mountain roadless areas would be managed to maintain the present roadless character. Green Mountain would be partially developed to provide a semiprimitive setting with primitive roads for recreational use. All of Deschutes Canyon would be recommended for Wilderness in this alternative, 9,350 acres, except for that portion that has been incorporated into the Wild and Scenic River System. The North Fork of the Crooked River would be retained as a wilderness study area, 1125 acres.

Segments of the North Fork Crooked River, Crooked River, and the Deschutes River were classified as Recreational or Scenic Rivers under the Oregon Omnibus Wild and Scenic Rivers Act. Four new management areas have been developed to incorporate these legislated areas into Alternative A (MA-23 North Fork Crooked River Recreation Corridor, MA-24 North Fork Crooked River Scenic Corridor, MA-G6 Crooked River Recreation Corridor and MA-G7 Deschutes River Scenic Corridor).

A more detailed discussion of roadless areas on the Forest and Grassland is presented in Appendix C.

**Scenic or Visual Resources**

Corridors adjacent to all of the principal roadways throughout the Forest and Grassland would be managed for scenic qualities, totalling 101,100 acres.

**Old Growth**

Old growth would receive a high emphasis under this alternative, with 45,030 acres dedicated as a management area. This represents 48 percent of the 93,800 acres remaining on the Forest and Grassland.

**Fuelwood Supply**

Firewood for personal use would continue to be
provided on both the Forest and Grassland. Generally, most firewood comes from timber harvest residues. Some juniper cutting also occurs. Road closures and the reduced timber harvest activity would limit access to firewood, supplying only 12,000 cords annually.

**Snag Dependent Wildlife**
Alternative C-Modified would provide 51 percent to 69 percent of the potential snag habitat on an average across the Forest and Grassland.

**Winter Sports**
The Bandit Springs area would be managed for cross-country skiers. Snowmobilers may access all areas of the Forest except for Bandit Springs, Lookout Mountain, and wilderness.

**Anadromous Fish**
Alternative C-Modified would provide for a gradual increase in the population of steelhead smolt over time (see Table 2-8). This increase would be primarily due to the improved riparian habitat gained through improved management practices and stream enhancement work.

**Historic Trail Preservation**
The Summit Historic Trail would be managed as specified in the Decision Notice issued for this trail in 1986. Rather than allocate this area as a management area, the appropriate VQOs would be applied and the integrity of the trail protected.

**Off-Road Vehicle (ORV) Use**
Under this alternative, steps would be taken to construct, reconstruct and designate existing trails for ORV use. The schedule calls for 95 miles in the first decade, increasing to 190 miles by the third through fifth decades. Some area closures would also be implemented in conjunction with trail designations and the identification of resource impacts.

**Round Mountain**
There would be no special provisions or allocations for Round Mountain under this alternative.

### Alternative E-Departure - Preferred Alternative in DEIS

**Goal and Purpose**
Alternative E-Departure emphasizes a combination of timber production, roadless recreation, and big game habitat. Timber is scheduled as a departure from nondeclining yield. Timber harvests are scheduled so that first decade volumes remain close to current levels and then decline gradually over the next 50 years. The alternative is designed to maintain local jobs in the short term. All resources are managed or maintained at moderate levels.

This alternative in the FEIS has the same 14 management area allocations as the DEIS. In addition, four new management areas have been added to update the alternative with the new wild and scenic river designations.

**Management Direction**

#### Timber Supply and Forest Management
Timber harvest is scheduled as a departure from the nondeclining yield harvest levels set in Alternative E. The objective is to approximate current harvest levels for one decade and then decline to a sustainable level. The actual trend would be a decline followed by a slight rise and then a leveling off (see Figure IV-2 from the Draft Plan, p. 35). The allowable sale quantity for the first decade would be 20.6 MMCF (123 MMBF), declining to 19.7 MMCF in decade two, and 16.1 MMCF in decade five. All timber would be managed under even-aged management strategies.

Timber management activities which are most economically efficient would be used while meeting other resource objectives. Other resource requirements for this alternative may either prohibit timber harvesting (old growth and roadless areas), lengthen rotations (riparian areas and scenic corridors), or alter thinning practices (big game emphasis areas).

#### Social and Economic Wants and Needs of Local Communities
Alternative E-Departure ranks second among the
alternatives with a PNV of $471 million. Employment in the logging, sawmill, and remanufacturing industries would increase about three percent in the short run, followed by a significant decline. The support and other sectors of the local economy would experience a modest increase. Payments to the counties would increase four percent.

This alternative would not be expected to significantly alter leisure lifestyles or community cohesion. The departure from a nondeclining harvest would adversely affect community stability over time.

Livestock Grazing and Allotment Management
Potential forage production could build over time as projected in Table 2-8. This would require construction of 138 acres of structural and 13,100 acres of non-structural improvements in the first decade. The forage utilization would be in concert with management practices to rehabilitate riparian areas. There is some likelihood that the AUM’s on some or all allotments may see up to 10 percent reductions in the first decade to meet riparian area management objectives. As riparian conditions improve in the future, additional forage could be made available.

Riparian Management
Major streams containing anadromous fisheries, or with high-valued resident trout fisheries, would be managed to achieve an “excellent” condition (9,400 acres). The remaining would be divided equally between “good” and “fair” conditions.

Transportation System
Eight hundred forty miles of road would be maintained for passenger car travel in the first decade, essentially no change from the current situation. This would be maintained out through the fifth decade. There would be approximately 3,050 miles of road maintained for high clearance vehicles in the first decade, only slightly lower than the current situation. Roads open to high clearance vehicles would decrease significantly through the fifth decade to 2330 miles.

A estimated 890 miles of road would be closed in the first decade, increasing to 2082 miles in the fifth decade. Roads would be closed to protect the investment, to protect public safety, to limit soil erosion and water quality degradation, and to increase wildlife habitat effectiveness.

Big Game Habitat
Big game habitat receives primary management emphasis on 253,320 acres of the Forest and Grassland. Most of this represents high priority winter range. In these areas, road use and cover quantity, quality, and distribution would be controlled to provide high quality big game habitat. A population of 3,170 elk could be supported in the first decade, declining to 2,780 in the fifth decade. This alternative would exceed the ODFW planning benchmark of 2,600 elk.

Roadless Areas and Wilderness Study Areas
The Rock Creek/Cottonwood Creek area, Silver Creek and the top of Lookout Mountain, would be managed to retain the present roadless character. The remainder of Lookout Mountain would be allocated to general forest. Green Mountain would be partially developed to provide a semiprimitive setting with primitive roads for recreational use. In the Deschutes canyon, an area of 2,500 acres would be recommended for wilderness. The remainder of the Deschutes canyon would be managed under a big game emphasis. The North Fork of the Crooked River would be retained as a wilderness study area, 1125 acres, until a decision is made on the BLM environmental analysis.

Segments of the North Fork Crooked River, Crooked River, and the Deschutes River were classified as Recreational or Scenic Rivers under the Oregon Omnibus Wild and Scenic Rivers Act. Four new management areas have been developed to incorporate these legislated areas into Alternative A (MA-23 North Fork Crooked River Recreation Corridor, MA-24 North Fork Crooked River Scenic Corridor, MA-G6 Crooked River Recreation Corridor and MA-G7 Deschutes River Scenic Corridor).

A more detailed discussion of the roadless areas on the Forest and Grassland is presented in Appendix C.
Scenic and Visual Resources
Forty-six thousand two hundred acres of travel corridors would be managed for scenic qualities. These include major roads, access roads to roadless management areas, and a special scenic recreation travel corridor on the Big Summit District.

Old Growth
Twenty-six thousand three-hundred and forty acres would be specifically allocated to old growth management. This represents 28 percent of the remaining old growth on the Forest and Grassland.

Fuelwood Supply
Personal firewood would continue to be provided for on both the Forest and Grassland. Generally, timber harvest residues provide the majority of wood gathered. This alternative would supply 13,100 cords annually in the first decade, declining to 10,000 cords annually by the fifth decade.

Snag Dependent Wildlife
This alternative would provide 46 percent to 50 percent of the potential snag habitat on an average across the Forest and Grassland, from the first through the fifth decade.

Winter Sports
A majority of the Forest and Grassland would be open for winter recreation. Bandit Springs would be managed for cross-country skiers. Snowmobilers could access all areas of the Forest except for Bandit Springs, the top of Lookout Mountain, and Wilderness. A special recreation corridor from Bandit Springs east, and south to Lookout Mountain, would be managed to provide pleasing scenery. This corridor would include the Round Mountain Trail.

Anadromous Fish
Alternative E-Departure would provide for a gradual increase in the population of steelhead smolt over time (see Table 2-8). This increase would be primarily due to the improved riparian habitat gained through improved management practices and stream enhancement work.

Historic Trail Preservation
The Summit Historic Trail would be managed as specified in the Decision Notice issued for this trail in 1986. It would not be allocated as a management area, but rather the appropriate VQQ's would be applied and the integrity of the trail protected.

Off-Road Vehicle (ORV) Use
No ATV trail development is planned under this alternative.

Round Mountain
The Round Mountain Trail would be managed as a part of the special recreation corridor from Bandit Springs to Lookout Mountain.

Alternative I (Preferred Alternative)

Goal and Purpose
Alternative I separates the plans for the Forest and Grassland. This is the result of public comment suggesting that the Grassland be handled in a separate plan to maintain its identity as a National Grassland. Alternative I is the final preferred alternative.

The Final Forest Plan expands the number of management areas from 14 in the Draft to 28. The expansion represents the Forest response to the public comments on the DEIS. Emphasis was increased in timber/forage production and recreation. A number of new management areas are designated to emphasize special features, including Stein's Pillar, Bandit Springs and Lookout Mountain.

The Final Grassland Plan expands the number of management areas from eight in the Draft to 16. As with the Forest Plan, the expansion is the result of public comment and new information. The change represents increases in management emphasis for wildlife, recreation, and riparian area management.

Management Direction

Timber Supply and Forest Management
A number of changes to the Draft Plan are incorporated into this alternative. Timber harvest would be scheduled on a nondeclining yield basis and there would be no scheduled harvest from the Grassland. The suitable land base for forest management activities within this planning period is 533,177 acres. Uneven-aged management would be applied to pon-
derosa pine stands with characteristics lending themselves to this type of management. The estimated scheduled timber volumes, harvest type, rotation age or size, and estimated potential contribution to ASQ by management area grouping are:

**Group I**

92,200 Acres - 11%
No scheduled treatment
1. Black Canyon Wilderness
2. Bridge Creek Wilderness
3. Mill Creek Wilderness
4. N.F.C.R. Wilderness Study
5. RNA's
6. Old Growth
7. Summit Trail (preservation)
8. Rock Creek/Cottonwood Creek Unroaded
10. Silver Creek Unroaded
11. Lookout Mountain
28. Facilities

**Group II**

18,130 Acres - 2%
Silviculture - Even- or uneven-aged
Rotation Age - 200 years
Diameter 20''+
Average annual cu ft. volume - 0.3 MMCF
15. Riparian

**Group III**

3,240 Acres - <1%
Silviculture - Even- or uneven-aged
Rotation age - 300 years
Diameter 30''
Average annual cu.ft. yield - <0.1 MMCF
12. Eagle Roosting
17. Stein's Pillar
19. Deep Creek
24. N.F.C.R. Scenic River

**Group IV**

28,110 Acres - 3%
Silviculture - Even- or uneven-aged
Rotation age - Pine 250 years, mixed conifer 200 years

Average annual cu.ft. yield - 0.4 MMCF
7. Summit Trail (retention)
13. Developed Recreation
14. Dispersed Recreation
16. Bandit Springs
25. Hwy 26 Corridor
26. Visual Management - (retention)
27. Round Mountain National Recreation Trail

**Group V**

32,140 Acres - 4%
Silviculture - Even- or uneven-aged
Rotation age - Pine 200 years, mixed conifer 150 years
Diameter - Pine 27'', mixed conifer 22''
Average annual cu.ft. yield - 0.6 MMCF
7. Summit Trail (partial retention)
18. Hammer Creek
23. N.F.C.R. Recreation River
26. Visual Management (partial retention)

**Group VI**

64,130 Acres - 8%
Silviculture - Even-aged
Rotation age - Pine 125 years, mixed conifer 90 years
Diameter - Pine 16'', mixed conifer 15''
Average annual cu.ft. yield - 0.9 MMCF
20. Winter Range

**Group VII**

606,690 Acres - 72%
Silviculture - Even- or uneven-aged
Rotation age - Pine 130 years, mixed conifer 90 years
Diameter - Pine 18'', mixed conifer 16'' (uneven-aged 20'')
Average annual cu.ft. yield - 16.8 MMCF
9. Rock Creek/Cottonwood Creek Helicopter
21. General Forest Winter Range
22. General Forest

The ASQ would be 19.0 MMCF (115 MMBF) per year in the first decade. Of this, approximately 82 MMBF per year for the first decade would be in ponderosa pine. The desired ASQ would be attained through a planned harvest schedule to allow
the reduction from the current situation to the 115 MMBF using a glide path shown in Figure 2-2.

Social and Economic Wants and Needs of Local Communities
Alternative I has the highest PNV of the alternatives, $501 million.

Employment in the logging and sawmill industries would increase about two percent (15 jobs). The commodity resource side of this alternative would provide a stable supply of timber and forage over time, providing community stability, barring any unforeseen disruptions in these supplies. Opportunities would also be created for diversification of the economy due to the increased emphasis on recreation, scenic and wildlife resources.

This alternative would have a positive effect on leisure lifestyles, providing a range of recreational needs and provisions for wildlife habitat. The balanced resource program would have a positive effect on community cohesion.

Livestock Grazing and Allotment Management
This alternative would incorporate new east-side forest utilization standards based on vegetation type, range condition and management strategies. Separate standards are provided for riparian areas and the remainder of the Forest and Grassland

Potential forage production could build as projected in Table 2-8. The emphasis on the improvement of all riparian areas to “excellent” condition, along with 138 acres of structural and 20,980 acres of non-structural range improvements, could provide for an additional capacity by the fifth decade of 84,000 AUM’s. The forage utilization would be in concert with management practices to rehabilitate riparian areas. There is some likelihood that the AUM’s on some or all allotments may see up to 10 percent reductions in the first decade to meet riparian area management objectives.

Riparian Management
All riparian areas would be managed as “excellent.” Riparian corridors on 40 miles (1,000 acres) of high value streams would be emphasized to provide “connective habitat.” Riparian area improvements and management practices would enhance 10,000 acres in the first decade and expand that to 17,500 acres by the fifth decade.

Transportation System
Eight hundred forty miles of road would be managed for passenger car travel in the first decade, remaining stable through the fifth decade, 850 miles. There would also be 2,330 miles of high clearance roads maintained in the first decade, slightly declining to 2,270 by the fifth decade.

There will be 1,560 miles of roads closed in the first decade, increasing to 2,190 miles by the fifth decade.

There would be additional emphasis on ORV management and control through the application of standards and guidelines and the Travel Plan. In addition, the need for additional planning to assess ORV management needs on open areas, such as General Forest (MA-F22) and General Forage (MA-G3), would occur as implementation actions.

Big Game Habitat
Big game habitat receives primary management emphasis on 230,480 acres. A major portion of this acreage recognizes winter range values, 206,930 acres on four management areas. The area receiving emphasis for winter range values in this alternative is an increase over the Draft. In this alternative
there is no specific allocation for big game summer range, however, road use and cover quantity, quality and distribution would be controlled to provide the desired habitat effectiveness. A population of 3,000 elk could be supported in the first decade, decreasing to 2,620 by the fifth decade. This alternative would exceed the ODFW planning benchmark of 2,600 elk.

Roadless Areas and Wilderness Study Areas

The Green Mountain proposal for semiprimitive motorized recreation (the area remaining roadless) was dropped for reasons of no apparent public interest or support. Also soil erodibility and slopes were found not to be suitable for that use.

A portion of the Rock Creek/Cottonwood Creek area would be managed for unroaded recreation. A portion of the area which was determined to be economical for timber management was allocated to general forest and unroaded helicopter management areas. Steeper areas were reserved for roadless area management, or helicopter logging to protect watershed, anadromous fisheries, recreation, and wildlife values.

The Silver Creek area would remain roadless and the boundary adjusted to a more manageable boundary along the canyon rim.

The Lookout Mountain area, allocated to unroaded recreation, increased from 2,950 acres to 15,660 acres in the first decade. The entire roadless area, plus road corridor, would be treated as a separate management unit. Planning for stand treatments would begin in the first decade. The lower portion of the management area would be managed for the enhancement of forest health, scenery, wildlife and recreation from the second through the fifth decades, leaving a 7,550-acre area unroaded.

A portion of the Deschutes River-Steelhead Falls Wilderness Study Area and a additional area outside the WSA in Squaw Creek are combined to form a 7,840-acre management area emphasizing semiprimitive, nonmotorized recreational opportunities and wildlife habitat management. The 5,200-acre draft wilderness proposal would be dropped. The majority of the remainder of the draft proposed wilderness was included in the Deschutes Scenic River Corridor classified by the Oregon Wild Rivers Act in 1988.

Eligibility and suitability determinations have been made for a portion of the Squaw Creek area. A 7.5 mile segment of the creek, 1,370 acres, from the Grassland boundary to the confluence with the Deschutes River would be managed as a "scenic river." In addition, it would be recommended for inclusion into the Wild and Scenic River System. This would be a preliminary recommendation that would receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.

A more detailed discussion of the roadless areas on the Forest and Grassland is presented in Appendix C.

Scenic or Visual Resources

The immediate foreground viewing area surrounding recreational developments (campgrounds) would be assigned a retention visual management objective. The miles of road with visual management objectives increased from the Draft to 384 miles in the Final. The width of the viewing corridor used in calculations was changed from more than 2,640 feet to 1,200 feet. The entire Summit National Historic Trail corridor was assigned a visual management objective relative to cultural aspects of the particular trail segment. Round Mountain National Recreation Trail management corridor reduced in width from >2,640 feet to 1,200 feet. Added were 560 acres of viewing area from Lake Billy Chinook reservoir on the National Grassland.

No middle ground viewing areas would be allocated as management areas.

Old Growth

Old growth would receive emphasis in this alternative with 19,990 acres dedicated in two management areas (MA-F6, MA-G5). Additional old growth would be retained in other management areas (wilderness,
the wilderness study area and RNA's), totalling 2,400 acres. That portion of the old growth on the Forest amounts to 23 percent of the 93,800 acres of old growth remaining. Alternative I also added 1,000 acres of connective habitat in the riparian management area allocation to link up old growth stands to enhance their effectiveness for old growth dependent species.

**Fuelwood Supply**

Personal use of firewood would continue to be provided for on both the Forest and Grassland. Generally, most firewood comes from timber harvest residues. In the first decade, 13,000 cords would be provided annually. This supply would decrease to 11,000 cords annually by the fifth decade.

**Snag Dependent Wildlife**

Alternative I would provide 47 percent to 54 percent of the potential snag habitat for the first through the fifth decades across the Forest and Grassland.

**Winter Sports**

The Bandit Springs Management Area, 1,580 acres, is allocated to provide winter recreational opportunities for cross-country skiing and other nonmotorized winter recreation activities. Most of the remaining Forest and Grassland would be open to snowmobile access, including Lookout Mountain. Exceptions would include such areas as winter range areas, wilderness and the wilderness study area.

**Anadromous Fish**

Alternative I would provide for a gradual increase in the population of steelhead smolt over time. This increase would be primarily due to the improved riparian habitat gained through improved management practices and stream enhancement work.

**Historic Trail Preservation**

The Summit Historic Trail would be treated as a management area allocation with emphasis on preserving the historic and scenic qualities of the trail, 9,560 acres.

**Off-Road Vehicle (ORV) Use**

Under this alternative, steps would be taken to construct, reconstruct and designate existing trails for ORV use. The schedule calls for 95 miles in the first decade, increasing to 190 miles by the third through fifth decade. Some area closures would also be implemented in conjunction with trail designations and the identification of resource impacts.

**Round Mountain**

The scenic qualities and recreational opportunities supplied by the Round Mountain Trail have been recognized in this alternative through the allocation of 1,000 acres as the Round Mountain Management Area.
Comparison of Alternatives

Overview

The purpose of Forest planning and the process of formulating alternatives has been discussed previously in this chapter. In this chapter, as part of the alternative selection and analysis phase, interalternative comparisons of alternatives have been made. The elements of alternatives that have been comparatively evaluated include:

- responsiveness to issues and concerns,
- management areas,
- resource outputs,
- environmental effects, and
- costs and benefits.

In addition to tables presenting information, there are narrative sections that qualitatively describe differences between the alternatives.

The following pages summarize in tables and narrative the outputs and effects that differ significantly among alternatives.

Summary of tables providing alternative comparisons:

Issues, Concerns and Opportunities

Alternatives with different goals and resource objectives present ways of responding to issues and concerns. Table 2-9 (pp. 2-78 through 2-79) displays how each alternative responds to the Forest and Grassland's issues and concerns. Table 2-10 (pg. 2-88) compares alternative timber outputs to historical levels.
Management Areas

Management areas are defined by the area where particular management prescriptions apply. Management areas are treated in accordance with Forest-wide standards and guidelines and the individual management area’s prescription in order to achieve a desired future condition. Standards and guidelines function to describe management practices, their intensity, and the timing to achieve intended goals and objectives for the management area.

At the same time, standards and guidelines must provide for protection of resources, and contain mitigation measures which minimize any adverse environmental effects.

The standards and guidelines were developed by an Interdisciplinary Team specifically to respond to environmental conditions on the Forest and Grassland. Some of these were adopted from the Regional Guide. For a more complete description of standards and guidelines refer to Appendix D.

Each alternative is represented by different combinations of management areas. The acres by management area may vary by alternative also (Tables 2-6 & 2-7). The management area allocations for each alternative are shown on the maps included in the map packets for this FEIS.

Land and resource management goals for each management area are summarized below. Management area goals and desired conditions from the DEIS have also been carried forward and are represented in Alternatives A, C-Modified, and E-Departure.

Draft Management Areas

MA-D1. General Forest

Emphasis:
The primary management objective is to produce timber and livestock.

Desired Condition:
Timber management activities will include planting genetically improved stock, natural regeneration, precommercial thinning, commercial thinnings, and regeneration harvests generally at or near culmination of mean annual increment. Timber stands will generally be even-aged, 20 to 40 acres in size, with relatively uniform spacing. The largest trees in managed stands will be 16 to 18 inches DBH. Forage production for livestock will be enhanced by most timber harvesting activities and by range improvement activities, including the use of prescribed fire and the construction of additional water sources.

MA-D2. Big Game Winter Range

Emphasis:
The primary management objective is to produce winter range habitat of sufficient quality to ensure high big game survival potentials.

Desired Condition:
A quality big game winter range habitat will be brought about, over time, through vegetative treatment, including timber harvests and prescribed fire. These activities will be designed to create an optimal relationship between the size and spacing of thermal cover units for maximum deer and elk use. Open road densities will be kept low to limit the amount of disturbance to big game from vehicle traffic. Livestock grazing will be monitored and controlled to ensure sufficient forage for big game.
Uneven-aged management has been added to Alternative C-Modified, and it will have an effect on a portion of this management area. It is not known at this time how close those acres managed under this silvicultural system will be to the desired future condition specified for this management area.

MA-D3. Big Game Summer Range

Emphasis:
Management is directed towards ensuring big game habitat of sufficient quality for high production levels of deer and elk.

Desired Condition:
A quality big game habitat will be brought about, over time, through timber harvest and other vegetative treatments. These activities will create an optimum relationship between the size and spacing of cover units and forage areas for maximum deer and elk use. Open road density will be kept low to limit the amount of disturbance to big game from vehicle traffic.

Uneven-aged management has been added to Alternative C-Modified, and it will have an effect on a portion of this management area. It is not known at this time how close those acres managed under this silvicultural system will be to the desired future condition specified for this management area.

MA-D4. Old Growth

Emphasis:
The management emphasis on these lands is to provide habitat for wildlife species dependent on old growth habitat.

Desired Condition:
Timbered stands of 300 acres or greater in size will contain mature and overmature trees in a multi-layered canopy. Standing dead and down material will also be a significant component of the stand. Stands managed for old growth will generally be distributed throughout the Forest. To create this pattern, existing old growth stands will be utilized where possible. If no suitable old growth exists, areas capable of becoming old growth will be managed to bring the stand to an old growth habitat condition as rapidly as possible.

MA-D5. Retention Foreground

Emphasis:
The primary management emphasis of these areas is to provide scenic views that retain or enhance natural beauty.

Desired Condition:
Lands in this management area are comprised of the seen area immediately adjacent to areas of very high recreational use. Management activities will only repeat form, line, color, or textures frequently found in a natural landscape. Changes to the scenery will not be visually apparent to the casual Forest user. Where possible, forested areas will contain a major component of large ponderosa pine in open, parklike stands.

MA-D6. Partial Retention Foreground

Emphasis:
Management in these areas is directed towards providing scenic views that partially retain natural beauty.

Desired Condition:
Lands in this management area are comprised of the seen area immediately adjacent to areas of high recreational use. Management activities may change form, line, color, or texture but should remain subordinate to natural patterns and not dominate the landscape. Where possible, forested areas will contain a major component of large ponderosa pine in open, parklike stands.
**MA-D7. Partial Retention Middleground**

**Emphasis:**
These areas provide scenic views that partially retain natural beauty, with man's activities remaining visually subordinate to the natural landscape.

**Desired Condition:**
Lands in this management area are located in the visual middleground adjacent to areas managed under a retention prescription (Management Area #D5). Management activities may change form, line, color, or texture but should remain subordinate to natural patterns and not dominate the landscape. When viewed from a highway, widely dispersed, small timber harvesting units will be visible, but will be shaped to the terrain.

**MA-D8. Wilderness**

**Emphasis:**
Protect the Wilderness ecosystems. Manage to maintain a natural setting and preserve solitude. (This management area has changed from the Draft and presently applies to the Deshutes Canyon-Steelhead Falls area for Alternatives C-Modified and E-Departure only.)

**Desired Condition:**
These areas are to be managed in a manner “...where the earth and its community of life are untrammeled by man...” and where “...natural processes operate without interference by man...” Opportunities for solitude and challenge are offered away from the sights and sounds of motorized mechanical vehicles or equipment. Scientific information may be sought without the intrusion of permanent improvements or motorized equipment. Special exceptions provided in the Oregon Wilderness Act will be allowed.

**MA-D9. Semiprimitive Nonmotorized**

**Emphasis:**
The management goal for these areas is to administratively provide near-natural, unroaded, and undeveloped recreational opportunities.

**Desired Condition:**
Motorized vehicles are excluded except for over-snow vehicles, allowing for a semiprimitive nonmotorized recreational experience. Generally, interaction between users is low, but there is often evidence of other users. Natural processes will generally be operating without human interference, but management may occur to protect or enhance roadless qualities.

Motorized equipment such as chainsaws may be used in the management and maintenance of these areas. Nonmotorized mechanized equipment, such as “mountain bikes” and wheel-barrows, is acceptable. River corridors that are eligible for designation as Scenic Rivers under the Wild and Scenic Rivers Act are included in this management area.

**MA-D10. Semiprimitive Motorized**

**Emphasis:**
The management emphasis on these lands is to provide challenging motorized recreational opportunities in a natural appearing environment free from developed roads, highway vehicles, and concentrations of people.

**Desired Condition:**
This Management Area contains selected roadless areas that meet these goals. Management is directed towards maintaining a natural appearing setting for off-road vehicle use while maintaining other resource values.
MA-D11. Developed Recreation

Emphasis:
The management goal at these sites is to provide and maintain safe, healthful, and aesthetically pleasing recreational facilities.

Desired Condition:
This applies to sites currently developed or planned for parking, camping, picnicking, boating and other recreational activities.

MA-D12. Research Natural Areas

Emphasis:
The management goal of these areas is to preserve Research Natural Areas (RNA's) as scientific benchmarks.

Desired Condition:
This management area contains natural or nearly undisturbed areas which are representative of important forest and range land ecosystems. These areas fulfill identified needs for completion of the Regional RNA system. The RNA's will preserve natural ecosystems for research, education, and comparison with those affected by human activities.

MA-D13. Riparian in Acceptable Condition

Emphasis:
The primary management emphasis of these areas is to improve poor riparian areas to a fair condition, and to maintain existing conditions in other riparian areas.

Desired Condition:
Streambank vegetation will be managed to maintain or improve streambank stability and fish habitat as needed to meet this objective. Water temperatures will generally not be increased in major streams. Temperatures in other streams will not deteriorate downstream fish habitat. Natural, large, woody material will be provided. Range allotment plans will reflect forage utilization levels necessary to meet brush and hardwood protection needs.

MA-D14. Riparian in Excellent Condition

Emphasis:
Management in these areas will ensure that riparian areas are maintained or improved to provide excellent streambank stability and fish habitat in 15 years.

Desired Condition:
Streambank vegetation will be managed to provide the amount of cover and shade needed to meet this objective. Water temperatures will not be increased in major streams, and may need to be decreased in some areas. Temperatures in other streams will contribute to improved downstream fish habitat. Natural, large, woody material will be provided to help achieve high quality fish habitat. Range allotment plans will reflect forage utilization levels necessary to meet brush and hardwood protection needs.

Forest Management Areas

The land and resource management emphasis and goals for the management areas for Alternative I are summarized on the following pages. The 28 management areas for the Forest and the 14 management areas for the Grassland are presented in narrative form to provide a picture of the physical description,
management emphasis, and desired future condition of each area. The standards and guidelines that apply to each of the Management Areas and the Forest-wide Standards and Guidelines are presented in Chapters 4 of the Forest and Grassland Plans.

MA-F1. Black Canyon Wilderness

Emphasis:
Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.

Desired Condition:
The Black Canyon Wilderness will be as natural as possible, with little evidence of human activity. The area will be a place of natural settings with opportunities for solitude. Present road access and hunter caches and camps will be rehabilitated so their presence is no longer a dominant land feature. Recreational improvements, such as trailheads and access trails, will be evident where they are necessary to control use in order to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Old growth stands will be evident within the Management Area, along with those wildlife species in the Ochoco National Forest which are dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, will be evident, along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where lightning starts occur.

MA-F2. Bridge Creek Wilderness

Emphasis:
Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude. The area will be managed as a trailless wilderness where people can use their orientation skills.

Desired Condition:
The Bridge Creek Wilderness will be as natural as possible, with little evidence of human activity. The area will be a place of natural settings where solitude may be sought. Present road access will be rehabilitated so that its presence is no longer a dominant land feature. Recreational improvements, such as trailheads and access trails, will not be evident, but entry points will be signed where necessary to control use and to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the Management Area, along with those wildlife species in the Ochoco National Forest dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resulting from past Mountain Pine Beetle infestations and other endemic insects and pathogens will be evident, along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where lightning starts occur.

MA-F3. Mill Creek Wilderness

Emphasis:
Protect the wilderness ecosystems. Manage use to maintain a natural setting and preserve solitude.
Desired Condition:
The Mill Creek Wilderness area will be as natural as possible, with little evidence of human activity. The area will be a place of natural settings where solitude may be sought. Present road access will be rehabilitated so that its presence is no longer a dominant land feature. Recreational improvements, such as trail heads and access trails, will be evident where necessary to control use to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. The stock driveway in the northeast portion of the Wilderness will be evident due to its routine use in association with the Mill Creek Allotment.

Old growth stands will be evident within the Management Area, along with those wildlife species dependent in old growth habitat on the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

Tree mortality, resulting from past Mountain Pine Beetle and other endemic insects and pathogens, will be evident along with associated changes in fuel loadings and plant succession. Fuel loadings will become very significant along the south side of Forest Road 27 and will pose a serious fire risk. Fire occurrence will be evident where lightning and human-caused starts occur. There may be planned ignitions to achieve wilderness objectives.

Minerals activities on valid mining claims will be evident along with authorized access under approved plans of operation.

MA-F4. North Fork Crooked River Wilderness Study Area

Emphasis:
Management will maintain the existing conditions of the area pending a decision by Congress on wilderness designation.

Desired Condition:
The wilderness study area will be as natural as possible with reduced evidence of human activity. The area will be a place of natural settings where solitude may be sought. Present road access, and hunter caches and camps, will be rehabilitated. Recreation improvements, such as trail heads and access trails, will be evident where necessary to control use in order to preserve wilderness qualities. Livestock use will be evident, but the successful application of allotment management requirements will also be evident. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures.

Old growth stands will be evident within the management area, along with those wildlife species in the Ochoco National Forest dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat.

The Final Environmental Impact Statement for Wilderness by the BLM has not been published, but a decision on the status of this area along with the adjoining BLM lands is pending. If these areas are not designated wilderness, they will be managed under old growth, riparian, and general forest standards and guidelines.

MA-F5. Research Natural Areas

Emphasis:
These tracts of land are areas where natural processes are maintained for research and education purposes. They will provide baselines against which other activities may be measured, sites for study of natural processes in undisturbed ecosystems, and gene pool preserves for both plant and animal species.

Desired Condition:
Natural conditions will be maintained. Any management activities within the RNA's will be directed at
maintaining the natural conditions of the area, and these human-caused changes to the ecosystem will not be readily evident. Continuing, nondestructive baseline studies may be occasionally visible in terms of equipment, instruments, and related activities.

Fire occurrence will be evident where natural lightning and human-caused fire starts occur.

MA-F6. Old Growth

Emphasis:
Provide habitat for wildlife species dependent on old growth stands.

Desired Condition:
Stands of old growth are not expected to change significantly over the next ten to fifty years, barring natural catastrophe. They will continue to provide habitat for a number of wildlife species, such as the pileated woodpecker and Rocky Mountain elk, and may become more extensively used by these species as the majority of the Forest moves towards a "managed condition." High levels of snag habitat will continue as individual trees within the stands die of old age, as well as from periodic infestations by insect and disease populations. Management activities and roads will generally not be evident. Fire occurrence will be evident where lightning and human-caused starts occur. Prescribed fire may be evident if natural fuels accumulate to dangerous levels, threatening the existence of the old growth stand, or where vegetation manipulation is needed to maintain stand structure and species composition. Grazing by livestock, as well as by big game wildlife species may be evident.

MA-F7. Summit National Historic Trail

Emphasis:
Protect the existing integrity of the Summit Trail. Enhance and interpret significant segments for public enjoyment and education. Pristine segments will be managed to protect, interpret, and preserve their historic qualities.

Desired Condition:
The Summit Trail will be a place where Forest visitors can enjoy the cultural and recreational resources offered in a visually pleasing environment. The majority of the trail route is along developed roads and will provide travel by highway vehicle, as well as by mountain bike and horseback. Vegetation may appear manipulated in widely dispersed areas in order to enhance cultural and recreational resources, but will generally not dominate the landscape. Interpretive facilities such as signs and landmarks may be visible in special, culturally significant areas.

The outer boundary of the management area will generally not exceed 600 feet on either side of the trail.

MA-F8. Rock Creek/Cottonwood Creek Roadless Area

Emphasis:
Provide for protection of soil, water, and fisheries, and for opportunities for nonmotorized recreational use and enjoyment. Maintain vegetation on steep slopes to prevent erosion and to protect water quality and the anadromous fishery.

Desired Condition:
Recreationists will see natural appearing areas free from motorized vehicle use. Recreational use, livestock grazing, prescribed fire and wildfire will occur, but the area will appear natural. These activities, along with any desired recreational improvements, will be the only visible impacts of direct human activities.

Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the Management Area,
along with those wildlife species in the Ochoco National Forest which are dependent on old growth habitat. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Structures may be constructed, or other work may be done to maintain or improve habitat for the anadromous fishery. The area will remain one where there are above average numbers of trophy-sized elk and deer. Tree mortality, resulting from past spruce budworm infestations and other endemic insects and pathogens, will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning and human-caused starts occur.

**MA-F9. Rock Creek/Cottonwood Creek Unroaded-Helicopter Area**

**Emphasis:**
Allow timber harvest while protecting the anadromous fishery, sensitive soils on steep slopes, and big game habitat.

**Desired Condition:**
The area will be unroaded. Timber harvest and associated activities will use helicopter systems. The area will remain unroaded with landings located outside the management area. Prescribed fire use will also be evident in some areas where its use is desirable to attain management objectives. Visible harvest impacts will generally be limited to vegetation modification with little soil or other surface disturbance.

Recreation improvements, such as trailheads and access trails, will be evident where necessary to enhance access. Livestock use may be evident, but the successful application of allotment management requirements will show acceptable grazing practices. Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the Management Area, along with those wildlife species dependent on old growth habitat in the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resulting from spruce budworm and other endemic insects and pathogens will be evident along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning and human-caused starts occur.

**MA-F10. Silver Creek Roadless Area**

**Emphasis:**
Protect and enhance the roadless qualities and provide nonmotorized recreational use.

**Desired Condition:**
Recreationists will see natural appearing areas free from motorized vehicle use. Recreational use, livestock grazing, prescribed fire and wildfire will be evident over time. These activities, along with any desired recreational improvements, will be the only visible impacts of human activities within the Management Area.

Riparian areas in less than desirable condition will show evidence of recovery from the application of mitigation and rehabilitation measures. Old growth stands will be evident within the Management Area, along with those wildlife species dependent on old growth habitat on the Ochoco National Forest. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, will be evident, along with associated changes in fuel loadings and plant succession. Fire occurrence will be evident where natural lightning and human-caused starts occur.
MA-F11. Lookout Mountain Recreation Area

Emphasis:
Maintain a natural setting, providing continued opportunities for high quality, semiprimitive recreational activities and wildlife habitat, while maintaining healthy forests.

Desired Condition:
General
The Lookout Mountain Management Area will become a well-known area for year-round recreational activities and will provide excellent habitat for big game.

Prescription Area A:
This area will comprise approximately 7,550 acres of Forest land in a semiprimitive state with no vegetation manipulation planned. The recreational user will experience a highly diverse, natural landscape with interspersed stands of trees, openings, rock outcrops, and talus. A tree species mix including early successional species such as ponderosa pine, western larch and lodgepole pine will be seen across the lower elevations of the landscape. Lodgepole pine, sub-alpine fir, white fir and Douglas-fir will dominate at the higher elevations. Pockets of mixed conifer old growth will be an integral part of the vegetation mosaic. Natural tree mortality will be evident.

Big game habitat will be excellent due to the secluded nature of the area, high elevation moist meadows, and good year-round springs with heavy dense cover. Elk wallows will be numerous and big game use will be evident.

The area will be roadless, with currently existing roadbeds exhibiting evidence of rehabilitation activities and revegetation. Man-made improvements will be subordinate to the natural landscape and will be present to enhance recreational use of the area. Typical improvements apparent to the recreational user may include trails, trailheads, signing, trail shelters, livestock fencing, and possible wildlife habitat enhancement projects.

Prescription Area B:
This area will comprise about 8,110 acres in a relatively natural appearing condition.

A variety of trails, roads, trail shelters, signs and other improvements for the benefit of recreational users may exist, but will be designed and managed to be subordinate to the natural landscape. Several existing roads into the Management Area will remain open for motorized travel to dispersed campsites and mining activities.

Vegetation may appear manipulated in widely dispersed places in order to enhance recreational opportunities and wildlife habitat resources; vegetation manipulation will not dominate the landscape or generally be evident to the casual Forest visitor. Various vegetation manipulation techniques will be used to promote healthy forests which are more resistant to catastrophic events that may detract from big game habitat or a recreational experience. As a result of these limited entries, ponderosa pine and western larch, which are tree species valued for their appearance, will become more abundant over time. These species will be interspersed in a mosaic of other mixed conifer species of various size and age classes, including stands of old growth mixed conifer and ponderosa pine.

Minimum standard roads designed for specific projects will exist in low densities on the more gentle ground. Road use will be restricted to project activities and roads will be closed upon completion of each project. Roadbeds and banks will be seeded with mixtures of legumes and grasses to improve wildlife habitat. The amount of activity occurring at any one time will be limited.

MA-F12. Eagle Roosting Areas

Emphasis:
Provide winter roosting habitat for migrating bald eagles from December through April.

Desired Condition:
An uneven-aged stand will contain large trees which are at least 22 inches DBH, and a few trees which are
36-40 inches at DBH. Roost trees generally are at least 22 inches DBH and have an open structure which allows eagles to land easily. Those trees actively being used will be preserved along with replacement trees in the same vicinity.

The area will be free of potentially disturbing human activity during the period from December 1 to May 1. When actual or potential roosting areas overlap with areas which have more restrictive prescriptions, the area will be managed under the most restrictive prescription as long as roost trees are maintained.

MA-F13. Developed Recreation

Emphasis:
Provide safe, healthful, and aesthetic facilities for people to utilize, within a relatively natural outdoor setting, while pursuing a variety of recreational experiences.

Desired Condition:
This Management Area will consist of natural-appearing areas with obvious man-made controls and structures to direct users, provide for comfort and sanitation, and protect the natural resources. Developed sites will be provided for a broad range of recreational opportunities.

New and upgraded sites will incorporate a barrier-free design.

Management activities will not be visually evident. Scenic views may be enhanced through harvest or thinning but will appear natural.

Facilities, roads, and trails will have a well maintained appearance and provide a safe recreational environment. When vandalism is a problem, public use may be prohibited on a seasonal basis.

MA-F14. Dispersed Recreation

Emphasis:
Provide a near-natural setting for people to utilize while pursuing outdoor recreation experiences.

Desired Condition:
Within the immediate dispersed site, management activities will not be evident to the casual observer. Activities may be evident in areas adjacent to the site, depending on the management prescription applied to them. Primitive, user-constructed structures or facilities, consistent with a site’s use, will be seen. Sites will be managed so that users tend to feel relatively isolated. A strategy will be developed that encourages individuals or groups to “find their own place.”

Livestock grazing may be evident, but the successful application of allotment management requirements will also be evident.

MA-F15. Riparian

Emphasis:
Manage streamside vegetation and habitat in order to maintain or improve water quality and meet temperature and turbidity levels as required by state standards under the Clean Water Act (See Forestwide Standards and Guidelines, Water; and Best Management Practices (BMP’S), Appendix G).

Desired Condition:
Riparian areas will exhibit a low but apparent level of management. Vegetation may or may not appear manipulated, depending on the condition of the stream. An abundance of wildlife species should be evident. Due to management restrictions and the low risk associated with these areas, the signs of natural or man-caused fire will be infrequent.

For management purposes, a special protection area (100 feet from the edges of perennial bodies of water) will be apparent. In addition, the streams listed below will receive extra protection to 200 feet
from the stream edge, in order to provide "connective habitat" for a variety of wildlife species on the Forest:

Trout Creek, Bear Creek, Drake Creek, Pine Creek, Allen Creek, Indian Creek, West Fork Bridge Creek, Porter Creek, Howard Creek, Fox Creek, Cottonwood Creek, Baldy Creek, Little Windy and Windy Creek, and Nicoll Creek. Roads not planned for future use will be obliterated and revegetated to a natural or near natural condition.

Within the limits of ecological potential, a shady, brushy condition with a canopy of alder, willow, aspen, or other deciduous vegetation will exist.

Where coniferous evergreens are a natural component of the ecosystem, a variety of size classes will exist to perpetuate the supply of shade and woody debris over time. Sites unable to support a canopy of deciduous or evergreen species will be characterized by vigorous stands of forbs, grasses, and grass-like riparian species.

Bank slopes containing high plant densities, thick root masses, embedded angular boulders, and old logs will also characterize these areas. Extensive scouring of streambanks will be an uncommon occurrence, as will soil deposition outside the norm for the individual stream system. Streambeds will be commonly covered by native aquatic growth on assorted sizes of rocks and boulders.

Where cobble and gravel bars are prominent, they will become covered by sandy loam soils as riparian vegetation filters and traps stream sediments. As stream banks are re-built and cutbanks stabilized, a narrower, deeper channel will gradually develop.

Springs and wet meadows are not specifically included in this management area prescription, but should receive appropriate protection as stated in Forest-wide Standards and Guidelines for Water, Chapters 4, Forest and Grassland Plans.

MA-F16. Bandit Springs Recreation Area

Emphasis:
Provide dispersed, nonmotorized recreational opportunities, within a setting where management activities are generally not evident to the casual observer. Expand the recreational activities and opportunities beyond winter recreation to year-round activities.

Desired Condition:
The Bandit Springs Recreation Area is expected to become an important winter sports use area on the Forest, as well as a setting for other year-round recreational activities, including environmental education, mountain bike riding, day hiking, hunting, and horseback riding. Developments to accommodate a broad spectrum of nonmotorized recreationists' needs will be built. Emphasis will be on enjoying the natural scenery, with interpretation aiding the casual visitor. Developments may include trail shelters, maintained trails, horse unloading ramps, toilets, information areas, parking, picnic areas, and signs.

Periodic manipulation of vegetation to meet recreation and visual objectives for the area will be apparent to the user. Timber stands will be managed to develop and maintain resistance to catastrophic events that would detract from the recreational experience. Both uneven- and even-aged silvicultural practices will be used. A road system will be visible, but secondary to the natural setting. Livestock use will also be evident.

MA-F17. Stein's Pillar Recreation Area

Emphasis:
Maintain a scenic, natural or natural-appearing setting associated with unique geologic formations, particularly Stein's Pillar. Provide roadless nonmotorized recreation with opportunities to enjoy nature.
Desired Condition:
The area will be a natural or natural-appearing place with a variety of volcanic plugs, topography, plant communities, and wildlife, where recreationists can enjoy nonmotorized recreation.

Ponderosa pine stands will have large, yellow-bark trees, particularly along the Stein's Pillar Trail. There will be a mosaic of these large-tree, open pine stands interspersed with juniper scab flats and fir stands. Created openings will blend with the natural appearance of the area. Scenic views will be created but management activities will not be evident to the casual observer.

The area will offer scenic views of Stein’s Pillar and other volcanic plugs, as well as the Ochoco and Cascade Mountains. Recreationists will enjoy nonmotorized activities, including hiking, picnicking, rock climbing, sightseeing, horseback riding, and group activities. These activities will mostly be day use.

Nonmotorized recreational opportunities and facilities will be provided. A rustic trail, designed and maintained for family day walks, will access Stein’s Pillar. There will be an associated trailhead and access route. The trail system may be extended to the north to tie to the Benefield road. Also, a safe way to the base of the pillars will be constructed to allow easier access for climbers and others. Interpretive facilities will highlight geological, recreational, historical, old-growth, and wildlife features, and the nearby wilderness.

Streamsides will be extremely shady and brushy with an abundance of tall overstory conifer trees and/or shorter hardwoods of alder, willow, and aspen. Streamsides will meet the Riparian Management Area objectives.

Deer and elk may use the area for winter cover, feed, and security. Deer and elk may summer throughout the area. A 300-acre Old Growth Management Area will be available for wildlife, such as the goshawk and pilated woodpecker. Snags will occur naturally, providing habitat for woodpeckers, nuthatches, owls, and other cavity nesters.

Livestock use will be evident, but the successful application of allotment management requirements will also be evident.

MA-F18. Hammer Creek Wildlife/Recreation Area

Emphasis:
Provide and maintain habitat diversity for a variety of wildlife species where open road density is minimal. Provide a scenic, semi-natural or natural-appearing setting for nonmotorized recreational opportunities.

Desired Condition:
Forested areas of ponderosa pine will be seen as a wide variety of size/age classes with a major component of large, yellow-barked pine. Mixed conifer areas will be a mosaic of open and closed canopy stands of various size classes to provide an optimum forage and cover mix for big game. Nonforested areas will generally appear natural in character, but with periodic evidence of livestock grazing. Riparian areas will be shady and consist of a mixture of trees and shrubs. Management activities will remain visually subordinate to the characteristic landscape.

Developed facilities such as trailheads, picnic/camp areas, and associated access routes will be evident on the periphery of the unit. Interpretive facilities will be available to highlight historical, recreational, and wildlife features.

Access roads to trailheads will be open. All other roads will be closed to motorized use and rehabilitated after management projects are completed.

MA-F19. Deep Creek Recreation Area

Emphasis:
Provide a near natural setting for recreational pursuits within the area.

Desired Condition:
Forested areas will contain large larch and ponderosa pine. Nonforested areas will generally appear natural in character with little immediate evidence of management activities. The riparian area will
contain abundant alder and other riparian hardwood species.

Dispersed recreational areas will be protected. Opportunities for camping in developed sites will be provided at Deep Creek Campground.

Trails may be developed that provide day hiking or interpretive recreational opportunities.

Management activities, including timber harvest and prescribed burning, will not be evident to the casual observer. Livestock use will be evident, but the successful application of allotment management requirements will also be evident.

MA-F20. Winter Range

Emphasis:
Manage for big game winter range habitat.

 Desired Condition:
Big game use on winter range will be the primary activity, with other management activities and human intervention restricted from December 1 to May 1. Habitat effectiveness for big game will improve over time, due to increases in both quality and quantity of thermal cover, and to reductions in open road density. Road and trail use will be limited to one mile of open access per section, from December 1 to May 1, but up to three miles per section will be available during the remainder of the year.

Vegetation cover types, key species condition, big game use, and domestic livestock grazing will be inventoried and mapped. Treatment units will be identified and treatments prescribed on a scheduled basis to maintain key forage and browse species. Treatments will be monitored to assure appropriate forage and browse allocations for big game.

Management, including vegetation manipulation, structures, and prescribed fire to maintain or improve winter range, may be apparent. Livestock use of forage will be conducted in harmony with big game winter range habitat needs.

Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, may be evident along with associated changes in fuel loadings and plant succession, in areas reserved for big game cover.

MA-F21. General Forest Winter Range

Emphasis:
Manage for timber production, with measures taken to maintain habitat effectiveness for big game. Design and implement management activities to recognize big game habitat needs.

 Desired Condition:
Big game use on winter range will be the primary activity, with other management activities and human intervention restricted from December 1 to May 1. Habitat effectiveness will slowly decrease in this area, mainly due to future reductions in quality and quantity of thermal cover. This decrease will not be as rapid as in MA-22 General Forest, due to specified road closures and other incidental wildlife improvements. Road and trail use will be limited to one mile of open access per section during December 1 to May 1, but up to three miles per section will be available during the remainder of the year.

Fire occurrence will be visible where lightning and human-caused starts occur and where prescribed fire is applied.

Management activities will take into account vegetation types and successional responses in order to apply prescriptions which have beneficial results for habitat. Areas of particular importance as big game habitat will be identified and management activities modified to complement, protect, or improve habitat. Livestock use of forage will be conducted in harmony with big game winter range habitat needs.

Tree mortality, resulting from past spruce budworm and other endemic insects and pathogens, may be evident along with associated changes in fuel loadings and plant succession, in areas reserved for big game cover.
MA-F22. General Forest

Emphasis:
Produce timber and forage while meeting the Forest-wide standards and guidelines for all resources. In ponderosa pine stands, management will emphasize production of high-value (quality) timber.

Desired Condition:
Most ponderosa pine stands and some mixed conifer stands on slopes less than 30 percent will exhibit the application of uneven-aged management. Trees up to 20 inches DBH will be seen in these stands, and the evidence of trees managed for high quality lumber (where the first log is relatively free of limbs) will be noted.

Most mixed conifer timber stands, most stands on slopes greater than 30 percent, and some pine stands not suitable for uneven-aged management will be seen as even-aged, with trees uniformly spaced and fully occupying the site, except in seedling and sapling stages. Regenerated stands will generally be 20 to 40 acres in size. A mix of species, with emphasis on the seral species such as pine and larch, will be evident where conditions permit. The largest trees will generally be 18 to 22 inches DBH, but larger ones may be found where left for snag replacements or other resource reasons. Trees will have full crowns and be relatively free of defect. Snags will be apparent over the area with potential snag habitat managed at the 20 percent level for Alternative B-Modified, and at the 40 percent level for Alternative I.

A variety of native grasses, sedges and forbs will be available for grazing animals. Competition from nonforage species such as sagebrush and juniper will not be a major problem. Most of the forested range lands will be in fair and good forage condition class. Forage use will be apparent, and improvements installed to facilitate stock distribution and effective use of available forage will be evident.

Following use for timber haul, local access routes with planned future use will generally be open to high clearance access (maintenance level 2) for Forest visitor and administrative use, unless there are significant reasons to do otherwise. Access routes/trails will be developed to offer a variety of terrain and experience levels for ATV’s, and users will be restricted to these areas. Recreational off-road motorized use will be allowed, but users will be encouraged to use designated routes in order to protect Forest resources such as soils and water quality.

Dispersed sites will be scattered throughout the area. These sites will be maintained in as natural a condition as possible.

Fire occurrence will be visible where natural lightning or human-caused starts occur, and where prescribed fire was applied.

MA-F23. North Fork Crooked River Recreation Corridor

Emphasis:
Maintain the appearance of a natural landscape in the foreground view from Road 42. Protect and enhance public use and enjoyment of the river segment.

Desired Condition:
This segment of the North Fork of the Crooked River will be a free-flowing river whose shorelines may be accessible by roads. The immediate river environment (up to one-quarter mile from the river) will appear natural, though there may be evidence of past and ongoing timber harvest and grazing. Developed and dispersed campsites and interpretive signage will be seen throughout the area. The use of prescribed fire may be evident where used to enhance the retention of featured tree species such as old growth ponderosa pine or western larch.
MA-F24. North Fork Crooked River Scenic Corridor

Emphasis:
Maintain and enhance a natural appearing landscape to protect the “scenic river” designation.

Desired Condition:
This segment of the North Fork of the Crooked River will be seen as a free-flowing river whose shoreline is accessed by a road. The immediate river environment (up to one-quarter mile from the river) will have an overall natural appearance, though there may be evidence of past timber harvest. Other management activities will be evident, including dispersed campsites and interpretive signing. A low standard trail will be developed that will require wading or rock-to-rock natural crossings. Prescribed burning will be apparent where used to enhance the retention of featured tree species such as large old growth ponderosa pine and western larch.

Several stands have been designated for old growth within the scenic river corridor. Where old growth restrictions are more restrictive than scenic river restrictions, the old growth prescriptions will apply.

Emphasis:
Maintain and enhance the scenery along U.S. Highway 26.

Desired Condition:
The U.S. Highway 26 Corridor will be managed to maintain the big tree appearance; activities will not be evident to the casual Forest visitor. Vegetation will be manipulated in order to provide a variety of size and age classes of timbered stands, including open parklike stands of old growth ponderosa pine, dense shaded stands of mixed conifer, and small openings with planted and natural tree seedlings. Both uneven- and even-aged stand conditions will exist.

MA-F26. Visual Management Corridors
(This includes all visual management areas outside of other special management areas, e.g. Highway 26, Summit Trail, etc.)

Emphasis:
Maintain the natural-appearing character of the Forest along major travel routes, where management activities are not evident, or are visually subordinate to the surrounding landscape.

Desired Condition:
Prescription Area A
This area will encompass about 86 miles of Forest roads and include approximately 9,300 acres of associated landscape. The outer boundary of the Management Area will generally not exceed 600 feet on each side the road. Retention will be the visual quality objective. Long-term management activities will not be visually evident to the casual observer.

Forest visitors will encounter a diverse landscape which reflects ecosystems where management activities appear as a natural condition.
Vegetation will be manipulated, but will reflect a natural forest setting. Stands of trees will exist in multiple age classes, from young seedlings to mature old growth in both uneven- and even-aged conditions. Unique characteristics of the landscape, such as rock bluffs and aspen clones, will be highlighted, where they are currently hidden from view due to existing vegetation.

**Prescription Area B**

This area will encompass about 174 miles of Forest roads and include approximately 23,960 acres of associated landscape. The outer boundary of the management area will generally not exceed 600 feet on each side the road. Partial retention will be the visual quality objective. Long-term management activities may be evident but will be visually subordinate to the characteristic landscape. Forest visitors will encounter a near-natural scenic view, with a diverse ecosystem reflecting a low level of management.

Vegetation will appear manipulated. Stands of trees, in multiple age classes in both uneven- and even-aged conditions, will occur in a background of rock outcrops, aspen clones and native grass communities.

**Prescription Areas A and B**

An established road system will be in place, but will have been designed to minimize the visual effect on the landscape. Grazing by livestock may or may not be visible immediately adjacent to these roads.

As a consequence of visual management, an abundance of wildlife may be viewed in the corridor. This might include big game, a variety of bird species, and fish. The affects of fire will be periodically evident as a result of natural and prescribed burning.

**Desired Condition:**

The visitor will note a naturally appearing forest along the majority of the trail route (visual quality objective of retention). The outer boundary of the management area will generally not exceed 600 feet on either side of the trail. The Round Mountain National Recreation Trail will be linked to trails on Lookout Mountain and the access road to the Summit of Round Mountain, as well as to Walton Lake Campground, through appropriate signing. Recreational improvements will be evident in those locations where necessary to protect the land, for public safety, and to enhance the public's enjoyment of the area.

Old growth stands will be seen within the management area. Fire occurrence will be evident where natural lightning and human-caused starts occur. Rehabilitation will be done in areas visually impacted by past management activity.

**MA-F28. Facilities**

**Emphasis:**

Provide a safe, efficient, and healthful working environment where structure design and layout of the site blend with the surroundings.

**Desired Condition:**

Sites will be efficiently designed work areas consistent with type and intensity of use. Employee wellness and public safety will be the primary design criteria. Color and design of structures and facilities will blend with the surrounding environment.

Traffic controls and signing will be designed to provide a safe driving environment. Roads and trails will be planned, designed, operated and maintained to levels sufficient to provide safe use for the intended traveler.

The historical significance of buildings and structures will be considered during any modifications to the site.

Employee residential areas will be designed to meet employee needs.

---

**MA-F27. Round Mountain National Recreation Trail**

**Emphasis:**

Protect and manage for scenic qualities which make the trail corridor an attractive recreational setting. Rehabilitate trail sites where management activities conflict with National Recreation Trail objectives.
Management activities, such as timber harvest, thinings, and fuel treatments for the protection of facilities from wildfire, may be apparent on a short-term basis.

**Grassland Management Areas**

**MA-G1. Antelope Winter Range**

**Emphasis:**
Manage for optimum winter range conditions for antelope.

**Desired Condition:**
This Management Area will consist of generally open grassland with shrub heights at or below 24 inches, but not over 30 inches in height. Range improvements that facilitate antelope migration will be constructed. Harassment and stress on wildlife caused by motorized vehicle traffic will be reduced. Fall greenup will be reserved for use by antelope during winter.

**MA-G2. Metolius Deer Winter**

**Emphasis:**
Manage for big game winter range habitat.

**Desired Condition:**
Management in this area will support the Oregon Department of Fish and Wildlife management objectives for the wintering deer population. A 60/40 forage/cover ratio, and a vigorous shrub overstory will be maintained. Private land will be acquired when possible. The implementation of seasonal road closures will reduce harassment and stress on wildlife from motorized traffic. Early season livestock grazing will be used as a vegetative management tool to maintain forage in a palatable condition. Fall greenup will be reserved for deer forage. A management plan for the entire winter range area will be developed in coordination with Oregon Department of Fish and Wildlife.

**MA-G3. General Forage**

**Emphasis:**
Manage for forage production and utilization in a manner consistent with general standards and guidelines for other resources.

**Desired Condition:**
Structural and nonstructural range improvements, prescribed fire to increase the palatability of desirable species, and livestock management will be used to maintain or increase forage production. The natural composition and cover values of native grasses, sedges, forbs and palatable shrubs will be retained. Competition from undesirable forage plants, such as sagebrush and juniper, that decrease range productivity will be reduced. Proper stocking levels and distribution will be employed to effectively utilize forage production without adversely affecting plant communities. Areas planted in crested wheat grass will proceed through natural succession to reestablish native plant species, unless specific resource management objectives can be better met by maintaining certain pastures in crested wheat grass. Aspen clones will be allowed to regenerate. The occurrence and increase of noxious weeds will be prevented. A variety of native and introduced grasses, sedges, and forbs will be provided for grazing animals. Improvements that facilitate stock distribution and the effective use of available forage will be installed.
MA-G4. Research Natural Areas

Emphasis:
These tracts of land are areas where natural processes are maintained for research purposes and education. They will provide baselines against which other activities may be measured, sites for study of natural processes in undisturbed ecosystems, and gene pool preserves for both plant and animal species.

Desired Condition:
Natural conditions will be maintained. Any management activities within the RNA's will be directed at maintaining the natural conditions of the area, and these human-caused changes to the ecosystem will not be readily evident. Continuing, nondestructive baseline studies may be occasionally visible in terms of equipment, instruments, and related activities.

Fire occurrence will be evident where natural lightning and human-caused fire starts occur.

If available, the private land on Haystack Butte RNA will be acquired.

MA-G5. Juniper Old Growth

Emphasis:
Provide habitat for wildlife species dependent on old growth stands.

Desired Condition:
The common flicker is the management indicator species. Stands at least 40 acres in size and not more than five miles apart will be maintained. Trees should be large with hollow centers and have broad, irregular-shaped crowns or spike tops. Most of the large trees, both live and dead, should support lichen growth. Cavities should be evident in the trees from either bole splits and/or limbs that have broken away from the tree bole. Some younger trees may be present along with various grasses, forbs, and shrubs.

Management activities and roads will generally not be evident. Fire occurrence will be evident where lightning and human-caused starts occur. Grazing by livestock, as well as by big game wildlife species, may be evident.

MA-G6. Crooked River Recreation Area

Emphasis:
Maintain the appearance of a natural landscape to enhance and protect recreational values.

Desired Condition:
The natural and scenic qualities of the river corridor will be preserved, as required by the Wild and Scenic Rivers Act.

A trail system and dispersed campsites will be developed to assist in public enjoyment of the area.

MA-G7. Deschutes River Scenic Corridor

Emphasis:
Manage for scenic quality and natural appearance of the landscape.

Desired Condition:
The natural and scenic qualities of the river corridor will be preserved as required by the Wild and Scenic Rivers Act. A trail system will be developed to provide access to the area. Dispersed campsites will be designated to aid in management of the area.

MA-G8. Squaw Creek

Emphasis:
Provide opportunities for semiprimitive nonmotorized recreation in a pristine canyon setting while protecting and enhancing the deer winter range habitat.
fisheries. A 1,370-acre corridor along the creek will be managed for its scenic quality as a “scenic river.”

Desired Condition:
A travel management program will restrict vehicle access seasonally, except for administrative and special uses. Private inholdings which facilitate management of the area will be acquired when possible. Recreational use, livestock grazing, prescribed fire and wildfire will occur, but the area will appear natural. Wildlife and fish species indigenous to the area will continue to exist at levels consistent with the available habitat. Fire occurrence will be evident where lightning and human-caused starts occur.

A corridor along the creek from the Grassland boundary to the confluence with the Deschutes River has been determined to be suitable for designation as a scenic river under the Wild and Scenic Rivers Act.1 This corridor will be managed to preserve and, or enhance its natural and scenic qualities.

MA-G9. Riparian

Emphasis:
Maintain riparian habitat, including streambank stability and fish habitat capability, at existing levels where the desired condition is met. On sites where the desired condition is not met, take steps necessary to bring riparian condition to its ecological potential. Allow no activities that will result in a deterioration of water quality in perennial and fish bearing streams.

Desired Condition:
General: On-the-ground work and management changes are needed to improve riparian conditions on approximately 1,250 acres of the Grassland, all but 400 acres have been completed. Remaining work will be completed in the first decade. However, 1 to 60 years for some of these actions fully as natural systems.

Specific projects are shown in the Riparian Improvement Schedule in Appendix A.

Work to restore riparian areas will have been completed, but not all riparian areas will have had time to recover to full biological potential. Many streams that presently flow only seasonally will flow year-round. The potential for overland flows and delivery of sediment to streams from upland areas will have been reduced by construction of improvements such as fences, the development of dispersed water sources, and adjustments in grazing systems. Water quality will be maintained or improved to meet state standards for temperature and turbidity.

Stream Channels: Establish a shady, brushy condition with a canopy of alder, willow, aspen, or other deciduous vegetation. Sites unable to support a canopy of deciduous species will be characterized by vigorous stands of forbs, grasses, and grasslike riparian species. Although cobble and gravel are often prominent features during the development of riparian stream courses, they become covered by sandy loam soils as riparian vegetation filters and traps stream sediments. As stream banks are rebuilt and stabilized, a narrower, deeper channel will gradually develop.

Springs: Manage springs to maximize water storage and support excellent condition riparian vegetation. These ecosystems should support deciduous vegetation where such vegetation was present in the past. At spring sites not associated with deciduous vegetation, the riparian area to support vegetation associated with excellent condition. These spring areas will not show signs of compaction, channeling, or head cuts.

Wet Meadows: Manage wet meadows to support vegetation associated with excellent conditions such as forbs, grasses, reeds, sedges, and rushes. These areas will not show signs of channeling or gully development of sufficient size to lower the seasonally saturated zone and change the plant community

1Administrative recommendation that will receive further review and possible modification by the Chief of the Forest Service, the President of the United States Congress has reserved the authority to make final decisions on designation of rivers and Scenic Rivers System.
type. These zones should be showing no signs of invasion from nonriparian species such as rabbitbrush, sagebrush, or juniper.

MA-G10. Rimrock Springs Wildlife Area

Emphasis:
Provide unique habitat (wetlands, ponds, springs) within the juniper-sagebrush steppe. Provide for nonconsumptive (viewing, photography) wildlife uses in a natural setting. Improve present habitat conditions and promote habitat diversity.

Desired Condition:
Increased opportunities for wildlife viewing and photography, including a barrier-free interpretive trail and a brochure will be provided. Barrier-free toilet facilities will be available at the trailhead. Interpretation of unique cultural resources will preserve early history of the area. Prescribed fire will be used to improve habitat.

MA-G11. Haystack Reservoir

Emphasis:
Provide users with a system of quality facilities that are safe and environmentally sound. Continue to emphasize camping, picnicking, boating, fishing, and swimming.

Desired Condition:
The existing partnerships will be continued and new ones explored to provide for the needs of the recreational users. Bureau of Reclamation (BOR) lands around the reservoir will be acquired to simplify management of the area; BOR would retain ownership and management of the dam. New and upgraded facilities will provide for barrier-free opportunities.

MA-G12. Cove Palisades State Park

Emphasis:
Manage for developed campgrounds and water related recreational activities.

Desired Condition:
The landbase needed by the State to operate a high-quality developed recreational facility on the shores of Lake Billy Chinook will be provided. Other resources within the park boundary will be managed to support this goal.

MA-G13. Lake Billy Chinook View Area

Emphasis:
Maintain the natural appearing character of the viewshed from Lake Billy Chinook, where management activities are not evident or are visually subordinated to the surrounding landscape.

Desired Condition:
The natural and scenic qualities of the management area will be preserved.

MA-G14. Dispersed Recreation

Emphasis:
Provide and maintain a near-natural setting for outdoor recreational experiences.

Desired Condition:
Within the immediate dispersed site, management activities will not be evident to the casual observer. Activities may be evident in areas adjacent to the site, depending on the management prescription applied to them. Primitive, user-constructed structures or facilities, consistent with the sites’ use, will be seen. Sites will be managed so that users tend to
feel relatively isolated. A strategy will be developed that encourages individuals or groups to "find their own place." Livestock grazing may be evident, but the successful application of allotment management requirements will also be evident.

MA-G15. Gray Butte Electronic Site

Emphasis:
Manage the site to provide low power output electronic equipment. Limit transmitters to a maximum of 150 watts.

Desired Condition:
All development should meet partial retention from important viewpoints. Minimize interference potential through facility design, location, spacing, capacity and establishment of site-noise floor limits. Meet user needs, and maximize utilization of the site. Three buildings and three towers will be allowed at the site.

MA-G16. Utility Corridors

Emphasis:
Accommodate energy-transmission facilities.

Desired Condition:
Future development will be confined to existing corridors. No windows for future development will be designated. Identify exclusion and avoidance areas. Through design and management, the use of lands allocated to power facilities will be optimized. The proliferation of separate rights-of-way will be discouraged to reduce the cumulative environmental impact of linear facilities. The creation of corridors in addition to those currently designated will be discouraged.

Interalternative Comparison of Resource Outputs, Environmental Effects, Activities, and Costs

By comparing the alternatives' response to issues and concerns (Table 2-9), and to outputs and effects (Table 2-8), a relationship between issues and environmental effects may be seen.

Many outputs and effects have been derived from the FORPLAN model described in Appendix B. Other environmental effects are discussed in Chapter 4. The glossary provides definitions and explanations of abbreviations and units of measure.

Economic Values and Responses to Major Issues, Concerns, and Resource Use and Development Opportunities

This section defines indicators that are used to show differences in how alternatives respond to the Issues, Concerns and Opportunities (ICO's). It also discusses indicators that are of central concern to the nation as a whole. Appendix A fully discusses each of these ICO's and the relevance of the re-
sponse indicators. The ICO's with the greatest influence on the alternatives and their associated response indicators follow.

1. **Timber Supply and Forest Management:**
   - allowable sale quantity in cubic feet, first and fifth decade;
   - allowable sale quantity in board feet, first decade;
   - average annual salvage;
   - unevenage management acres.

2. **Social and Economic Wants and Needs of Local Communities:**
   - Present Net Value (PNV);
   - number of Forest-dependent jobs,
   - payments to counties.

3. **Livestock Grazing and Allotment Management:**
   - Permitted Livestock Use in AUM's, first and fifth decades.

4. **Riparian Area Management:**
   - acres of riparian area in excellent condition, first and fifth decades.

5. **Transportation System:**
   - miles of primary road, end of first decade.

6. **Big Game Habitat:**
   - potential deer population, fifth decade;
   - potential elk population, first and fifth decades.

7. **Roadless Areas and Wilderness Study Areas:**
   - acres allocated to roadless recreation.

8. **Scenic or Visual Resources:**
   - acres allocated with scenic resource emphasis.

9. **Old Growth:**
   - acres allocated/dedicated to old growth emphasis.

10. **Fuelwood Supply:**
    - annual firewood supply in M acres, first and fifth decades.

11. **Snag Dependent Wildlife:**
    - average percent of potential cavity nester habitat, first and fifth decades.

12. **Winter Sports:**
    - areas available for winter recreation pursuits.

13. **Anadromous Fish:**
    - production of Steelhead smolt (smolt /meter sq.), first and fifth decade.

14. **Historic Trail Preservation:**
    - acres allocated for Summit Historic Trail.

15. **Off Road Vehicle (ORV) Use:**
    - miles of ATV trail, first and fifth decades.

16. **Round Mountain:**
    - area with recreation and scenic resource emphasis, planning period.

**Interalternative Comparisons and Major Trade-offs**

**Introduction**

This section summarizes relationships between economic values and the responses of the alternatives to the issues, concerns, and opportunities (ICO's). The purpose is to identify economic and noneconomic comparisons and trade-offs that can be quantified as ICO response indicators. To provide a partial framework for assessing comparisons and trade-offs, the long-term resource demands of the national, regional, and local communities have been

summarized. Selected economic values and quantified indicators of responsiveness to ICO's are tabulated (Table 2-9). Finally, differences and similarities among individual alternatives are summarized in terms of major trade-offs among competing objectives or responses to expressed issues, management concerns, or resource use and development opportunities. A complete understanding of differences among alternatives requires reading all of Chapters 2 and 4.

National, Regional, and Local Overview

National projections predict demands will rise for all outputs from National Forests (RPA). At the same time, there is also strong demand to protect and enhance environmental quality. Demands and prices for commodity production are generally determined in national and regional markets. Demand for timber from this Forest is high. Most timber sales are competitively bid to prices significantly higher than appraised prices. When national and regional markets are strong, prices are frequently bid upwards of $200 per thousand board feet for ponderosa pine. Demand for livestock forage is also high since the Forest and Grassland are the primary sources of summer forage in this area. All allotments are currently grazed, and the desire to utilize additional forage, or take over any unused allotments, is always high.

Demands for outdoor recreation uses are essentially local or regional. Recreationists on this Forest are predominantly local. The main exceptions are the fall hunting seasons which draw hunters from more populated areas of the state. Total recreational use of the Forest is predicted to rise about 59 percent in the next 50 years (see Tables 3-14 & 3-15, FEIS, Chapter 3).

Forestry Program for Oregon (FPFO)

The Oregon Department of Forestry has developed, in conjunction with the State Board of Forestry, the “Forestry Program for Oregon.” The objectives for this program as they relate to the Ochoco National Forest are discussed in detail in Chapter 4 of this FEIS. The preferred alternative (Alternative I) and Alternatives B-Modified, A and E-Departure would all meet the FPFO objectives for the planning period. Chapter 4 of this FEIS discusses the FPFO in more detail.

Summary of Environmental Consequences

Effects on Resources that Vary by Alternative

Oregon State Air Quality Implementation Plan

The current Forest and Grassland prescribed fire program is producing 10 to 20 tons/year of total suspended particulates (TSP). This amount varies by alternative. Fugitive dust from construction activities and traffic also occurs.

Cultural Resources

Cultural and archaeological sites will be protected in all alternatives. However, the possibility of damage, vandalism, and discovery of sites will be greater in alternatives that emphasize commodity resources.

Developed Recreation

The Forest maintains 30 developed recreation sites; 96 miles of trail, 15.8 miles of which are designated “National Recreation Trail”; and seven small reservoirs. Alternatives consider the development of additional recreational facilities, including trails, campgrounds and impoundments. The associated recreational activities can result in environmental effects of a local nature, such as vegetation loss, soil compaction, erosion, and conflicts with other resources, such as wildlife, timber harvest activities and grazing of livestock.

Dispersed Recreation

Over 445,000 visitor days of use are received annually, and recreational use continues to increase. This
amount of dispersed recreational use calls for controls on off-road vehicle use to prevent noise pollution, and damage to soil, vegetation, and aesthetics. It also calls for road closures to maintain habitat security for wildlife, to prevent damage to road surfaces, and to prevent conflicts with other resource management activities such as log hauling. The alternatives affect the amount of unroaded area available for semiprimitive and other dispersed recreational activities.

Energy Conservation
Activities on the Forest and Grassland which generally have a positive net energy balance are firewood harvesting and forage production. Generally, all other activities consume more energy than they produce. The average range that energy consumption from planned National Forest activities exceeds energy yields has been estimated to be in the magnitude of three to five billion BTU’s per decade.

Fire and Fuels
There are an average 108 wildfire ignitions per year. Prescribed fire is being increasingly used as a management tool. Approximately 15 to 20 thousand acres of slash are treated with prescribed fire annually. Use of fire in management can have effects on soil erosion, short-term appearances, air quality, vegetation productivity, plant community, species composition, and fuels.

Floodplains and Wetlands
Considerations for floodplain management as required by EO 11988, and protection of wetlands, EO 11990, are incorporated into all alternatives.

Human Resource Programs and Civil Rights
The Forest and Grassland will continue to participate in these programs in accordance with laws, administrative opportunities, and economic availability of programs. Minorities and economically disadvantaged groups will not be adversely affected by any of the alternatives.

Landscape Appearance
Emphasis on maintaining scenic quality within road corridors varies by alternative. Significant effects on landscape appearance are related to timber harvest practices; dispersion of cutting units; protection and management of riparian areas; and road location, design, and densities, all of which are related to direction in the management prescriptions in Chapters 4 of the Plans.

Livestock Grazing
Livestock grazing is maintained at nearly current levels for most alternatives considered. Livestock grazing activities, if not carefully managed, can cause soil compaction, impact streamside vegetation, affect water quality of stream habitat for fisheries, compete with wildlife, affect plant community composition and productivity over time, and alter the appearance of natural settings. Water developments and salt intended for livestock also benefit wildlife.

Minerals
There is little real difference in the effects on mineral production or mineral leasing between alternatives. The effects on mining operations and minerals leasing would be reflected in operation plans and lease stipulations, for example, alternatives proposing unroaded area management and research natural areas could result in attachment of no occupancy stipulations to specific leases. Mineral leasing provides returns to local governments in terms of receipts.

Old Growth Habitat
Old growth habitat is identified for protection and management for purposes of wildlife habitat and genetic diversity. The amount and dispersion varies by alternative. Protection of old growth habitat results in reduced timber harvest levels.

Prime Farmlands, Forestlands, and Rangelands
All the alternatives propose actions which are consistent with the intent of the Secretary of Agriculture direction for protecting and managing prime lands.

Research Natural Areas
Research Natural Areas (RNA’s) preserve places
for the purpose of research and maintaining genetic diversity. The maximum increase in area proposed for RNA's is 2,630 acres. The designation and protection of RNA's can affect timber harvest level, mineral leasing, road system development and grazing activities. Because of the small acreage involved, these consequences are minimal regardless of alternative.

Riparian
Approximately 800 miles of streamside area, plus wet meadows and lake shores, have been identified on the Forest as riparian area. While only an estimated two percent of the total Forest and Grassland area is considered riparian it receives the most intensive and concentrated use of any land area. More than 50 percent of the recreational use occurs there; transportation corridors are located along stream bottoms, grazing in the past has been intense; important wildlife habitats are found there, streamside areas provide productive timber sites; and fisheries habitat is dependent, in part, on the condition of streamside vegetation. Nearly all Forest activities have either direct or indirect effects on riparian areas and water quality. Protection and restoration of riparian areas can impact other activities over the short term.

Roads and Off-Road Vehicles
Over 4,550 miles of roads have been constructed on the Forest and Grassland. Management and maintenance of this transportation system requires closures and restrictions at times to protect road surfaces, other resources, and public safety. Travel planning for on-road and off-road vehicle use has placed more restrictions on vehicles and motorized use of the Forest and Grassland in order to protect resources.

Social and Economic
The Forest and Grassland directly influences a six county area which contains a population of about 110,000. Socio-economic consequences are related to economic stability of communities, livelihoods in terms of numbers and types of jobs, local government revenues, lifestyles, and community cohesion. Alternatives favoring timber and other commodity uses tend to impact livelihoods and lifestyles dependent on amenity values, and vice versa. On this Forest, the production of net cash returns to the U.S. Treasury, levels of employment, and payments to counties are directly dependent upon the level of timber production. These benefits are less under alternatives that place more emphasis on nontimber issues, such as those associated with wilderness and roadless areas, high levels of scenic quality, and vegetative diversity. The benefits associated with minerals are similar for all alternatives.

Threatened and Endangered Species
The only Federally listed species observed on the Forest and Grassland are the peregrine falcon and bald eagle. Neither is a known permanent resident. All Federal and State listed species are protected in all alternatives as provided for in the standards and guidelines in Chapters 4 of the Forest and Grassland Plans or Appendix D of this FEIS.

Formal consultation with the Fish and Wildlife Service (FWS) was initiated through request by the Forest Service in October 1986. The resultant FWS consultation addressed the possible effects of selecting Alternative E-Departure in the DEIS. The consultation was limited to the bald eagle and the peregrine falcon, both federally classified as endangered. The biological opinion of the FWS is that the implementation of Alternative E-Departure in the DEIS would not likely jeopardize the continued existence of the bald eagle and peregrine falcon.

There has been continued informal consultation between the Ochoco National Forest and the FWS since the DEIS. The FEIS incorporates a number of changes that have resulted from both the formal and informal consultation. Among them are the allocation of 570 acres to an Eagle Roosting Management Area (MA-F12) for all the alternatives, specific monitoring requirements for threatened and endangered species and direction to develop site specific management plans for the roosting sites during implementation of the Forest and Grassland Plans.

Timber Management
Timber production and associated management and cultural activities has the greatest influence locally
on jobs and economics of any resource on the Forest. An array of alternatives ranging from 15.6 million cubic feet production per year to 21.8 million cubic feet is examined in the environmental impact statement. The alternatives considered emphasize utilization of appropriate silvicultural systems which may be either even- or uneven-aged depending on field conditions and objectives. Timber management and associated activities such as road construction, reforestation, thinning, harvest, slash disposal, and various site treatments have a wide variety of effects on other resources, particularly soil, water, air, wildlife, fisheries, landscape, recreational experiences, and socio-economics. Practices and management requirements are applied that minimize adverse effects.

**Toxic and Hazardous Materials**
Activities that may occur on the Forest and Grassland involving the use or disposal of hazardous or toxic materials are required to meet all State and Federal laws and provisions. Therefore, provisions and procedures for dealing with any of these materials are the same for all alternatives.

**Unroaded Areas**
The areas remaining that have not been designated as wilderness or Wild and Scenic Rivers, totaling 52,880 acres, are treated in the alternatives. The range of alternatives provides for varying degrees of development, or retention of roadless characteristics for semi-primitive recreation.

The most significant conflict of maintaining unroaded areas is with timber production. Approximately 38,430 acres will be managed in an unroaded condition for semi-primitive recreation under the preferred alternative.

**Utility and Transportation Corridors**
All alternatives recognize State and County road corridors. Utility corridors are also recognized and no alternatives result in any conflict with movement of power or energy throughout the area.

**Wild and Scenic Rivers**
An inventory conducted by the National Park Service under Public Law 88-29 and Public Law 90-252 identified segments of the Deschutes, Crooked River, and North Fork Crooked River for study and potential classification under the Wild and Scenic Rivers Act. The Oregon Rivers Act of 1988 classified segments of these rivers. All alternatives provide for the protection of the rivers until required planning for their management is complete.

Eligibility and suitability determinations have been made for a portion of the Squaw Creek area. A 7.5 mile segment of the creek, 1,370 acres, from the Grassland boundary to the confluence with the Deschutes River would be managed as a "scenic river." In addition, it would be recommended for inclusion into the Wild and Scenic Rivers System. This would be a preliminary recommendation that would receive further review and possible modification by the Chief of the Forest Service, the Secretary of Agriculture, and the President of the United States. Congress has reserved the authority to make final decisions on designations of rivers as part of the National Wild and Scenic Rivers System.

**Wilderness Establishment**
Three wilderness areas totaling 36,200 acres were established under the Oregon Wilderness Act of 1984 on the Ochoco National Forest. A range of options was considered for the Deschutes-Steelhead Falls area which the Oregon Wilderness Act identified for further study. No wilderness is being recommended. A 7,840 acre semi-primitive nonmotorized management area is being established which involves part of the WSA, some of the remaining portion is included in the classified Deschutes Scenic River. North Fork Crooked River area is addressed in a separate study by the BLM. The BLM recommended no wilderness in their draft EIS for this area.

**Wildlife**
Important game species habitat, namely deer and elk, is afforded some degree of protection in all alternatives, but its management is emphasized in certain ones. Snag and old growth forest habitat is provided at varying levels throughout a range of alternatives. Fish habitat protection is related to those alternatives emphasizing management of riparian areas. Management activities and uses on the
Forest and Grassland directly and indirectly affect wildlife and fisheries habitat. Road construction, timber harvest, timber cultural practices, livestock grazing, recreational uses, prescribed fire, and firewood cutting are common activities on the Forest and Grassland which can affect wildlife and fisheries habitat. Alternatives, management requirements, standards and guidelines, and project design all incorporate means to minimize impacts on wildlife and their habitat.

Probable Adverse Environmental Effects that Cannot be Avoided

1. Soil displacement or erosion can be expected to result from planned management activities, such as vegetation removal, slash disposal, log skidding, prescribed fire, construction and maintenance of roads, trails, transmission facilities, recreation sites and others. Soil productivity would be maintained except for sites dedicated to roads, skid trails, log landings, recreation sites, and other facilities or uses that may compact the soil, alter the soil profile, or deplete nutrients. An estimated one percent of the Forest and Grassland area would be occupied by roads or facilities. Experience has shown that temporary road surfaces can be re-vegetated, but the productivity is reduced. Forest-wide, an estimated 10 percent of cable-logged areas and 30 percent of tractor logged areas would experience increases in soil bulk densities or compaction. These factors, in turn, have indirect effects relating to reduced wildlife habitat, vegetation productivity, occurrence and spread of noxious weeds, and increases in stream sedimentation.

2. Prescribed fire use may be expected to contribute to total suspended particulates (TSP) in the atmosphere, to periodic increases in haze, and reduced visibility.

3. The natural appearance of the landscape and forest would change over time, with the natural and characteristic features as they exist today giving way to more domination in places by management activities and results of management.

4. Forest vegetation would be altered in respect to species composition, stand structure, and age. Existing mature forest “suitable” lands would be subject to management treatments. Where feasible, mixed conifer stands would be replaced with currently more economically or silviculturally desirable species (primarily ponderosa pine). Other management treatments include overstory removal of old growth ponderosa pine from multistoried stands, resulting in a reduction in basal area, and removal of less desirable species within densely forested areas by thinnings. Intensively managed or regulated forests may provide less habitat for species dependent on old growth forest, snags and down material, and provide less scenic settings, species diversity, and habitat diversity.

5. Average size of trees that are harvested would change over time to smaller material as old growth and existing mature forest is converted to younger stands. This would have an effect on types of harvest equipment and wood processing, and machinery and manufacturing requirements; and likely will bring a shift towards cubic foot management rather than board feet.

6. Approximately 93,110 acres on the Forest and Grassland remain roadless. With the exception of 36,200 acres designated as wilderness, 4,030 acres designated as wild and scenic rivers, and 52,880 acres remaining available, opportunities for semiprimitive recreation may decrease over time.

7. Increased road densities, improvement in access, subsequent increases in human presence, and continuing expansion of management activities can result in reduction of wildlife habitat security, harassment of wildlife, increased road kills, physiological stress in wildlife species resulting in altered behavior and productivity, and changes in hunter attitudes and experiences over time. The preferred alternative provides for road management closures and restrictions which would reduce open road density over the next five decades.
8. Actions to improve riparian conditions may result in increased costs to grazing management, e.g., installation of improvements (fencing and water developments), herding, transport to control stock distribution and use, and possible temporary reductions in animal unit months.

9. Current procedures cannot insure that all cultural resource sites will be located. Some sites could be inadvertently destroyed or damaged. Such impacts are unavoidable pending advances in inventory techniques.

10. Forest users could encounter more controls and restrictions over time as management intensity, resource competition, and human populations increase.

Short-term Uses of the Environment and Maintenance of Long-term Productivity

From a perspective that each generation is trustee of the environment for succeeding generations, an objective of the Plans is to provide for the proper and continued development of resources in a manner that maintains economic viability, yet maintains local natural heritages, such as, wildlife habitat, outdoor recreation opportunities, water quality, scenic qualities, and livestock grazing. The preferred alternative emphasizes a balanced mix of uses and intensive commodity (timber, range) production on suitable places in order to help provide economic stability, but also attempts to provide for the protection of other resources (soil, water, wildlife habitat, aesthetics).

While the Plans involve harvest of mature timber, sustaining or improving long-term productivity is planned for through intensive forest management practices (e.g. reforestation and thinnings). This may result in future utilization of smaller trees to maintain harvest levels over time. Lands were identified as “unsuitable” for sustained yield timber management due to regeneration difficulties. Dispersion of timber harvest activity, retention of old growth, and protection of riparian areas and big game habitat have all been planned to prevent impairment of long-term land and resource productivity.

Construction of roads, mechanical slash piling, and log skidding are short-term uses that can reduce long-term vegetation productivity.

Increases in road densities, improvement in access, subsequent increases in human presence, and continuing management activities have the potential in the near future to create effects that will affect long-term productivity of wildlife habitats, aquatic systems, and local socio-economic aspects.

Irreversible or Irretrievable Commitment of Resources

This plan deals with both developed and undeveloped or roadless lands. Lands where road systems, plantations, thinnings, and structures are established represent a type of economic commitment that commits the land to those activities. These investments represent “sunk funds” from an economic standpoint and are not retrievable, nor do they necessarily have any “liquidity,” over the planning period.

The specific acres, estimated to be one percent of the total Forest and Grassland area, upon which roads and facilities are constructed represent a loss of soil/vegetation productivity and unaltered landscape.

Use of rock for road surfacing and construction purposes, estimated to be 200,000 tons annually on the Forest and Grassland, is an irreversible and irretrievable commitment of a resource, but is not considered critical because of the abundance of good quality rock in this locale.

Undeveloped and roadless areas once allocated for development will, within a relatively short time, become irretrievably unsuited for wilderness classification. In the case of lands already intensively developed by roading, a high degree of irreversibility exists; whereas, in the case of undeveloped lands, frequently a wide range of management options exists.

Dasmann, et. al., in Ecological Principles for Economic Development, 1973 (pp 22-23), recognized six
broad development levels for lands, each representing progressively greater commitment of resources. The development levels are:

1. The land can be left in a completely natural state and reserved for scientific study, educational use, wilderness, watershed protection, and its contribution to landscape stability.

2. It can be used as a park, refuge, or reserve with the natural scene remaining largely undisturbed to serve as a setting for outdoor recreation and an attraction to tourism.

3. It can be used for limited harvest of its wild vegetation or animal life, but maintained for the most part in a wild state—serving to maintain landscape stability, support certain kinds of scientific or educational uses, provide for some recreation and tourism, and yield certain commodities from its wild populations.

4. It can be used for more intensive utilization of its wild products as in forest production, pasture for domestic stock (recreation), or intensive wildlife production. In this case, its value as a “wild” area for scientific study diminishes, but it gains usefulness for other kinds of scientific and educational uses. Its value for (some) tourism and outdoor recreation diminishes, but is not necessarily lost. Its role in landscape and watershed stability is changed, but may be maintained at a relatively high level.

5. The wild vegetation and animal life having been removed in part, it can be intensively utilized for the cultivation of planted tree crops, pastures, or farming crops.

6. The wild vegetation and animal life having been almost completely removed, it can be used for intensive urban, industrial, or transportation purposes.

So long as any of the first three choices are taken, the option remains open to change to any of the others. In the fourth choice, the options for restoring the land to any of the first three levels are reduced, but not eliminated. Lands allocated to development are likely to approach the fifth and sixth level over time. This would largely prohibit any shift to other alternatives on those acres.

For Alternative I, with the resource allocations proposed herein, 19 percent of the lands are committed to categories of “low” or “moderate” irreversibility; about 80 percent of the land that is proposed for intensive timber culture, transportation systems, special uses, and rangeland management can be categorized as “moderately high.” Another one percent would be considered “high” irreversibility of irretrievability for commitment of resources (Table S-10, FEIS Summary).

**Timber Supply and Forest Management**

**Comparison of Past, Present and Alternative Timber Harvest Levels**

The potential yield (PY) under the current timber management plan is the total harvest level that could be sustained assuming intensive forestry practices on all available acres. This includes adjustments to meet multiple resource objectives. This was calculated to be 20.86 MMCF (139.5 MMBF) and adjusted to 20.4 MMCF (136.5 MMBF) in 1984, as a result of the Oregon Wilderness Bill. A similar value was not calculated for the alternatives. It would be equivalent to a maximum timber FORPLAN run for each alternative if unsuitable acres were included in the available acreage base.

The programmed allowable harvest under the current timber management plan is that part of the potential yield scheduled for harvest in a specific year (see Table 2-10). It was calculated for the current plan by: (1) reducing the acreage base by the acres of marginal land that we did not plan to treat, and (2) by reducing yields based on difference in acres of intensive management (planting of genetically improved stock and precommercial thinning) predicted under the potential yield and what was actually planned to be accomplished. (This process was known as the “earned harvest effect” (EHE)). This could be adjusted annually if there was signifi-

---

1/ The current plan did not have a category called “unsuitable” so there was no reduction in available land base for lands that could not be reforested. It did have a category called “marginal” which included steep slopes and critical soils, and stagnated submerchantable lodgepole. Some harvesting was programmed from these lands but it was a separate component and could not be substituted for “standard” volume or vice versa.
cant change in acres of intensive management practices or in marginal land treated from what was programmed. This was originally calculated to be 19.86 MMCF (132.7 MMBF) and was adjusted in 1984 to 19.46 MMCF (129.8 MMBF). This is equivalent to the Allowable Sale Quantity (ASQ) plus the salvage volume.

Table 2-10 displays the past actual sold and cut volume, planned harvest level from the existing plan, and range of harvest levels for each alternative. The range of harvest levels shown shows the highest and lowest predicted harvest level in board feet for the first decade. All volumes are average annual figures for a particular decade. This table also displays the estimated volume of ponderosa pine for this same period. Additional timber resource information by alternative and benchmark is also presented in Table 2-11.

The local industry is most interested in the ponderosa pine volume, and it has the greatest impact on the local economy, since much of the pine lumber is remanufactured to molding and other products locally. It is estimated that the sell volume has included 90 to 100 MMBF of pine in recent years. The current inventory shows 67 percent of the total volume is in ponderosa pine (see Appendix E). So the pine harvest in all alternatives will be 67 plus or minus five percent of the total harvest volume. However, the actual pine volume scheduled for harvest will vary considerably by alternative during the next five decades.

Effects of the Alternatives on the Ponderosa Pine Harvest
The range of ponderosa pine volume by alternative is displayed in Figure 2-3.

Alternative A has the highest volume of pine during the first decade due to the large proportion of harvesting in the first decade in two-story pine types. The volume decreases by about 30 MMBF after the first decade and remains at a relatively low level for the next four decades.

Alternative B-Modified would provide about 85 MMBF of pine during the first decade. Alternative B-Modified would maintain the highest level of pine during the first five decades of all the alternatives.

Alternative E-Departure has a first decade volume of 87 MMBF and declines to an estimated 52 MMBF in the fourth decade.

Alternative C-Modified would provide about 63 MMBF in the first decade, remaining constant through the fifth decade.

The pine volume in the long term (decades six and beyond) depends on harvest level and intensity of management. Alternative I provides for a stabilization of the ponderosa pine harvest over time, as does the other alternatives.

Uneven-aged Management
Uneven-aged management has been included in Alternatives B-Modified, C-Modified and I. This silvicultural system was included in these alternatives in response to public interest in its application as an alternative to clearcutting. Expectations would be increased size of ponderosa pine crop trees (20 inch DBH), improved conditions of forested habitat for wildlife and more desirable scenic qualities.

The range of acreage of ponderosa pine which would be managed with uneven-aged silvicultural systems is shown in Table 2-9 and Figure 2-4.

1/ Note that due to different bases for calculation, these figures may not be directly comparable. However, they may be used to show changes in specific components for calculations over time. All calculations were done in cubic feet. The volumes in this table are estimates based on board foot/cubic feet ratio.

2/ Yield of timber projected for the period of 1980 to 1989, as calculated for the 1980 Timber Management Plan and adjusted for 1984 Oregon Wilderness Bill. The Programmed Allowable Harvest (P A.H.) is the sawtimber from green and salvage sales scheduled for harvest.

3/ Allowable sale quantity calculated for the current land and resource management plan direction, projected into the future using new scientific information, such as yield tables and suitability for timber harvest, and using FORPLAN analysis model.

4/ Estimated volume of ponderosa pine that is included in green sale volume.

5/ Average volume sold was not adjusted for "buy-back" volume.

6/ Reduction in all but E DEP is due to change in BF/CF ratio and estimated reduction in salvage volume as more stands become managed. Change in E DEP is mostly due to the planned departure from even-flow.

7/ Actual firewood volume is based on years 1985 to 1988. Essentially all of this was sold as personal use. Planned volume is the estimated amount if firewood available. Typically less than half of this will be utilized.

1/ Tentatively suitable land for all alternatives is 533 M Acres

2/ This is based on 1972 land classification system and adjusted for Amendment #1 of the Timber Plan.
Social and Economic Wants and Needs of Local Communities

This section compares and discusses the economic consequences of the alternatives. The comparisons focus on present net value (PNV), market and nonmarket values, costs, net receipts, returns to treasury, and non-cash benefits. Each alternative has non-quantifiable benefits and costs which should also be considered when attempting to rank the alternatives in terms of net public benefits. This section also discusses the social effects of the alternatives. Appendix B provides additional discussion on social and economic evaluations of the alternatives.

Differences in Present Net Values

Present net value (PNV) is the primary quantitative measure of economic efficiency used for all benchmarks and alternatives. It is also an important measure of the dollar value of the alternatives. PNV has been calculated to be the sum of all market and nonmarket priced values, less all management costs for the 50-year planning horizon, discounted to present values using a four percent interest rate. The relationship between PNV and net public benefits is discussed on pages 2-3 through 2-4 in this chapter.

The Max PNV benchmark and six alternatives are ranked by decreasing PNV in Table 2-12. Table 2-14 provides further detail on discounted costs and benefits by resource group. The Max PNV benchmark is provided as a reference point only. It is an estimate of the discounted net economic returns the Forest could receive for its priced resources if they were managed solely to maximize present net value.

The main factor influencing patterns in PNV, benefits, and costs is timber management. Timber values represent from 53 percent to 65 percent of the total dollar values in the alternatives. Values produced from selling timber are, in general, far in excess of related costs. As timber harvest levels decrease across alternatives, discounted costs and benefits, PNV usually decrease as well. This pattern is due mainly to non-timber resource objectives restricting timber practices and harvests. Although recreation related benefits (including hunting and fishing) do make up a significant portion of the total dollar benefits (28% to 41%), increases in these dollar benefits do not make up for the PNV lost from timber. Therefore, the greater the non-timber resource objectives, the lower the timber discounted benefits and costs, and PNV.

This general pattern is modified by the intensity of the timber management activities employed. Some alternatives schedule timber practices and harvests at the most economically efficient level, given other resource objectives (Alternatives C-Modified, I, and E-Departure). Other alternatives apply more intensive timber practices to achieve the highest timber volumes possible, given other resource objectives (Alternatives A, B-Modified, and NC). This results in higher timber benefits, but also higher costs and lowered PNV. In each of these two groups of alternatives the general pattern discussed above holds. The exact combination of non-timber resource objectives and timber management intensity determines the ranking in PNV of these two groups together.

The PNV of the NC Alternative is an estimate. It is also based on a programmed harvest level of 129 MMBF. If the estimate was based on the potential yield of 136.5 MMBF, the PNV would be significantly higher.

The Forest and Grassland are considered to have potential energy resources. However, very little testing and development has taken place to date. No estimates have been made of future extractions, so energy values were not included in the economic analysis. However, oil and gas leasing provides significant returns to the Treasury and to counties. The alternatives have little effect on mineral activities.

Differences in Costs

Capital investment costs include trails, roads, reforestation, timber stand improvement, prescribed burning, and physical structures for range, recreation, fish, and wildlife. Other costs include operating and maintaining facilities, program management, and support costs associated with management of
other resources. Capital investment costs pertain mostly to roads and timber stand management. For example, 76 percent (Alternative C-Mod) to 95 percent (Alternative A) of capital investment costs are associated with road construction and timber management. The majority of operation and maintenance costs are program management, followed by support funds necessary to carry out timber programs.

Because most costs are associated with timber management, the higher the timber output, the higher the costs. Generally, capital investment costs decrease significantly over time due to declining road construction and timber stand improvement practices. Operation and maintenance costs remain fairly constant over time except for alternative E-departure's where timber volume declines over time.

Fixed costs represent a relatively small portion of the total costs (20% to 30%). The remainder of the cost for each alternative varies with the objectives of the alternative.

Costs associated with timber practices and harvests constitute a large portion of the total costs. Alternative B-Modified has the highest cost of any alternative and only 29 percent of the discounted cost is directly attributed to resources other than timber and roads. Road construction and reconstruction is almost entirely tied to timber harvests on this Forest. Alternative C-Modified has the lowest cost of any alternative and the highest benefits associated with amenity outputs, yet only 35 percent of the costs can be attributed to resources other than timber.

Differences in Economic Benefits and Cash Flows

The total economic benefits of the alternatives come from priced resources which include both “market” outputs, and those with “assigned” values. Market values represent the unit price of an output that is normally exchanged in a market. On this Forest, timber is the primary market output, accounting for over 90 percent of the market outputs and 50 percent to 65 percent of the total economic benefits of the alternatives. Other market outputs include livestock grazing, campground use, special use permits, and minerals leasing. Assigned values represent the unit price of an output not normally exchanged in a market. Various analytical techniques were used to estimate values that people would be willing to pay for these benefits. Outputs with assigned values include dispersed recreation, wilderness use, hunting, fishing, and water quality improvement. Hunting and fishing are the major assigned values, comprising from 16 to 26 percent of the total economic benefits. The remaining 18 to 24 percent is split in different proportions, depending on the alternative, among livestock grazing, developed recreational use, dispersed roaded recreational use, and dispersed non-roaded recreational use.

Total market values range from 62 percent (Alternative C-Modified) to 70 percent (Alternative B-Modified) of the total economic benefits. Alternatives in the high end of this fairly narrow range have relatively high timber benefits and/or relatively lower fish, wildlife, or recreational values. The opposite is true for alternatives in the low end of the range.

Cash receipts are revenues returned to the Forest and Grassland for stumpage, grazing permits, campground fees, leasable minerals, and special use permits. However, the Forest generates economic benefits to users which are not realized in terms of cash flows. These are referred to as “noncash benefits.” They refer to the benefits individual resource users receive when they are charged less for the resource than they would be willing to pay, or current market prices indicate they should pay. Noncash benefits are the difference between the full economic value of the resource and the fees actually paid to use that resource. Table 2-13 displays the relationships between total receipts, total budget costs, net receipts, and noncash benefits for each alternative in order of decreasing net receipts. All alternatives receive more money than they spend (net receipts are positive). Fish and wildlife provide the most noncash benefits in all alternatives, followed by recreation, then range. Timber provides nearly all of the cash receipts.

Generally the proportion noncash benefits contribute to total economic benefits increases as net receipts decrease. The decrease in net receipts as

1/ Direct comparisons of benefits and costs by individual resource provide broad indications of specific relationships, but they may be misleading because many costs are nonseparable under multiple-use management

2/ These costs include general administration, cultural resources, lands and minerals, human resources, and protection
noncash benefits increase is a result of more land and resources being allocated to producing noncash benefits, thus lessening the resources available to produce cash receipts.

Table 2-13 (decade one) as compared to Table 2-12 shows that alternatives with higher net receipts in decade one generally have higher PNV's. This trend holds true in all but one case.

This case involves Alternative NC. In Table 2-12, Alternative NC has the lowest PNV, but in Table 2-13 it has the third highest net receipts. The cause of this is two-fold: first, it has the lowest non-cash benefits of all the alternatives, and secondly, Alternative NC is different from the other alternatives in that it does not ensure all management requirements. This allows more of the higher value ponderosa pine stands to be harvested in decade one. However, to satisfy particular harvest scheduling requirements, cash receipts drop off dramatically after the first decade. Table 2-13 shows that the net receipts for Alternative NC drop in rank from third in the first decade, to last in the fifth decade. Alternative NC also harvests timber at levels beyond that which is efficient in order to meet current sale levels. This results in higher total receipts, but also higher costs resulting in lower PNV's. As a result, Alternative NC has relatively high net receipts in decade one, but a relatively low PNV.

When decade five from Table 2-13 is compared with Table 2-12, the relationship between net receipts and PNV's is not as strong as it was for the first decade. The ranking of alternatives from highest net receipts to lowest net receipts shows the same changes from decade one to decade five. Alternatives E-Departure and NC have higher net receipts in the first decade than in later decades, while Alternative B is ranked higher by net receipts in decade five than in decade one. Because of the PNV discounting computations, high returns in early decades will affect the PNV more than high returns in later decades. The exception is NC, because the drop in net receipts is so sharp the net receipts in decades two to five outweigh the high first decade receipts, thus lowering the PNV.

Comparing the first and the fifth decades in Table 2-13, all alternatives show an increase in net receipts. The major factor is a decrease in costs because much less road building is necessary in the fifth decade. Also, real stumpage prices increase over time.

Noncash benefits for all alternatives increase from decade one to decade five. Part of this increase is a result of a projected increase in recreation demand. The rest of the increase can be attributed to habitat management for big game and fish. The time lag between habitat improvement and an increase in hunting and fishing causes benefits to show up most dramatically in future decades. The percent increase between decades one and five in noncash benefits ranges from 13 percent in the high commodity alternatives, to 28 percent in Alternative C, an amenity oriented alternative.

Social Effects

Direct Effects

The direct effects of the alternatives include the following:

- Employment levels produced by the alternative's mix of outputs (see Table 2-15);
- The amount of the Forest budget;
- The amount of 25 percent monies paid to the counties.

Indirect Effects

The previously mentioned effects of the various alternatives would produce effects on the social fabric of the area as follows.

Effects on Occupational Lifestyles

For loggers and sawmill workers, Alternative B-Modified would increase employment by 44 jobs, which is around four percent of total logging and sawmill employment. Alternatives A, I, and E-Departure would produce increase of 14, 15, and 28 jobs respectively.

For workers in remanufacturing operations, the changes range from a three percent employment

Merchants benefit from any alternative. The smallest gain, 21 jobs, is in Alternative A; the largest gain, 65 jobs, occurs in Alternative E-Departure. Small town merchants hire a smaller proportion of employees than do other business. Therefore, these figures are considered to understate the gains to the merchants. When these merchants do hire employees, they often work part time and for low wages. These jobs are often taken by women. Often these jobs provide a secondary income for a family.

Effects on Leisure Lifestyles
Alternative C-Modified would provide for the most recreational activities. Elk and fish are at the highest levels of any of the alternatives, as are opportunities for roadless recreation. Landscapes appear most natural to the driver or hiker. Fuelwood gathering is the one activity which is at its lowest.

At the other end of the scale, Alternative A provides, in general, the least recreational opportunities. Roadless areas and fish are at the lowest levels. Unlike the other alternatives, there is no construction of trails for hiking, ATV’s, cross-country skiing, or snowmobiling.

Generally speaking, Alternative B-Modified provides the next lowest level of recreational opportunities. Roadless areas and elk are low. The scenery is the lowest of all the alternatives. However, fuelwood is at its highest; and trail construction and increased numbers of fish improve the picture.

Alternatives E-Departure and I provide an intermediate situation. Alternative I provides more roadless areas, trails, and fish; while Alternative E-Departure offers slightly more elk plus a provision for a semiprimitive motorized area.
Effects on Social Structure: Community Cohesion and Stability

"Community Cohesion" is an estimation of whether a given alternative will tend to unify or polarize a community. While a diversity of opinions in a community is generally desirable, it is assumed that polarization of the community is harmful and that cohesion is beneficial. It is further assumed that polarization will be caused by the adoption of an alternative which greatly favors one point of view over others. In contrast, the selection of an alternative that meets to some extent the desires of diverse participants is assumed to produce cohesion.

Judging by this criterion, Alternatives B-Modified and C-Modified would produce polarization. The public response to E-Departure, the Draft Preferred Alternative, included many negative comments about its "departure" harvest schedule. Under Alternative A, existing polarization would not diminish. Alternative I is the one alternative judged likely to promote some degree of community cohesion.

Livestock Grazing and Allotment Management

Alternatives E-Departure, I and B-Modified all seek to increase the forage available over time. Alternative B-Modified is the most aggressive of the three in its emphasis on forage production. Alternative C-Modified emphasizes amenities over commodity resource use and accordingly shows the lowest forage production for livestock. Alternatives NC and A maintain about the current level of forage production over time.

Riparian Area Management

All alternatives show some progress toward meeting the public and management concerns over livestock impacts to riparian areas. Alternatives NC and A would improve the least amount of riparian area over time, generally limiting the rehabilitation and enhancement to anadromous fisheries. Alternative E-Departure would improve more acreage by adding additional enhancement work on key trout fisheries, as well as to anadromous fisheries. Alternatives B-Modified, I and C-Modified would include rehabilitation and enhancement to bring 17,500 acres to "excellent" condition by the fifth decade. The desired future condition for these three alternatives would be "excellent for all of the 20,240 acres of riparian area on the Forest and Grassland."

Transportation System

The primary difference between the alternatives is in the management strategy for the miles of road maintained open for public travel. All alternatives close and restrict use on some roads to protect the investment, to provide for public safety, to reduce soil erosion and degradation of water quality, and to
increase the wildlife habitat effective in key areas on the Forest and Grassland.

**Big Game Habitat**

A number of the alternatives provide for big game habitat through the dedication of or emphasis on management for winter range characteristics. The indicator for the responsiveness of the alternatives to this issue is the potential population levels of elk and deer that could be maintained. Table 2-9 and Figure 2-8 illustrate the responsiveness of each of the alternatives.

Table 2-9 and Figure 2-9 illustrate the areas allocated or dedicated to a wildlife management strategy (includes old growth and eagle roosting areas but is reflective of emphasis for big game).

**Roadless Areas and Wilderness Study Areas**

A number of the alternatives allocate or manage areas for unroaded recreation (nonmotorized and without roads). Table 2-10 and Figure 2-10 illustrate the area that will be maintained in an unroaded condition for the life of the planning period.

The North Fork of the Crooked River Wilderness Study Area, 1,125 acres, is incorporated in all the alternatives.

**Scenic or Visual Resources**

Public and management concerns for the maintenance of the scenic qualities on the Forest and Grassland resulted in provisions for scenic resource emphasis along key travel corridors for a number of the alternatives. This is in addition to the visual quality objectives assigned to all alternatives. Table 2-9 and Figure 2-11 illustrate the area allocated or dedicated to a visual resource management emphasis.

**Old Growth**

Old Growth areas have been designated according the Regional definition for all the alternatives considered in this FEIS. The range of acreage allocated is presented in Table 2-9 and Figure 2-12. Those alternatives with higher emphasis on commodity outputs, such as Alternative B-Modified,
have lower allocations with total existing old growth rapidly depleting over time. On the other end of the spectrum, alternatives such as C-Modified with amenity value emphasis, allocate larger areas to old growth and will retain larger acreages over time.

Fuelwood Supply

All the alternatives would supply a portion of the fuelwood demand on the Forest and Grassland. Those alternatives that have higher levels of timber harvest activity would supply a higher percentage of the demand. The amenity alternative, C-Modified, would provide the least amount of fuelwood. Those alternatives such as I, which would stabilize the timber supply over time, would provide a more consistent supply than alternatives which depart from an even flow of timber harvest and experience a long-term reduction in harvest. A similar reduction in available fuelwood would shadow the decline in timber harvest.

The fuelwood supply for each alternative for decades one and five is presented in Table 2-9 and is illustrated in Figure 2-13.

Snag Dependent Wildlife

All the alternatives provide for the maintenance of a portion of the potential snag dependent species habitat. The ability of any alternative to provide snag habitat is directly related to its timber harvest strategy. Those alternatives with the higher timber harvest levels over time will have less ability to provide a portion of the potential habitat. The percentage of potential snag habitat is presented by alternative in Table 2-9 and is illustrated in Figure 2-14.

Winter Sports

All the alternatives are responsive, to a degree, to the public interest in having areas available for winter recreation. All the alternatives except for NC and A would provide for winter recreation at Bandit Springs through a 1,580-acre management area allocation. This area is presently closed to snowmobilers to allow for cross-country skiing and similar nonmotorized winter recreation pursuits.

The top of Lookout Mountain would be open to snowmobile use on all the alternatives except for C-Modified and E-Departure.

Anadromous Fish

All the alternatives provide for the rehabilitation of key riparian areas along all anadromous fisheries, and schedule enhancement activities to provide for maintenance or enhancement of steelhead production. Estimated smolt production over time is displayed in Table 2-9. It is planned to be the same for all the alternatives, that is anadromous fish production is assured at this level for all alternatives.
Historic Trail Preservation

The Summit Historic Trail is presently designated as a National Historic Trail and would retain that status for all the alternatives. Alternative I allocates 9,560 acres to protect the existing integrity of the trail and to preserve its historic and related scenic qualities.

Off-Road Vehicle (ORV) Use

The off-road vehicle use issue is an administrative problem for all the alternatives. At this point in time it is more of a social issue than one of resource impacts. All the alternatives would have adequate regulations in place to deal with resource impacts. Off-road use by ATV’s, snowmobiles and motorbikes is seen as not being compatible with some resource emphases. Off-road use would be prohibited on all the alternatives for areas allocated as wilderness, wilderness study areas, and wild and scenic rivers - a total of 41,355 acres amounting to four percent of the Forest and Grassland.

Off-road use would be restricted to designated routes and prohibited from December 1 to May 1 for eagle roosting management areas (570 acres) for all alternatives.

The Bandit Springs area, in Alternatives B-Modified, E-Departure, I and C-Modified, would prohibit snowmobile use on 1,580 acres.

Alternative I would include a number of additional off-road vehicle use closures and restrictions. Motorized use would be prohibited on an additional eight management areas, a total of 35,580 acres amounting to four percent of the Forest and Grassland. Off-road use would be restricted to the summer months (closed December through April) to protect such resources as big game winter range on 186,790 acres amounting to 20 percent of the Forest and Grassland.

Alternatives B-Modified, C-Modified and I would begin to develop an ATV trail system to manage off-road use. The Forest and Grassland program for ATV trails is illustrated in Tables 2-8 and 2-9. The intent would be to move towards designating off-

Round Mountain

None of the alternatives provide for any special resource allocations for the Round Mountain area, except for Alternatives B-Modified and I which allocate 1,000 acres along the Round Mountain National Recreation Trail corridor to provide for management of its scenic and recreational values. Activities and uses which take place on Round Mountain are considered to be part of the multiple uses which occur in the general forest.

Chapter 3

Affected Environment

Introduction
This chapter presents an overview of conditions, land uses, and resources as a foundation for understanding the changes that would take place in response to the alternatives discussed in Chapter 2. It describes the physical, biological, social, and economic environments of the Ochoco National Forest and Crooked River National Grassland. The following is a list of the resources that will be discussed.

AIR QUALITY
BIOLOGICAL DIVERSITY
CULTURAL RESOURCES
FACILITIES
FIRE
FORAGE
FOREST HEALTH
FOREST RESIDUES
FUELWOOD
LANDS
MINERALS AND ENERGY
OLD GROWTH:
RECREATION
SCENIC RESOURCES
SOCIAL AND ECONOMIC
SOIL
TIMBER
TRANSPORTATION SYSTEM
UNROADED
WATER
WILD AND SCENIC
WILDERNESS
WILDLIFE AND FISH

Changes between Draft and Final

As a result of public comments, Forest management activity, and Congressional action, Chapter 3 of the DEIS has been updated to accurately reflect the significant environmental changes. Data included on population, incomes, harvest volumes, operating costs, and revenues have been updated to the most current figures available. In addition, portions of the text have been reorganized and rewritten to improve clarity and readability. Significant additions are:

A discussion in the Recreation Section of the Oregon Omnibus Wild and Scenic Rivers Act, and the eligibility and suitability of a 1,370 acre segment of Squaw Creek for possible designation to the Wild and Scenic River System;

A major section on Biological Diversity;

A major section on Old Growth with updated inventory figures;

A section on Forest Health which places the former Forest Pest: : discussion in an ecological context;

A section on Forage which mentions uses of the resource other than for livestock grazing;

A discussion of the Cultural Resource Inventory Plan in the Cultural Resource Section,

A discussion of the Ochoco National Forest and Crooked River National Grassland's unique contributions to the State's economy in the Social and Economic section; and

A discussion of the supply and demand for timber at the national, regional, and local levels in the Timber Section.
Location

The Ochoco National Forest and Crooked River National Grassland are located near the geographic center of Oregon (Figure 1-1). Combined, they occupy approximately 956,877 acres in the southern part of the Blue Mountain Physiographic Province, which includes the Blue, Ochoco, and Maury Mountains.

Being too large to effectively administer as one unit, the Blue Mountain Reserve was split, by Executive Order, into four National Forests on July 1, 1908, thus forming the Deschutes, Malheur, Whitman, and Umatilla National Forests. The Ochoco National Forest was created in 1911, by combining parts of the Deschutes and Malheur National Forests.

Headquartered in Prineville, the Ochoco National Forest is part of the former Blue Mountain Reserve. The reserve, established in 1906 by President Theodore Roosevelt, was divided into east and west units.

In 1960, the 111,379-acre Crooked River National Grassland came under the administration of the Ochoco National Forest. The land was returned to government ownership in the late 1930's, with the purchase of submarginal and drought-stricken homesteaded lands under the Resettlement Administration and the Bankhead-Jones Act.
Land Ownership

Land Ownership in the Ochoco National Forest and Crooked River National Grassland is fairly well consolidated in four parcels of land in five counties. Crook, Harney, Jefferson, Wheeler, and Grant Counties are home to the Ochoco National Forest and Crooked River National Grassland.

Parcels of land belonging to the Bureau of Land Management, State of Oregon, and private parties are intermingled and border the Ochoco National Forest. Management of these lands within the boundaries of the Ochoco National Forest can, and may continue to, conflict with the management of the Ochoco National Forest. Adverse impacts on resources may result, and the potential for trespass is also a possibility.

Climate

The climate of the Ochoco National Forest and Crooked River National Grassland is relatively arid. Annual precipitation ranges from less than 10 inches to over 30 inches at higher elevations. The Cascade Mountain Range intercepts much of the moisture-laden air coming from the Pacific Ocean. Areas to the east of the Cascades are in a “rain shadow.” The climatic effects of the rain shadow and central Oregon’s elevation are low relative humidity, low rainfall, large daily temperature fluctuations, and cool average temperatures. The central Oregon area is often referred to as a “high desert.”

Geology and Topography

The Ochoco National Forest includes moderate to gentle slopes with elevations ranging from 2,200 to 7,000 feet. The Crooked River National Grassland consists of rolling range interspersed with deep canyons and volcanic buttes.

The physiographic province of the Blue Mountains provides the diverse topography of the Ochoco National Forest. Mountain ranges, faulted valleys, and synclinal basins formed through time by volcanic activity have left some of the oldest rocks in Oregon in the Ochoco National Forest. Around the Forest’s periphery are some very rugged canyons and buttes with steep slopes and rock outcrops.

The Crooked River National Grassland is located in four major physiographic provinces: the Rolling Hills, the Mid-basin Plains, the Mid-basin Lava Buttes, and the East Cascade Plateau. The Crooked River National Grassland consists of rolling range country interspersed with deep canyons and volcanic buttes. The buttes are found mostly in the southern portion of the Crooked River National Grassland. The canyons generally run south to north and were formed by the Crooked and Deschutes Rivers.

Resources

Timber harvest has a large economic influence in the five counties in which the Ochoco National Forest is located. The revenues generated from timber harvest not only provide income for the timber industry, but also to the economy of the counties as a whole.

Summer forage is an important part of the Ochoco National Forest and Crooked River National Grassland. Cattle and sheep belonging to 115 permittees graze annually. This amounts to 75,000 animal unit months (AUM’s).

The Forest and Grassland provide a variety of habitat for an estimated 350 to 400 wildlife species. Hunting and viewing big game are major recreational attractions. The Oregon Department of Fish and Wildlife coordinates management activities with the habitat provided by the Forest and Grassland: producing an estimated 22,600 mule deer, 2,300 elk, and 750 antelope. Other significant habitats provided by the Ochoco National Forest and Crooked
River National Grassland include old growth, snags, and riparian areas.

More than 500 miles of streams support cold water fisheries. Approximately 200 additional miles of streams have the potential to support cold water fisheries, however, due to low flows, high water temperatures, and lack of pools, fish habitat is sometimes greatly reduced in the summer. A few streams on the Ochoco National Forest that are part of the John Day and Deschutes River drainages provide conditions for limited anadromous fish spawning. Average annual runoff from the Ochoco National Forest is estimated to be 574,000 acre feet.

Recreational opportunities vary from rockhounding to snowmobiling, and include horseback riding, driving for pleasure, camping, hunting, fishing, and cross country skiing. Various boating, camping, and picnicking sites exist throughout the Ochoco National Forest and Crooked River National Grassland.

Camping is a major recreational use. Water-related sites, and those along main transportation routes, are heavily used. Use on weekends and holidays varies from 80 to 130 percent of developed capacity. The more remote sites are, in general, lightly used except during holidays and hunting season. Total recreation visitor days are estimated to be 430,000 annually.

Three classified wilderness areas, and one “further study” area lie within the Ochoco National Forest and Crooked River National Grassland. One Research Natural Area has been designated, and five others have been proposed. Over 1700 cultural resource sites have been documented, with about 1000 of these being prehistoric sites.

Mineral activities and mining claims, though generally not commercially productive, exist on the Ochoco National Forest. Some minor prospecting for cinnabar and gold occurs. A major activity is hunting for semiprecious stones. About 800,000 acres have been identified as having significant oil and gas potential, and over 20 percent of the Ochoco National Forest and Crooked River National Grassland is leased for possible oil and gas exploration and development.

The area’s vegetation has been described in detail by Hopkins and Kovalchik in “Plant Associations of the Crooked River National Crooked River National Grassland” (1983), by Hall in “Plant Communities of the Blue Mountains in Eastern Oregon and Southeastern Washington” (1973), and by Kovalchik in “Riparian Zone Associations, Deschutes, Ochoco, Fremont, and Winema National Forests” (1987).

Soils on the Ochoco National Forest and Crooked River National Grassland have developed under the influence of a semi-arid climate from parent material of principally volcanic origin. North slope surface soils are primarily recent ash deposits. Good water permeability is associated with deeper soils. Lower elevation soils range from silt loam to sandy loams. Rocky areas of very thin soil and low productivity, called “scablands,” occur in places.

Air Quality

National Ambient Air Quality Standards have been developed by the Environmental Protection Agency under authority of the Clean Air Act Amendments (PL 91-604). The standards establish acceptable levels for certain pollutants including total suspended particulates (TSP). Although air quality surfaced as an issue during scoping for the Regional Guide, it is closely tied to Forest issues relating to residue management, visuals, and any other use of fire to protect and enhance Forest resources.

A potential for short-term air quality impairment from dust is created by a variety of management practices. Machinery operations related to timber harvest often raise clouds of dust. Log hauling on roads is another source of dust as is prescribed burned areas on windy days. Road construction and maintenance machinery operations are also dust contributors, both in the actual road work and in the rock crushing operations. The impacts are usually of a local nature and of short duration.

Visibility on and adjacent to the Ochoco National Forest and Crooked River National Grassland is affected by the emission of suspended particulates from fire. The Bend-Redmond-Madras-Prineville area experiences regional haze problems several times each year due to an accumulation of smoke from numerous agricultural and wildland burns, from local fires and from fires west of the Cascades. The contribution of smoke from west of the Cascades is occasionally great enough to cause voluntary curtailment of local burning to avoid further degradation. Regional data, presented in the Final Environmental Impact Statement for the Pacific Northwest Regional Guide (May 1984), indicates that the Ochoco National Forest contributes approximately 30 percent of the emissions generated in the Bend-Redmond-Madras-Prineville area. These emissions come almost entirely from prescribed fire.

Fire has been used on the Ochoco National Forest and Crooked River National Grassland to treat slash, to manage wildlife habitat, and to improve forage for livestock. Records show a steady increase in the use of prescribed fires over the past two decades. As a result, the number of days per year with reduced visibility have also increased.

The primary use of fire has been to treat timber harvest residues (slash). Currently, prescribed fire is used to treat 15-20 thousand acres of slash annually from past and current timber sales. This activity produces 8 to 14 thousand tons of total suspended particulates (TSP) in smoke emissions. Most of this activity occurs in spring and fall. The TSP production for wildfires is highly variable. Estimates range from 25 tons in years of infrequent wildfires to 4000 tons in years of numerous wildfires.
Biological Diversity

Biological diversity refers to the distribution and abundance of plant and animal species and communities on the Ochoco National Forest. Elements of biological diversity include, but are not limited to:

- Viability, distribution and abundance of wildlife and plant populations;
- Structure and composition of forests;
- The role of agents such as fire and insects;
- Long-term productivity, and
- Fragmentation of scarce community types.

The law (36 CFR 219.27) requires that management prescriptions, where appropriate and to the extent practical, preserve and enhance the diversity of plant and animal communities, including endemic and desirable naturalized plant and animal species. These communities should be at least as great as those expected in a “natural” Forest, and the diversity of tree species should be similar to that existing in the planning area. Reduction in diversity may be prescribed only where needed to meet overall multiple-use objectives.

A discussion of the biological processes occurring on the Ochoco National Forest is basic to understanding whether or not management practices have the potential for adversely altering diversity.

Biological Processes and Long-Term Productivity

Soil

Soil, a basic nonrenewable resource, is the foundation on which biological diversity is maintained. All plant and animal life on the Forest and Grassland is either directly or indirectly dependent on maintenance of long-term productivity of our soils. By definition, the components of long-term soil productivity include:

- Surface litter and topsoil layers;
- Soil organic matter and its replacement,
- Soil organisms and biological systems; and
- Soil porosity, structure, drainage and aeration.

Three general soil types occur on the Ochoco National Forest. Each of these types reacts somewhat differently to management activities and possibly to other outside influences such as pollutants and atmospheric depositions.

</tr>
</tbody>
</table>
Natural and Human Influences
In addition to soils, long-term productivity can be described as the ability of the forest to withstand impacts from both biotic and abiotic influences. Insects, diseases, wildfire, atmospheric deposition, silvicultural treatments, and harvesting practices are primary examples of influences that can have both positive and negative affects on the “health of the forest,” and therefore, long-term productivity of the resources therein (See Forest Health, this chapter for a more detailed discussion). It is believed that the presettlement forest was maintained in a relatively healthy condition with frequent natural fire (Hall, 1976; Volland and Dell, 1981). These low intensity fires had a significant affect on soil development, as well as vegetative species composition, distribution and density. The elimination of wildfire, introduction of intensive livestock grazing, and harvest of timber have had a profound effect on the ecological processes throughout the forest (See Fire, this chapter, for a more detailed discussion). Many believe that significant increases in forest pest outbreaks, such as spruce budworm, are a direct result of fire control (Schmidt, 1983). The affects of fire elimination on soils are less understood, but there is some indication that long-term soil productivity may actually be enhanced (on some soil types) as a result of increased organic materials which were historically eliminated by fire (Harvey, Jurgensen, Larsen and Graham, 1987).

Vegetation and Biological Diversity
The vegetation of the Ochoco National Forest and Crooked River National Grassland can be described by using “plant associations” and “vegetation types.” Each plant association indicates the presence of a specific type of environment.

Plant Associations
The vegetation of the Ochoco National Forest consists of forested and nonforested plant associations. These plant associations are distributed according to elevation, soil type, topography, and precipitation. Ecologists use the presence and abundance of indicator plants to classify certain types of environments. This reduces the numerous combinations of vegetation into classes called plant associations.

Vegetation Types

For administrative planning and analysis purposes, the plant associations identified by Hall (1973), and Hopkins and Kovalchik (1983) have been combined into nine vegetation types as follows: mixed conifer, ponderosa pine, low site ponderosa pine, pine-shrub transition, juniper-shrub, shrub-grassland, grassland, meadow, and scabland. The first three are considered forested vegetation types and the last six are nonforested types.

Forested Vegetation Types

The mixed conifer type occurs on portions of the Ochoco National Forest with the most precipitation (25 inches or more) and/or on northern and eastern aspects where evaporative losses from solar radiation are minimal. Approximately 95 percent of the Forest’s mixed conifer stands are mature (over 100 years old) and single or multi-story in structure. This type is dominated by stands of ponderosa pine, Douglas-fir, white fir, western larch, and lodgepole pine. Understory vegetation is comprised primarily of pinegrass, elk sedge, and heartleaf arnica. Silviculturally, these stands are often treated in a similar manner since it is frequently not feasible to manage the understory due to disease, insect, and physical damage interactions. Treatments most often involve a regeneration cut (clearcut, shelterwood, or some modification of either) and subsequent reforestation, either naturally or artificially.

At mid to lower elevations, the ponderosa pine vegetation types receive less precipitation. Their occurrence is also associated with southern and western aspects. About two-thirds of the ponderosa pine stands are two-storied or multi-storied in structure, and contain small amounts of Douglas-fir. Ground vegetation is comprised of elk sedge, blue-bunch wheatgrass, fescue, and bitterbrush. These stands have varying amounts of large old growth ponderosa pine (overstory trees) with younger trees of pine or other species below (understory). The understory is also variable in terms of the number and size of the trees, but can usually be managed silviculturally after the overstory removal without additional reforestation.
Low site ponderosa pine types generally occupy a transition area between the predominant, higher elevation pine type and nonforested areas. This type is dominated by ponderosa pine and juniper. Ground vegetation is comprised of fescue, bluebunch wheatgrass, bitterbrush, Sandberg bluegrass, and mountain mahogany. Individual tree harvest occurs on these types, when sufficient advance reproduction of commercial species already exists.

Nonforested Vegetation Types
Below the forested types, tree-shrub (pine-shrub transition and juniper-shrub) vegetative types occur. Precipitation and evaporative losses are limiting to most trees on these sites, except juniper and an occasional ponderosa pine. The grassland vegetation type receives the least precipitation of the vegetation types discussed, less than 10 inches annually, and generally occupies the lowest elevations.

Dry, moist, or wet meadows occur locally, depending on the availability of water throughout the summer and fall. Scablands have relatively less vegetation cover than the other vegetation types due to their rocky and shallow soils. A discussion on the major plant species that occur in each of these vegetation types follows.

Pine-Shrub Transition - This type is dominated by juniper and ponderosa pine. Understory vegetation includes sagebrush, bitterbrush, and wheatgrass.

Juniper-Shrub - This type is dominated by juniper and sagebrush. Understory vegetation consists of wheatgrass and fescue.

Shrub-Grassland - This type is dominated by sagebrush, bitterbrush and rabbitbrush. Herbaceous vegetation consists of fescues and wheatgrass.

Grassland - This type is dominated by bunchgrass, wheatgrass, and sagebrush. Juniper may also occur in significant amounts on this vegetative type.

Meadow - This type is dominated by tufted hairgrass, oval-head sedge, and Nebraska sedge. The ratio of sedges to grasses increases in moist meadows.

Scabland - This type is dominated by bluegrass, oatgrass, and rigid sage.

Riparian Areas
Riparian areas are adjacent to water. They are where plants occur that are dependent on a perpetual source of water, and that are a significant component of the diverse ecosystem. Riparian sites include stream banks, active channel shelves (e.g. gravel bars), active flood plains, and overflow channels (Kovalchik, 1987).

The Ochoco National Forest has approximately 19,000 acres of riparian areas that are associated with about 800 miles of streams. The Crooked River National Grassland has about 2,090 acres of riparian acres along approximately 30 miles of streams. These riparian areas amount to 2 percent of the land base.
Abundance and Distribution of Different Plant Successional Stages

**Forested Areas**

The abundance and distribution of various timbered successional stages has possibly the greatest affect on the overall biological diversity of plants and animals on the Ochoco National Forest. A “managed” forest, represented by a wide variety and distribution of successional stages, is likely to maintain more resistance to insect and disease outbreaks, wildfire, and other potentially destructive forces. Variety also increases both the vertical and horizontal diversity, which increases habitat for wildlife species. Historically, diversity was much lower because large acreages of the Ochoco National Forest were maintained as large open ponderosa pine stands by frequent, low intensity fires.

Table 3-3 shows existing acres of different forested successional stages (Stages 1-6) on the Ochoco National Forest.

</tr>
</tbody>
</table>
Old Growth
Old growth (Stage 6 vegetation) has been recently inventoried for the ponderosa pine and mixed conifers vegetation types. This successional stage is of importance because of its diverse stand structure and because of its ability to provide cavity nesting habitat. A total of 93,800 acres have been identified and mapped. Of these, 30,300 lie within Wilderness and Research Natural Areas.

Old growth in the juniper-shrub type has yet to be mapped; however, 740 acres have been reserved on the Crooked River National Grassland.

For a further discussion of the old growth resource, refer to the Old Growth section of this chapter.

Nonforested Areas
Nonforested plant associations on the Forest and Grassland include: 1) dry and wet meadows which are found throughout the Forest, generally at higher elevations; 2) sagebrush/bunchgrass and sagebrush/bunchgrass/juniper sites which are found at lower elevations of the Forest, and over much of the Grassland; and 3) the various scabland community types which are found throughout the Forest, except on north aspects.

Successionally, the nonforested types are not changing since the majority are at or near climax. A shift, however, has been noted from a historical fire climax to the more recent nonfire climax type. Trees are encroaching on many meadows and juniper is invading many of the lower elevation sites due to lack of fire.

Distribution of Forested and Nonforested Vegetation as an Element of Diversity and Habitat
Forested and nonforested areas are distributed in a random, mosaic fashion across the Ochoco National Forest. Compared to the surrounding “high desert,” the Forest offers a greater diversity of habitats, and this is not duplicated in the immediate central Oregon area. The Forest is relatively isolated from its neighboring national forests, and adjacent forest lands of other ownership are not extensive.

It is this great variety of vegetative diversity that provides habitat for over 378 terrestrial wildlife species (See Wildlife and Fish Elements and Biological Diversity). Food, cover, and water (essential wildlife habitat) exist across the Forest and Grassland in quantities capable of supporting large numbers of both game and nongame species. Riparian areas and their associated water resource are the most critical wildlife habitats, supporting possibly as much as 75% of all terrestrial wildlife species on the Forest and Grassland. Perennial streams usually support trout and other species of fish. The riparian vegetation is of critical importance for escape cover, stream shade, and streambank stability as it maintains water quality and aquatic habitat. Riparian areas can also serve as forested connectors (connective habitat) between original or primary habitats for many species. Pileated woodpeckers, a management indicator species, are likely to use these travel lanes to move between primary reproductive and feeding areas (Bull, 1989).

Undisturbed Ecosystems and the Role of RNA's

Ecosystems that are substantially undisturbed represent rare conditions on the Ochoco National Forest and Crooked River National Grassland. Preservation of this element of biological diversity is one of the objectives of the Research Natural Area program.

Research Natural Areas (RNA's) are tracts of land where specific natural features are preserved and natural processes are allowed to occur for research, education, and conservation purposes. The primary reasons for preserving these tracts are to provide:

1. Baseline areas against which the effects of human activities in similar environments can be measured;
2. Sites for study of natural processes in undisturbed ecosystems, and
3. Gene pool preserves (gene pool conservation) for plant and animal species, particularly rare and endangered types.

RNA's offer biologists and other natural resource scientists opportunities to study biota, environments, and ecological processes with a minimum of disturbance to installed studies.

The Ochoco National Forest has one established RNA, the Ochoco Divide Research Natural Area (2,035 acres) on the Big Summit Ranger District. The Crooked River National Grassland does not have any established RNA's.

Central and eastern Oregon currently lack adequate representation of natural features in the RNA system. In a cooperative effort with other Federal agencies, as supported by the Federal Committee on Research Natural Areas, the Ochoco National Forest and Crooked River National Grassland were reviewed to determine if areas existed that met RNA needs as identified in “Research Natural Area Needs in the Pacific Northwest” (Dryness et al., 1975). Coordination with the Bureau of Land Management by Forest Service ecologists led to the identification and proposal of five additional RNA’s on the Ochoco National Forest and Crooked River National Grassland.

A comprehensive Establishment Report must be prepared for each RNA proposed on National Forest system lands. Prior to the establishment of a proposed RNA, the Establishment Report is submitted to the Chief of the Forest Service for approval.

A complete description of the existing and proposed research natural areas can be found in Appendix E. Figure 3-7 shows the approximate locations of the established and proposed RNA's. Table 3-4 displays the acreage, location; and major characteristics of the proposed RNA's.

A proposed RNA on the Crooked River National Grassland called “The Island” has also been identified as a potential National Natural Landmark by the National Park Service. National Natural Landmarks are areas representing the best examples of the ecological and geological features composing our Nation’s natural history. The National Park Service has identified The Island area as 1) the largest and most pristine example of western juniper/big sagebrush/bluebunch wheatgrass community in the Columbia Plateau, and 2) the best example of the pumice western juniper steppe community.
Wildlife and Fish Elements and Biological Diversity

The abundance and distribution of animal species is a key element of biological diversity. Typically, animals are dependent upon or frequently use certain vegetation types or successional stages that have been previously discussed. Consequently, managing for the maintenance of diversity of vegetation ensures a diversity of wildlife habitats and continued existence of healthy populations. This contention will be tested through the monitoring of management indicator species.

Management Indicator Species

To help determine the effects of management activities on wildlife and fish habitat, several species and groups of species were chosen as management indicators. The habitat requirements of management indicator species are assumed to be similar for other wildlife and fish species. If a selected species and its habitat are influenced significantly by management activities, like effects can be expected on other fish and wildlife species with similar habitat requirements. The indicator species were selected in conjunction with the Oregon Department of Fish and Wildlife (ODFW). The selected species are listed in Table 3-5 along with their respective types of habitat.

1/ Wildlife species that excavate cavities in snags

Brook and Rainbow Trout were picked as an indicator group. The Salmonids have a broad distribution across the Forest and are of economic importance resulting from commercial and recreational harvest. The group generally has similar habitat requirements which are narrow enough to ensure viability of most other game fish. The habitat requirements make the group a good indicator of riparian habitat and aquatic habitat condition for the Ochoco National Forest and Crooked River National Grassland.

Pileated Woodpeckers serve as an indicator for other species that require large snags, large amounts of down-dead wood, and large trees with defect. The pileated woodpecker represents the presence of favorable habitat for species that require mature forest and old growth habitat. It may also indicate the presence of favorable habitat for secondary cavity nesters, such as Northern flying squirrel, pygmy owl, saw whet owl, and flammulated owl.

We have incomplete knowledge of current pileated woodpecker populations and habitat requirements, but 93,800 acres on the Forest are currently suitable old growth habitat. The majority of existing old growth habitat occurs as mixed conifer stands on the north part of the Ochoco National Forest. This results in an uneven distribution of old growth across the Forest. Current direction calls for maintenance of 36,975 acres of old growth over time. Currently, 28,000 acres are dedicated for pileated habitat, while the remainder is recruited through long rotation management.

Primary Cavity Excavators and the Common Flicker were selected to represent the species that utilize snags and old growth juniper habitat respectively. The common flicker is probably the only primary cavity excavator that is capable of creating cavities in juniper (Thomas, 1979). The Forest and Grassland do not have population estimates for primary cavity excavators or flickers at this time.
Primary Cavity Excavators were selected to represent the species that require snag habitat that is often reduced by forest management activities. Also, this group of species has high public interest and serve as predators of forest insect pests. The primary cavity nesters serve as ecological indicators for a large number of species and for secondary cavity users, like swallows, blue birds and bats.

Present snag densities are relatively high (80-100 percent of potential populations) in most mixed conifer stands. However, due to past entries for salvage logging and firewood gathering, snag densities are relatively low in ponderosa pine stands (20-60 percent of potential populations). Current direction is to manage for 40 percent of potential populations as stands are entered for timber harvest. Only lodgepole pine snags are currently available for firewood gathering.

Rocky Mountain Elk were selected as an indicator species to reveal changes in big game habitat. The elk was selected because of public interest and the recreational value of big game.

Cultural Resources

The cultural resources of the Ochoco National Forest and Crooked River National Grassland include a variety of prehistoric and historic sites which represent perhaps 10,000 years of human use and settlement. Presently, over 1,700 cultural resource sites have been documented on the Ochoco National Forest and Crooked River National Grassland. Approximately 1,000 of these sites are prehistoric, providing evidence of the occupation and land use patterns of Native Americans. The remaining 700 sites document Euro-American activities over the past 150 years.

Prehistory

Most of the prehistoric sites on the Ochoco National Forest and Crooked River National Grassland are called lithic scatters, i.e. they consist of chipped stone tools and the by-products of tool manufacture. Native Americans used a wide variety of materials in adapting to their environment, but artifacts fashioned from wood, natural fibers, bone, and hide usually decay when subjected to harsh weather, moisture, and/or acidic soil conditions. Chipped stone tools and flakes are often all that remain at a site after centuries of occupation. As a group, the prehistoric lithic scatters have been determined eligible for the National Register of Historic Places.

History

Historic sites on the Ochoco National Forest and Crooked River National Grassland provide direct evidence of how settlers lived and how their actions affected the land. For instance, remnants of the Paulina Deadline (circa 1900), which marked the boundary between lands allocated for cattle grazing and those allocated for sheep grazing, are still present on parts of the Ochoco National Forest. While the conflict between cattle ranchers and sheep herders is widely known, such material evidence of this conflict is rare. Similarly, early mining activity on the Big Summit Ranger District is documented by abandoned mines at Scissorsville and at the Amity, Blue Ridge, and Independent mines. The Crooked River National Grassland contains vestiges of extensive homesteading during the early twentieth century. While successful homesteads have generally remained in private ownership, these latter public lands contain evidence of the more typical and often anonymous homesteaders.
Inventory Status

The Cultural Resource Overview for the Ochoco National Forest and Crooked River National Grassland was completed in 1987 under contract with Heritage Research Associates (Minor, Beckham, Toepel, and Greenspan, 1987). This document summarizes data for all historic and prehistoric sites; a synopsis of the cultural resource inventory is provided in the Overview (Ibid.: pp. 193-199). This document is used to provide contexts for the assessment of cultural resource significance, assist in cultural interpretation, develop a Cultural Resource Inventory Design, and provide basic background and reference material.

The Ochoco National Forest and Crooked River National Grassland are still in the process of gathering basic information about the location and nature of their cultural resources. By October 1, 1988, approximately 30 percent of the Ochoco National Forest the Crooked River National Grassland had been inventoried at varying degrees of intensity. The Ochoco National Forest and Crooked River National Grassland will not attain a complete inventory of its acreage by 1990, as directed by Executive Order 11593. Given recent levels of support and activity (5 year average = 26,000 acres/year) it would take approximately 25 years to inventory the remaining acreage. The current inventory of cultural resource sites is summarized in Table 3-6.

The Interim Cultural Resource Inventory Design is currently under review by the Oregon State Historic Preservation Office. This design, as required by the 1987 Lithic Scatter Programmatic Memorandum of Agreement, serves to incorporate current inventory data and regional research questions regarding area prehistory and history with a comprehensive means for locating cultural resources in broad areas proposed for treatment under the schedule of proposed land and resource management activities.

The design provides guidance in the development of Ranger District-project survey designs. It outlines two basic types of inventory; initial and secondary (re-survey). Initial surveys will be conducted in areas previously unsurveyed. Secondary surveys are conducted in areas inventoried where previous surveys were not adequate, where ground conditions have changed since initial entry, and where information on site frequency indicates new levels of cultural resource predictability.

The design keys the predictability of cultural resource site location to environmental variables. It recognizes three levels of site frequency: high, normal, and low. These variables are then employed to predict site frequency and selectively survey large, topographically diverse project areas such as timber sales.

A complete inventory (100% survey) is undertaken for known, reported and suspected cultural resource sites and areas. Pedestrian transect surveys (transect interval less than 50 M) are conducted in areas identified as containing one or more variables indicating a predicted high or normal site frequency. On project areas indicating low site frequency, a 20% sample will be obtained via additional pedestrian transect surveys through random and convenience sampling. For projects less than 100 acres (e.g. spring developments, recreation sites, pipelines and road corridors) a complete 100% survey will be undertaken.

Source: Ochoco Cultural Resource Management Files
The Ochoco National Forest and Crooked River National Grassland is investigating ways to increase the reliability of its inventory efforts. The current inventory design was created as a fluid plan to be constantly improved upon during its implementation, and as the result of new data and interpretations of existing data.

Facilities

The Ochoco National Forest and Crooked River National Grassland have 103 buildings, 36 potable water sources and nine dams. The buildings are located at five administrative sites and six fire lookout sites. The buildings include offices, residences, crew quarters, shops, warehouses, storage buildings, lookouts, and tree coolers. Several buildings built before 1937 have National historic significance. Maintenance has been adequate to keep the buildings serviceable and structurally sound. Changes in forest management and methods of work have caused some structures to be extensively remodeled to retain their usefulness.

Efficient management of the Forest will continue to require administrative sites based on resource needs, budget, and personnel needs. A Facilities Master Plan for buildings will be prepared as part of the implementation of the Forest Plan. It will guide the acquisition, continued use, and disposal of forest buildings.

The water systems serve administrative sites, developed and dispersed recreation sites. Most of the recreation water systems need to be reconstructed to meet current State standards for construction. This work is scheduled to be completed in the next three years.

There are nine dams on the Forest over 10 feet in height. Four of the dams are Forest owned and operated, four are operated under special use permits, and one by a public utility company. The Forest-operated dams store water for irrigation. The Forest also has dozens of small dams which impound seasonal water for wildlife and livestock.

The Forest plans to improve existing dams where appropriate. No new dams are foreseen at this time.

Fire

Natural Fire and Ecological Effects

Ponderosa pine types have experienced a natural fire frequency of 5 to 15 years (Hall, 1976; Volland and Dell, 1981). Fires burning in these stands can be of low intensity due to light fuel accumulations maintained by frequent underburning. This vegetative type covers the largest portion of the Ochoco National Forest. Ponderosa pine's thick bark, high crown, and specialized water conducting system make it well adapted to resist damage by fire (Hall, 1976). Fire prepares mineral seed beds for seedling establishment, thins reproduction, prunes lower tree branches, stimulates grass and forb growth, maintains open park-like stands (Hall, 1976; Volland and Dell, 1981), and recycles nutrients from dead organic material.

The natural fire frequency in the mixed conifer type is thought to be 25 to 70 years (Martin, 1982). This forest type exists in moist drainage bottoms and on north aspects, which accounts for a longer fire frequency. Tree species common to this timber type are...
Douglas-fir, ponderosa pine, white fir, western larch, and lodgepole pine. Moderate to high-intensity surface fires, with occasional torching or crowning of trees, occurred in these stands. Heavier fuel accumulations in this type account for the more intense fires. Low limbs and waxy, resinous needles in white fir and Douglas-fir aid torching and crowning. As a result, these species are selectively decreased in stands so that a higher frequency of ponderosa pine and western larch remain. Vertical continuity of fuels is minimized and canopy closure is inhibited. Fire reduces residue loading and exposes mineral soil seedbeds.

A fire frequency of one to ten years is thought to be normal for grassland ecosystems (Martin, 1982; Volland and Dell, 1981). These fires spread quickly and are of low intensity. They frequently cover vast acreages. Growth and vigor of many native grasses, forbs, and brush are stimulated by fire. Frequently occurring natural fires of the past retarded expansion of most brush species and western juniper, thus maintaining a higher component of grasses and forbs in these ecosystems than is found today.

Due to fire suppression and exclusion policies of the past 80 years, the natural ecological cycles involving nutrients, energy, and vegetation dynamics have been altered. Timber harvests have somewhat replaced fire's ecological role through removal and disposal of woody fuels. Grazing also changed vegetation types by removing fine fuels such as grasses, forbs, and succulent brush species. However, neither timber harvest nor grazing duplicates past fire effects. As a result, formerly open pine stands are being replaced by a mosaic of closed canopy, multistoried stands that cover large areas of the Ochoco National Forest. These stands are highly flammable and are more susceptible to destruction by wildfire than the natural fire-maintained open stands that existed previously (Hall, 1976; Volland and Dell, 1981).

Wildfire

Wildfires are common occurrences on the Ochoco National Forest and Crooked River National Grassland during the dry season. There are an average of 108 wildfire starts per year; 80 percent of these are caused by lightning. Abandoned campfires make up 60 percent of the human-caused fires. Risk from human-caused ignitions is beginning to increase as recreation and hunting use increases. The average area burned by wildfire under current suppression management is 750 acres per year.

Prescribed Fire

Up until the late 1970's, fire suppression policies increased the risk of a damaging wildfire. Since then an understanding of the role of fire in ecosystems has caused a return of fire to forest management. The use of prescribed fire on the Ochoco National Forest and Crooked River National Grassland reduces the risk of severe wildfire in treated areas. Approximately 20,000 acres of timber harvest each year requires a variety of residue treatments, including prescribed burning. Prescribed burns for other resource management and natural hazard reduction are conducted on several thousand acres each decade. Prescribed fires are often planned to emulate natural fire frequencies.
Forage

Much of the forage resource consists of native grasses that grow in a variety of plant communities ranging from grassland to juniper/shrublands. In addition, forage is made available through timber harvest. Dense canopies of trees intercept sufficient light to inhibit forage development on the forest floor. Timber harvest opens up the canopy creating an increase in forage production. Within plantations, the grass can become a problem by reducing seedling survival and inhibiting growth. The forage is utilized by deer and elk for food, however, the major use is for livestock grazing.

Current Status of Livestock Use

The Forest and Grassland supply forage for approximately 14,000 cattle and 3,500 sheep annually. This forage provides summer grazing for livestock belonging to 105 permittees throughout the five surrounding counties. The carrying capacity for range allotments is based on forage production and the forage requirements for livestock. The unit of measure is an animal unit month (AUM), which equals 800 pounds of utilizable forage. Forage requirements for a mature cow with a nursing calf for one month is approximately 1.3 AUM’s. Approximately 75,000 AUM’s are permitted annually.

Cattle numbers permitted on the Forest and Grassland have not varied significantly over the past decade; however, there has been a conversion from sheep to cattle. This conversion has occurred during the past twenty years. This can be attributed to economics, predator problems, and to a diminishing supply of herders. Most ranching operations throughout the area remain traditional cow-calf operations where the calves are sold each fall.

Grazing Allotments

The Forest and Grassland have a combined total of 90 grazing allotments. Most allotments are subdivided by fences into two or more “pastures.” These pastures are incorporated into grazing systems that rotate livestock use on a scheduled basis. A few remaining allotments that are small, isolated, and usually with mixed ownership, do not have fenced subdivisions. These are scheduled for grazing during a specific season.

Many range allotments have forage in upland areas that receive only light use or no use due to a lack of water or low level of management. Allotment plans are being updated to effectively use this upland forage through herding, fencing, and water developments. The goal is to graze this upland forage and to reduce the use where livestock have concentrated in the past, such as riparian areas. More intensive management is also being used to control use of forage in riparian areas. Any long-term change in numbers or season of use is subject to the requirements of an updated allotment plan.
Vegetation condition data for the Forest and Grassland is mostly outdated. Due to restricted budgets, very little vegetation analysis has been done in the last twenty years. Recent allotment management plans have been prepared using the old data which has been field verified and updated. No data is available that accurately reflects condition classes over the entire Forest and Grassland. Best professional judgement indicates the majority of the uplands are one condition class better than 20 years ago. Some riparian areas have improved, and others have remained degraded. New plant association guides for vegetation analysis are to be published for the Ochoco National Forest in 1989.

Demand

The ability of local ranchers to utilize Forest and Grassland forage during the summer months, while producing several crops of hay on the base ranch for winter use, is economically essential to many ranches. Allotments have been fully occupied for many years. When an allotment becomes available it is quickly filled. This indicates the continuing high demand for forage available on the National Forest and Grassland.

Forest Health

Historically, fire has played a major role in determining the kind of vegetation that occupied the lands of the Ochoco National Forest and the Crooked River National Grassland. Natural fire was responsible for limiting the accumulation of forest residues, eliminating overly dense and stagnant pockets of ponderosa pine reproduction, and retarding succession to more tolerant conifers such as white fir and Douglas-fir.

With the exclusion of fire, the vegetation has substantially changed and the stability of the vegetation systems has been significantly reduced. Because of the increase in fuel loading, the probability of a high intensity wildfire that can damage overstory trees has increased. This effect is currently being mitigated through the Forest’s prescribed burning program. Overly dense thickets, which are predisposed to insect attack because of their low vigor, are being addressed through the prescribed burning and thinning programs. The tolerant conifers which are increasing in abundance on the cooler and moister sites, are more susceptible to insect outbreak and root pathogens as well. Consequently, the Forest’s vegetation is more at risk from insect and disease than it was in presettlement times.

Major insect epidemics occur periodically on the Ochoco National Forest. In the 1950’s, a major outbreak of Douglas-fir tussock moth (a defoliator of white fir and Douglas-fir) occurred. This outbreak was controlled with a massive spray program. In the mid 1970’s, even-aged lodgepole pine stands were maturing and became susceptible to mountain pine beetle attacks. Most of these stands have suffered severe mortality (90% or more of the trees killed). An outbreak of western spruce budworm, a defoliator, occurred in the early 1980’s. This outbreak is still occurring and has affected almost every mixed conifer stand in the Ochoco National Forest. Spraying was considered in an environmental analysis in 1983 and 1984, but no treatment was attempted except on a small research plot in 1984.

Insect and disease losses are principally addressed through silvicultural treatments. Harvesting and thinning techniques are selected to control dwarf mistletoe, mountain pine beetle, Western spruce budworm, Western pine beetle, heart rot, and root rots. Proper timing of slash treatment and thinning operations is used to control the pine engraver beetle.

The major threats to forest health on the Ochoco National Forest and the Crooked River National Grassland can be divided into the following five categories: bark beetles, defoliators, dwarf mistletoe, root diseases and stem decays, and animals. Each of these categories is discussed below.
**Bark Beetles**

Insects that lay eggs beneath the bark of host trees are referred to as bark beetles. Larvae emerging from the eggs tunnel and feed on the tree’s cambial layer (Doliner 1984). These include mountain pine beetle, western pine beetle, pine engravers (Ips), and fir engravers. These are a major problem in pine types. The damage from these insects increases in over-stocked or over-mature stands (Mitchel, et al, 1983).

**Dwarf Mistletoe**

This is a parasitic flowering plant which has no apparent leaves, and occurs only on above-ground parts of conifers (Doliner 1984). Damage to the host includes growth reduction and lowered wood quality. Mistletoe may kill or predispose the host to attack from other pests (Graham 1967). Dwarf mistletoe damage on ponderosa pine and Douglas-fir is a major concern on the Ochoco National Forest. Western larch may also be seriously infected in more localized areas. The amount of stand infestation and subsequent growth loss is frequently increased by partial harvest and long rotations.

**Defoliators**

Insects that consume tree foliage are referred to as defoliators. These include western spruce budworm and Douglas-fir tussock moth. These are a major concern in mixed conifer stands, and damage from these insects occurs primarily in multi-aged or over-mature stands. These insects can also cause damage or destruction to cones and seeds (Wickman, et al, 1981, Gara 1981, Schmidt 1983).

**Root Diseases and Stem Decays**

These diseases are caused by a variety of fungi that infect the host tree through root contact or past injury. Damage from root rots and stem decay include growth loss, wood decay, and tree mortality. Rots and decay also predispose the infected tree to insect attack. The most common root rots are laminated, Fomes annosus, and Armillana root rot. The most common stem decay is caused by Indian paint fungus. Mortality and usable wood loss can occur. Management activities that increase losses are partial cutting, which maintains susceptible species on the site, and logging.

**Animals**

Both wild and domesticated animals can cause damage to trees. Damage to small trees from wild animals is primarily caused by big game (elk and deer) and pocket gophers. Damage to large trees from wild animals is primarily caused by porcupines. Damage from domesticated animals is primarily caused by livestock grazing.
Other Pests

Other forest pests, such as the larch casebearer, impact the trees in the Ochoco National Forest at times, but the magnitude of damage is significantly less than those listed above.

Forest Residues

Existing Condition

The Forest currently carries approximately 17 million tons of forest residues in the form of dead woody biomass. Activity residues make up 360 to 720 thousand tons at any one point in time. The rest, 16.2 million tons, is an accumulation of natural dead and down woody material.

Descriptions of the natural vegetation types in this area prior to significant fire exclusion and other management activities (Hall, 1976), provide background information which can be used to estimate natural residue loadings in the Blue Mountains. In ponderosa pine types, residual pine types were typically in the 5-10 ton range with isolated areas ranging up to 30 tons. Most of the loading was in large woody material that survived the last fire (or fell since then), and needle and grass accumulation since the last fire. Duff layers were typically shallow, 1-2 inches due to frequent ground fires (see the discussion on local fire history in this chapter). In mixed conifer types, residue loadings were typically 10-20 tons per acre with more woody branch-type material in addition to the larger logs. Duff layers were also deeper, in the 2-4 inch range. This is due to the longer return interval of fire in these damper sites.

An analysis by Forest Interdisciplinary Team members (specialists from wildlife, range, watershed, timber and fire management) indicates that an average of 10.4 million tons of woody residues Forest-wide would provide an acceptable level of dead and decaying biomass to maintain long-term site productivity in local stand types. This represents a per acre loading of about 10.9 tons and is within the range of 8-14 tons per acre recommended for Inland Douglas-fir and associated species (Harvey, et al 1987).

Disposal of this apparent excess (about 7 million tons) is the crux of this management question and this analysis. See Chapter 2 and 4 for discussions on mitigation measures associated with treatment of excess residues and unwanted vegetation. Also, see Chapter 4 for a detailed discussion of the consequences of the alternatives on this resource.

Objectives

Determining how much and what kind of dead woody biomass to leave on site for maintenance or enhancement of long-term productivity. There is a lack of good, local information on how much is desirable for our sites. The most applicable recent work was for Inland Douglas-fir types of the northern Rocky Mountains of Idaho, Montana, and NE Washington. Most current literature dealing with Oregon applies to the wetter forest types of the Cascades and west of the Cascades. The dry, east-side types have not been intensively studied.

The large amount of residues on hand allows for considerable flexibility in adjusting the desired level upward if future research shows that need. There is ample room to take advantage of a wide variety of utilization and disposal options while still retaining adequate levels of residue for site productivity needs. Manipulation of woody residues is a practical mitigation measure to ameliorate the effects of timber harvest, which removes much of the standing crop
and often creates major soil disturbance (Harvey, et al, 1987). Forest Service Region 6 direction (FSM 2403, R-6 Supplement 345, 3/85) provides guidance on ways to deal with residue management. Briefly, it states that residual woody biomass shall be considered first for retention on-site for long-term productivity. Any excess to that site need shall be made available for further utilization prior to any disposal.

The best utilization of material excess to site productivity needs, and the best disposition of material excess to utilization demand, remain as problems to be resolved.

**Resource Concerns**

Periodic drought and high lightning fire occurrence may limit the levels of forest residues that can be reasonably maintained on the ground and still prevent unacceptable wildfire losses.

Lack of the right temperature/moisture conditions (especially in ponderosa pine and associated species types) may limit the speed of organic decomposition commonly experienced in warmer/wetter environments, such as western Oregon and Washington (Harvey, et al, 1987). This can lead to accumulation of site nutrients in above-ground biomass out of reach of the roots in the soil layers. Many dry soils of the Intermountain West approach deficiencies in one or more nutrients within 125-150 years due to above ground nutrient storage in dead woody biomass (Behan, 1970).

Leaving too much residue above natural levels increases the likelihood of unacceptable damage to soils and vegetation from wildfires when they do occur (Hall, 1976; Harvey, et al, 1987; Boyer and Dell, 1980, Volland and Dell, 1981).

Too much residue on a site may inhibit herbage production and access for wildlife and livestock (Hall, 1976; Volland and Dell, 1981). Tree planting costs increase rapidly with increased residue loads.

**Fuelwood**

For many years firewood gathering was an incidental program on the Ochoco National Forest and Crooked River National Grassland. Firewood from the desired species and of the desired size was readily available close to towns for the relatively few local residents using wood fuel. Larch and juniper were the primary species utilized.

As a result of the oil crises of 1974 and 1979, many people began to view wood as an economical and reliable method of home heating. Firewood permits issued by the Ochoco National Forest and Crooked River National Grassland increased from 303 in 1971 to a peak of 7,361 in 1981. As a result, firewood close to population centers is now generally scarce, and smaller pieces of less desirable species must be used.

Lodgepole pine has become a favored species in recent years, primarily due to an increase in the number of dead snags caused by mountain pine beetles. Timber sale residues have also become a major source of firewood. The practice of yarding unmerchantable material to landings adjacent to roads has helped make this wood available.

The volume of firewood removed from the Ochoco National Forest and Crooked River National Grassland has declined since 1984 to less than 6,000 cords annually. This is due to a combination of factors, including high employment levels, abundance of dead lodgepole on the Deschutes National Forest, and the lack of quality wood cutting areas close to population centers on the Ochoco National Forest and Crooked River National Grassland. Future demand for firewood will depend on factors such as: the relative costs of alternate energy supplies, the distance of firewood supplies from towns, levels of logging residue available, and competition for the use of logging residues from the chip market.
Lands

The Ochoco National Forest and Crooked River National Grassland administer a lands adjustment program that frequently requires coordination with other land management agencies and private landowners to obtain easements and implement land exchanges. Land easements are obtained to provide temporary or permanent access to National Forest lands through other ownerships. Land exchanges are sought to consolidate land ownership in order to improve administrative efficiency.

The special use program deals with permits for special uses. Special use permits cover all uses other than timber sales, firewood permits and Christmas tree permits.

Lands

The Ochoco National Forest and Crooked River National Grassland have about 195,300 acres of private, State of Oregon and other Federal lands within their administrative boundaries. Proposals for land adjustments on intermingled lands are received from the various owners and managers. The Forest Service also participates in land exchanges with other government agencies, such as the State of Oregon and the Bureau of Land Management. The Ochoco National Forest and Crooked River National Grassland exchange lands primarily to block-up management areas or to acquire lands needed to meet management objectives. Congress has not authorized any funds for the purchase of lands by the Ochoco National Forest or Crooked River National Grassland.

Of the 132,970 acres of private land found within the boundaries of the Ochoco National Forest, the majority, approximately 110,000 acres, lies in large tracts along the fringe of the main Ochoco National Forest block. The remaining 23,000 acres of private land consist of numerous scattered parcels. Eighty acres of State of Oregon land are found within the Ochoco National Forest boundary - a 40-acre parcel near Mahogany Butte and a 40-acre parcel near Allen Creek. Approximately 6240 acres of isolated parcels of National Forest System lands are scattered within large private tracts. Administration and management of these parcels is generally difficult and expensive.

Table 3-7 shows the acreages in other ownerships within the boundaries of the Ochoco National Forest and Crooked River National Grassland.

The 52,670 acres of private land within the Crooked River National Grassland consists of numerous scattered parcels, while the State of Oregon lands and other Federal lands are mostly concentrated along the Crooked, Deschutes, and Metolius Rivers. Land ownership on the east side of the Crooked River National Grassland is much more consolidated than the west side. There are, however, isolated parcels of both private and National Grassland land on the east side.

The Forest Service leases 2,695 acres of land on the Crooked River National Grassland to the State of Oregon for the Cove Palisades State Park. This lease will expire April 19, 1990, but will automatically be renewed for 15 years unless written notice is given by either party 90 days prior to the termination date. The State of Oregon has been responsible for the development and operation of the recreational facilities, while the Forest Service maintains control over minerals and fire management.
Special Uses

Special use permits are issued for a variety of uses and activities. Some examples include: electronic sites, telephone lines, roads, reservoirs, pipelines, airstrips, endurance rides, dog field trials, and other organized group events. Special use permits are grouped into several categories. A summary of the special use permits on the Ochoco National Forest and the Crooked River National Grassland, by category and Ranger District, is displayed in Table 3-8.

1/ Category

100 = Recreation
200 = Agriculture
300 = Community
400 = Industry
500 = Public Information
600 = Energy Generation & Transmission
700 = Transportation
800 = Utilities & Communications
900 = Water
The Ochoco National Forest and Crooked River National Grassland provide transmission corridors and facility locations for various utilities. Eight major transmission lines, 230 KV or larger, cross the Crooked River National Grassland. Numerous small power lines serve wells and residences located throughout the Ochoco National Forest and Crooked River National Grassland. A 36-inch natural gas pipeline crosses the east side of the Crooked River National Grassland from north to south, two smaller lines branch from this mainline to supply the communities of Madras and Prineville. Several telephone lines (buried and overhead), along with two electronic communication sites, are located on the Ochoco National Forest and Crooked River National Grassland.

**Demand**

The demand for electrical and telephone facilities has been increasing each year as more and more parcels of private land scattered throughout the Ochoco National Forest and Crooked River National Grassland are developed for residential purposes. The demand for transmission facilities is also increasing as population centers in Oregon and California increase. The western leg of a proposed Alaska Natural Gas Transportation System, a 42-inch line, is proposed to parallel the existing 36-inch line on the Crooked River National Grassland. In December 1988, the Federal Energy Regulatory Commission received an application requesting the authority to expand the pipeline system. If this authority is granted, construction on this western leg could begin within 2 years. The construction of another major electric transmission line has also been proposed. This line would cross only private land within the boundaries of the Ochoco National Forest.

**Minerals and Energy**

Mineral commodities are classified by law into three categories: locatable, leasable and saleable. The manner in which each is managed, and the authority of the Forest Service to control the exploration for and development of each commodity, varies considerably.

**Locatable Minerals**

Locatable minerals are those minerals which, when found in valuable deposits, can be acquired under the General Mining Laws of 1872, as amended. Examples of locatable minerals on the Ochoco National Forest include, but are not limited to, gold, mercury (cinnabar), and uncommon varieties of gemstones. Citizens and those who have declared their intent to become citizens of the U.S., have a statutory right to explore vacant unwithdrawn public land for these minerals. Upon discovering a valuable deposit, they have a right to locate, mine, and remove the minerals.

Forest Service control of these activities is limited to minimizing impacts on surface resources. This is accomplished by requiring that mining operations are conducted in accordance with an approved plan of operations. The Forest Service reviews the plans of operations to ensure that environmental protection standards are met. These include standards for air, water, cultural resources, and threatened and endangered species. Assuring prompt reclamation or restoration of disturbed lands is accomplished as part of the operating plan process.

The mine operator is required to submit a proposed plan of operations whenever mining operations are likely to cause significant surface disturbance. After receiving a proposed plan of operations, the Forest Service will conduct an environmental analysis and determine whether an environmental impact statement is necessary. The District Ranger will then do one of the following: (a) approve the plan, (b) notify the operator that the proposed operations do not require a plan of operations, (c) notify the operator of any necessary changes in, or additions to, the plan.
of operations, or (d) notify the operator that an environmental impact statement must be prepared before the plan can be approved.

If unforeseen surface disturbance occurs during mining operations, the Forest Service may require the operator to furnish a modified plan of operations. In this situation, mining operations may continue unless the operations are causing resource damage that is unnecessary, unreasonable and irreparable.

Designated wilderness areas and other withdrawn areas are not open to mining claim location. However, these areas are subject to valid existing rights perfected prior to the date the area was withdrawn. Refer to Table 3-9 for a list of areas withdrawn from location under the mining laws.

Acquired lands are not subject to location under the 1872 Mining Law, but are subject to mineral leasing under the Acquired Lands Leasing Act as “hardrock leasables.” Most of the Crooked River National Grassland was acquired under Title III of the Bankhead-Jones Farm Tenant Act.

The primary locatable minerals sought on the Ochoco National Forest and Crooked River National Grassland are cinnabar (mercury), gold, and semiprecious gemstones (agate, thunder eggs, jasper, etc.). There are approximately 1,000 mining claims located on the Ochoco National Forest National. Most of the Crooked River National Grassland is not open to mineral entry under the general mining laws.

**Mercury and Gold**

Approximately 8,080 acres on the Big Summit and Prineville Ranger Districts are classified as having high potential for the occurrence of cinnabar (from which mercury is extracted) or gold. An additional 86,400 acres on these Districts, and approximately 19,250 acres on the Crooked River National Grassland are classified as having moderate potential for the occurrence of mercury or gold. Refer to maps entitled Mineral Potential - Locatable Minerals and Mineral Potential - Oil and Gas for a display of where the potential for discovery is concentrated.

A high mineral potential is used where geologic characteristics, favorable for resource accumulation, are known to be present, and evidence exists that indicates mineral concentration or mineralization has taken place. On the Ochoco National Forest, the rating of high mineral potential is based on past mineral production. Refer to Table 3-10 for a list of mines on the Ochoco National Forest which are known to have produced mercury or gold.

A moderate mineral potential exists where geologic

---

3-36
conditions are favorable for mineral accumulation, but where the evidence of mineralization is questionable or has not yet been found. Areas classified as having a moderate potential could be reclassified as having high potential if new information is acquired, or if economic conditions change.

Areas classified as having moderate mineral potential exhibit one or more of the following characteristics:

1. The area is underlain by rocks of the Clarno Formation which have been intruded by igneous rocks, faulted or hydrothermally altered (this is the geology of producing mines in the area).

2. Agate, jasper or thundereggs have been found in the area (these indicate the presence of a epithermal mineral deposit, the type of mineral deposit mined in the area).

Mining companies have been conducting extensive exploration for large, low-grade epithermal deposits of gold in central and eastern Oregon during the past several years. The discovery of a major gold deposit in eastern Oregon triggered a "rush" in 1988. Large, low-grade gold deposits are generally extracted using open pit mining and heap leaching techniques. On the Ochoco National Forest, the areas classified as having moderate or high potential for the occurrence of gold or mercury are underlain by large, low-grade epithermal deposits, and the Forest and Grassland are experiencing some exploration activity. Thus, the potential exists that the Forest or Grassland could become the site of a major gold mine. This event would trigger an Environmental Impact Statement (EIS) and Forest Plan Amendment.

The rest of the Ochoco National Forest is classified as having a low mineral potential for locatable minerals. This rating is assigned to areas where geologic characteristics are unfavorable for mineral accumulation, or where there is no significant evidence of mineralization.

Areas of the Ochoco National Forest, near the Spanish Gulch and Maury Mountain mineralized areas, are classified as having low potential, because even though they are close to Forest Service land, the geologic features occurring at the mines do not occur on the nearby Ochoco National Forest lands.

Semiprecious Gemstones
Thundereggs, jasper, agate and petrified wood are collected by rockhounds on the Ochoco National Forest. Central Oregon is nationally known for its rockhounding opportunities, and this popular activity is important to the local economy.

Hunting and collecting rocks and minerals as a hobby does not require a permit or mining claim if the specimens are collected for personal, noncommercial use. Thundereggs, jasper and agate are locatable minerals, and several individuals have located mining claims and are mining these materials commercially. The Prineville Rockhound Club maintains four mining claims for public use, and the Tualatin Valley Gem Club maintains one claim on the Prineville District for these materials. By law (Act of September 26, 1962; 76 Stat. 652), petrified wood is not locatable. Limited quantities of petrified wood may be collected from public lands on a free-use basis.

Leasable Minerals

Leasable minerals are mineral commodities that have been specifically excepted from the General Mining Law by Congress, principally through the following acts: the Federal Onshore Oil and Gas Leasing Reform Act of 1987, the Mineral Lands Leasing Act of 1920, the Mineral Leasing Act for Acquired Lands of 1947, the President’s Reorganization Plan No. 3 of 1946, and the Geothermal Act of 1970. Leasable minerals include oil and gas, geothermal resources, and locatable mineral deposits with acquired status (hardrock leasables). These minerals are subject to exploration and development under leases, permits, or licenses granted by the Secretary of Interior.

The Secretary of Agriculture, through the Forest Service, has consent authority for leasing of geothermal resources and hardrock leasable minerals on all National Forest System lands. The Federal Onshore Oil and Gas Leasing Reform Act of 1987 contains key provisions altering the Forest Service’s authority for the management of leasable minerals.

The Secretary of Agriculture now has consent authority for the issuance of oil and gas leases on National Forest System lands. In addition, no oil and gas permits to drill may be granted without the analysis and approval of a surface use plan by the Forest Service. Regulations implementing these authorities have been published as a proposed regulation in the Federal Register and are being finalized at the National level.

The availability of reserved lands for mineral leasing depends on whether the implementation of development activities could meet land management direction. On acquired lands, permits or leases are subject to conditions ensuring that the lands are used for the purpose for which they were acquired or are being administered.

The policies and procedures by which mineral use authorizations for federally owned leasable minerals are to be processed may be found in the Interagency Agreement between the Forest Service and the Bureau of Land Management (BLM) dated June 19, 1984.

Oil and Gas

The original authority for classification of mineral potential on public lands rested with the U.S. Geological Survey (USGS). This agency classified the State of Oregon in 1976. The following criteria were used to define lands as prospectively valuable for oil and gas:

1. The area is underlain by a section of sedimentary rocks, either marine or nonmarine, 1,000 feet more in thickness;

2. The sedimentary strata have not been metamorphosed or intruded by igneous rocks to the extent that any oil or gas would have been driven off; and

3. The fact that the rocks may now be under a thick cover of lava or other type of deposit does not eliminate them.
Using these criteria, approximately 85 percent of the Ochoco National Forest and Crooked River National Grassland was classified as being prospectively valuable for oil and gas (refer to Map of Mineral Potential - Oil and Gas).

In 1982, the responsibility for classification was shifted from USGS to the Minerals Management Service, and then to the Bureau of Land Management. In 1984, the BLM proposed the following as a new definition for “prospectively valuable for oil and gas”:

A classification of public lands in which geologic data suggest that the underlying rocks may contain the potential for hydrocarbon accumulation.

Unfortunately, due to a lack of funding and staff, the BLM has not reclassified Oregon for oil and gas potential.

The oil and gas potential of the Ochoco National Forest and Crooked River National Grassland remains poorly defined. Although much of the Ochoco National Forest has been leased for oil and gas, very little exploration or development has occurred. One well was drilled in the Maury Mountains (T17S R23E Section 31). This well encountered marine sediments beneath the tertiary volcanic cover. However, much more work will be necessary before the potential is well-understood.

Geothermal Energy
The Oregon Department of Geology and Mineral Industries has classified the entire Ochoco National Forest and Crooked River National Grassland as favorable for the discovery of geothermal resources. This classification is based on various geothermal, volcanic and tectonic phenomena, including thermal wells, youthful volcanism, mineralization, and anomalous concentrations of faults and lineaments. However, approximately two-thirds of Oregon is given this classification, and it is probable that only parts of this area are truly underlain by thermal waters.

An unnamed spring producing 10 grams per minute of 85°F water is located at T19S R26E Section 5, on the Snow Mountain Ranger District. Two thermal wells are located near the boundary of the Crooked River National Grassland, southeast of Madras. One well, located in NE1/4 NE1/4 Section 24, T11S R13E W.M., intercepts water measuring 25°C (77°F); the other well, with water at 21°C (70°F), is located in SE1/4 NE1/4 Section 24, T11S R13E W.M.

Hydro-electric
The development of hydro-electric power facilities on the Ochoco National Forest and the Crooked River National Grassland is limited by low runoff and unfavorable economic constraints. Existing developments occur at Pelton and Round Butte dams on the Deschutes River, and at Opal Springs on the Crooked River. Several sites have been considered for development that would create impoundments on National Forest System lands, but no licenses have been granted by the Federal Energy Regulatory Commission.

Saleable Minerals
Saleable minerals include common varieties of sand, stone, gravel, pumice, pumicite, cinders, and clay. In general, these minerals are of wide-spread occurrence and are of relatively low unit value. They are generally used for construction materials and for road building purposes. Saleable minerals which have some property giving them distinct and special value, remain locatable. Before a deposit can be sold, a determination of “common variety” must be made by minerals staff and legal counsel.

These materials are disposed of under the authority of the Materials Act of July 31, 1947, as amended by the Act of July 23, 1955. Disposal of saleable minerals from public lands administered by the Forest Service is at the discretion of the Forest Service.
Saleable minerals may be disposed of through competitive sale, sale by negotiated contract, or by preference right negotiated sale. Free use permits may be issued to nonprofit associations or government agencies. Mineral materials on lands acquired under the authority of the Bankhead-Jones Act may be disposed of only to public agencies, and are only to be used for public purposes.

The Ochoco National Forest and Crooked River National Grassland produce approximately 147,850 cubic yards of rock annually. This rock is used by the Forest Service, National Grassland, the State of Oregon, and local counties and cities to maintain their roads and highways.

**Access Restrictions**

Mineral and energy resources on the Ochoco National Forest and Crooked River National Grassland have been classified in terms of “potential” and “existing land access restrictions.” Table 3-11 displays the existing land access restrictions in each mineral and energy potential category.

Categories for mineral and energy potential refer to the degree that geologic conditions are favorable for the occurrence of locatable and leasable sources. In this table, “locatable” refers to gold and cinnabar deposits on the Ochoco National Forest. “Leasable” refers to oil and gas on both the Ochoco National Forest and Crooked River National Grassland, and also to gold and cinnabar on the Crooked River National Grassland.

For each mineral and energy potential category, access restrictions have been applied to all lands within the boundaries of the Ochoco National Forest and Crooked River National Grassland, according to specific resource management objectives.

For locatable minerals, the acreage listed as withdrawn represents those areas listed in Table 3-9. The areas classified as having high access restrictions include: wilderness study areas, research natural areas, roadless areas, scenic and recreation rivers, old growth, and developed recreation areas. Areas with moderate access restrictions include: big game winter range, eagle roosting areas, riparian areas, trails, and visual management corridors. All remaining areas, not placed in the withdrawn, high, or moderate categories, have been placed in the low access restriction category.

### TABLE 3-11

</tr>
</tbody>
</table>

1/ The total locatable area does not equal the total leasable area due to the provisions of the Bankhead-Jones Farm Tenant Act that require most of the Crooked River National Grassland to be administered under the leasable system.
For leasable minerals, the acreage listed as withdrawn represents wilderness areas. In the areas classified as having high access restrictions, leases will be issued with "no surface occupancy" stipulations. In areas having moderate access restrictions, leases will be issued with stipulations restricting operating seasons or requiring facilities be set back from specified features.

**Demand**

The demand for mineral and energy resources will continue to increase as developed sources decline, and as populations increase. The degree of exploration and development of new sources will fluctuate with economic changes, and mineral and energy shortages.

The collection of semiprecious gemstones may increase slightly, depending on population trends and leisure time activities.

**Old Growth**

Old growth is an important component of the Ochoco National Forest and the Crooked River National Grassland. The old growth stage in plant succession supports a unique combination of features that provides habitat for over 100 wildlife species, and contributes to biological diversity. Old growth also enhances visual and recreational qualities of the Forest and Grassland.

During the most recent inventory, conducted in 1987, old growth was identified (using the Regional definition) as "any stand 10 acres or greater in size with the following general characteristics: 1) contains mature or overmature trees in the overstory that are well into the mature growth stage; 2) usually contains a multi-layered canopy and trees of several age classes; 3) standing dead trees and down material are present; and 4) evidence of man's activities may be present, but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand."

The 1987 inventory was conducted primarily by Ranger District personnel. Stands were delineated using information from aerial photograph interpretation, stand exam data, and local knowledge. Field verification of stand boundaries and condition was not completed for all stands. A total of 93,800 acres of ponderosa pine and mixed conifer old growth were identified and mapped. Of this, 20,500 acres lie within wilderness.

The inventory used in the Ochoco National Forest and Crooked River National Grassland DEIS, conducted in 1982, identified a total of 80,000 acres of ponderosa pine and mixed conifer old growth (along with more than 50,000 acres of old growth juniper). The difference in the estimated totals obtained from the two inventories appears to be due to the old growth definitions and criteria that were used. The 1982 inventory used more specific stand characteristics (which were designed primarily to meet wildlife habitat objectives) than those identified in the Regional definition. Furthermore a 50-acre, rather than 10-acre, minimum size constraint was used for stand selection. Therefore, the broader definition used for the 1987 inventory allowed inclusion of additional stands.

The following definitions were used for the allocation process.

1) Suitable Old Growth meets the Regional definition and provides reproductive habitat for the pileated woodpecker. To the extent possible, 300 acre contiguous stands of old growth were selected, and stands were distributed across the Forest in a 1 per 12,000 acre block pattern.

2) Capable Old Growth does not meet the Regional definition but exists in a site which is capable of producing old growth characteristics in the future. The assumption was made that all lands able to produce 20 cubic feet per acre per year of wood are capable of eventually producing suitable old growth. Capable areas were allocated to expand an old growth stand to 300 acres, or to distribute stands in a pattern that will meet long-term habitat requirements for the pileated woodpecker.
3) Allocated Old Growth (either suitable or capable) is permanently set aside as wildlife habitat during the planning process.

4) Unallocated Old Growth meets the Regional definition but has not been set aside as wildlife habitat during the planning process. Unallocated areas may exist in general forest, wilderness, roadless, and research natural areas.

Recreation

Outdoor recreational opportunities on the Ochoco National Forest and Crooked River National Grassland are generally less primitive than those found on many other National Forests in the Pacific Northwest. A combination of easy terrain, high quality stands of pine timber, and good forage for livestock prompted early commercial use of the area. As a result, 89 percent of Ochoco National Forest lands have been accessed by roads for various management activities.

Recreational Opportunities Spectrum (ROS)

Recreational opportunities on the Ochoco National Forest and Crooked River National Grassland were classified using the ROS land classification system (Clark and Stankey, 1979). ROS inventory identifies recreational settings that vary from an undisturbed natural environment with little human contact to a highly modified environment with frequent human contacts. It serves as a basis for defining the types of outdoor recreational opportunities the Ochoco National Forest and Crooked River National Grassland might best provide. Table 3-12 lists and summarizes the recreational opportunities by ROS classification. The reader is referred to the glossary for specific definitions of each ROS classification.

Developed Recreation

The Ochoco National Forest and Crooked River National Grassland currently maintain 22 campgrounds, 4 boating sites, and 4 picnic areas. These developed recreational facilities have a capacity to accommodate 1880 persons at the same time.
Dispersed Recreation

There are an estimated 950 dispersed recreational sites on the Ochoco National Forest and Crooked River National Grassland that are frequently used during the summer and fall. Most of these sites have no facility development (e.g., toilets, drinking water, tables). Some of the more heavily used sites do have minimal facilities for resource protection and public health purposes, such as pit toilets and potable water.

Specific dispersed recreational opportunities available include hiking, backpacking, picnicking, camping, hunting, fishing, gathering forest products, trail biking, driving for pleasure, bird watching, water skiing, rockhounding, off-road vehicle travel (see Appendix D, Travel Plan, in the Ochoco National Forest Plan), swimming, horseback riding, mountain biking (see publication, “Developing Mountain Bike Opportunities on the Ochoco National Forest, available at the Forest Supervisors Office), winter sports, general leisure, and sightseeing.

### Off-Road Vehicle Use

The use of ORV's on the National Forest and Grassland Systems has been recognized as a legitimate recreational pursuit when in concert with the environmental setting, when the effects are minimized on the land and other resources, when public safety is provided for, and when conflicts with other users are controlled. The Forest has been operating under the 1977 ORV Plan to date. This Plan provides both controls and monitoring measures.

The use of ORV's was initially identified as an issue on the Henderson Flat area on the Grassland. It was not carried forward in the original ICO's for the DEIS because it was specific to the Grassland and was seen as a local issue that could be dealt with outside the planning process. Henderson Flat continues to be a problem however, and has been the subject of criticism by some publics, including a recent appeal on a decision to sign an existing trail for ORV use. The Prineville Ranger District has also received recent criticism about ORV use and environmental damage.

Problems with ORV use presently fall into two categories: 1) environmental damage when use occurs during periods when soils are subject to damage, and when use occurs on sensitive areas, such as riparian areas, and 2) social issues surrounding those who own and wish to pursue ORV use opportunities on the Forest and Grassland, and those who want to preclude such use as being inappropriate and in conflict with other resources. Off-road vehicle use continues to be a popular recreation pursuit on the Forest and Grassland.
Trails

The Ochoco National Forest and Crooked River National Grassland maintain 96 miles of trails. A majority of the trails exist as short segments of a formerly extensive system that has largely been replaced with roads. Two of the trails, Twin Pillars and Round Mountain, are designated National Recreation Trails. Portions of the Summit Trail have been designated a National Historic Route. Segments of the 19th century Camp Watson Military Road can also be found intact. Approximately 97 miles of snowmobile routes and nine miles of cross-country skiing routes exist.

National Recreation Strategy

The Ochoco National Forest is committed to the National Recreation Strategy goal of providing customer satisfaction with more, high-quality recreation services. Customer satisfaction will be improved by seeking out new ideas, providing interpretive services, promoting an outdoor ethic, providing opportunities to all user groups, promoting tourism that will help build strong communities and improve quality of life, and matching human resource needs with recreational opportunities. Partnerships with private enterprise, other agencies, and user groups will be developed to encourage, establish, and sustain a diverse and balanced range of recreational opportunities. The Ochoco National Forest and Crooked River National Grassland will be seeking partners to help to develop and maintain recreational facilities, test innovative ideas, establish mutual cooperation, represent groups with special needs, and provide funding.

Demand

The Ochoco National Forest and the Crooked River National Grassland is heavily utilized for the following four activities.

1. Rockhounding - The Ochoco National Forest and the Crooked River National Grassland contain numerous locations where gemstones may be found. These are of significance regionally, if not nationally, and attract visitors from many areas.

2. Big Game - The Ochoco National Forest and the Crooked River National Grassland contain excellent big game hunting opportunities for both deer and elk, which are also a major attraction to hunters statewide. Many of the hunters come from western Oregon locations, notably Portland and the Willamette Valley.

3. Water-Related Recreation - The relatively few lakes and reservoirs (Antelope, Walton, Billy Chinook, Haystack, and Delintment) on the Ochoco National Forest and Crooked River National Grassland receive heavy use.
4. River-Related Recreation - Sections of the Crooked River, North Fork of the Crooked River, and the Deschutes River have all been classified as Recreational or Scenic under the Oregon Wild Rivers Act. Lower Squaw Creek has been determined eligible for further study under the National Wild and Scenic Rivers Act. Numerous other managed recreation sites are located on the Ochoco National Forest and Crooked River National Grassland. Most are significant only within the Zone of Influence identified earlier in this chapter. These include designated recreation areas at Stein's Pillar, Bandit Springs, Deep Creek, and Lookout Mountain.

Off-road vehicle use is not, at this time, considered a "major" recreational use on the Forest except in specific isolated areas (e.g., Henderson Flats). Demand is expected to increase.

Current recreational use relies heavily on the road system. Road related uses total approximately 90 percent of the present recreational use. The predominate recreational activities are camping, motorized travel, picnicking, and hunting. Recreational use by year and ROS classification is shown in Table 3-13. Recreational use is measured in Recreation Visitor Days (RVD's), which are defined as recreational use of an area for a 12 hour period. The drop in total RVD's between 1970 and 1975 is attributed primarily to the oil embargo and the resulting gas shortage. The overall trend conforms closely with population trends, however, resulting in expectations of continued increases in recreational use for the foreseeable future.

Estimates of future recreational use depend on many uncertain factors and should be viewed as trends useful for making relative comparisons. The following assumptions were made to estimate future recreational demands:

1) For most forms of recreation uses demand follows population trends;

2) Stream fishing demand varies directly with fish habitat and populations; and

3) Construction of trails, trailheads, and campsites shifts demands higher for some categories of recreation use.

Table 3-14 displays a representative set of demand projections by ROS class. The Roaded Natural/Rural category has been split into two categories to show the differences between developed and dispersed recreation.

Scenic Resources

The Ochoco National Forest and Crooked River National Grassland encompass a variety of vegetation, climatic, and geologic zones. These zones can be observed from the Crooked River National Grassland’s rolling range country that is interspersed with deep canyons and scattered volcanic buttes to the Ochoco National Forest’s extensive stands of ponderosa pine and unique rock features. Most visitors travel through the Ochoco National Forest on Highway 26, which passes through open park-like stands of old growth ponderosa pine. The degree of visitor sensitivity to these stands is difficult to quantify, but the public is perceived to enjoy seeing large yellow-barked pine trees in open park-like settings.

The appearance of the Ochoco National Forest and Crooked River National Grassland has changed over time. Elimination of fire, and an accompanying change in plant succession, has had the most effect. In the past, these changes have been gradual and not always readily evident to the casual observer. Recent intensive management practices, such as timber harvest, wildfires, livestock grazing, and road construction, have increased the apparent rate of change on the landscape, and modifications have become more obvious. Visual impacts of clearcutting and prescribed burning are the most notable.

The scenic resources of the Ochoco National Forest and Crooked River National Grassland have been inventoried in terms of Visual Quality Objectives (VQO’s). These categories are based on the presence or absence of distinctive scenery, proximity to viewpoints, and the amount and type of traffic through viewing areas. Each category describes the degree of acceptable alteration from the natural landscape that would be consistent with scenic objectives. Land in the “preservation” category consists of the existing wilderness areas. The “retention” category contains roadless areas managed to retain roadless characteristics under current plans, and foreground corridors along major roads and trails. Corridors along other heavily used roads fall into the “retention” and “partial retention” categories. Remaining lands are inventoried as “modification” or “maximum modification”. These two categories have been grouped, since the effects on management are very similar. A detailed description of these categories can be found in the glossary under the heading “Scenic Quality Objectives.” Table 3-15 shows the amount of Forest and Grassland presently in each category. Figure 3-10 illustrates the appearance typified by timber harvest activities in each category.

### Social and Economic Setting

The “Zone of Influence” for the Ochoco National Forest has been examined at three levels.

Zone of General Influence: the area on which the Ochoco National Forest has a definite and measurable effect.

Zone of Primary Influence: the area which the Ochoco National Forest significantly affects.

Zone of Extended Influence: this is the largest area on which the Ochoco National Forest makes an impact. The effect of the Forest might not be significant on any single community outside the Zone of General Influence; nevertheless, the total effects on all such communities are significant.

### Zone of General Influence

The Zone of General Influence for the Ochoco National Forest and Crooked River National Grassland consists of six Oregon counties. The Ochoco National Forest is located in Crook, Grant, Harney, and Wheeler counties. The Crooked River National Grassland lies entirely in Jefferson County. Deschutes County is added to the Zone of General Influence because its population and economy make use of Ochoco National Forest and Crooked River National Grassland resources. These six counties are shown in Figure 3-11, and the amount of Ochoco National Forest and Crooked River National Grassland acreages in each county are shown in Table 3-16.

A “Socio-economic Overview” containing more detailed information was prepared for the six-county region, and is located in the Ochoco National Forest Supervisor’s Office.

Zone of Primary Influence

The Zone of Primary Influence is considered to be only those counties which are directly affected by the management decisions of the Ochoco National Forest. Crook and Harney counties constitute this zone.

The Forest's contribution to the economies of Crook and Harney counties is substantial, but it varies over time. It depends upon how much timber of what species is processed locally. This in turn is related to timber prices, which tend to rise and fall with the general health of the national economy. (The higher the price of the timber, the less significant hauling costs are, and the greater the percentage that may be purchased by more distant operators.) Another factor involved is the desire of local remanufacturing companies to buy local milled lumber. Even the personalities of mill executives can affect decisions to buy or not to buy Forest timber.

Figures from 1987 indicate that one million board feet of Forest ponderosa pine generates 11 local jobs and $220,000 (1987 dollars) of local income. One million board feet of associated species generates three local jobs and $60,000 in income.

Crook County

Crook County has a population of 13,500 with 5,455 people living in Prineville, the County seat and only incorporated city. Out of a total of 4,270 wage and salary jobs in the county, 1,600 (37%) are in wood processing, and an additional 830 (19%) are in government (Business and Employment Outlook, District 10, 1988-89).

Prineville has 13 employers with more than fifty employees. Of these, seven are milling or re-milling firms, four are governmental agencies, and the remaining two are the Pioneer Memorial Hospital and the Les Schwab tire production facility. Sawmill employment has declined from 620 jobs in 1977, to 450 in 1988. A dramatic increase in millwork employment (from 540 jobs in 1977, to 1200 in 1988) has compensated for this decline, however.

Prineville's wholesale and retail trade sectors compete with the Bend urban area 35 miles away and, to a lesser extent, with the Redmond area 18 miles away. Retail sales per capita for the State of Oregon are $5454; they are $6467 for Deschutes County and only $2857 for Crook County (Oregon County Economic Indicators 1984, pp. 1 and 17).

Harney County

Harney County has 7,100 inhabitants including 4,175 residents of Burns and Hines. The county has a wage and salary employment of 2,180 jobs. This includes 460 (21%) wood products jobs and 720 (38%) government jobs (Business and Employment Outlook, District 14, 1988-89).

Since 1980, when the Hines Mill closed and was put up for sale, the Harney County economy has rebounded. Snow Mountain Pine purchased the mill, invested in plant modernization, and diversified the product line. Currently, mill employment is at a lower level than before the modernization, and the Burns/Hines economy is still substantially dependent on the milling of logs. The analysis of Harney County contained in this document assumes that Snow Mountain Pine will be able to continue production at its present level of output.
Changes in the Structure of the Wood Products Industry

The wood products industry has been undergoing significant and fairly rapid changes. Major changes include:

- New "small log" log mills designed to process the smaller diameter of timber that will be increasingly harvested in the future;
- Increased mechanization, both in the woods and in the sawmills; and
- Increased mechanization in the remanufacturing mills, along with production of more "finished" projects.

It is somewhat difficult to compare the future employment levels that will be produced by the small log mills with the historic employment levels produced by the large log mills. On the one hand, more work is needed to produce the same volume, on the other, more of the work is mechanized.

The effects of increased mechanization, both in the woods and in the sawmills, have been reported both in the popular media and in professional literature. One study in Montana shows that the output of lumber per sawmill worker increased more than 80% from 1980 to 1986 (Keegan and Polzin, 1987). Another Montana study shows a doubling in lumber output per dollar cost (Keegan, Martin, and Stevenson, 1987). This second article also states that there are factors other than modernization that contribute to these increases, but the authors attribute two
thirds of the change to modernization. Lumber production levels, they say, were nearly as high in 1986, as in the boom period of the late 1970’s, but employment is far less.

Local counties have followed the same pattern of resumed high production with less employment. The Ochoco National Forest obtained data regarding employment and production levels from the mills in Crook and Harney counties for the years 1977, 1981, and 1987. The totals are shown in Table 3-17.

* MBF: Thousand board feet

Total Sawmill Production and Employment, Crook and Harney Counties

The figures in Table 3-17 show that nearly the same output was produced in 1987 as in 1977, but with 60 percent fewer employees. Also, the number of mills declined from seven to five.

The remanufacturing industries have also been improving their plants, but the effects seem to be different. One might assume that here also, mechanization would cost jobs. However, the plants are producing more “finished” products such as complete door casings, or laminates of hardwood over pine. Remanufacturing employment in Crook and Harney counties has steadily increased over the last ten years, which seems to indicate that this mechanization is creating jobs, not eliminating them.

### Zone of Extended Influence

The Zone of Extended Influence is considered to be the State of Oregon. The Forest affects this extended zone in three significant ways.

A portion of Forest timber is milled or remanufactured outside the other Zones of Influence but inside the State.

Elk and deer hunters come from many parts of the State, especially Portland and other cities in the Willamette Valley. An estimated 6200 RVD’s are generated annually in big game hunting from this zone.

Other recreational users come to the Forest from throughout the state.

One million board feet of Ochoco National Forest ponderosa pine produces 14 jobs statewide, and $290,000 in income. One million board feet of associated species generates five jobs and $100,000 in income.

### Social Setting

The Social-Economic Overview of the Ochoco National Forest and Crooked River National Grassland lists six “lifestyle” categories into which many of the six-county residents fall. These categories are Native Americans, ranchers, loggers, mill workers, small-town merchants, and government employees.

The Native Americans consist mainly of the Warm Springs Confederated Tribes located in Wasco and Jefferson counties (the largest group), and the Paiutes in northern Harney County.

All of the lifestyles occurring in the area are affected by decisions relating to management of the Ochoco National Forest and Crooked River National Grassland. The rancher, the logger, the mill worker, and the Native American depend directly on the Ochoco National Forest for jobs, wood, and forage. Significant numbers of public service employees’ jobs are related to the Ochoco National Forest, and the local merchants depend on the economic well-being of all groups. Thus, significant

1 Spitz, J. 1982 Socio-Economic Overview of the Ochoco National Forest and Crooked River National Grassland. Mime 137 p
changes in Ochoco National Forest management can affect lifestyles and community well-being.

Residents of the area are involved with Ochoco National Forest activities relating to leisure. Their lifestyles emphasize recreational uses of the Ochoco National Forest and Crooked River National Grassland in many ways.

Demographics

Table 3-18 and Figure 3-12 present population figures for the region. Deschutes County was the fastest growing county in the state during the 1970's, and rapid growth is anticipated through the end of the century. Nearly 60 percent of the people in the six-county area lived in Deschutes County in 1980. The percentage is projected to rise to 66 percent by the year 2000. Jefferson County is also growing rapidly and will soon be the second most populous county in the six-county area.

The remaining counties are more rural and will not likely share in the anticipated growth. Crook, Grant, and Harney counties grew substantially in population during the 1970's when the timber market was strong, but the population has remained stable or decreased during the years 1980 - 1985. Wheeler County's sawmill closed in the 1970's, resulting in a population decline for that decade. The projections from 1980 through the year 2000 predict little change in population for those counties.

Table 3-19 displays data about minorities in the area. Jefferson County has the largest percentage of minorities because of the Warm Springs Indian Reservation and a large Hispanic population. Hispanics are the largest minority group in the other counties (except Wheeler, which has no recorded minorities) and are the fastest-growing minority group in the six-county region.

Indian Rights and Claims

The American Indian Religious Freedom Act (Public Law 95-341) of 1978 states, “That henceforth it shall be the policy of the United States to protect and preserve for American Indians their inherent right of freedom to believe, express, and exercise the traditional religions of the American Indian, Eskimo, Aleut, and Native Hawaiians, including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonies and traditional rites.” Under the Tribes of Middle Oregon Treaty of 1855, rights such as hunting, fishing, and root gathering are reserved to the Tribes in the area ceded by the Tribes.

Source: Business and Economic Outlook, Program Year 1988 and 1989, JTPA Districts 10, 12, and 14 Chapters 2 and 6 State of Oregon Employment Division, Department of Human Resources
Both the Warm Springs Confederated Tribes and the Paiutes have traditional areas of the Ochoco National Forest for root gathering and berry picking.

During the development of this FEIS and Ochoco National Forest Plan, recognition was given to the importance of the Comprehensive Plans for both the Warm Springs Confederated Tribes and the Paiutes of Northern Harney County.

Economic Conditions

Table 3-20 gives an economic picture of the region. Wages are around 10% lower than the state average and 20% lower than the national average (not shown). Employment in the region is higher than the state average. However, the percentage of those who are "economically disadvantaged" and the percentage of Aid For Dependent Children (AFDC) recipients generally follow the state average. The exception is Wheeler County, which has the most unemployment, the highest percentage of economically disadvantaged persons, the highest per capita income, and no AFDC claims.

Figure 3-13 shows the economic make-up of the six counties. Most of the manufacturing sector is the milling or remilling of timber, and much of the government sector concerns forestry. Combining these sectors together gives a rough idea of the importance of the wood products industry in each county. This combination is indicated by the shaded areas on the graphs.

The Deschutes County and Jefferson County economies are the most diversified; the timber industry is surely important, but there are other well-developed economic sectors also. In contrast, Crook and Grant counties are heavily dependent on timber, and to a somewhat lesser extent, Harney County is also. Wheeler County's private economic sectors are small by contrast. The government sector dominates there.

A special factor of economic importance is the 25 percent monies, i.e. the distribution of 25 percent of total federal receipts to the counties. These monies are distributed according to the proportion of National Ochoco National Forest and Crooked River National Grassland acres in each county, and are often an important part of the counties' budgets. Data for fiscal year 1983 is shown in Table 3-21. Crooked River National Grassland monies are handled in a separate account from Ochoco National Forest monies.
Soil

Soil development across the Ochoco National Forest and the Crooked River National Grassland has been influenced primarily by geologic events and climate, along with the interactions of topography, time, vegetation, and biological processes. Soil development has occurred on assorted geologic materials that were covered by volcanic ash from Mt. Mazama (Crater Lake) about 6700 years ago. Basalt and andesite flows are the primary materials on much of the Forest east of Lookout Mountain (approximately 40% of the total Forest and Grassland area). Older andesites, basalts, and pyroclastic sediments underlie most of the area to the west of Lookout Mountain (approximately 23 percent of the total area). Soils are often weathered to clays in this portion of the Forest. Resistant welded tufts are found extensively south of Snow Mountain (approximately 17 percent of the total area). The remaining 20 percent of the Forest and Grassland contains scattered pockets of highly weathered tuffaceous sediments, recent landslide debris, sedimentary rocks, rhyolite, and metasedimentary rocks.

The Soil Resource Inventory (Ochoco National Forest, 1977) for the Ochoco National Forest and Crooked River National Grassland identified 111 different land types occurring separately or in combination with other land types. Land types reflect differences in soil, vegetation, and landforms. There are approximately 10-12 different soil types represented in this classification. Three broad soil type categories have been identified for use in management activities: volcanic ash, residual, and nonforest soil types. Table 3-22 describes the three soil types and their related management implications in general terms.

Volcanic Ash Soils

These soils compose 30 percent of the entire Forest and Grassland area, and approximately half of the forested lands. Ash soils were formed from widespread air-fall volcanic ash deposited from Mt. Mazama about 6700 years ago. The present distribution of volcanic ash soils has resulted largely from the influences of topography and elevation on wind and precipitation patterns. Most of the more recent air-fall volcanic ash deposits from Mt. Mazama have been re-worked onto north and east slopes, basins,
and broad upland plateaus. The present dry climate of the Forest and Grassland does not favor the weathering of volcanic ash soils.

**Residual Soils**

These soils (comprised of loess, volcanic ash, old and weathered volcanic ash, and residual materials) compose 30 percent of the entire Forest and Grassland area, and approximately half of the forested lands. Residual soils are clayey soils that were formed from widespread continuous air-fall volcanic ash deposited between 20 and 30 million years ago. These soils lack the distinct volcanic ash layer, which has either eroded off or mixed with the underlying soil materials. Residual soils are found on south facing slopes, exposed slopes with northerly aspects, and as buried soils on north and east exposures.

As a rule, residual soils have thicker, darker surfaces and exhibit better cohesion than volcanic ash soils. Residual soils are nongravelly to gravelly with a loam, silt loam, or clay loam texture. These soils have better structure than ash soils and are more resilient.

</tr>
</tbody>
</table>

Ash soils range in color from dark brown to yellowish brown, with many deposits being light gray to nearly white when dry. They have a sandy loam texture with a gritty feel, and are homogenous with little structural development. Gravels and cobbles are prevalent in these soils due to colluvial action (the movement of rock fragments and other soil materials as a result of gravitational action) and uprooting of trees by wind.

Ash soils are generally found on the more moist sites. These soils compact easily, are susceptible to displacement, but are also the most productive soils on the Forest.
However, the productivity of residual soils is lower than ash soils, and reforestation on residual soils can be difficult on drouthly sites.

**Nonforest Soils**

These soils make up the remaining 40 percent of the area. These soils are generally more shallow and have a higher rock content than the other two soil types. Nonforest soils with sparse ground cover, low water holding capacity, and on southerly aspects have high erosion hazards. Some of these soils have little vegetative cover at the present time, and there is no potential to increase this protective ground cover. There is high potential for stream sedimentation and other types of water degradation resulting from management activities on these soils.

**Cumulative Effects/Long-Term Soil Productivity**

Soil is a basic nonrenewable resource. The demands for sustained timber and forage production create a need for maintaining long-term soil productivity. The ability of soils to remain productive depends largely on the management practices allowed. Future management will likely include rest rotation grazing systems, shorter rotations of timber, the use of fertilizers, mechanical timber harvesting, and more complete utilization of woody residues. The cumulative effect of repeated activities, over a long period of time, has the greatest potential of lowering forest soil productivity. Thus, the maintenance or enhancement of the soil resource is, by necessity, a primary goal of management.

By definition, the components of long-term soil productivity have been identified as the preservation of:

1. Surface litter and topsoil layers,
2. Soil organic matter and its replacement;
3. Soil organisms and biological systems; and
4. Soil porosity, structure, drainage and aeration.

Air and water movement into and within the soil affect biological activity, and ultimately nutrient availability necessary for vigorous plant growth. Changing the soil properties through human activities which induce compaction, puddling, erosion, displacement, or mass movement (Boyer, 1981) will lower the site’s ability to produce. In particular, soil compaction on many sites has led to decreased water infiltration, accelerated erosion of topsoils, and damage to soil biological systems.

The goal is to maintain or enhance soil productivity. This allows the Forest Soil Program to measure, quantify, and evaluate the effects of management activities on the natural capacity of soils to heal after disturbances. The “Forest-Wide Standards and Guidelines” (Appendix D) for soils provide a basis from which to measure these changes.

The prevention of damages before they occur is better than trying to rebuild the productive capacity. In the past, the Forest has used soil moisture as a criteria to control ground skidding equipment. This has had limited success because of varying soil moisture levels within a sale area. The current emphasis is toward a “fixed ground skidding” network designed to concentrate the disturbance within allowable levels. Where lands exceed these levels of soil damage, reclamation measures are warranted. These may include tillage of compacted soils, back blading of mounds or berms, fertilization, or spreading of biologically rich organic materials to rebuild the organic matter levels.

“Caring for the land” starts with good land stewardship and ethic. This will require changes to many of our presently acceptable operations. These changes will take time, but on many sites we have just begun the cutting cycles which will go on, generation after generation, for hundreds of years.
Timber

Management of the timber resource affects many other resources and has significant economic affects. Timber management activities affect fish and wildlife habitat, recreation, water, and forage, as well as other resource values and uses. Economic returns from timber sales contribute significant sums to both the Federal Treasury (approximately $28 million in 1988) and local counties (over $7 million in 1988).

Historical Perspective

Past management practices have had a major influence on today's conditions. In the late 1800's, the Forest was mostly open pine stands with grass or scattered pine reproduction in the understory (The Oregon Trail, 1977). Grazing and repeated wildfires (see Fire, this chapter) perpetuated this condition into the early 1900's (Hodgson, 1913). In the mid 1900's, fire prevention and control of grazing permitted the establishment of white fir and Douglas-fir on the upper elevations and north slopes and
dense thickets of ponderosa pine on south slopes. In the 1940's and 1950's logging became a major influence on the Forest. Logging at this time emphasized partial cutting in ponderosa pine stands. Generally, the old growth pine was removed, leaving an understory of pine seedlings and saplings. Stocking was usually clumpy with openings occurring between thickets of pine reproduction. Mixed conifer stands were generally avoided because they were found on steeper slopes and contained less valuable species. When these stands were logged, only the ponderosa pine was removed, accelerating succession to white fir and Douglas-fir.

Timber harvest in the 1960's and 1970's also emphasized partial cuts from two-storied stands of ponderosa pine. Many of the residual understories have been thinned. The Forest completed a total of 39,000 acres of thinning between 1972 and 1984. Some shelterwood regeneration cutting in ponderosa pine types and clearcutting in mixed conifer types also occurred in the latter part of this decade.

Timber Resource Plan

Timber harvesting in the 1980's was conducted under the direction outlined in the Timber Resource Plan for the Ochoco National Forest. This Plan was approved by the Regional Forester on May 1, 1979, and was implemented on October 1, 1979. The Timber Resource Plan was intended to be in effect for 10 years (Fiscal Year 1980 through Fiscal Year 1989) or until amended, superseded or replaced.

Since implementation in 1979, the Timber Resource Plan has been amended once. In 1984, the Oregon Wilderness Act allocated 9845 acres of previously available commercial forest land to wilderness. In response, the Timber Resource Plan was amended to reflect the necessary change in the land base, as well as in the programmed harvest.

Timber Harvest Levels

Past timber harvest levels have been influenced by the Ochoco National Forest's programmed sale level and by economic conditions. Table 3-23 shows the programmed sale level, the actual sale level, and the actual harvest level for the past twenty years. The much higher actual sale level than programmed sale level in 1970-1974 was due to salvaging of a large blowdown. The much lower cut levels during the 1980's reflects the decline in building and construction related to the recession. The programmed harvest levels represent the regulated volume that can be compared to the allowable sale quantities in Table 2-8, Chapter 2 - Alternatives, Including the Proposed Action.

NOTE: Programmed Sales include regulated volume only, Actual Sales and Cut includes total volume
1/ Volumes shown are average annual sawlog material in millions of board feet
2/ Transition quarter when start of fiscal year was changed from July to October
3/ This was not adjusted for 273.7 MMBF of turnback volume
4/ This figure was adjusted to 128.8 after passage of the Oregon Wilderness Act of 1984
Economics

Timber sales originating on the Ochoco National Forest have contributed significant amounts of revenue to the Federal Treasury and to local counties (Table 3-24). Gross receipts to the Federal Treasury have varied from 7.3 million dollars (1982) to 28.4 million dollars (1988). The low points in 1982 and 1983 reflect the slowdown in housing construction during the recent recession.

Timber sale costs are shown in Table 3-24. Other than in 1984, annual expenses directly associated with the timber sale program have averaged approximately seven million dollars. The high costs in 1984, resulted from high road construction costs relating to unusual market conditions and timber sale extensions.

Below-Cost Timber Sales

Disregarding 1982, annual receipts from Ochoco National Forest timber sales have been approximately 2 to 3 times larger than timber sale program costs. The relatively low receipts in 1982 were equal to the costs at that time. There are very few sales (less than one percent) on this Forest that return less than the costs ("below cost" sales). Those that do are generally sales for beetle-killed lodgepole pine, other salvage, or special situations such as the removal of hazard trees from campgrounds or administrative sites.

Present Conditions

The classification of Ochoco National Forest lands, in terms of timber production, has changed between this FEIS and the current Timber Resource Plan (1980). These differences reflect changes in multiple resource management objectives that have taken place locally, regionally and nationally during the last 10 years.

Within the Ochoco National Forest, approximately 533,180 acres, or 63 percent of the net National Forest System acres, are available, capable, and suitable for timber production (see Table 3-25). The remaining 37 percent of these acres fall into one of the categories in Table 3-25.

The 533,180 acres of Ochoco National Forest lands, that are available, capable, and suitable for timber production, have been stratified into three vegetation types: low site ponderosa pine, ponderosa pine, and mixed conifer. The three timber types were defined based on similarities in tree species composition and productivity. Vegetation types represent an aggregation of plant associations. Table 3-26 displays the productivity and acreage in each type. Approximately two thirds of the acreage is occupied by ponderosa pine stands.

</tbody>
</table>
Ponderosa pine and western juniper dominate the relatively arid low site ponderosa pine type. Ponderosa pine and some Douglas-fir occur in the ponderosa pine type. The mixed conifer type includes ponderosa pine, white fir, Douglas-fir, western larch, Englemann spruce, and lodgepole pine. Quaking aspen is found occasionally in moist areas.

Estimates of vegetation types from the most current (1982) timber inventory are summarized below. Table 3-27 displays existing standing timber volume data, for each of the Forest's four Ranger Districts, in terms of million cubic feet (MMCF) and million board feet (MMBF). The acreage and volume figures shown do not include lands in designated wilderness or research natural areas.

Low site pine types generally occupy a transition area between the ponderosa pine type and non-forested areas. Scattered individual pine trees or clumps are intermingled with juniper, mountain mahogany, and nonforested openings. Generally individual trees are harvested on these types only when sufficient advance reproduction already exists.

One third of the ponderosa pine stands are relatively even-aged. The other two thirds of the ponderosa pine stands are two-storied or multi-storied in structure. These stands have some large old growth ponderosa pine (overstory trees) with younger trees of pine or other species below (understory). The understory is variable in terms of the number and size of the trees and is generally manageable.

Approximately 95 percent of the Forest's mixed conifer stands are mature (over 100 years old) and single- or multi-storied in structure. These stands contain mixtures of ponderosa pine, white fir, Douglas-fir, western larch, and lodgepole pine. Generally, it is not feasible to manage the understory of mixed conifer stands.

The two major timber types (ponderosa pine and mixed conifer) have been subdivided into four categories to reflect the size of the trees present and the approximate age of the stand. The four categories are:

- **Sapling-** even-aged stands or plantations with trees not yet large enough for commercial harvest;
- **Pole-** generally even-aged stands capable of providing commercial products, but younger than culmination of mean annual increment (biological rotation age);
- **Sawtimber-** generally even aged stands older than culmination of mean annual increment (biological rotation age); and
- **Two-storied-** two-storied or multi-storied stands containing an overstory of sawtimber sized trees and a definite understory.

These categories are averages, representing a broad range of field conditions. Table 3-28 displays the acreages in each category by timber type.

**Tree Improvement Program**

The improvement of any species through genetic selection is dependent upon sufficient natural genetic variation. All of the commercial tree species found in the Ochoco National Forest show considerable natural genetic variation. Consequently, these species lend themselves to improvement through a tree improvement program.

In 1975, the original tree improvement plan for the Ochoco National Forest was approved by the Regional Forester. Since that date an active tree improvement program has been in effect. The original tree improvement plan was revised in 1980 and will be revised again in 1989. The tree improvement plan for the Ochoco National Forest covers all of the Ochoco National Forest and that portion of the Burns Ranger District, Malheur National Forest, located in the Silvies-Malheur Breeding Block.
The tree improvement program for the Ochoco National Forest has the following goals:

1. Ensure the application of genetic principles to natural or artificial regeneration systems.

2. Provide improved seedling stock for artificial regeneration (reforestation). This includes:
   a. Selecting a minimum number of superior trees ("select trees" or "parent trees") from wild stands, based on their phenotype or outward appearance, for each commercial species.
   b. Establishing natural stand seed production areas for species in which sufficient seed cannot be collected from select trees.
   c. Establishing mass selection plantations (plantation seed production area established with progeny from select/parent trees) for species placed in low-level programs.
   d. Establishing untested seed orchards for species placed in intermediate-level programs (none are planned at this time).
   e. Establishing tested seed orchards and evaluation plantations for species placed in high-level programs.

3. Develop and maintain a broad genetic base for all species for gene conservation and the preservation of genetic diversity.

4. Develop and implement suitable advanced generation breeding strategies for all tree improvement program intensity levels (low, intermediate, and high).

Since the Ochoco National Forest began its tree improvement program in 1975, 2380 parent trees have been selected from the wild population, and two ponderosa pine seed orchards and 19 ponderosa pine evaluation plantations have been established.

For more detailed information on the tree improvement program for the Ochoco National Forest, see the Tree Improvement Plan. A revision of this plan will be completed in fiscal year 1989.

Vegetation Management

Vegetation is considered undesirable when it hinders the achievement of management objectives. Undesirable vegetation includes grasses, shrubs, and noxious weeds, as well as noncrop tree species. Undesirable vegetation can compete with crop trees for water, nutrients, and light during the early stages of development. This competition can greatly delay the regeneration of desirable forest trees.

The treatment of undesirable vegetation on the Ochoco National Forest and Crooked River National Grassland has included: prescribed fire, manual, mechanical, biological and chemical treatment methods. The use of chemicals, however, has not been available since 1984. In that year, the Pacific Northwest Region of the Forest Service was enjoined from using chemicals for vegetation management until an adequate "worst case analysis" had been prepared. In lieu of a worst case analysis, a Final Environmental Impact Statement has been prepared on Managing Competing and Unwanted Vegetation in the Pacific Northwest Region. The decision of the Regional Forester concerning this FEIS was made on December 8, 1988, and includes the use of all tools available for managing competing and unwanted vegetation, including chemicals. After subsequent appeals and mediation through the U.S. District Court in Portland, Oregon, the injunction was lifted on May 24, 1989, by Judge James M. Burns. This decision, however, reflects the Regional Forester’s desire to reduce the Pacific Northwest Region’s reliance on herbicides, and emphasizes 1) the prevention of vegetation management problems, 2) the preference for the use of non-herbicide methods and 3) that the use of herbicides will require special considerations.

The Ochoco National Forest and Crooked River National Grassland have not used chemicals for the treatment of competing or unwanted vegetation since the injunction issued in 1984, but will maintain options for chemical use under the direction of the final Record of Decision and FEIS for Managing Competing and Unwanted Vegetation in the Pacific Northwest Region.
Timber Supply and Demand

Timber Supply and Projections for the Pacific Northwest Region

The principal projections used in developing long-range plans and programs for the management of national forests are contained in the Forest and Rangeland Renewable Resources Planning Act (RPA) Assessment and 1984 Update. These projections focus on the situation for the long-term (50 years), and do not necessarily recognize current short-term regional fluctuations. A summary of those projected RPA trends (year 2030) for timber supplies follows.

Hardwoods

The current balance between growth of wood and its removal shows that the hardwood forests and eastern softwood forests can support additional timber harvests; however, this balance will change, and future harvests, particularly in the decade beyond 2000, could vary over a wide range. Nonetheless, if commercial timberland owners continue to respond to price and inventory changes, timber harvests can be increased substantially in most geographic regions during the next few decades. The largest hardwood increase will be in the South, which is expected to rise from about 3.4 billion cubic feet from 1980 to 9.4 billion cubic feet in 2030 (RPA, 1984).

Softwoods

Total projected softwood roundwood harvests would rise 24 percent from 9.6 billion cubic feet in 1980 to 11.9 billion cubic feet in 2030. Though the outlook is for increased softwood harvests nationally, there are important differences among the major softwood timber producing regions.

In the Douglas-fir subregion, projected annual harvest from 1980 to 1990 is about 2.3 billion cubic feet. It then declines slightly to about two billion cubic feet per year. This level is roughly maintained through the rest of the 50-year projection period (RPA, 1984).

In contrast, the other major source of softwood timber harvest is the South, which is projected to rise from about 4.1 billion cubic feet in 1980 to 7.3 billion cubic feet in 2030. Much of the expansion in the South with softwoods, as well as hardwoods, is due to the fact that its wood products production has become more diversified compared to other regions of the country.

Timber Demand and Projections for the Pacific Northwest Region

Over the next ten years, timber demand from the Pacific Northwest will grow slowly. Although there is a backlog of unfulfilled housing demands, the future will depend primarily on strength in personal income and the availability of affordable housing and financing. In addition, projections of exports to the Pacific Rim countries show a continuing slow economic growth. The analysis acknowledges there will be a declining trend in the construction sector. Structure replacement, rather than new construction, will characterize the market. The projections for increases in demand may be described as considerably restrained and cautious (Nomura, 1981).

The long-term outlook for the solid wood products industries contains a number of challenges. Evaluation of recent data and information indicates that the demand for timber is changing to a moderate rate of increase as compared to the slowdown that occurred in the early 1980's.

The ability to sustain this increase on a long-run basis is linked to the critical issue of costs. The short-term future of timber and wood products demand is clouded by factors such as the severity and length of the housing and wood products recession that began in 1980. The long-term trends in wood, availability of wood substitutes, and a shift in business management strategies and methods, all contribute to a potential shift in future demand (Haynes and Adams, 1985).

Wood supply will continue to be an issue in the sense that it will be highly dependent on the ability of producers to lower costs to be competitive with wood substitutes (Schallau, 1986).

Although overall current timber supply levels in the Pacific Northwest Region may be capable of meeting future demand, there are some problems within the subregional market areas. This needs to be recognized in terms of a shifting of industry within the
region, and also in the shifting emphasis on the types of wood products produced, as well as the ability of the subregion to supply the various kinds of wood needed.

With a new vision for the future and a concerted effort by the wood products industry to broaden the economic base, the Pacific Northwest could, in time, regain much of the previous strength of one of its larger revenue-generating, basic industries.

A broader vision of the future that includes developing a flexible regional basis for stabilizing wood supplies and applies to forward-looking perspective on wood fiber management, will also allow the Pacific Northwest Region to increase exports to international markets. To achieve this, the forest products industry will need to learn the workings of a different market system and provide more products in the form demanded (Campbell, 1983). In addition, actions by industry, such as modernizing facilities, adopting state-of-the-art technology, reducing costs, and diversifying into other sectors of production (similar to what the southern region has done) could help to rebuild and stabilize the wood-based sectors of the region (Schallau, 1985).

Supply of Timber from the National and International Perspective

Currently, part of the timber formerly supplied by the Pacific Northwest Region is being supplied by the South and Canada. However, the supply situation from these other sources can change in as little as six years or certainly within 15 years. The projected change indicates a drop in supply capability of 30 to 50 percent from the current relatively high levels. The South should be able to maintain or show a slow increase in harvest because of its remaining inventory and some substitution of hardwoods. However, both the economic and physical supply of softwoods from that area may begin to show decline by the year 2030.

At about the same time, this drop in supply capability begins to occur for the other sources, the growth of wood fiber on private lands in the Pacific Northwest could then become a major source of supply for softwoods to meet national and international demand. Further, during the period before the private lands in the region regain their full supply potential, the public forest would be viewed as a major, relatively stable, supply of wood fiber (Schallau, 1985).

Local Timber Supply

To put the timber supply potential of the Ochoco National Forest in the context of its relationship to the Oregon timber industry in the six county general zone of influence, it is necessary to consider the timber supply picture of the area as a whole.

Historically, the Ochoco National Forest has supplied an average of 127 MMBF of timber per year - 21 percent of the total timber harvested from lands in the six county general zone of influence. This percentage has been relatively stable over the last two decades with the exception of one year where the closure of a mill caused defaulting of timber sale contracts. Because of this long-term stability, it is
assumed that this supply picture will continue into the future. Table 3-29 summarizes the timber harvested, by ownership, from lands in the six county general zone of influence.

Currently, the timber volume marketed from the Ochoco National Forest comes from natural stands, many of which have succeeded to white fir and Douglas-fir. The silvicultural objective of the harvest is to create and even-aged stands. Consequently, three categories of logs are available to mills: 1) large ponderosa pine (greater or equal to 20 inches); 2) small ponderosa pine (less than 20 inches), and 3) small white fir and Douglas-fir.

In the long-run, with conversion to a managed forest, both the large ponderosa pine and the small white fir and Douglas-fir components will be decreasing. At this time, the supply of timber will be more uniform in quality than is currently available.

The three major influences on the potential supply of timber from the Ochoco National Forest are: 1) the number of acres available for harvest; 2) the harvest flow schedule (nondeclining even-flow, or some departure from even-flow); and 3) the intensity of management on those acres. The acreage available is important, because the standing timber volume available for harvest is directly related to acreage. Departure from nondeclining even-flow can temporarily increase harvest levels, but also results in a decrease in harvest levels sometime in the future. Management intensity will have the greatest influence on potential supply levels on the Ochoco National Forest, because it affects the growth rate of trees. The future timber supply outputs for the Ochoco National Forest and the associated environmental consequences of these outputs are discussed by alternative in Chapters 2 and 4, respectively, of this document.

Local Timber Demand
Timber demand has been assessed for the Forest through the 1980 Renewable Resources Planning Act (RPA) and the State of Oregon Forestry Program. The Forest Service’s Pacific Northwest Region has distributed the 1980 RPA program goals to the 19 Forests in the Region. The Ochoco National Forest was assigned a goal of 25 million cubic feet (150 million board feet) to be sold annually for the next 50 years.

The Ochoco’s share of the Forestry Program for Oregon as identified by the State, increases over time as shown in Table 3-30.

Current programmed sale levels are estimated to be approximately 21 million cubic feet annually.

The demand for Ochoco National Forest timber is confined to the six county zone of general influence. Very few logs leave this immediate area for primary processing. Excluding Deschutes County, few logs are imported to the rest of the zone of general influence for primary processing. This situation may change if timber supply is curtailed to mills in western Oregon.

During the 1980’s, adjustments were made in the milling sector of the economy to adjust for the local supply shortage. One mill closed in 1982, and others were retooled to more efficiently handle the smaller timber that is more commonly available. Currently, it is estimated that the primary processing industry is operating at 78 percent capacity. Approximately, one third of the milling capacity is now designed to handle small wood.

Within the zone of general influence, mills range in their dependence on the Ochoco National Forest timber from about 20 to 95 percent. Typically the mills designed to handle large pine logs are the most dependent on timber from public lands.

The relatively high values returned from past timber sales on the Ochoco are a result of the competitive pressures exerted through bidding on timber sales. Stumpage prices received for old growth ponderosa pine have commonly ranged from $100 to $300 per thousand board feet. Nearly every sale offered has been bid on by two or more purchasers pushing prices significantly higher than those appraised (overbid). This suggests that the demand for increased offerings of timber volume is present and is likely to continue, provided economic conditions permit profitable product conversion.

3-72
Transportation

A transportation system is vital to the management and use of the Ochoco National Forest and Crooked River National Grassland. Although primarily constructed to facilitate timber harvest, the existing transportation system also aids other land and resource management by providing access for recreation, reforestation, firewood gathering, range management, minerals exploration, and most other activities. Road related recreation (camping, picnicking, and hunting) accounts for 90 percent of the Forest and Grassland’s recreational use. Roads are also important for fire protection.

Existing Condition

In 1989, the transportation system on the Ochoco National Forest and Crooked River National Grassland consisted of 4554 miles of roads that are interconnected with the county, state, and federal road systems. Functional classification of forest roads are arterial, collector, and local roads. Arterial roads are primary roads that provide main access into the Ochoco National Forest and Crooked River National Grassland. Collector roads are secondary roads accessing smaller land areas, and generally provide linkage between arterial, public, or other collector roads. Local roads serve as the terminal roads or provide minor linkage with other roads. The entire transportation system on the Ochoco National Forest and Crooked River National Grassland can be found in the publication “Ochoco National Forest Road Atlas.” This publication is available at the Forest Supervisor’s Office in Prineville.

Since the transportation system on the Ochoco National Forest has been developed primarily to support timber and range management activities, its development has been concentrated on the more gentle south slopes found on the southern portions of the Ochoco National Forest. This part of the Ochoco National Forest (approximately two-thirds of the total area) has the transportation system needed to provide access for most present and future management activities. There are an average of 4.1 miles of existing road for each square mile in developed areas. The northern one-third of the Ochoco National Forest has a less extensive transportation system and has more difficult terrain for road construction. Most of the roadless area on the Ochoco National Forest occurs here. Roads occupy about one percent of the total land area.

Primary access to the Crooked River National Grassland is provided by state highways and county roads. These roads are suitable for passenger car use. The remainder of the transportation system on the Grassland is composed of roads constructed by previous land owners (prior to 1960, the area was composed of homesteaded lands). These roads were designated as Public Usage Roads by Jefferson County. Under this designation, the county assures that the roads remain open to public use. However, the roads are to be maintained by the public that uses them. Under terms of a cooperative agreement with Jefferson County, the Forest Service maintains approximately 84 miles of these roads for public and administrative use. These roads are normally suitable only for high clearance vehicle use and are impassable or closed seasonally during wet weather. The Grassland has more roads than are necessary for management, but the Public Usage designation prohibits closure. The open, flat terrain generally makes road closure ineffective. Approximately nine percent of the National Grassland has been identified as roadless.

Road Standards

Approximately 910 miles, or 20 percent of the total road system, are arterial and collector roads that are maintained and generally considered safe for passenger car travel at speeds less than 25 miles per hour. The remaining 3644 miles (80 percent) of roads are local roads that are designated as high clearance access roads. Examples of high clearance vehicles include pickups and all purpose vehicles.

Roads under the jurisdiction of the Ochoco National Forest and the Crooked River National Grassland are designated as “development roads.” These
roads are not classified as public roads, and for this reason, the Forest and Grassland have the authority to regulate or restrict their use. Consequently, approximately 11 percent of the total road system, is closed on either a long-term or seasonal basis for the protection of other resources.

Until recently, most roads were constructed to relatively high standards. This was done to avoid traffic management problems, extend the log hauling season, and avoid road damage during wet weather. Economic pressures combined with more vigorous analysis has led the Ochoco National Forest to use lower standard roads, in many cases, than may have been used in the past. This change necessitates more active traffic management by the Ochoco National Forest, including temporary delays, seasonal road closures, and detours.

**Expected Development**

Use of the road systems on the Ochoco National Forest and Crooked River National Grassland is expected to increase. Continued use of the system is closely tied to the level of future management activities and recreational use. Most future road construction will likely take place on the northern slopes of the Ochoco National Forest where costs are expected to be higher than the historic average.

**Unroaded Areas**

In response to the Wilderness Act of 1964, the Forest Service initiated the first Roadless Area Review and Evaluation (RARE) in 1972, to identify study areas for possible inclusion in the National Wilderness Preservation System. An “unroaded area” is defined as an area exclusive of improved roads constructed or maintained for travel by means of motorized vehicles intended for highway use. RARE identified nine roadless areas totaling 115,705 acres on the Ochoco National Forest and Crooked River National Grassland.

The findings of the first RARE had not been acted upon when, in 1977, the Forest Service began a second study known as “RARE II.” The first phase of RARE II was to identify areas suitable for wilderness status, not to decide whether such areas would be designated as such. The second phase was to recommend which unroaded areas should be allocated for wilderness or other designations, which for multiple use, and which for further study.

On the Ochoco National Forest and Crooked River National Grassland, RARE II, completed in 1979, designated one roadless area comprising 10,000 acres in the inventory of unroaded areas. Of those inventoried acres, a total of 108,547 acres actually met the roadless criteria. Table 3-31 displays the roadless areas identified under RARE II and their current status.

Approximately 93,110 acres on the Ochoco National Forest and Crooked River National Grassland remain unroaded. This remaining unroaded area includes 36,200 acres in three officially designated wilderness areas, 4030 acres managed as wild and scenic rivers, and 52,880 acres unclassified. Much of this area contains steep slopes, erosive soils, low value timber stands, and/or represents places in which it is difficult to construct roads. The unclassified acreage of unroaded area is contained in six separate unroaded areas: Green Mountain, Lookout Mountain, Rock Creek, Cottonwood, Silver Creek and Deschutes Canyon-Steelhead Falls. These unroaded areas are described briefly here, and in detail in Appendix C.

**Green Mountain**

This unroaded area contains terrain that is more rugged than most of the Ochoco National Forest, but is otherwise fairly typical. The southern portion of the area consists of ponderosa pine stands interspersed with nontimbered openings. The remaining area contains dense mixed conifer stands. The Green Mountain Trail serves the primary recreation use of the area, i.e. off-road vehicle use and hunting. Current direction for the area is to provide high quality big game habitat and to manage for timber production.
Lookout Mountain
This unroaded area contains sub-alpine and alpine type plant communities interspersed with large openings. The large, open plateau at the top of the mountain is unique to the Ochoco National Forest and visible from U.S. Highway 26. The majority of the timbered slopes contain mixed conifer stands, but pure lodgepole and ponderosa pine stands also occur in the area. Lookout Mountain is popular for big game hunting, snowmobiling, cross country skiing, hiking, and horseback riding. As a part of the deliberations leading to passage of the Oregon Wilderness Act of 1984, the Senate Committee on Energy and Natural Resources recommended that the Forest Service “examine the feasibility of continuing the current use in the National Forest Plan and determine the land allocation in the Forest Plan.” Current direction is to emphasize recreational values and maintain the character of the forest over time, without permanent removal of this area from timber production.

Silver Creek
This unroaded area is a shallow canyon area with a basalt outcrop around the canyon rim. It features old growth ponderosa pine stands and scattered small openings, which make it unique in that all other unroaded areas on the Ochoco National Forest are dominated by mixed conifer stands. This area is also the only roadless area on the south end of the Ochoco National Forest (Snow Mountain District). Portions of a proposed Research Natural Area lie in Silver Creek. Primary recreational uses are hunting and fishing. The main canyon area (approximately 3300 acres) is currently managed as a roadless area. Current direction for the surrounding upland area is to develop it for timber production.

Rock Creek
This unroaded area contains deep canyons, 800 to 1000 feet in depth, and consequently, represents one of the most rugged areas on the Ochoco National Forest. The upper portions of the area are primarily open ridge tops and talus slopes. Timbered stands contain old growth mixed conifer. Diverse habitats in the area support a variety of wildlife, including wintering bald eagles, and possibly wolverines. Primary use of the area is for hunting and fishing. Current direction is to provide high quality big game habitat and to manage for timber production.

Cottonwood
This unroaded area contains ridges and canyons which form a steep, deeply dissected landscape. Stream bottoms and north-facing slopes are densely covered with mixed conifer timber stands, while southerly aspects contain open ponderosa pine stands and natural openings. Diverse wildlife habitats are believed to support black bear, wolverines, and mountain lions. Hunting and fishing are the primary recreational uses. Current direction is to provide high quality big game habitat, and to manage for timber production.

Deschutes Canyon-Steelhead Falls
This unroaded area is unique from several standpoints. It contains deep, sheer canyons along the Deschutes River and Squaw Creek which support productive riparian areas and fish habitat. Pockets of ponderosa pine and juniper occur in the narrow stream bottoms. The surrounding plateau area contains juniper, sagebrush, bitterbrush, and grasses. It is the only unroaded area on the Crooked River National Grassland. The area is popular for fishing, hunting, and sightseeing. The Deschutes Canyon-Steelhead Falls unroaded area was placed in the “Further Study” category by RARE II; for this reason the Oregon Wilderness Act of 1984 directed that this area be studied for potential wilderness designation through the forest planning process.

The Oregon Wilderness Act of 1984 released all of these unroaded areas except the Deschutes Canyon-Steelhead Falls area from being considered for wilderness in this plan. These areas are to be managed for multiple use in accordance with current land management plans, and not necessarily for
protection of wilderness suitability. Recommendations concerning the future management of these unroaded areas, including the Deschutes Canyon-Steelhead Falls area, are presented in the alternatives described in Chapter 2.

Figure 3-14 displays the general location of the remaining unroaded areas on the Ochoco National Forest and Crooked River National Grassland, and Table 3-32 shows the size and estimated recreational use capacity of each area.

1/ Includes area designated as wild and scenic river
Water

Watersheds on the Ochoco National Forest and Crooked River National Grassland are characterized by relatively low precipitation and humidity, rapid evaporation, abundant sunshine, and wide monthly and daily ranges in temperature. Mean annual precipitation on the Forest is 21 inches with a range from 11 inches at lower elevations to 33 inches at the highest elevations. Precipitation on the Grassland averages 10.5 inches and ranges from 7 to 19 inches. Most of this precipitation occurs between October and June, and over half falls as snow.

The average annual precipitation for all watersheds on the Ochoco National Forest yields approximately 574,000 acre feet of runoff. More than 80 percent of this runoff occurs during the months of February through May, with 35 percent occurring in April alone. Streamflow on the Forest is lowest during September. Runoff from the Crooked River National Grassland is minimal, except for major storm events. Surface flow in streams and rivers on the Crooked River National Grassland largely results from runoff originating outside the Grassland boundary, or from groundwater.

Most Ochoco National Forest streams drain into the Crooked River, a tributary of the Deschutes River. The north slopes of the Big Summit and Paulina Ranger Districts, and the east slopes of the Paulina Ranger District, empty into the John Day River. The majority of runoff from the Snow Mountain Ranger District flows into the Malheur/Harney Lakes basin, which has no surface outlet. The watersheds of the Crooked River National Grassland drain into the Deschutes River directly, or via the Crooked River. Figure 3-15 depicts the locations of the watersheds on the Ochoco National Forest and Crooked River National Grassland.

Watershed Conditions

Watershed conditions on the Forest and Grassland range from undisturbed to deteriorated. The cause of deterioration is linked to human activities which have taken place over the last 150 years. Beaver trapping and timber harvest in riparian areas have reduced the stream's ability to capture sediment and to slow runoff. Roads and skid trails constructed adjacent to streams have concentrated runoff, accelerating bank erosion and downcutting. Livestock concentration near streams has damaged bank vegetation, increased mass wasting of upper banks, and degraded water quality. Many streams experience increased stream temperatures and sedimentation from these activities. After several decades of these types of impacts, the natural ability of some watersheds to recover and to return to a stable condition has been reduced. Problems associated with damaged streambanks are compounded by the occurrence of a major storm event.

The water quality in most streams meets applicable State Water Quality Standards most of the time. However, approximately 50 percent of the total miles of streams on the Ochoco National Forest are in a degraded condition. Streams in poor condition have seasonal problems with turbidity and temperature. On-going and future management activities are designed to upgrade these streams to excellent condition; however, full recovery of all currently degraded streams will probably not be achieved for several decades.

Physical stream surveys have been conducted on most of the perennial streams on the Ochoco National Forest and Crooked River National Grassland. The existing stream conditions have been classified as acceptable or unacceptable. Streams in acceptable condition have at least 80 percent of the banks in stable condition, and a minimum of 80 percent shade, or 100 percent of the potential shade.

A summary of stream conditions on the Ochoco National Forest and Crooked River National Grassland is displayed in Table 3-33.

Cumulative Effects/Major Storm Events

Cumulative effects of past and present land management practices have contributed to the unacceptable condition of many Forest watersheds. These “cumulative effects” have the potential to result in degraded water quality or stream habitat conditions. The risk is highest when a watershed that has been made more hydrologically sensitive experiences a major storm event.

In order to monitor these cumulative effects and to provide an assessment of risk, a watershed sensitivity rating system has been developed. This system indicates the relative risk of a watershed not meeting water quality goals when developed for timber or range management. Each of the 26 major watersheds on the Ochoco National Forest and Crooked...
River National Grassland have been assigned a sensitivity rating of low, medium or high. Criteria used to develop the watershed sensitivity rating include soil depth, compaction hazard, road density, slope, fisheries value, and existing and potential riparian condition.

Each watershed has also been assigned a "threshold value." The threshold value identifies the upper limit of timber harvest without incurring significant damage from a major storm event. The threshold value is a reflection of the watershed sensitivity, with low thresholds indicating high sensitivity. Table 3-34 displays the sensitivity ratings and threshold values assigned to each of the 26 major watersheds on the Ochoco National Forest and the Crooked River National Grassland.

On watersheds where project scoping identifies an issue or concern regarding the cumulative effects of activities on water quality or stream channels, a cumulative effects assessment is made. This includes land in all ownerships in the watershed. Activities on National Forest System lands in these watersheds will be dispersed in time and space at least to the extent necessary to meet minimum management requirements. On intermingled ownerships, scheduling efforts will be coordinated.

### Stream Dynamics and Potential Impacts

The frequency and magnitude of storm events has a major effect on the character of drainages. Frequent storm events of low magnitude (less than one year return period) carry so little energy that the affect on a drainage is small. Large storm events (100 year return period) are so rare that, although their immediate effect is great, their long-term impact is only moderate. It is the intermediate events (5-25 year return period) which exhibit both sufficient energy and frequency to exert a major impact on channel morphology.

The majority of stable channels on the Forest are defined by the two year average annual flow. Flows greater than the two year event overflow the natural banks and inundate the flood plain. With bank overflow, flow velocities decrease markedly and sediment in transport is deposited, building floodplains and increasing soil fertility.

When the stream channel becomes incised, flow events greater than the two year return period are contained within the main channel. These larger magnitude flow events result in a greater amount of energy being released within the channel. The result is a continued excavation of channel bottom and banks, lowering of the floodplain water table, and destruction of fish habitat through pool filling and streamed gravel cementation.
Livestock grazing, timber harvest, and road construction can adversely impact stream systems. These activities can decrease evapotranspiration, increase snowpack, raise stream temperature, compact the soil, and create water repellent soil layers. These potential effects can be mitigated through the use of Standards and Guidelines (Appendix D) and Best Management Practices (BMP's). Effects on resources will need to be monitored.

Water quality criteria have been established by the State of Oregon under direction of the Clean Water Act. Water quality goals for streams are set on an individual project basis to meet these criteria. During environmental analysis, an Interdisciplinary Team (IDT) will select appropriate BMP's that are designed to protect the water resource. These selected BMP's are used in the preparation of the timber sale contract or other project plan. Individual projects are then monitored to determine whether or not the selected BMP's contribute to meeting the established water quality goals.

**Riparian Areas, Floodplains, and Wetlands**

**Riparian Areas**

Riparian areas are associated with streams, springs, lakes and other bodies of water. They are sensitive to land use activities and require special attention. Conservation and protection of riparian areas is a national concern.

Maintaining the integrity of riparian areas is essential to the maintenance of water quality. In addition to providing stream bank stability, riparian communities serve as filter strips to prevent sedimentation from remote non-point sources of erosion. They also serve as a source of woody material which stabilizes streambanks, and provides nutrients to the stream ecosystem.

Riparian areas and their associated water resource are a focal point for recreation, including fishing, camping, boating, hiking, and hunting. In addition, many wildlife species are dependent on this diverse habitat for food, cover, and water. Of the 378 terrestrial wildlife species found in the Blue Mountains, 285 are dependent upon or use riparian habitat more than any other ecosystem. (Thomas, 1979). Perennial streams usually support trout and other species of fish. The riparian vegetation is of critical importance for escape cover, stream shade, and streambank stability in order to maintain water quality and aquatic habitat for trout and other cold water fish species.

**Floodplains**

As defined in Executive Order 11988, floodplains are those areas subject to a one percent (100-year recurrence) or greater chance of flooding in any given year, and need to remain unmodified so they can pass floods safely. Because of the terrain found on the Ochoco National Forest and Crooked River National Grassland, floodplains are located within riparian areas and are generally contained within 100 feet of stream banks. Roads, road crossings, campgrounds, grazing and timber harvest are the primary causes of impacts to floodplains on the Ochoco National Forest and the Crooked River National Grassland.

3-87
Wetlands
Wetland basins collect and hold water, buffering the effects of floods and conserving moisture for drier seasons of the year. Executive Order 11990 requires the conservation and protection of wetlands for their unique values. The Ochoco National Forest and Crooked River National Grassland do not have an inventory of wetlands separate from the riparian classification.

Demand
Surface flow from the Ochoco National Forest is in demand for irrigation. The quantity used is small when compared with that distributed by irrigation canals from local reservoirs. Except during drought periods, the supply of water for surface flow irrigation exceeds the demand. Throughout the life of this plan, the cost of irrigating additional lands is expected to be prohibitive.

Runoff from the Ochoco National Forest is captured by downstream reservoirs for later use. Two major reservoirs fed by the Ochoco National Forest, the Ochoco and Prineville reservoirs, have a combined capacity to store over 200,000 acre feet of water. Half of the Ochoco Reservoir's basin is administered by the Ochoco National Forest and 84% of the runoff originates on Forest land. Only 19% of the Prineville Reservoir basin is Forest land, however, this portion generates 39% of the runoff. The Haystack Reservoir on the Crooked River National Grassland is a redistribution reservoir that is supplied water through the North Unit Main Canal of the Deschutes River. The watersheds of the Crooked River National Grassland do not contribute significant amounts of water to this reservoir. The major consumptive use of reservoir water is for agricultural crop irrigation, with demand being highest from April to September. Water sports, fishing, and other recreational activities are also important and increase uses of the water in these reservoirs.

Direct uses of water by the Forest Service include water developments for livestock and wildlife, campgrounds, fire control, dust abatement and administrative sites. The largest volume of water appropriated by the Forest Service is used for livestock watering. Some water use rights are reserved to the Forest Service (e.g. fighting fires), others the Forest Service has applied for and received through the State of Oregon (e.g. water developments), and other rights are obtained through temporary permits (e.g. dust abatement). An emerging issue on the Ochoco National Forest is the need to recognize the importance of maintaining continuous flows within perennial channels, as well as a natural range of flows within all channels. These types of flows are important for channel maintenance and for the survival of fish and wildlife species dependent on this water.

Ground water yields from wells vary greatly. Lands of the Ochoco National Forest are underlain by a variety of massive, fractured, or jointed volcanic rock and interbedded water-laid deposits. As a consequence, water yield from wells on the Forest ranges from less than 5 gallons per minute (gpm) at hand pump wells in campgrounds, to between 25 and 200 gpm from wells at administrative sites. The majority of these wells have some artesian properties.

Wild and Scenic Rivers
In 1968, through an act of Congress (Public Law 90-542), the National Wild and Scenic Rivers System was created. The policy of the United States, as established in the Act, is "... that certain selected rivers of the Nation which, with their immediate environments, possess outstandingly remarkable scenic, recreation, geologic, fish and wildlife, historic, cultural, or other similar values, shall be preserved in free-flowing condition, and that they and their immediate environments shall be protected for the benefit and enjoyment of present and future generations."

The Wild and Scenic Rivers Act defines three classes of rivers: "wild," "scenic," and "recreational." Wild river areas are those rivers, or sections of rivers, that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These
represent vestiges of primitive America. Scenic river areas are those rivers, or sections of rivers, that are free of impoundments, with shorelines or watersheds still largely primitive and natural appearing. Limited access by roads may occur in places. Recreational river areas retain natural, free flowing characteristics, but shorelines may show evidence of some agricultural or forestry uses, past water diversions, or existing minor improvements or diversions.

Crooked River

The portion of the Crooked River that flows through the Crooked River National Grassland has been designated as "Recreational." This area is to be managed by the Bureau of Land Management.

North Fork of the Crooked River

The portion of the North Fork of the Crooked River that flows through the Ochoco National Forest has been designated in three segments. The first segment, from the river source to where the river enters the Big Summit Prairie has been designated as "Recreational." The second segment, from where the river exits the Big Summit Prairie to the confluence of Deep Creek, has been designated as "Recreational." The third segment, from the confluence of Deep Creek to the Ochoco National Forest boundary, has been designated as "Scenic." The portion of this river, between segments one and two, that flows through the Big Summit Prairie (private land), has no official designation under the Oregon Wild and Scenic Rivers Bill.

Lower Squaw Creek

Lower Squaw Creek on the Grassland has been evaluated for its eligibility and suitability for designation as a "Scenic River" in the Wild and Scenic Rivers System. The suitable segment runs from the Grassland boundary to the confluence with the Deschutes River, 1,370 acres.

The possible recommendation of this segment of Lower Squaw Creek is discussed in Chapter 2 of this FEIS under Alternatives B-Modified and I. Any recommendation would be preliminary, and would receive further review and possible modification by the Chief of the Forest Service, the Secretary of Agriculture, and the President of the United States. Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System.
Wilderness

On June 26, 1984, President Reagan signed the Oregon Wilderness Act (Public Law 98-328). This Act resulted in wilderness designation for the following three roadless areas on the Ochoco National Forest: Black Canyon, Bridge Creek, and Mill Creek (Figure 3-23). Wilderness plans have been developed for the Bridge Creek, Mill Creek, and Black Canyon areas, and can be found in Appendix F of the Forest Plan. Each wilderness area is described briefly here.

Black Canyon Wilderness

This wilderness area (approximately 13,400 acres) is dominated by steep, xeric canyons with shallow streams in the bottoms. Almost half of the area consists of nontimbered openings on the ridge tops and south facing slopes. The timbered areas consist of mixed conifer and old-growth ponderosa pine stands. The varied and diverse vegetative conditions provide excellent habitat for nearly 300 different species of wildlife. The area provides yearlong habitat for both deer and elk. There are seven entry points into the area, tying 14.5 miles of trail together to access the canyon bottom. The rugged, steep, and broken terrain of the canyon allows for isolation and solitude, offering one of the most primitive recreational opportunities on the Forest.
**Mill Creek Wilderness**

This wilderness area (approximately 17,400 acres) has a variety of terrain, from steep, broken, lattice-type patterns of ridges and canyons, to an almost flat plateau area. The area is mostly old-growth mixed conifer with some high elevation meadows and small openings. There are many small streams and an abundance of riparian habitat. There are several valid gemstone mining claims that utilize primitive roads for motorized access. An 18-mile trail system covers much of the area and connects several campgrounds located just outside the Wilderness boundary. The opportunities for solitude are low due to the proximity of Forest roads and heavy recreational use.

**Bridge Creek Wilderness**

This wilderness area (approximately 5,400 acres) contains an escarpment that essentially divides the area into two plateaus. Over half of the vegetation is dense mixed conifer, and the remaining area is predominantly a "dog hair" thicket of lodgepole pine. The area contains a working irrigation system consisting of a dam, pipeline, flume, and ditch. The absence of maintained trails in this area provides opportunities for recreational experiences with little chance of encountering other people. Current use is relatively low.
Wildlife and Fish

Wildlife

The Ochoco National Forest and Crooked River National Grasslands provide habitat for a wide variety of wildlife. Over 375 different species of reptiles, amphibians, birds, and mammals are known or expected to occur on the Ochoco National Forest and Crooked River National Grassland.

Wildlife habitat provided by the Ochoco National Forest is not duplicated in the immediate area. The Ochoco National Forest is relatively isolated from its neighboring national forests, and adjacent forest lands are not extensive. Compared to the surrounding "high desert," the Ochoco National Forest offers a greater diversity of habitats.

The Ochoco National Forest and Crooked River National Grassland have become a popular focal point for hunters due to the large deer population, the occasional trophy sized elk, and the relative closeness to population centers west of the Cascades. Wildlife viewing and fishing are also popular recreational pursuits.

Mule Deer

Mule deer reached high density levels during the late 1950's and early 1960's. A decline in deer population followed with a leveling by the mid-1970's. Deer populations have remained relatively constant since. Considering loss of natural winter ranges and increased agricultural depredation, the Oregon Department of Fish and Wildlife (ODFW) set a management objective of 22,600 mule deer. Current population levels supported by the Ochoco National Forest and Crooked River National Grassland habitat approximate this objective.

Wildlife Study Areas

In addition to the above wilderness areas, approximately 1,125 acres of land administered by the Ochoco National Forest are included in the Bureau of Land Management's North Fork Wilderness Study Area (OR-5-31). The BLM Draft Environmental Impact Statement (April 1985) for wilderness in Oregon's public domain lands, selected a "No Wilderness" alternative for this area. Wilderness characteristics on Ochoco National Forest lands will be protected until a Final Environmental Impact Statement is issued, and a decision is finalized.

The Deschutes Canyon-Steelhead Falls roadless area (Figure 3-6) on the Crooked River National Grassland was also affected by the Oregon Wilderness Bill. This area was placed in the further planning category by the second Roadless Area Review and Evaluation (RARE II). The Oregon Wilderness Bill directed that areas in this category be analyzed in the forest planning process and a recommendation of wilderness or nonwilderness be made as a result of that process. The Forest Service and Bureau of Land Management have jointly studied the area's wilderness potential as reported in Appendix C. Recommendations for wilderness designation, continued roadless area management, or further development of the area are presented in the alternatives described in Chapter 2.
Rocky Mountain Elk

Rocky Mountain elk populations on the Ochoco National Forest were lower prior to 1975. Fearing competition with deer for the winter range resource, the ODFW traditionally held an either sex elk hunting season. With new information, the ODFW initiated controlled harvest on antlerless elk during the mid-1970's. This modification of the hunt resulted in a slow but steady increase in elk numbers during the past few years. Now there are approximately 2,300 elk on the Ochoco National Forest according to a 1989 ODFW estimate.

Antelope

Antelope have slowly increased in population and have expanded their range on the Ochoco National Forest for the past two decades. No significant additional increase in their population is anticipated since the suitable habitat appears to be fully occupied. The current population on the Ochoco National Forest is estimated to be 590 animals. Antelope on the Crooked River National Grassland and adjacent private lands are estimated to be between 70 and 160 animals. This herd has grown from an introduction of twelve animals by the ODFW in 1969.

Small Game and Furbearers

Small game on the Ochoco National Forest and Crooked River National Grassland are not abundant. The most common are California valley quail, morning dove and waterfowl. Ruffed and blue grouse, snowshoe hare, and common snipe are less abundant.
The most common furbears are beaver, muskrat, mink, long- and short-tailed weasels, raccoon, bobcat, and coyote. Presently, beaver trapping for pelts is not allowed on the Ochoco National Forest and Crooked River National Grassland. Beaver are increasing by natural recruitment and by relocation of live-trapped “problem” beaver from other areas.

Demand
The demand for wildlife provided can be divided into two categories: consumptive and non-consumptive. Probably the best examples of consumptive demand for wildlife are hunting and fishing. The Oregon Department of Fish and Wildlife (ODFW) has established desired population levels (management objectives) for some big game species. The ODFW management objective for mule deer is 22,600. The previous level for elk, 1200, has been raised to the current management objective of 2,600. These management objectives have been used as indicators of demand during the planning process.

Though not quantified, non-consumptive wildlife demand is a recognized aspect of habitat management. Examples of this type of demand are viewing and photographing wildlife. The recent development of the Rimrock Springs Wildlife Viewing Area on the Crooked River National Grassland is an example of providing for this demand. Trails and viewing sites are provided to enhance wildlife viewing opportunities.

Fish
The Ochoco National Forest and Crooked River National Grassland have about 800 miles of streams. Two major rivers, the Crooked River and Deschutes River, flow through the area adjacent to portions of the Crooked River National Grassland. Only the North Fork of the Crooked River is bounded by significant amounts of Ochoco National Forest.

The Ochoco National Forest and Crooked River National Grassland have about 500 miles of streams that support rainbow trout. Brook trout are present in 20 miles of stream. Redband trout are found in streams on the Snow Mountain Ranger District.

Rough fish species (bridgelip and coarse scale) present in streams which compete with trout include suckers, dace, and sculpins. The Ochoco National Forest has three lakes (reservoirs) that provide trout fishing: Walton Lake, Delintment Lake, and Antelope Reservoir. The Crooked River National Grassland encompasses part of the Haystack Reservoir and Lake Billy Chinook shorelines. These reservoirs support trout and other warm water fish, including brown trout, kokanee, mountain whitefish, small and largemouth bass, chiselmouth, and black crappie.

The Ochoco National Forest and Crooked River National Grassland have another 195 miles of streams identified as having the potential to support rainbow trout when stream condition is improved.
Anadromous Fish
Anadromous fish habitat is now present in approximately 42 miles of stream in the northern sections of the Ochoco National Forest. These streams are used by steelhead. The estimated number of adults using these streams for spawning is 304. An additional 45 miles of perennial streams flow into stream reaches where spawning occurs. These additional stream miles are important in maintaining water quality where spawning and rearing occur.

Demand
Trout and the warm water game species are of economical value for recreational fishing. Steelhead, economically valued for commercial and sport fishing, are used by Indians for economic and ceremonial purposes. The Grassland and the portion of the Forest which occurs north of the Paulina Highway (State Hwy. 380) are included in the ceded area established in the Treaty of 1955 between the U.S. Government and the Indian tribes of Middle Oregon. This includes the Confederated Tribes of Warm Springs.

Table 3-35 lists the drainages and associated tributaries on the Forest that support anadromous fish.

Viable Populations
The Ochoco National Forest and the Crooked River National Grassland must maintain viable populations of all native and desired non-native plant and animal species. This was accomplished by defining management requirements for those species or habitats that were considered limiting or sensitive to management activities. These species and habitats are represented by management indicator species. For a further discussion of management indicator species see the Biological Diversity section in this chapter. Species listed as Threatened, Endangered, or Sensitive require additional measures to ensure their survival and recovery.

Threatened, Endangered, and Sensitive Species
The Endangered Species Act of 1973 requires that all Federal agencies protect threatened and endangered species and their habitats to aid population recovery. The U.S. Fish and Wildlife Service has responsibilities for maintaining Federal threatened and endangered lists for animals. Two species on these lists, the peregrine falcon and the bald eagle, have been observed on the Ochoco National Forest and Crooked River National Grassland. Other species have been listed by the U.S. Fish and Wildlife Service in a category indicating that insufficient data exists for a formal determination to be made.

* Data not available

** From actual and estimated use based on stream inventories from 1959-1965 Oregon Department of Fish and Wildlife, John Day, Oregon

*** Estimated adult escapement to spawn
Management of habitat for threatened and endangered animal species is designed to promote recovery of the species leading to their removal from threatened or endangered lists. Habitat management for sensitive species is planned to avoid any effects that might cause the species to become threatened or endangered.

**Threatened Species**
Bald Eagles winter on the Ochoco National Forest. Winter roost sites, an important part of their habitat component, are known to exist on the Big Summit, Prineville, Paulina, and Snow Mountain Ranger Districts. Roost sites are also suspected on the Crooked River National Grassland as well, no nestingsites have been found. A Bald Eagle winter roost study, contracted by Oregon State University was completed in 1987. The purpose of the study was to locate roost sites and develop guidelines for protection. A Bald Eagle Recovery Plan is schedule for completion in 1989, which will provide specific direction for management of roosting sites.

**Endangered Species**
Peregrine Falcons are occasionally observed on the Ochoco National Forest or Crooked River National Grassland. Infrequent sightings indicate migrating individuals. There are no known nestingsites on the Ochoco National Forest or the Crooked River National Grassland.

**Sensitive Species**
The Regional Forester has responsibility for designation of sensitive species. Sensitive species are not on federal lists. Regional Forest Service policy is that species listed by the State of Oregon as threatened, endangered, or sensitive, and not on Federal lists, will be considered sensitive by the Forest Service. The most current list of Region 6 Sensitive Species for the Ochoco National Forest and Crooked River National Grassland is shown in Table 3-36.

Chapter 4

Environmental Consequences

Introduction

The purpose of this chapter is to disclose the environmental consequences (effects) of the six alternatives described in Chapter 2, based on currently available scientific and/or analytical information. Effects are discussed for “components of the human environment,” which includes the natural and physical environment and the relationship of people with that environment. Discussions are not necessarily limited to effects that occur on the Ochoco National Forest and Crooked River National Grassland, but also include a reasonable assessment of effects on both people and natural resources within the entire affected area, as discussed in Chapter 3.

Changes Between the DEIS and FEIS

Many changes were made between the Draft and Final Environmental Impact Statements which resulted in changed analysis and environmental consequences discussed in this chapter. Based on public comment to the DEIS four additional issues, concerns and opportunities (ICO’s) were added to the original list of twelve (see Issues, Concerns and Opportunities - Chapter 1). The four added ICO’s include: Anadromous Fish, Historic Trail Preservation - Summit Trail, Off Road Vehicle (ORV) Use, and Round Mountain. Issues of regional and national importance have also evolved, or increased in intensity since the DEIS. These include: biological diversity, forest residues (related to long term productivity), forest health (formerly discussed as “forest pests”), and old growth (formerly discussed under “vegetation”).

Eleven alternatives for management of the Forest and Grassland were presented and analyzed in the DEIS. Some alternatives were subsequently modified or dropped from further detailed study. Two alternatives were added to respond to the ICO’s and public comments. One of these alternatives (Alternative No Change [NC]) was added in response to the Supplement to the DEIS, which was simply a continuation of the existing Ochoco National Forest Timber Resource Plan. The other (Alternative I - Preferred) is a completely new alternative. See Chapter 2 for detailed discussion of final alternatives.

Regional and Washington Office (U.S.D.A. Forest Service) reviewers of the DEIS commented that many of the discussions on environmental consequences revolved around Forest and Grassland programs of work, rather than on the actual environment. In addition, some public comments suggested that environmental consequences were inadequately addressed in the DEIS. Changes in discussions in this chapter of the FEIS reflect those comments, as well as higher order changes in regulations, policy and procedures germane to the National Environmental Policy Act of 1969.

Major Assumptions

Management requirements, as discussed in detail in Chapter 2, are a legal requirement of NFMA (National Forest Management Act) and are designed to limit the potential environmental effects of any of
the alternatives. Standards and guidelines, as discussed in Appendix D, serve as specifications for implementing the management requirements and as an enforcement mechanism for meeting the desired future conditions associated with the respective alternatives. All effects disclosed in this chapter (4) assume that standards and guidelines are being met for all of the alternatives. Environmental effects of management would be unacceptable in the absence of these standards and guidelines, because they would result in a reduction of long term productivity of Forest and Grassland resources.

Some routine operations that the Forest engages in are considered environmentally insignificant. These are discussed in this chapter (Activities with No Significant Environmental Effects).

This chapter contains complex discussions about the environment, and the reader's understanding of it will be improved with a thorough review of both Chapter 2 and Chapter 3. Environmental components are the subject of the analysis in this chapter and have been introduced in the same order in Chapter 3. Outputs such as timber harvest levels vary by alternative and are presented in Chapter 2. The objective of this chapter is to further elaborate on the environmental effects that would occur as the result of producing the outputs, programs and resources discussed in the previous chapters, by alternative. Because of the issues, concerns and opportunities, some of the "programs and resources" are also discussed as environmental components (e.g. timber supply). Environmental components are introduced alphabetically and discussed in various detail, based on the significance of the issues, concerns or opportunities surrounding them. These components include:

- Air Quality
- Biological Diversity
- Cultural Resources
- Facilities
- Fire
- Forage
- Forest Health
- Forest Residues
- Fuelwood
- Lands
- Minerals and Energy
- Old Growth
- Recreation
- Scenic Resources
- Social and Economic
- Soil
- Timber
- Transportation System
- Unroaded Areas
- Water (including Riparian Areas, Wetlands and Floodplains)
- Wild and Scenic Rivers
- Wilderness
- Wildlife and Fish

For each environmental component, the following discussions are provided: (a) direct effects, (b) indirect effects, (c) cumulative effects, (d) mitigation measures, and (e) conflicts with other plans and policies.

Direct Effects are those caused by an action, that occur at the same time and place of the action. An example would be the increase in growth rate of trees on a particular parcel of land as a result of a properly applied silvicultural treatment, or an increase in water turbidity (and therefore a decrease in water quality) as a result of excessive soil erosion.

Indirect Effects are those caused by an action but are later in time or farther removed in distance from the action; however, they are still reasonably foreseeable. An example would be the increase in growth rate of trees on a particular parcel of land as a result of a properly applied silvicultural treatment, or an increase in water turbidity (and therefore a decrease in water quality) as a result of excessive soil erosion.

Cumulative Effects are those that result from the incremental impact of an action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such other actions. Cumulative effects can result from individually minor but collectively significant actions taking place over a period of time. Use of heavy machinery for logging or slash piling may have unnoticeable effects on soil after just one
entry, but repeated use over a period of years may compact that soil to the point where it is no longer able to grow vegetation. This would be a clear example of a “cumulative effect” of a management action on the soil resource.

**Mitigation Measures** are actions taken to reduce the risk associated with an environmental effect. The objective may be just to reduce the severity of the effect, or to eliminate the effect altogether. From the CEQ Regulations (40 CFR 1508.20), mitigation includes:

1. Avoiding the effect altogether by not taking a certain action or parts of an action.
2. Minimizing effects by limiting the degree or magnitude of the action and its implementation.
3. Rectifying the effect by repairing, rehabilitating, or restoring the affected environment.
4. Reducing or eliminating the effect over time by preservation and maintenance operations during the life of the action.
5. Compensating for the effect by replacing or providing substitute resources or environments.

**Conflicts with other plans and policies** for a specific resource might include, as an example, a discrepancy in planned outputs of big game from the Forest, versus those planned or scheduled by the Oregon Department of Fish and Wildlife.

Following the disclosure of effects by environmental component are five special sections which discuss: (a) the relationship between short term uses of man’s environment and the maintenance and enhancement of long term productivity, (b) irreversible and irretrievable commitments of resources associated with the preferred alternative (I), (c) unavoidable environmental effects associated with the preferred alternative (I), (d) other specifically required disclosures, and (e) conflicts with other federal, regional, state and local plans (including Indian Reservation Plans) as an overview.

**Activities with No Significant Environmental Effects**

The Forest engages in some management activities that do not involve significant environmental effects. These activities are categorized as routine operations, and individually or cumulatively have been found to have no significant effects based on public issues or experience with the procedures normally employed by the Forest Service. Routine operations include such things as renovation and upkeep of facilities, trail maintenance, actions controlled by permit systems including firewood gathering, collection of plant materials, outfitter and guide services, placement and maintenance of climatological instruments, custodial maintenance, administrative actions, and others.

Other actions of limited size or magnitude have also routinely been found to produce little or only limited short-term effects on the environment. This determination for future actions involves careful consideration by Forest officials, but may be addressed as categorical exclusions (40 CFR 1508.4) in environmental assessment and project planning. Some low impact silvicultural treatments, pest management activities, range and wildlife improvement projects, watershed improvement projects, mineral and energy activities, land transfers and other vegetation management activities may fall in this category (7 CFR 1h.3). Some actions categorically excluded require a maintained project file, as well as preparation of a Decision Memo; these are subject to review under 36 CFR 217.6.
Environmental Consequences of the Alternatives

Air Quality

Two by-products of management activities prescribed in the alternatives have the potential of significantly affecting air quality. They are smoke and dust. The quantities of these pollutants have indirect effects on visibility and in limited circumstances on human health.

Direct Effects

Dust

A potential for short-term air quality impairment from dust is created by a variety of management practices. Machinery operations related to timber management often raise clouds of dust. Traffic on roads is another source of dust. Prescribed burn areas can also be a source of dust on windy days, depending on time of burn, subsequent rainfall and revegetation. Road construction and maintenance machinery operations are also dust contributors both in the actual road work and in rock crushing operations. These impacts are usually of a local nature and short duration.

Anticipated levels of fugitive dust from these management activities are considered too low for detailed projections. They will also tend not to vary greatly among alternatives. They will be discussed further in the mitigation section.

Smoke

The principal smoke emissions affecting visibility are the fine particulates added to an airshed. Particulates contributed to the air by activities are measured by tons of total suspended particulates (TSP).

Smoke contributes most of the particulate material that originates from the Forest and Grassland. The two major sources of smoke for the area are from wildfires and prescribed burning.

The TSP production from wildfires is highly variable, estimates for the Ochoco National Forest and Crooked River National Grassland range from 25 tons/year in years of infrequent wildfires to 4,000 tons in years of numerous wildfires.

The TSP production from prescribed burning will vary among the alternatives, depending on the mix of management activities such as range improvements, timber management practices, wildlife habitat improvement, road construction, and natural residue hazard reduction. The following assumptions are made in the discussion of smoke-generated TSP’s:

The estimated TSP’s contributed by smoke from wildfires will not vary among alternatives and therefore are not included in projections.

TSP production rate used was 25 pounds per ton of activity residue consumed and 40 pounds per ton of natural fuels consumed (personal communications with Dave Sandberg, PNW Forest Residues Lab, Seattle, WA, 1989).

Table 4-1 depicts a decline in emissions projected for all alternatives over time. This is due to the expected gradual reduction in natural residue loadings from current levels and an increase in utilization of activity residues. All alternatives level off and reach an equilibrium of 4 to 6 thousand tons of TSP per year near decade four.
Table 4-2 displays the percent change in the production of TSP’s from the 1983-85 Baseline established by Region 6 (U.S.D.A. Forest Service, 1988). The Forest will meet the State’s goal of a demonstrable reduction in emissions from Eastern Oregon sources (State of Oregon, 1987). See Cumulative Effects for further discussion of this Forest’s TSP contributions in relation to the State of Oregon and Region 6 of the Forest Service.

There is also an indirect effect on winter air quality in local urban communities through the fuelwood provided by the Forest and Grassland. This form of utilization of former waste residue helps reduce smoke emissions from the Forest but now tends to concentrate those emissions in the towns. A discussion of this indirect effect is included in the Fuelwood section of this Chapter.

### Indirect Effects

#### Visibility

Smoke and dust reduce visibility. There is a direct relationship between TSP amounts and visibility impairment. For example, the amount of visibility impairment (measured in days of smoky conditions) will be twice as much if TSP production doubles. The percent change from present TSP levels can be interpreted as resulting in a similar percent change in visibility quality. The effects of each alternative on visibility can be seen in Table 4-2. The reductions in TSP levels represent a similar reduction in visibility impairment compared to the 1983-85 Baseline period.

#### Human Health

The FEIS on Managing Competing and Unwanted Vegetation (U.S.D.A. Forest Service, 1988) provides a detailed investigation into the effects of smoke on human health. The following is a summary of that investigation pertinent to this FEIS:

Short-term effects due to high level exposures immediately adjacent to prescribed fires or wildfires include "...eye irritation, coughing, and shortness of breath in moderate-to-heavy smoke...." This type of exposure is generally experienced only by forest workers since the general public is not normally involved in such activities.
Documentation of adverse effects from long-term exposure to wildland fire smoke is virtually nonexistent. Forest workers are at some risk of low-level exposure contributing to such health effects as emphysema or lung cancer. Long-term effects from even lower levels of smoke experienced by the public-at-large are less well known. Individuals with chronic lung disease or other respiratory ailments may experience additional irritation from the infrequent episodes of stagnated smoky airmasses.

There are a number of potentially toxic components known to exist in wildland smoke. However, the levels experienced under normal conditions and exposures are well below any levels known to cause harmful effects on humans. Some of the more common are carbon monoxide, carbon dioxide, carbon particles, and trace amounts of a number of chemicals that may enter the lungs on the surface of particulate matter. Close to 90 percent of the particulate matter is small enough (less than 2.5 microns diameter) to penetrate deeply into the lungs.

Some of the components (polycyclic aromatic hydrocarbons) are known carcinogens under exposures much higher than that documented from wildland smoke. Other components, such as the aldehydes, are acute irritants. These are most likely to affect forest workers who receive high exposures at burn sites.

Cumulative Effects

Visibility

Because of the regional scope of visibility effects and problems, Region 6 of the Forest Service has been conducting cumulative effects analysis on TSP production through subregional analysis of emissions (for example, Eastern Oregon). The FEIS for Managing Competing and Unwanted Vegetation (U.S.D.A. Forest Service, 1988) contains the latest information on this continuing analysis. In that analysis, the Ochoco National Forest contributed approximately 15 percent of the emissions from Forest Service sources in Eastern Oregon. The Eastern Oregon subregion is projected to reduce emissions by 23 percent under the selected alternative in the Vegetation Management Plan. The Ochoco National Forest and Crooked River National Grasslands will contribute to that reduction in all of the Alternatives in this FEIS.

Human Health

The projected reductions in emissions for all alternatives should continue to widen the gap between probable exposures and any possible health effects, chronic or acute.

Mitigation Measures

These general mitigation measures are applied to the extent commensurate with the resource goals and objectives of each project.

Dust

Fugitive dust abatement will be aided through:

- Road watering, oiling or paving as warranted by conditions.
- Controls on machinery operations timing in relation to other use activities.
- Dust abatement controls on stationary sources such as rock crushing operations.

Smoke

Smoke abatement techniques provided in the Vegetation Management FEIS will be guidelines for the Forest and Grassland.

Protection of visibility in Class I areas and the overall air quality is an important objective. All prescribed burning will be done in accordance with all state and local air quality regulations. Special care will be taken to prevent smoke from affecting the visibility in Class I areas during periods of high visitor use (closest to the west are the Central Cascade Wildernesses, but more likely to be affected is the Strawberry Wilderness to the east).

Prescribed burning will be planned to avoid smoke intrusion into smoke-sensitive areas identified in the Oregon Smoke Management Plan (Bend is the closest).

The “best available technology” will be used to reduce smoke, taking into account other land management practices and costs, as determined on a case-by-case basis. The “best available technologies” applicable to prescribed burning on the Forest and Grassland include, but are not limited to:
Utilization of woody material prior to disposal of excess.

Reducing felling breakage through directional felling.

Rigorous mop-up of prescribed burns where long duration smoldering of duff may be a problem.

Rapid (mass) ignition to reduce smoldering phase of combustion.

Burning only during optimum conditions, including burning at the highest fuel moistures practical in order to reduce fuel consumption, time ignitions in coordination with surrounding land managers to avoid overloading local air masses, and avoid burning during stable atmospheric conditions which decrease the probability of adequate smoke dispersion.

Vegetation treated with herbicide will not be burned for at least one year.

Conflicts with Other Plans
Smoke management plans in existence (Oregon State and Madras Seed Growers) provide a cooperative framework to minimize conflicts between prescribed fire users in scheduling burns. These will also minimize conflicts with other users of the Forest and Grassland and surrounding country.

Biological Diversity

Direct Effects
Management of vegetation for the production of goods and services is a primary activity on the Forest and Grassland. As a result, the abundance and distribution of plants and animals is constantly changing. Maintenance of biological diversity is essential to the long-term goals of the Forest; outputs of both commodity and noncommodity resources are dependent upon sustaining diversity. Compared to the "natural forest" of presettlement times, all alternatives have significant effects on biological diversity. Refer to Chapter 3 for discussions on how diversity has changed from historic times to its current condition.

Effects Common to All Alternatives
Regardless of the alternative considered, the ecosystem will continue to change. Soils, as a living component of the ecosystem, have changed and will continue to change due to the elimination of fire. Most plant communities have been accumulating high fuel loadings for over a century, and the danger of catastrophic wildfires that destroy forest floor organic materials is increasing. On the other hand, these increases in organic materials have probably increased the productive potential of soils on some sites (Harvey, et al, 1988). In the absence of fire or comparable processes, most plant communities will change towards "climax conditions," represented by vegetative species that are able to survive and reproduce continually. Most mixed conifer timbered communities will eventually be dominated by white fir, replacing those species such as ponderosa pine, western larch, lodgepole pine and Douglas fir. Western juniper will continue to invade grassland/shrub communities, and is already considered by many the "natural species" on these sites.

None of the alternatives are designed to return the Forest and Grassland ecosystems to that which existed historically. Even though management objectives for wilderness and research natural areas include limited re-introduction of natural and prescribed fire (See Appendix D, Standards and Guidelines), and management prescriptions for timber harvesting and forage production are to a great degree based on "reversing the successional trend"
in both forested and non-forested communities, National Forest goals for the production of goods and services preclude a return to the "natural forest." Hence, it is significant that biological diversity as represented by the "natural forest" of the past is an irretrievably lost resource, particularly in respect to vast acreages of open pine/grassland vegetation that are believed to have occurred over most of the Forest.

However, all of the alternatives except Alternative No Change are designed to meet legal requirements (36 CFR 219.27) for the preservation and enhancement of diversity of plant and animal communities to the extent practical. Management requirements (Appendix F), land allocations, and standards and guidelines (Appendix D) represent tools for achieving legally mandated, and socially desirable levels of protection for all species of plants and animals, while providing needed outputs of goods and services to the nation. See Table 2-8, Chapter 2, to reference the following discussions concerning the effects on biological diversity.

**Alternative No Change**

Alternative No Change has the highest potential for reducing overall biological diversity on the Forest and Grassland. As management requirements for prevention of serious environmental impacts are not applicable to this alternative, it can be inferred that significant effects would occur with its implementation, including probable loss of minimum habitat for major wildlife indicator species, such as the pileated woodpecker, and degradation of water and riparian related resources.

Data is not available to determine the future condition of the forest under this alternative in terms of distribution of successional stages over time (see Table 2-8, Chapter 2). Based on the high levels of timber production with this alternative, though, it is reasonable to assume that accelerated liquidation of mature and overmature stands would result in a relatively young forest over most of the acreage available for management, and that later successional mature and old growth stands would be concentrated in wilderness and unroaded areas.

**Alternative B-Modified**

Alternative B-Modified, with an emphasis on commodities production but modified to provide amenities important to the local community, will tend to reduce biological diversity over the long term. Timber production levels approaching maximum possible potential will tend to hasten the liquidation of old growth at a rate that will shift the structure of the forest to early successional stages. High use of uneven-aged management in this alternative will help to reduce the visible effects, but late successional stages of mature trees and old growth will be highly concentrated in wilderness and limited unroaded areas. Old growth, planned at minimum levels for dependent wildlife species, will tend to be fragmented across the managed forest, with interconnective habitat limited to that offered by riparian, and to some extent, visual management allocations. Research Natural Area allocations are limited to two areas: Ochoco Divide and The Island, which do not provide representation of a cross-section of plant community types across the Forest and Grassland, therefore limiting gene pool reserves for plant and animal species. Snag habitat for cavity nesters remains at relatively high levels in the short run but declines to 33 percent of potential by the fifth decade, lower than all other alternatives except NC. As this and all alternatives provide for legally sufficient protection of threatened and endangered plants and animals, no future extinctions are projected, but the risk of extinction is higher than with the other alternatives except No Change, as options for providing future habitat needs (currently unpredictable) are limited. Since this alternative does provide for maximum acreages of excellent riparian, as with Alternative C-Modified and I, fish and wildlife habitat as a component of biological diversity will be maintained for a variety of species. As riparian areas represent primary habitat for over 75 percent of species on the Forest and Grassland, this represents a positive, significant effect on biological diversity.

**Alternative E-Departure**

Alternative E-Departure, with a short-term emphasis on high commodities production (especially timber), but with declining emphasis over time, will also reduce biological diversity, but substantially less than
legal guidelines allow, and also less than either Alternatives No Change or B-Modified. Wilderness, unroaded areas, old growth, and Research Natural Areas are represented with relatively large acreage allocations with this alternative, which provides a large reserve where natural processes are generally allowed to occur. Snag habitat for cavity nesters is maintained at high levels, with 55 percent of potential at the end of the fifth decade, but riparian in excellent condition is limited to 9.4 thousand acres, or about 50 percent of Alternatives B-Modified, I, or C-Modified. Within the intensively managed areas of the Forest, stand conversion of old growth to early successional stages occurs at a rapid rate, and with almost full dependence on even-aged management, meaning that diversity is primarily maintained horizontally, in contrast to uneven-aged management which tends to provide vertical diversity (if all successional stages are represented). Old growth allocations for dependent wildlife species are about 45 percent above minimum required for maintenance of viable populations, but no specific allowances for interconnective travelways between habitats is recognized.

Alternative A
Alternative A represents current direction, or “No Action” required by NEPA and is a basis for comparison with the other alternatives. It has been revised since 1979 (date of Decision Notice) to include management requirements to bring it in line with the National Forest Management Act (NFMA) of 1976, and therefore meets minimum acceptable levels for maintenance of biological diversity. Allocations to wilderness, unroaded, Research Natural Areas, and “excellent riparian” are limited (similar to B-Modified, except riparian, which is less in A), therefore providing a relatively small reserve where natural processes are allowed to occur, generally unimpeded. Snag habitat is provided at levels similar to B-MOD, E-Departure, and I (52 percent). Very little use of uneven-aged management is scheduled in this alternative, therefore minimizing visual and structural stand diversity provided through other alternatives such as B-Modified, I and C-Modified. Old growth is provided, but on a rotating, managed stand basis (as opposed to dedicated), which provides some level of risk that old growth conditions cannot be replicated through silvicultural means. Alternative A is just slightly better than Alternative B-Modified in terms of assuring maintenance of long-term productivity and biological diversity.

Alternative I (Preferred)
Alternative I is designed to provide a mix of commodities and public amenities as a response to public issues, concerns and opportunities, primarily from the local and state area. While Wilderness and Research Natural Areas are allocated at relatively large acreages, both old growth and unroaded area acreages are relatively small, representing a limited area where natural processes are generally allowed to occur. Maximum acreage of excellent riparian is an important aspect of this alternative, with additional mitigation for connective travelways provided for movement of wildlife species, especially between old growth habitats. This is significant in that it provides additional options for genetic exchange between wildlife populations, and raises the level of awareness for future management of this potentially critical habitat, which is not recognized in the other alternatives. Large acreages of uneven-aged management are provided within a mosaic of even-aged forested areas of varying rotation lengths; this represents increased diversity within the manipulated portion of the Forest over Alternatives No Change, B-Modified, and E-Departure, even though overall distribution of different successional stages is similar. Snag habitat is maintained at high levels, increasing over current levels to about 54 percent of potential in the fifth decade.

Alternative C-Modified
Alternative C-Modified probably provides the best representation of biological diversity (future maintenance) of all the alternatives (see Table 2-8, Chapter 2). This alternative provides the largest acreage allocations to Wilderness, unroaded areas, old growth, Research Natural Areas, excellent riparian (equal to B-Modified and I), retention and partial retention visual quality objectives, and snag habitat. No acres are allocated to fully intensive timber management practices, and forage production is reserved for use for big game and other wildlife. A more
equitable distribution of plant successional stages (forested) is provided over the long term than the remaining alternatives, therefore providing increasing options for management to deal with uncertain changes to the ecosystem. Large acreages of uneven-aged stand management are provided within a mosaic of well distributed even-aged stand and species types. High levels of both game and nongame wildlife species are provided, thus representing a major, critical component of diversity.

From a negative standpoint, infestations of serious insect and disease populations are more likely to persist over time with this alternative (see Effects on Forest Health, this chapter), because of the current and continuing habitat that this alternative provides (e.g. for spruce budworm, tussock moth). Increases in wildfire acreage and intensity is highly probable with this alternative, because of the large acreage of untreated natural fuels persisting over time. Mitigation of these two critical effects is possible (see Mitigation Measures, this section).

Indirect Effects

“Biological Diversity” relates to the distribution and abundance of different plant and animal communities and species; in essence this represents the total living ecosystem on the Ochoco National Forest and Crooked River National Grassland; therefore further discussions of indirect effects on the environment are unnecessary. Other effects discussions provided in this chapter (e.g. Wildlife and Fish, Old Growth, Soils, etc.) are in fact discussions about biological diversity, but are separated in order to provide specific insights into each of them as individual components.

Cumulative Effects

No quantitative analysis was completed to determine the cumulative effects of the alternatives on biological diversity. The Forest has instead chosen major indicators of diversity and developed quantitative and qualitative representations of these indicators. These include:

- Riparian Areas in Excellent Condition
- Riparian Areas Designated for Connective Habitat
- Snag Habitat for Cavity Nesters
- Existing Old Growth
- Acres of Forested Land by Successional Stage
- Acres of Nonforest Land by Plant Community Type
- Maintenance of Viable Populations of Sensitive Plant and Animal Species

The first six have been quantified and projected over the fifty year planning horizon. Table 4-3 displays these for decades 1, 2 and 5 of the planning period. The last indicator (viable populations) is not quantifiable, but instead represents a management objective (requirement) for all Forest and Grassland activities.

These indicators are probably inadequate to describe biological diversity in total because current knowledge concerning all components necessary for maintenance of diversity is also inadequate. There is, though, mounting evidence on an international scale that “keeping all of the pieces” (of the ecosystem) is essential for long-term production of goods and services to the public, as well as to life itself. All of the alternatives are designed to provide legally mandated levels of diversity; therefore, no significant, cumulative effects are predicted. The risk of initiating a future significant effect on biological diversity probably lies in the level of lands allocated (or more appropriately, not allocated) to nonhuman consumption or use. Based on this assumption, the alternatives can easily be risk rated by level of allocation to this function, as shown in Table 4-4.

Mitigation Measures

Fire has historically been one of the primary forces for change and diversity east of the Cascades (Hall, 1976). Without a thinning agent such as fire, most tree species tend to stagnate in a closed canopy condition, shading out much of the understory forbs and shrubs leading to a marked reduction in total species diversity and productivity (Volland and Dell, 1981). The diversity of plants is what drives the diversity of animals which depend on them for shelter and subsistence (Ream, 1981). Therefore, major reintroduction of fire into the ecosystem appears to be an effective way to recapture diversity, as represented by the “natural forest.” But, conflicts with other resource objectives (e.g. air quality) will probably reduce its effectiveness, through significant limitations on burning. Within these limitations though, the Forest has developed prescribed burning prescriptions, designed to emulate natural fire frequencies by plant community type (see Standards and Guidelines, Appendix D, and Forest and Grassland Plans, Chapters 4).

Silvicultural prescriptions are also designed (where compatible with other resource emphases) to “reverse the successional trend” in forested stands. This includes (in some cases) the use of regeneration harvest on transitional plant community types, where fire exclusion has allowed non fire adapted species to invade (e.g. white fir and Douglas-fir). Reforestation and stand maintenance with early succession species (such as ponderosa pine, western larch and lodgepole pine) is very effective in recapturing stand conditions indicative of presettlement times.

Conflicts with Other Plans and Policies

Other than Federal legal requirements (36 CFR 219.27) for maintenance of biological diversity, no specific objectives of Regional, State or local agencies are known to exist.

Cultural Resources

By comparing general resource activities (e.g., recreation, range, or timber) against their potential to “discover” or “impact” sites, the relative effects of the alternatives on cultural resources can be appreciated. Specific resource activities can have both a negative (destruction or removal) and positive (discovery) effect on cultural resources.

Effects to cultural resource sites include direct, indirect and cumulative impacts as the result of intentional and inadvertent damage (negative) to the cultural evidence left by past Forest and Grassland users.

Effects in general are the result of ground-disturbing activities. The risk of impacting sites is directly related to the amount of ground-disturbing activities conducted in a given area. The positive effects to the cultural resource program are: finding and protecting significant archaeological, historic and cultural sites; and increasing our knowledge of past Forest and Grassland users. These effects are reflected in the varying emphases of the alternatives.

The rate at which cultural resources will be depleted in the future (i.e., vandalized, lost to erosion, scientifically excavated) involves several factors. These factors include the timber and beef markets, recreational use of the Forest, funding levels, and academic research interests.

The following resource activities have been identified as possessing significant interactions with cultural resources: Recreation, range, timber, riparian, mineral and energy development, transportation, and fire (Bryant, 1982, Haase, 1983, Philipek, 1985, Schuster, 1984; and others).
Direct Effects

Direct effects which can threaten cultural resource sites are most often associated with road building, timber harvesting, trail and campground construction, reservoir construction, livestock trampling and the development of springs for human or livestock use.

Direct effects to cultural resources may be realized as recreational facilities are developed or expanded. The construction of campground facilities, reservoirs, boat ramps, or trails can disturb significant cultural resources, as these facilities are often associated with areas of higher site potential (e.g., meadows, springs, terraces, promontories, and ridgetops). Associated increases in recreational use of the Forest would result in additional visitors, increasing the potential for unauthorized collection of artifacts and excavation (looting) of sites. Incidents of vandalism, intentional or otherwise, would likely increase.

Positive effects associated with the expansion or development of recreational facilities would include a concomitant increase in opportunities to enhance and interpret significant cultural resource sites for public education and enjoyment.

Significant interactions between cultural resources and range-related activities are most directly associated with livestock levels, water developments, and mechanical treatment programs. For example, breakage or displacement of artifacts through trampling can be severe, depending on the number of livestock and the density of artifacts/sites. The development of springs and reservoirs for livestock use can impact cultural resources occurring in and around the developed areas. The relative stability of many seeps and springs, reflected in their recurring use by Native American as well as Euro-American groups, increases the possibility that significant sites may be adversely affected by such development activities.

Nonstructural range improvements include the use of prescribed fire, broadcast seeding, and chemical applications to reduce competition from non-palatable species. These practices are not necessarily threats to cultural resource sites. Prescribed burning can increase the effectiveness of cultural resource surveys by enhancing ground visibility in heavily vegetated areas. Similarly, water developments and mechanical treatment practices afford an opportunity to inventory additional acres in advance of the associated activities.

Excavations or impoundments to create stock watering reservoirs can have obvious effects on cultural resource sites, either through the excavation activity itself or in the resulting inundation of stream terraces. Mechanical treatment to enhance forage production, achieved through the use of heavy equipment, can generate substantial ground disturbance which threatens archaeological sites. Plowing, disking, drilling, pushing, piling, and chaining represent potential mechanical treatment practices.

Timber sale activities involve cultural resources more than any other Forest activity. Haul road and landing construction, tree felling, skidding, slash disposal, and tractor yarding are among those activities which have the potential to alter or destroy surface or shallow buried sites. Silvicultural treatment of timber sale areas may result in direct effects caused by increased ground visibility, presence of tree planting crews and ground disturbance by equipment. On the other hand, the timber management program results in direct positive effects on cultural resources; the inventory data base can be continually evaluated, with the goal of compiling sufficient data to support scientifically sound efforts at cultural resource site allocation and inventory design.

Stream alluviation can preserve, yet obscure, such sites by burying them under successive layers of alluvium. Streambank erosion can both expose and destroy buried sites which otherwise might not be observed. Cultural resource sites on this rather arid Forest are strongly associated with water. The management of riparian areas produces a positive direct effect of providing opportunities to inventory those drainages with significant terrace development and/or streambank erosion.
Mineral and energy development activities (geothermal and oil and gas exploration, placer or lode mining) would cause ground disturbance to areas with both historic sites (historic mines and districts) and archaeological sites. The remnants of early mining activities at the Mayflower, Amity, Blue Ridge, and Independent mines represent historic sites which may meet National Register eligibility criteria. Various treatment options (including mitigation measures) for these eligible historic sites would have to be considered prior to the resumption of mining.

The re-introduction of mining at levels even approaching historic work seems unlikely for the foreseeable future, however, any increase in mining activity would result in an increased likelihood of cultural resource site discovery and possibly degradation.

The effects of road construction on cultural resource sites are obvious. Because the major components of the Forest's transportation system are sometimes superimposed on historic and, to a lesser degree, prehistoric routes of travel, the likelihood of direct impacts to cultural resource sites is high. The development or improvement of transportation systems would increase the potential for cultural resource site discovery and degradation by land and resource users. As previously unroaded areas are entered, cultural resource inventories, once afforded a degree of de facto protection, would be threatened.

Brush disposal through controlled burning can result in direct impacts to the surface components of archaeological sites if the fireline intensity is high. Fire suppression and brush disposal activities can lead to the discovery of cultural resource sites by crews who may inadvertently or intentionally disturb them. Suppression of wildfires can adversely affect significant cultural resources. The emergency nature of these activities frequently demands an immediate response that may override traditional cultural resource procedures. Fire management activities can also have the positive direct effect of increasing the visibility of such sites, thus increasing our inventory and knowledge.

Effects by Alternatives

Highlights of the direct effects to cultural resources by the five alternatives include:

Alternative B-Modified
Potential effects to cultural resources will be increased as the timber harvest level is expanded to attain the timber outputs in the first decade (130 million board feet). Opportunities to inventory and evaluate cultural resource sites will increase. The relatively small number of range structural improvements (138) will limit associated effects. The high level of road construction (14 miles/year) would lead to the potential for increased conflicts with cultural resource sites.

Alternative E-Departure
Potential effects to cultural resources are associated with intensive timber management practices producing 123 million board feet in volume. A trail system with 132 miles of new trail and the projected construction of 138 range structural improvements will increase potential threats to sites while enhancing the Forest's site survey data. Corresponding emphasis on unroaded opportunities and big game outputs maintain anonymity (and thus, protection) of cultural resources. In general, opportunities to locate and evaluate cultural resource sites will be moderate.

Alternative I (Preferred)
The timber harvest level is moderate for the first decade at 123 million board feet. Opportunities to inventory and evaluate sites will increase in response to the range and timber emphases. The corresponding emphasis on unroaded recreation will afford a degree of site protection through continued site anonymity.

Alternative A
While intensive timber management practices will result in a harvest level for the first decade at the same level as Alternative I (123 million board feet), they do so without the component of uneven-aged management. Only 27 structural range improvements will be made and no new trails will be constructed. Overall, potential impacts to cultural resources will not differ significantly from the current situation.
Alternative C-Modified
This alternative would provide for the lowest timber volume of any alternative (94 million board feet). Similarly, annual AUM’s would be reduced by 12 percent. The emphasis on obtaining excellent riparian conditions on 15,600 acres of land would increase the opportunity to inventory areas of generally high site potential (e.g., terraces). Elsewhere, the low levels of timber and range development would serve to insulate significant cultural resources from potential adverse effects. The potential for site vandalism would increase, as the trail system would be greatly expanded (e.g., 187 miles of new trail, first decade).

Indirect Effects
Direct effects to cultural resource sites caused by various ground-disturbing management activities would potentially reduce opportunities to enhance and interpret cultural resources. Recreational activities with some reliance on cultural resources or cultural heritage interests would be impacted if adverse effects to cultural resources were always mitigated through data recovery.

On the other hand, increased management activities can also provide opportunities for site treatments that result in increases in recreation opportunities with cultural resources, such as: interpretive and historic trails, reconstructed historic structures and interpretive signs and sites.

Range improvements in the vicinity of springs and seeps may be constrained by the treatment needs of cultural resource sites. Cultural resource values could reduce the opportunities for range improvements and capacities, but it is unlikely that it would be to a significant degree.

The availability of timber resources and their contribution to local and regional economies can be affected to a limited degree by the presence and treatment needs of National Register eligible cultural resource sites. Preservation in place or data recovery treatment of buried archaeological sites could result in limitations upon timber resources, silvicultural prescriptions and reforestation efforts.

The presence of cultural resource sites along streams and creeks could result in the enhancement or protection of alluvial terraces and other streamside features. In this case positive indirect effects could result to watersheds if cultural resources were preserved and stabilized in-place.

The availability of mineral and energy resources as contributors to local and regional economies could be affected by cultural resource values to a limited extent. The presence of National Register eligible historic mining and associated structures or cultural resource sites in proposed energy development areas or utility corridors may require treatments and mitigative measures that would slightly increase the cost of mining and energy development.

Significant cultural resource sites located in the proposed locations of new and reconstructed transportation systems, travel corridors and trails must be treated. This treatment can range from preservation in place through project modification and site avoidance to mitigation through complete data recovery of the site and its cultural resource values. In general these indirect effects would be felt by users of these transportation systems and would cause impacts to social and economic systems.

The indirect effects of cultural resource upon other Forest and Grassland resources not discussed above are considered to be minor to nonexistent and hence are not treated in this section.

Cumulative Effects
The cultural resource review and compliance process has provisions for the consideration of cumulative effects on National Register listed or eligible sites (cf., 36 CFR 800). Cumulative effects are associated with past, present, and reasonably foreseeable future actions (40 CFR 1508.7). With regard to cultural resources, cumulative effects can best be viewed as indirect effects which are later in time and farther removed in distance from a proposed undertaking (36 CFR 800.3(a)). They are more closely linked to changes in the integrity of a site's setting, feeling, or association, rather than to immediate site effects such as physical destruction or alteration.
Management activities which possess a greater potential to alter not only a site's physical integrity, but also its environmental setting or ambience, have a greater potential for cumulative effects on cultural resources. In this light, timber, fire, transportation, range and recreation have a higher risk in declining order of causing cumulative effects to significant cultural resource sites on the Ochoco Forest.

Mitigation Measures
Adverse effects to significant cultural resources will be mitigated through project redesign or data recovery. *Treatment of Archeological Properties - A Handbook* (ACHP 1980) will be used to guide the development of data recovery plans. Additionally, coordination with the State Historic Preservation Office (SHPO) and Advisory Council on Historic Preservation will be conducted as per 36 CFR 800, the Lithic-Dominated Sites Programmatic Memorandum of Agreement, and the Depression-Era Programmatic Memorandum of Agreement (see Standards and Guidelines, Appendix D).

A cultural resource inventory (survey) will be conducted prior to the initiation of any project activity which involves ground disturbance, regardless of the selected alternative. All sites will be evaluated against the National Register eligibility criteria. Adverse effects to significant sites will be avoided by project redesign or mitigated through the development of case-specific mitigation plans.

A variety of techniques can minimize or eliminate the adverse effects of timber harvesting on significant sites. These techniques include directional felling of trees, hand piling of slash, designation of skid trails, logging over snow, the construction of protective earthen padding over site areas in road corridors and, of course, avoidance of sensitive areas.

An opportunity exists to involve cultural resource specialists in planning responses to wildfire suppression needs. For example, the specialist can be consulted in planning the location of firelines, access roads, and base camps.

Similarly, the Forest Archeologist will be assigned to the Forest Fire Rehabilitation Team, thus affording timely cultural resource input following the destruction of vegetative cover.

Conflicts with Other Plans and Policies
Conflicts with the State of Oregon's comprehensive goals and priorities for historic preservation planning are not expected due to the review and compliance relationships between the Forest and Oregon SHPO as required by Federal law and policy regarding cultural resource management.

Conflicts can result with heritage/preservation plans issued by various Indian Tribes or Confederations holding ceded lands rights and privileges or cultural and religious interests in lands administered by the Ochoco National Forest and Crooked River National Grassland. However, consultation between the Forest and the respective Tribal Councils or their representatives will minimize or eliminate such conflicts.

Conflicts may arise between the plans and desires of local communities, county historical museums, Indian Tribes and the like over the treatment of cultural resource sites and the curation and storage of prehistoric and historic artifacts. However, such conflicts can be minimized or eliminated through the public comment and appeals process required for all cultural resource treatment and allocation decisions.

In some cases, planned increases in recreation development and facilities by the State of Oregon, other Federal Agencies or Counties can produce increased potential for direct and cumulative effects on cultural resources; however, no discrepancies are known at this time regarding cultural resources between the Forest and other agencies.

Facilities
On the Ochoco National Forest, facilities include buildings, water systems, and dams. Levels of construction and maintenance of these facilities was not varied by alternative in preparation of the Forest Plan. Instead maintenance will be guided in the implementation phase through the preparation of a Facilities Master Plan. Decisions on building acquisition, use and disposal of forest buildings will be documented in this Plan.
Water systems at recreation and administrative sites will be reconstructed as needed to meet the current State standards. Irrigation and Livestock watering dams will be maintained or improved, but no new structures are foreseen.

No significant direct, indirect, or cumulative effects are foreseen with these projects.

**Fire**

Assumptions and Interactions

Natural processes and management activities affect the amount and characteristics of wildfire and prescribed fire in the environment. Significant interactions affecting area burned and fire intensity are changes in:

- vegetation;
- residues;
- ignition sources; and
- control effectiveness.

Assumptions important to this discussion are:

Wildfire will burn approximately 7,500 acres per decade under all alternatives. The variation in acres burned from year to year is from less than 100 to over 4,000. It appears that any variation between alternatives would be insignificant in comparison to natural variation. Therefore, individual alternatives were not modeled and no differences between alternatives are being estimated.

Prescribed fire use and characteristics are affected by a wide variety of management practices related to wilderness, range, timber, wildlife, and hazard reduction. All use of fire directly relates to two principal goals: live vegetation management and dead vegetation (residues) management. The management prescriptions associated with the Forest Plan are the basis for the estimation of the amount of prescribed fire use.

**Vegetative and Residue Changes**

Vegetation change and residue manipulation affects local residue profiles. The fuel profile determines the character of fire in both intensity and the area burned. Vegetation and residue manipulation includes all aspects of utilization or control of the live and dead plant materials on the Forest. These include range and wildlife habitat improvements, timber management practices, firewood collection, and wildfire hazard reduction programs.

**Ignition Sources**

Ignition sources accompany human activities. Anything that can create a spark, flame, or excessive heat can start a fire under the proper fuel and weather conditions. Ignition sources from human activities increase the frequency of fire above natural levels caused by lightning. Ignition sources may include friction of a yarding cable across a punky log, sparks from a tractor track sliding on a rock, hot carbon particles from an exhaust, a cigarette, campfire, or arson.

**Control Effectiveness**

Control effectiveness depends on a variety of interrelated activities. These include: residues manipulation to retard the spread or intensity of wildfires, early detection to catch wildfires when they are small, suitable access to speed suppression response, and appropriate suppression response (both forces and strategies).
**Direct Effects**

**Vegetation/Residue Changes**
Table 4-5 displays the level of prescribed fire that will occur by the various alternatives. Fires will change the vegetation and residue profile of an area. This in turn will affect the character of future fires. Generally, burned areas will first be revegetated by herbaceous vegetation. This type of vegetation will result in future fires having rapid rates of spread, low fire intensities, and low resistance to control efforts. Thus, in those alternatives with a relatively large prescribed burning program, the extent of future wildfires may be greater. However, the amount of resource damage will be decreased.

Industrial operations source fires currently average five per year. They cause 75 percent of the human caused acreage loss and 90 percent of the dollar cost and loss. A change of one or two fires per year is all that is anticipated due to changes in operations activities among the alternatives. The average size of operations fires is 30 acres with a suppression cost of $40,000 and resource loss of $15,000.

**Control Effectiveness Changes**
No significant change in this is expected. The most direct effect of the alternatives on this subject is the lowering of average fire intensity through the reduction in average residue loading projected in the effects section on Forest Residues. Total residues

1/ This consists of fuel treatment for a variety of management objectives in range, wildlife, and vegetation management and is not specifically related to fire hazard reduction

2/ Residue treatment (after timber harvest activities) to meet a variety of management objectives, but primarily related to fire hazard reduction

3/ Prior to the fire suppression activities of the past 80 years the natural fire level probably burned 28,000 acres annually. This is based on a weighted average for the different vegetation types on the Forest and Grassland. Current treatment levels range from 15 to 22 thousand acres per year.

---

**Ignition Source Changes**
The largest change anticipated in ignition sources is expected in the increased recreation demand shown in Table 2-8, FEIS Chapter 2. This increased demand and use (11 percent to 381 percent depending on the category) is expected to increase human-caused wildfires from this source by approximately 50 percent. This is not a significant increase in total fire load. The Forest and Grassland experience about 10 fires per year due to recreation sources. Five more per year is only a five percent increase in the current total of 107 (includes 92 lighting ignitions per year). Remaining after treatments will decline from 16 to 19 percent by the fifth decade. This will translate into a similar reduction in average fire intensity. The improvement in control effectiveness, however, is almost equally offset by the expected increase in numbers of human-caused fires, mentioned above, and by an expected decrease in the amount of timber activity with its related residue treatment, personnel, and equipment. Both of these decrease control effectiveness.
Indirect Effects
Changes in extent and intensity of fire (wild or prescribed) in the ecosystems associated with the Forest and Grassland have significant effects on many resources, programs, and outputs.

Air Quality
This resource can be significantly affected by the amount of fire in the environment. See Effects on Air Quality, this chapter.

Biological Diversity
Fire has historically been one of the primary forces for change and diversity east of the Cascades (Hall 1976). In general, most tree species in the Blue Mountains province tend to stagnate in a closed canopy condition without a thinning agent such as fire. This condition shades out much of the understory forbs and shrubs leading to a marked reduction in total species diversity and productivity (Volland and Dell, 1981). The diversity of plants is what drives the diversity of animals which depend on them for shelter and subsistence (Ream, 1981).

The amounts of prescribed fire use projected in Table 4-5 come fairly close to that level experienced by the Forest historically. This should provide near normal levels of diversity provided fire is applied under a variety of intensities, in different times of the year, and with due regard to the site specific conditions.

Cultural Resources
There should be minimal effects on cultural resources of a prehistoric nature. Historic structures, however, could be destroyed. See Effects on Cultural Resources, this chapter.

Facilities
No significant effects are expected unless a prescribed fire escapes and threatens facilities. Fence lines and signs are the most likely affected.

Fire
Control effectiveness is not expected to change significantly over time for any of the alternatives. See Table 2-8, FEIS Chapter 2 (Fire). The reasons for this are the offsetting changes going on; an increase in ignitions and a decrease in residues from present levels.

Forage
The amount of fire (natural or prescribed) in the ecosystem has a significant effect on forage production and quality (Hall, 1976; Volland and Dell, 1981). Production increases for several years in grassland communities and for a few years in timber stands (depending on canopy cover). Palatability is increased also, but for a shorter duration than production increases.

Alternatives B-Modified, I, and C-Modified stay within five percent of historic fire levels, therefore coming close to natural forage rejuvenation cycles. Alternatives NC and A stay about 10 percent below historic rejuvenation cycles, providing lower production and quality of forage. E-Departure would drop from 8 to 21 percent below historic levels of rejuvenation.

Forest Residues
Other than utilization by society, levels of residues are controlled primarily by the amount of fire in eastern Oregon ecosystems (see Effects on Forest Residues, this chapter).

Alternatives B-Modified, I, and C-Modified stay within five percent of historic fire levels, therefore coming close to a natural level of residue recycling. Alternatives NC and A stay about 10 percent below historic recycling levels, providing higher levels of forest residue. E-Departure would drop from 8 to 21 percent below historic levels of recycling and would provide the highest level of forest residues.

Fuelwood
The level of fire on the Forest and Grassland should not significantly impact the amount of fuelwood available, providing mitigating guidelines emphasizing utilization before disposal of residues are initiated.

Insects and Disease
Significant effects (both good and bad) can occur depending on the intensity and periodicity of fire in the environment. Too much fire intensity can injure trees, predisposing them to insect attack and/or disease entry. Too little fire can cause stand stagnation leading to insect attack and can allow significant buildup of diseases in decaying organic matter which
in turn can infect crop trees. Too little fire can also lead to invasion of stands by successional species not adapted to the periodic severe drought common east of the Cascades. Insect epidemics are common in these conditions, causing severe mortality and setting up excessive residue accumulations leading to severe stand replacement fires much hotter than would be the case under a more natural fire periodicity.

All of the alternatives have approached the use of fire with this in mind. Alternatives B-MOD, I, and C-MOD stay within five percent of historic fire levels therefore coming close to a natural level of fire periodicity appropriate for local ecosystems. Alternatives NC and A stay about 10 percent below historic fire periodicity. E-DEP would drop from 8 to 21 percent below historic levels of fire periodicity.

Minerals and Energy
No significant effects.

Old Growth
In the short term (the next decade or two) there should be no significant effects from the alternatives. However, given the current restriction on use of prescribed fire in these stands, residues will continue to accumulate to high levels. Douglas-fir and true firs will continue to replace ponderosa pine and larch, insects and disease will increase causing more mortality, drought will inevitably recur, and eventually an ignition will provide the start of a stand replacement fire which will be next to impossible to control within the old growth stand.

Periodic low to moderate intensity fire is the only way to maintain a stand of "Old Growth" ponderosa pine or to maintain ponderosa pine as a component of local mixed conifer stands. In either case, ponderosa pine will fade from the picture through mortality and lack of regeneration. The longer fire is excluded, the less chance of successfully reintroducing it without stand destruction.

Recreation
Fire affects recreation through effects on other resources such as forage, scenic resources, and wildlife and fish.

Scenic Resources
Short-term effects of fire are evident to forest visitors passing near recent fires of any kind. While most people are not pleased by the appearance of a burn during the first year or two, most are supportive of the use of fire to maintain open stand conditions and provide for the improvement of wildlife habitat. The visual variety provided by the Type One natural fire regime of this area (frequent fires of low to moderate intensity) has high scenic resource value (Bacon and Dell, 1985).

All of the alternatives have approached the use of fire with this in mind. Alternatives B-Modified, I, and C-Modified stay within five percent of historic fire levels therefore coming close to a natural level of fire periodicity appropriate for local ecosystems. Alternatives NC and A stay about 10 percent below historic fire periodicity. E-Departure would drop from 8 to 21 percent below historic levels of fire periodicity.

Social and Economic
No significant impact.

Soil
Fire is an important natural phenomena in local ecosystems. It provides a decomposer function to recycle nutrients from accumulating organic matter above ground back into the soil organic horizons for continued plant nutrition (Hall, 1976). Without this action, soil nutrient deficiencies begin to occur 100 to 150 years after the last fire. The reason for this is the local climate. It is dry, with long hot summers and long cold winters. Effective organic decomposition occurs during a relatively short period of the year (spring and fall). This situation allows the accumulation of site nutrients in dead and dying vegetation above the soil structure. The accumulation beyond the reach of roots continues until the stand stagnates. At this point soil nutrient stability is achieved.
at a balance of slow uptake and slow return. The frequent return of fire in this system prevented soil nutrient deficiency and resulting stand stagnation by completing the oxidation process called organic decomposition.

Significant impacts are avoided by all alternatives through the amount of fire prescribed (approaching natural levels) and through mitigation measures incorporated into the alternatives.

Timber
Approximately half of the total prescribed fire (see Table 4-5) projected in the alternatives is directly related to the timber program in the form of slash disposal after sale and silvicultural activity. While the estimates shown are primarily for hazard reduction purposes, Martin (1976) lists several silvicultural objectives served as well, including:

- Provides site preparation for natural and artificial regeneration.
- Removes barriers to planting.
- Reduces vegetation competition.
- Recycles nutrients into the soil.
- Removes shelter from predators of animals destructive to seedlings.

Total acreage of activity fuels treatment using fire affects 90 percent of the sale activity acres in each alternative.

Alternative NC range is 12,500 to 14,600 acres per year.
Alternative B-Modified range is 12,900 to 16,100 acres per year.
Alternative E-Departure range is 9,500 to 14,100 acres per year.
Alternative I range is 9,300 to 15,200 acres per year.
Alternative A range is 12,500 to 14,600 acres per year.
Alternative C-Modified range is 12,800 to 16,100 acres per year.

Transportation
No significant effect.

Water
No significant effect as long as normal mitigation measures applicable to all alternatives are carried out to prevent erosion and minimize impacts on riparian zones (see Effects on Water, Mitigation Measures, this chapter).

Wilderness
Because of the importance of fire in local ecosystem dynamics (see preceding discussions), all alternatives have projected a near normal fire occurrence in the wilderness areas. This will range in periodicity from ten to a hundred years depending on the wilderness and its vegetation associations. In light of the small size of the areas and the continuous nature of fuels and vegetation between wilderness and surrounding areas, human ignition prescribed fire will be the option of choice until such time as a more natural mosaic of vegetation and fuel conditions exist inside and outside of the areas (FSM 2324.2). Once this is established, a more extensive use of natural ignition prescribed fire will be possible. When prerequisite prescribed fire planning has been accomplished for each wilderness plan, the application of appropriate prescribed fire can commence. In the meantime, all ignitions within wilderness on the Forest will be considered wildfire and will be suppressed using appropriate suppression response.

Wildlife and Fish
The effects of the prescribed fire levels on wildlife and fisheries will be driven by the effects on habitat structure already discussed in previous paragraphs. Alternatives E-Departure, NC, and A would have the least benefits for wildlife (but well within acceptable range). Alternatives B-Modified, I, and C-Modified would have the most benefits with regard to wildlife.

Cumulative Effects
There will be a gradual reduction in average fire intensity levels for wildfire and prescribed fire as the current residue loads return to more natural levels. This will lead to lower relative costs in both the use of prescribed fire and the suppression of wildfires.
Damage from wildfire will decrease as residue levels return to more natural levels.

Judicious use of prescribed fire will help return vegetation and residue levels to a more natural mosaic. This will in turn continue the existence of suitable habitat for local fauna and reduce the chances of catastrophic wildfire with higher than normal intensities and extent.

Biological diversity and site productivity will be maintained or improved through the maintenance of a more natural presence of fire in those ecosystems adapted to its presence.

Mitigation Measures
The following activities are proposed to prevent or ameliorate the adverse effects of too much or too little fire in the ecosystem.

Monitor the effectiveness of fire management direction (provided by the Forest Plan) in meeting resource needs. Make adjustments as needed based on running average analysis of the past two to five years experience to detect trends.

Maintain effective cooperative agreements with adjacent land managers to provide for cost effective resource protection and management through the sharing of current knowledge, skills, personnel, and equipment.

Improve residue utilization to reduce fuel loads, thereby reducing average intensity levels of prescribed fire, reducing expected damage from wildfire and also reducing costs of fire management through lower personnel needs.

Apply mitigation measures relating to prescribed fire use discussed under other resource area sections in this chapter (especially Air Quality, Forest Residues, and Soils).

Conflicts with Other Plans and Policies
There are no known conflicts with other plans and policies.

Forage and Livestock Use

Direct Effects
Forage production potentially increases with all alternatives as a direct result of timber harvest, non-structural and structural range improvements, and prescribed fire (see Table 4-6).

Forage
Timber harvest opens up tree canopies, allowing sunlight to reach the ground, which increases forage production. In recent years, timber harvest has become more intensive with more overstory removal, shelterwood, clearcutting, and group selection. This has the potential to boost forage production more than “selective” harvesting (see Table 2-8, FEIS Chapter 2 Timber); these all are predicted to increase forage production over present levels. The degree of increase varies by alternative. Using total acres of harvest, the alternatives can be ranked in order of increasing forage production as: C-Modified, I, A, E-Departure, B-Modified, and No Change. Alternative A is higher than Alternative I, even though I has slightly more total harvest acres, because Alternative A has more acres in even-aged management. It is thought that acre for acre, even-aged management produces more forage than uneven-aged management. These projections do not take into account quality of forage, effects of grazing management, or other activities and uses on vegetation productivity.
Prescribed burning of natural fuels and range improvements (primarily jumper removal and prescribed burning) can increase forage production (Hall, 1976). Table 2-8 in Chapter 2 (Forage), shows acres of prescribed burning of natural fuels and acres of non-structural range improvement. However, it is assumed here that the most important influence on forage production is timber harvest, the ranking in order of increasing forage production shown above is unchanged even with the effects of prescribed burning and non-structural range improvements.

Grazing by domestic livestock removes forage and converts it to a commodity. Properly done, livestock grazing has minimal environmental effects. Likewise, use of forage or vegetation by wildlife or recreational livestock, or leaving it ungrazed for recreational purposes, contributes to important uses and enjoyment of the National Forests. Grazing effects diversity in plant communities and can affect species composition and conditions of plant communities. Properly timed, grazing will maintain and encourage a number of highly palatable and nutritious plant species in the community, and plant vigor will be high. Grasses will include a large proportion of perennial species that tend to decrease with improper grazing use. For many plant communities these would include blue bunch wheatgrass and Idaho fescue. Shrubs and forbs will vary depending on the plant community.

Improperly done, livestock grazing can have adverse environmental effects. Repeated heavy grazing that is not properly timed can reduce species diversity and shift species composition toward greater undesirable species, and noxious weeds. Plant species diversity will be low, as will plant vigor. Annual grasses such as cheatgrass and perennial grasses that tend to increase with heavy grazing (i.e. sandberg wheatgrass), will replace the more desirable and palatable decreaser species. Forbs and shrubs will vary depending on the plant community. In some communities, grasses can be almost completely replaced by weedy forbs. Less desirable species result in lower productivity and can impact other uses on the Forest and Grassland. If the impacted areas are along stream sides and wet meadows, water quality, fisheries, and recreation can be affected.

Indirect Effects
The predicted increases in forage production have the potential to increase usable forage for livestock and wildlife, if proper management is done (see Mitigation). Livestock AUM's available for harvest by alternatives are shown in Table 4-7. As discussed above, AUM's are affected by differences in timber harvest acreages, non-structural range improvements and prescribed burning. Other factors that affect AUM's are differences in structural range improvements and riparian prescriptions (see Effects on Water, this chapter, and paragraph below).

Livestock Use
Analysis and modeling done for the Ochoco National Forest and Crooked River National Grassland has indicated that, theoretically, a forage surplus exists on a forest-wide basis after meeting the needs of both the game and livestock for each alternative. Therefore, it has been assumed that forage is not a limiting factor for big game numbers in any alternative. This is not to say that localized competition does not occur where livestock use has exceeded allowable use. Those localized situations are in fact recognized to exist, and are an effect resulting from intensive livestock use under extensive management systems.

Riparian prescriptions in the alternatives are designed to improve streamside conditions (see Management Prescriptions, Chapter 2). As conditions improve, they should produce more forage and increase plant species diversity with a larger variety of herbaceous and woody species. Along with the vegetation changes, improvement in the stream channels and water quality will result. Alternative B-Modified, C-Modified, and I have one riparian prescription which is designed to improve riparian conditions in all watersheds to "excellent condition." They will, therefore have similar effects on diversity, riparian condition, and forage production. Alternatives NC, A and E-Departure have two riparian prescriptions which will result in some watersheds having "excellent condition" riparian areas, and some watersheds having only "fair condition" riparian areas. The fair condition riparian areas would have less variety in herbaceous and woody plant species, which means less diversity. Channel conditions, water...

</table>
quality, and wildlife habitat would also be less desirable than for other alternatives. Table 4-8 shows the differences in “excellent condition” riparian, by alternative.

Increased forage production may have an indirect effect on wildfire hazards. Herbaceous vegetation that is not utilized by livestock and wildlife dries up in the latter part of the summer and becomes fine fuels. These fuels can increase the risk of fire and help fires spread (see Effects on Fire, this chapter).

Forage production has a direct effect on potentially available AUM’s, which in turn has an indirect effect on the local economy, community cohesion and lifestyles (see Effects on Social and Economic Issues, this chapter). Since all alternatives have the potential to increase AUM’s over time, these effects are mostly short-term in nature and reflect the changes the livestock grazing industry is faced with throughout the western U.S. on public lands.

Cumulative Effects

Forage production will increase with the implementation of all of the alternatives, as discussed above. This is in itself a cumulative effect that results from a number of actions occurring over time on the Forest and Grassland. Availability of this forage for both livestock, wildlife and scenic resources will provide increasing, positive cumulative effects over the planning period. Any negative cumulative effects would result from improper allocation of this increasing resource to one or more uses at the expense of others. Based on the increasing level of concern from both management and the public about proper allocations of resources, this is unlikely to occur.

Because 50 percent of the riparian areas on the National Forest grazing allotments are in less than satisfactory condition, measures necessary for their recovery may result in temporary reductions in permitted stocking on those allotments with degraded riparian areas and poor range conditions. The reductions in permitted stock may effect the economics of the grazing operations on affected allotments, even though jobs associated with grazing in general are not expected to go either up or down (significantly) with any of the alternatives (see Direct Effects on the Social and Economic component of the environment, this chapter). But the long-term benefits of such actions are improvements in water quality, wildlife habitat, and forage production.

Mitigation Measures

Standards and guidelines are developed for each alternative (see Appendix D). These will be used in developing individual allotment management plans (AMP), which will ensure that livestock grazing is properly done.

Forage utilization standards (Standards and Guidelines, Appendix D) identify what level of use can be made of forage while either maintaining satisfactory conditions or improving unsatisfactory conditions to satisfactory.

Application of intensive grazing systems such as rest rotation, deferred rotation, double rest, riparian pasture, holistic, etc., if properly done, provide for distribution and use of forage, while not exceeding utilization standards and all resource management objectives.

Timing of use by domestic livestock is used to meet vegetation management objectives.

Fencing can be used to exclude or better control use of domestic livestock or preferred areas that tend to get overused.

Monitoring of use and conditions will provide basis for adjustment of management and permitted stock where necessary to assure that grazing objectives and satisfactory conditions are achieved.
Forest Health

Direct Effects

"Forest Health" is a condition where living and nonliving influences on the Forest and Grassland, (e.g. insects, diseases, atmospheric deposition, silvicultural treatments, harvesting practices, fire, interrupted plant succession) do not threaten management objectives either now or in the future. Deposition of air pollutants and potential changes in climatic conditions (e.g. the Greenhouse Effect) have tremendous potential for reducing forest health and therefore long-term productivity of associated resources (Knauer, et al, 1988). National concern for this issue resolves primarily around insects, diseases, and atmospheric deposition effects. It is beyond the scope of this analysis to discuss atmospheric effects, therefore, discussions revolve around those agents over which the Forest has some degree of control.

Fire plays a major role in maintenance of forest health on the Ochoco National Forest. Too much fire intensity can injure trees, predisposing them to insect and/or disease entry. Too little fire interrupts natural ecological cycles in many plant communities on the Forest and Grassland, historically leading to tree stand stagnation or species conversions to undesirable species, also leading to insect or disease infestation. Insect epidemics, in particular, are common in these conditions, causing severe mortality, fuel accumulation, and eventually, stand replacement fires.

There are many naturally occurring organisms that have the ability to alter the forest environment. Of particular concern are those organisms that may negatively affect establishment and growth of trees. Most common of these are defoliating insects, bark beetles, fungal pathogens, dwarf mistletoe, small mammals, big game, and livestock. The risk of forest stand damage from these pests by implementing the alternatives through various management activities is discussed below.

Defoliators

Insects that consume tree foliage are called defoliators. Of particular concern are the western spruce budworm and the Douglas-fir tussock moth, both have produced Forest-wide epidemics in recent years. Host tree species (e.g. white fir and Douglas-fir) will increase as a result of natural regeneration on mixed conifer types, especially with a light harvest, which maintains shaded conditions favorable for those species (Hall, 1973; Minore, 1979, Seidel, 1979). This can contribute to increased defoliator populations and subsequent damage (Carlson, 1983). Other defoliators, such as larch casebearer are a concern but populations are not expected to change significantly as a result of selecting a particular alternative. Tree planting that emphasizes non-host tree species (pines and larch) may reduce defoliator habitat and damage to future stands. Both precommercial and commercial thinning may reduce height diversity in a stand, reduce the proportion of host species and maintain stand vigor, all of which may reduce damage from defoliators (Carlson, 1983). Harvesting of mature timber by clearcutting or shelterwood eliminates the habitat for defoliators and thus can reduce their populations. Small isolated timber harvest areas have little impact, but scheduled harvests over large acreages may significantly reduce populations by
reducing the proportion of host species and breaking up the continuity of desirable habitat (Carlson, 1983). Overstory removal can have similar effects if the host trees are removed. Selective harvests maintain host species in stands and create an uneven-aged condition which encourages the increase of defoliator populations and damage (ibid.).

Numerous natural controls play a part in regulating defoliator populations. Birds eat large numbers and are particularly effective in young stands (Garton, 1983; Wickman, 1981). However, as trees mature and conditions favoring defoliators improve, the effectiveness of birds in controlling defoliators decreases (Campbell, 1983; Carlson, 1983; Wickman, 1981).

**Bark Beetles**

Bark beetles are that group of insects that lay their eggs below the bark of host trees. The larvae tunnel and feed in the inner bark (Doliner, 1984). The interactions of management activities on bark beetles are:

The most effective control of damage from bark beetles is to maintain trees in a vigorous condition (Sartwell, 1976; Amman, 1977, Dolph, 1983). This can be accomplished through precommercial or commercial thinning. The degree of stocking required to maintain cover for big game (60 to 100 sq.ft./acre of basal area) may not maintain bark beetle resistant stands in pine types (Dolph, 1983).

Harvesting of mature and overmature stands, prompt salvage of infested trees and maintenance of non-susceptible species are other activities that can reduce bark beetles. Bark beetle populations may continue to remain high but not necessarily epidemic in areas where control measures are not applied, such as in classified wilderness.

**Root Rots and Stem Decays**

This includes a variety of fungi or bacteria which cause diseases that infect the roots (root rot) or stem (stem decay) of host trees and cause growth loss, mortality of trees, or decay of sound wood. Loss in infested stands is estimated to be as high as 75 percent of normal growth (Filip, 1983). The following activities can affect the occurrence of root rots:

Natural regeneration in mixed conifer stands may result in an increase in root rots and stem decays in subsequent stands. This is based on the assumption that the new stand would be dominated by true fir (Seidel, 1979). Planting can reduce root rots and stem decays in future stands if resistant species are used (Seidel, 1981; Schmitt, 1984).

Clearcutting infested stands followed by regeneration with resistant species can reduce future incidence of root rots and stem decays (Filip, 1983; Dolph, 1980, Seidel, 1981). Shelterwood harvests can have the same effect as clearcutting if resistant species are used for reforestation, but infected shelter trees may provide a source for the new stand’s infestation. Sanitation and salvage cutting can remove obvious infected trees, but increases likelihood for future occurrence of rots (Schmitt, 1984). Selection cutting may increase infestation from root rots and stem decays (Dolph, 1980, Schmitt, 1984; Filip, 1983).

Commercial and precommercial thinning can reduce root rots and stem decays by removing infected or wounded trees, increasing the proportion of resistant species, and maintaining stand vigor in some cases (Dolph, 1980; Roth, 1977). However, care must be taken to prevent injury to residual trees or the benefits of thinning may be lost (Aho, 1977; Dolph, 1980).

Forest stands with little or no timber management activities would have endemic levels of fungal activity similar to what presently exists except when wildfires occur, reducing the number of more susceptible tree species, such as those that occur in true fir stands.

**Dwarf Mistletoe**

Dwarf mistletoe damages the host by reducing growth, lowers wood quality, and kills or predisposes its host to attack from other pests (Graham, 1967). Dwarf mistletoe on ponderosa pine and Douglas-fir is of primary concern on this Forest. The following section discusses the timber management activities that may occur in the alternatives considered and the activities’ effect on dwarf mistletoe.
Reforestation by planting or natural regeneration can reduce dwarf mistletoe by removing infection sources (Dolph, 1980), selecting resistant species (Seidel, 1981), and creating an even-aged stand (Barrett, 1979). Planting is usually more successful than natural regeneration to reduce mistletoe because of more control over these factors.

Clearcutting is an effective way to eliminate dwarf mistletoe in a forest stand as it removes the infection source (Dolph, 1980; Seidel, 1981). Shelterwood harvests with later overstory removal can reduce dwarf mistletoe infestation if the overstory is removed before regeneration is three feet tall (Dolph, 1980). Sanitation and salvage harvests in mature stands to reduce mistletoe have not been effective. In fact, repeated sanitation and salvage cutting creates a multiple-aged condition which can favor the spread of dwarf mistletoe (Barrett, 1979). Selection harvest also creates multiple or uneven-aged conditions which tend to promote spread of dwarf mistletoe (Seidel, 1981; Barrett 1979).

Both precommercial and commercial thinning are effective methods of removing dwarf mistletoe-infected trees. Thinned ponderosa pine stands sometimes outgrow the vertical spread of dwarf mistletoe (Barrett, 1985).

Small Mammals
Small mammals that damage trees include rodents such as rabbits, pocket gophers, ground squirrels, mice, voles and porcupines. These animals feed on tree seedlings and seeds, directly affecting reforestation of an area. Some interactions are:

Timber harvesting tends to increase small mammal populations as it increases the abundance of ground vegetation on which many feed (Stoszek, 1976). Even-aged management especially increases the amount of food available for small animals, such as pocket gophers, which have caused serious damage in plantations.

Scarification or broadcast burning for site preparation will temporarily reduce all or part of the above habitat (Stoszek, 1976, Crouch, 1976). As a result, populations may change locally, but the overall effect on total small mammal populations over time is expected to be insignificant.

Comparisons of Alternatives

Defoliators
Research literature is compelling towards use of management prescriptions that utilize even-aged management (in mixed conifer) and the use of prescribed fire for control of defoliators. The objective is to "reverse the successional trend" created by nearly a century of fire suppression, selective harvesting (without proper follow-up cultural practices), and an overall lack of awareness of ecological principles. Significant outbreaks of defoliators have occurred recently, and will in all likelihood continue in the future. The long-term effects are unknown, but if predictions are accurate, recurring large scale defoliations will be common until forest stands are brought under an "integrated pest management" strategy. Effects will probably be cumulative.

Alternatives No Change and B-Modified would be most effective in reducing losses to defoliators because of the large number of acres treated, followed by A, E-Departure, I and C-Modified. But all of these alternatives would provide significantly reduced risk over the situation today.

Bark Beetles
Alternatives No Change and A are probably the most effective at reducing the risk from bark beetle damage, followed by B-Modified and I. E-Departure would be lower because of the larger acreage with big game emphasis, and Alternative C-Modified would have many acres at high risk from bark beetles.

Root Rots and Stem Decays
All alternatives would be effective in reducing these risks from root rots and stem decays in lands managed for varying levels of timber production. Alternative No Change, A or E-Departure would be most effective. Other alternatives (B-Modified, I, and C-Modified) would also reduce damage below today's level but probably not as effectively because of the amount of uneven-aged management.
Dwarf Mistletoe

Alternative No Change, A or E-Departure would be most effective for prevention of dwarf mistletoe. Alternatives B-Modified, I, and C-Modified would also reduce damage below today's level, but probably not as effectively as other alternatives because of the amount of uneven-aged management.

Small Mammals

Animal damage from small mammals will probably increase with those alternatives that emphasize even-aged management (especially clearcutting and shelterwood harvesting). The alternatives can be ranked according to the risk associated with this interaction as follows:

- **High Risk**
  - Alternative B-Modified
  - Alternative No Change
  - Alternative A
  - Alternative E-Departure
  - Alternative I
  - Alternative C-Modified

- **Low Risk**

Indirect Effects

Maintaining a healthy forest condition provides numerous positive benefits; recent (1987) Congressional Appropriations hearings on the Forest Service surfaced increasing public concern about maintenance of healthy forests to insure long-term production of many benefits, including timber, scenic resources, wildlife habitat and others (Knauer, et al, 1988). Likewise, conditions favoring an “unhealthy forest” reduce these same resource potentials.

Stagnate stands of ponderosa and lodgepole pine are predisposed to attack by bark beetles. When this occurs, cover for wildlife is reduced or eliminated, visual quality is lowered, and timber productivity temporarily foregone. These affects will many times last until the stand is either naturally or artificially (planted) regenerated, and has grown for fifteen to twenty years, at least. This is an irretrievable loss of that particular resource value for an extended period of time.

Defoliation by spruce budworm, tussock moth and others can last up to ten years or longer. Similar effects to bark beetle damage occur except that it usually is temporary (tussock moth causes more mortality) and wildlife cover is not eliminated. Loss of timber productivity and reduction of visual quality are the primary indirect affects from defoliation.

Root rots and stem decays tend to increase with poor timber management practices (such as excessive tree damage during logging and slash piling) and tend to affect that resource the most. Innoculum built up in stands occurs over time and the affects are slow and incessant; many times these affects are not noticeable to the untrained observer until epidemic levels occur. Cover for wildlife will be reduced over time, even though during initial infection stages, this affect is minimal. Without management, monitoring, and treatment of root rots and stem decays, timber stands eventually “fall apart,” eliminating timber, wildlife and scenic values.

Dwarf mistletoe (a parasite) also builds up to damaging levels at a relatively slow rate, and death of trees occurs after long periods of time, depending on the species which is infected. Again, only severe damage is noticeable to the untrained observer, but affects are long lasting, and when serious, only relieved with stand regeneration. The major indirect affect is on timber production, but with long lasting infestations, visual quality, wildlife cover, and other resource values are reduced.

Cumulative Effects

During conditions where populations are above normal, all of the organisms discussed under “Direct” and “Indirect Effects” (with the exception of small mammals), are symptomatic of forest stand conditions that are not in line with natural processes on the Ochoco National Forest. Changes in major species composition (as the result of exclusion of fire) have created conditions favorable for these organisms to flourish, and cumulatively there is substantial long-term risk to management objectives, including timber production, wildlife cover, visual quality and outdoor recreation. In some mixed conifer stands, dwarf mistletoe, root rots, and spruce
budworm have been found together, causing stand damage to the point where the only option is to replace the stand with species adapted to site conditions (ponderosa pine, western larch and lodgepole pine). In some pine stands, dwarf mistletoe can predispose trees to attack by bark beetles, creating cumulative stand damage.

Computer models are available to predict damage from individual organisms (and to some degree, multiple organisms) over time. But, the ability to predict the overall cumulative effect of these organisms on the Forest resources is low. Based on available information, the alternatives can be ranked in terms of their risk of maintaining conditions favorable for cumulative, negative effects on forest health. Assumptions are: 1) wilderness and unroaded areas, where use of fire for forest stand maintenance is not an integral part of management, will provide future “breeding areas” for defoliators, bark beetles and dwarf mistletoe. Stem decays will also be prevalent, but root rots will probably stay at low, endemic levels, 2) the Forest will maintain sufficient quality control in treated stands to minimize infestations, which will hold true for all of the alternatives, 3) those alternatives which emphasize uneven-aged management will have a higher risk of sustaining higher levels of defoliators, dwarf mistletoe, and root rots; and 4) alternatives with higher timber harvest schedules will treat more acres in the short term, therefore reducing habitat for major insects and diseases (assuming that #2 holds true). The ranking by alternative is:

**High Risk**
- Alternative C-Modified
- Alternative I
- Alternative E-Departure
- Alternative No Change
- Alternative A

**Lower Risk**
- Alternative B-Modified

**Mitigation Measures**
There is a risk of insects and/or diseases increasing to epidemic populations in large blocks of mature or overmature timber (such as in wilderness or old growth areas) and in situations where single species (monocultures) dominate stands. This risk can be reduced by managing adjacent stands for maximum resistance, i.e. resistant species, low densities, young age classes, and maintaining a diversity of species.

The following practices are used to reduce the damage resulting from root rots and stem decays: favoring resistant species (Schmitt, 1984), managing stands to rotation ages of 125 years or less (Aho, 1977), and treating stumps in areas of known infestations (Schmitt, 1984). These measures may be moderately successful except in severely infested stands. In the latter situation, natural regeneration should not be done if timber production is a goal (Filip, 1983).

See Standards and Guidelines for Forest Health (Appendix D) for additional mitigation measures.

**Conflicts with Other Plans and Policies**
There are no known conflicts with other plans or policies. There is a possibility of conflict with state or private agencies in control of future defoliator outbreaks on areas adjacent to wilderness or roadless areas, as it may not be cost effective for the Forest Service to spray these areas. If they were not sprayed they would provide a reinfection source for adjacent lands. This is a likely situation with the Lookout Mountain area, as it borders privately owned timber lands.
Forest Residues

Direct Effects
Projected levels of forest residues on the Forest are shown in Table 2-8, Chapter 2. All alternatives show a gradual decline over time. The differences between alternatives are negligible. The same table shows a comparison between alternatives on how forest residue levels would relate to the desired residue level for maintenance of long-term site productivity. Tables 4-9 and 4-10 expand on that analysis.

Alternative No Change
By the fifth decade, total pretreatment residues will have declined 17 percent compared to the present levels. Residues in excess of site needs will have declined by 35 percent. Total residues remaining on site after treatments will have declined by 17 percent and will be approximately 25 percent greater than needed for long-term site productivity.

Alternative B Modified
By the fifth decade, total pretreatment residues will have declined 13 percent compared to the present levels. Residues in excess of site needs will have

FOREST RESIDUES
Percent of Desired for Long-Term Site Productivity

TABLE 4-10
Forest Residues in Excess of Long-Term Productivity Needs
(Thousand Tons)
declined by 28 percent. Total residues remaining on site after treatments will have declined by 17 percent and will be approximately 26 percent greater than needed for long-term site productivity.

Alternative E-Departure
By the fifth decade, total pretreatment residues will have declined 18 percent compared to the present levels. Residues in excess of site needs will have declined by 38 percent. Total residues remaining on site after treatments will have declined by 16 percent and will be approximately 27 percent greater than needed for long-term site productivity.

Alternative I (Preferred)
By the fifth decade, total pretreatment residues will have declined 14 percent compared to the present levels. Residues in excess of site needs will have declined by 29 percent. Total residues remaining on site after treatments will have declined by 17 percent and will be approximately 26 percent greater than needed for long-term site productivity.

Alternative A
By the fifth decade, total pretreatment residues will have declined 17 percent compared to the present levels. Residues in excess of site needs will have declined by 35 percent. Total residues remaining on site after treatments will have declined by 17 percent and will be approximately 25 percent greater than needed for long-term site productivity.

Alternative C-Modified
By the fifth decade, total pretreatment residues will have declined 14 percent compared to the present levels. Residues in excess of site needs will have declined by 30 percent. Total residues remaining on site after treatments will have declined by 19 percent and will be approximately 22 percent greater than needed for long-term site productivity.

Indirect Effects
Changes in residue levels brought about by the alternatives have the following significant indirect effects on other resources, outputs, and programs:

Air Quality
As residue levels decrease through time (see Chapter 2, Table 2-8) the amount of excess residues to remove from the land will be less. This is one of the major factors in the reduction of smoke emissions from prescribed burn treatments of these residues (see Chapter 2, Table 2-8, Total Suspended Particulates Output).

Biological Diversity
The kind and quantity of woody biomass residues on the land have a significant effect on the types of flora and fauna able to exist on or utilize the land (Harvey, et al, 1987; Hall, 1976). While the levels of residues will be decreasing, they will remain well above the levels required for maintenance of long-term site productivity (see Tables 4-9 and 4-10).

Cultural Resources
The gradual reduction in residue levels will allow for lower impact disposal methods (less mechanical and lower intensity prescribed fire) in the future. In the meantime, the amounts of residue present tend to hide cultural resource sites (this can be good or bad) and the treatments may be more likely to damage the sites.

Facilities
No significant effect.

Fire
Levels of dead woody residues have a significant effect on fire intensity and the resultant effects on the environment (Hall, 1976; Boyer and Dell, 1980; Volland and Dell, 1981). See Effects on Fire, this chapter, for a detailed discussion on fire effects. Given the projected decline in average residues with time (see above) fire intensities should decrease over time. This will have a further effect of lower suppression costs and lower damage from wildfire. Prescribed fire should become less intense, as well as easier to apply.
Forage
Forage type, amount, and quality are affected by the level of forest residues. The reduction in residue levels will make more space available to above ground growth of forage species. Most of the nutrients from those residues burned will return to the rooting zones and be available for reuse more quickly than through organic decay in our dry climate. Careful maintenance of sufficient decaying woody material in the organic soil horizons will provide nutrient storage sites for the recycling nutrients (Harvey, et al, 1987). See further discussion of nutrient cycling effects under Soils in this section and in the Soils section of Chapter 4.

Forest Health
Decaying forest residues provide a pool of insects and decay organisms that can harm, as well as benefit the forest (Harvey, et al, 1987) The desired residue levels in this Plan provide a balance between the positive and negative contributions to forest health. The gradual return toward the desired level (see Table 4-10) is a deliberate attempt to avoid taking off too much residue until better information is available for this Forest.

Fuelwood
The reduction in excess residues forecasted will gradually approach the demand levels for fuelwood.

Lands
No significant effect.

Minerals and Energy
No significant effect.

Old Growth
No significant effect beyond those discussed in Effects on Biological Diversity, Soils, Wildlife and Fish, this chapter.

Recreation
Dispersed recreation areas will see a gradual reduction in levels of residues as part of the return to more open, park-like stand conditions where prescribed burning and other treatments have occurred.

Scenic Resources
See Recreation in previous paragraph.

Social and Economic
The excess residues shown in Table 4-10 indicate a potential utilization resource available to the local communities in the form of a variety of miscellaneous wood products and fuel wood supply. The amount available will decline over time as shown in all alternatives.

Soil
Levels of dead, decaying forest residues are extremely important to the physical structure of the soil as well as the associated nutrient cycling from the soil to living plants, to dead organic matter, and back to the soil (Harvey, et al, 1987; Boyer and Dell, 1980). The last step occurs through oxidation of dead organic matter by either slow organic decay or by the rapid process of fire.

Erosion prevention is another important function of forest residues in that they intercept precipitation and reduce overland flow of water. The declining levels of residues in the alternatives remain well above the levels considered necessary for maintenance of the above factors important to long-term site productivity.

Timber
Timber stand regeneration is affected in a number of ways by the levels of forest residues remaining on site (Harvey, et al, 1987). The forest residue levels projected in the alternatives provide moderate barrier potential to tree planting while still providing an abundance of shading material and future decayed wood material important for moisture and nutrient reserves, and mycorrhizal activity sites.

Transportation System
No significant effect.

Water
Residue levels affect the hydrologic cycle of a forest through interception by above ground debris, and through percolation rates modified by soil organic matter (Harvey, et al, 1987). The levels of residues projected should maintain more than adequate amounts to maintain soil characteristics in support of clean water production from the Forest.
Wildlife and Fish
Forest residues are an important part of both wildlife and fisheries habitat. They function as shelter and food sources for a large variety of terrestrial, avian, and aquatic fauna (Pierovich, et al, 1975). See Wildlife section of this chapter for further discussion. The projected residue levels in all of the alternatives will provide enough material to meet anticipated needs.

Cumulative Effects
Cumulative effects of changes in levels of forest residues will be expressed through discussions in a variety of other resources and programs including:

  - Air Quality
  - Biological Diversity
  - Fire
  - Forage
  - Forest Health
  - Fuelwood
  - Soil
  - Timber
  - Water
  - Wildlife and Fish

Detailed discussions on cumulative effects related to the above resource and program areas incorporate the expected levels of forest residues implicitly or explicitly.

Mitigation Measures
The Pacific Northwest Region of the U.S. Forest Service has provided broad direction concerning the proper consideration of the retention, use, and disposal of forest residues (FSM 2403, R6 SUPP 345, 3/85). In summary:

  - Forest residues will be managed as a resource important to long-term productivity. With this in mind:
    - Retention on site is the first consideration.
    - If there is more material than is needed for long-term productivity considerations, utilization of excess is the next consideration
    - If there is still excess material on the site, the third priority is disposal.

Disposal methods will consider costs, impact on site and resources, and ability to meet a variety of resource objectives.

In response to this direction the Forest is formalizing a Residue Management Plan which will ensure that project level planning will take into account the above considerations.

Conflicts with Other Plans and Policies
There are no conflicts with the plans and policies of other agencies or adjacent land owners.

Fuelwood

The public considers the harvesting of fuelwood an issue on the Ochoco National Forest. The record number of permits issued for firewood was 7,361 in 1981; this has declined to less than 6,000 cords in 1984. Future demand is uncertain, but is directly related to local employment levels and energy prices. The major source of fuelwood currently is the cull material left after logging operations.
Direct Effects
The availability of fuelwood is related to the timber harvest level. In addition to providing cull material at the landing, the timber program also builds and opens roads which improves access to natural mortality in timber stands. Consequently, the alternatives with the highest timber harvest level provide the most available fuelwood. The levels of fuelwood production by alternative are displayed in Table 4-11. As can be seen, availability exceeds current demand for all alternatives through the fifth decade, even though the quality of firewood may be reduced. Large diameter, standing or fallen dead firewood will become harder to find and publics will have to depend more on residues from slash piles, etc., which may be small diameter limb wood. State and federal air quality concerns may reduce the desirability of firewood use in the future, or at least make it less desirable economically.

Indirect Effects
As traditional fuelwood becomes harder to find, more people may switch to other sources of heat or obtain more fuelwood from commercial sources. People may shift fuelwood demand to the Deschutes National Forest because of the extensive supplies of quality, dead lodgepole pine.

The falling of snags for fuelwood may effect the populations of cavity nesting species but standards and guidelines (Appendix D) are designed to protect habitat for these species, regardless of the alternative. The alternatives provide for different management allocations for snag habitat, and those with lower allocations exhibit more risk of serious impacts from firewood gathering violations. Table 4-12 displays snag habitat allocations for the different alternatives over the planning period. Alternative B-Modified (and probably No Change) contains the

</table>
highest level of risk in the long run, due to the relatively low level of snag habitat projected in the fifth decade (33 percent). The minimum level for sustaining viable populations of cavity nesters is 20 percent, so none of the alternatives (including B-Modified) are considered to have serious affects on snag habitat.

Although fuelwood collection reduces the total suspended particulates from slash disposal operations, particulates increase in the towns where the fuelwood is consumed. Currently, no restrictions have been applied to consumers by the State regarding wood stove use in the Forest’s zone of influence. But, because of precedence in other communities in the state, it can be assumed that regulation of wood stoves will occur in the future.

Cumulative Effects
The cumulative effects of the timber harvest program in all alternatives will result in a reduction of size and amount of cull material available. Also, as stands are brought under management, the amount of natural mortality will decrease. Consequently, other lands (private or public) may serve as the supplier for the fuelwood consumer. No significant indirect effects (cumulative) are predicted, including those potential effects on cavity nesters as standards and guidelines are designed to maintain habitat well above minimums (20 percent).

Mitigation Measures
The Forest can make more material available through leaving roads open longer or allowing fuelwood cutting instead of precommercial or early commercial thinning. This is an administrative process that could be done with any alternative, but may conflict with other objectives including road closures for wildlife, soil protection and maintenance.

The Forest fuelwood program prohibits cutting of dead, standing trees (except for lodgepole pine) and should prevent most falling of snags for the benefit of cavity nesters, therefore reducing the indirect effects on this other important resource. But, based on experience, there will still be some unauthorized falling of dead trees, particularly western larch snags.

If urban air quality becomes an issue in the future, the Ochoco National Forest will cooperate with restrictions applied by State or County governments regarding fuelwood use as a means of mitigating indirect affects on air quality.

Conflicts with Other Plans and Policies
There are no known conflicts with other plans or policies.

Lands

Under all alternatives, the land exchange program will result in a more consolidated land ownership pattern, reduced administrative costs and fewer trespasses. Because land exchanges account for only a small change in the number of acres managed by the Forest and Grassland, this activity does not constitute any significant environmental effects, either directly, indirectly or cumulatively.
Special Use Permits

Direct Effects
Special use permits are issued for a variety of uses and activities on the Forest and Grassland (see FEIS Chapter 3). The different alternatives (NC, B-Modified, E-Departure, I, A And C-Modified) emphasize different mixes of resource outputs, including those that may require special use permits (e.g. outdoor recreation events). Selection of one alternative over another may result in a shift in the types of special use permits requested of the Forest, because of the long term shift in resource emphasis that certain alternatives exhibit. For example, Alternative C-Modified emphasizes amenity-oriented resource outputs such as developed, dispersed and backcountry recreation; this could ultimately result in an increase in recreation-type permits. In contrast, Alternatives NC and B-Modified emphasize commodity-oriented outputs such as timber harvest and livestock grazing. Special use permits would probably tend to follow a more utilitarian approach with these alternatives, simply because the Forest would (in the long term) become less desirable for extensive recreational use; the Forest and Grassland would appear more manipulated. But none of the alternatives have been designed to specifically exclude different uses of the Forest; all have been prepared in a framework of multiple use. Therefore, no significant direct effects on the special use permit system are anticipated.

Indirect or Cumulative Effects
Issuance of special use permits for utility corridors (powerlines and energy transmission), can have significant indirect effects on other resources. Land is many times taken out of production from other uses, or at least reduced in terms of availability. None of the alternatives propose additional utility corridors for the foreseeable future. Any proposals for this use would require analysis through revision or amendment of the selected alternative. Therefore, no significant indirect (or cumulative indirect) effects are anticipated.

Mitigation Measures
Standards and guidelines (Appendix D - Lands) stipulate measures to take in order to mitigate the effects of actions on other resource values (indirect effects). Central to these measures is that any proposed action must be consistent with emphases associated with individual management areas; this applies to issuance of special use permits as well (including utility corridors). All applications for permits must be reviewed through an interdisciplinary process in accordance with NEPA regulations. Mitigation measures for pipelines, power lines and phone lines may include:

Erosion control (minimum clearing widths);
Revegetation (primary with grasses and other noninterfering vegetation);
Removal of hazard trees along right-of-ways;
Construction of diversions or settling ponds near water crossings, or limit construction to specific seasons;
Location or camouflage to mitigate visual affects on the landscape; or
Restriction of off-road vehicles to limit soil erosion.

Conflicts with Other Plans and Policies
None have been identified.

Minerals and Energy

Direct Effects
Restrictions on access and the timing of operations are applied to mineral and energy exploration and development to ensure protection of other resources. The extent of these restrictions varies by alternative. Table 2-8, Chapter 2 (Minerals and Energy) displays access restriction as percent of the Forest and Grassland withdrawn, highly restricted, moderately restricted or with few restrictions. Alternative C-Modified restricts access the most, while Alternatives NC, A, and E-Departure restrict it the least.
Alternatives B-Modified and I are similar in that there is a moderate level of access restriction; the differences lie mainly in the low to moderate categories.

Indirect Effects

Mineral and energy development can have significant impacts on other resources. At the present level of activity on the Forest and Grassland, these effects are minor. However, if activity increases in the future, these effects could become significant. Because Alternative C-Modified restricts access the most, the indirect effects discussed below would be least under this alternative. Conversely, the significance of these effects would be greater under Alternatives NC, A and E-Departure.

Because mining removes land from production, it could result in a reduction in biological diversity, soil productivity, forage, timber, and wildlife habitat. Grass is often planted to rehabilitate mines and oil well sites, which could mitigate the effects of forage available to livestock and wildlife.

The remnants of early mining activities at the Mayflower, Amity, Blue Ridge and Independent mines represent historic sites which may meet National Register eligibility criteria. Attempts to reestablish any of these mines could result in the destruction of historic sites.

Recreational opportunities are limited or lost in areas of active mineral and energy development. Mining could negatively impact the character of unroaded areas and wilderness areas (existing claims only). Open pit mines, tailings piles, mill sites and oil well and storage facilities all have negative visual impacts. The staking of mining claims for agates or thundereggs might preclude the free use of those areas by rockhounds.

Placer mining has a direct effect on water quality, because it increases turbidity. Placer mining also kills fish eggs by silting in gravel deposits. Similarly, erosion from tailings piles can increase sedimentation in streams. The leaching of chemicals used in mineral processing could also decrease water quality.

Noise generated by road building, blasting and heavy equipment use could disturb wildlife. Wildlife habitat may be lost to open pit mining, placer mining, or the construction of mills. Oil well drilling can create openings in timber, which may benefit or harm wildlife.

Cumulative Effects

At present levels of activity, the cumulative effects of mining on other resources is probably insignificant.

There is some potential for increased interest in mining of locatable minerals, particularly gold and mercury. A proposal for a major site would trigger an Environmental Impact Statement and Amendment to the Forest Plan. Increased activity from mining operations could have cumulative effects including those resulting from decreased water quality (and therefore reductions in fish production). About 86,400 acres on the Forest and 19,250 acres on the Grassland have "high potential" for mineral occurrence. In a "worst case" situation, all of these acres could be placed under mining production, causing a cumulative affect on major resources on the Forest including timber, forage, wildlife, visuals, and water quality.
Mitigation Measures
The effects of mineral and energy development on other resources is mitigated through the use of operating plans and permits. The plans and permits contain site-specific restrictions and rehabilitation requirements to minimize and mitigate adverse environmental impacts. A proposal for a major mining operation on the Forest or Grassland would require an Environmental Impact Statement and/or Forest Plan amendment.

Wilderness areas are withdrawn from mineral entry and energy leasing. No new mining claims may be established, and no energy leases may be issued in these areas. In addition, some facilities, developed recreation areas and a strip of road along Highway 26 have been withdrawn from mineral entry. A detailed discussion of these withdrawals may be found in FEIS Chapter 3.

Restrictions on oil and gas leasing to protect other resources are listed in Appendix D, Standards and Guidelines. As appropriate, leases may be issued with “no surface occupancy” stipulations, seasonal use stipulations, stipulations requiring drilling and storage facilities be set back a specified distance from an area or feature, or stipulations requiring that facilities be located out of view or camouflaged.

Mining claimants must have an approved operating plan before beginning any surface-disturbing operation. Operating plans in some areas, such as eagle roosting sites, will include a stipulation prohibiting activity from December 1 to May 1. In other management areas, measures will be included to ensure that operations meet management emphasis as much as is reasonable and economically possible.

All operating plans include a rehabilitation plan, and claimants are bonded to ensure that reclamation work is performed.

Conflicts with Other Plans and Policies
None have been identified.

Old Growth

Direct Effects
Issues over old growth are very complex and exist on a local, regional and national level. The reader is encouraged to review other chapters of this document before proceeding with the environmental consequences on old growth discussed here, in order to get a better picture of the existing condition (Chapter 3) and alternative proposals for management of old growth (Chapter 2). Some of the information from these chapters has been repeated here, but is limited to that needed to understand the effects.

As of December 1988, there were approximately 93.8 thousand acres of old growth (meeting the Regional Guide definition) on the Ochoco National Forest. An additional 50 thousand acres of “juniper old growth” (not meeting the Regional Guide definition) also exist, primarily on the Crooked River National Grassland. Total acres of inventoried old growth (93.8 thousand acres) will decline with every alternative as a direct result of timber harvesting. The rate of decline does not vary appreciably by alternative, but the difference in amount remaining at the end of the first, third and fifth decades varies
by almost 100 percent. Alternative No Change maintains the least amount at the end of 5 decades (about 40 thousand acres); Alternative C-Modified maintains the most (about 78.2 thousand acres). Table 4-13 displays how different alternatives treat the existing old growth over time, by major species groups (ponderosa pine and mixed conifer).

There are approximately 574 thousand commercial, forested acres on the Ochoco National Forest. Table 4-14 displays the percentage of these lands that will be remaining in old growth at the end of the five decade planning horizon. There are no estimates of the percentage of these total forested acres that were in old growth condition prior to the establishment of the Ochoco National Forest (1908).

1/ Includes only old growth meeting the Regional Guide definition, does not include "old growth juniper" on the Crooked River National Grassland.
Indirect Effects

Wildlife Habitat

Indirectly, reductions in old growth will result in declining habitat for old growth dependent wildlife species and therefore may reduce the breeding viability needed to maintain current populations. Pileated woodpeckers (management indicator species) require both reproductive habitats (old growth) and secondary feeding areas (high snag levels) of equal acreage in close proximity to each other (A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service, June 1986). These combined habitat conditions are needed at no less than one per 12 to 13 thousand acres in order to maintain a viable breeding population. Secondary feeding areas may be of little value to dependent species, if the reproductive habitat is not available. On the contrary, reproductive habitat (old growth) should always contain characteristics of secondary feeding areas, in order to be classified as old growth.

Alternative No Change does not include provisions for secondary feeding areas, as Management Requirements have not been applied to it. In addition, only about 1/3 of the acres of old growth allocated in this alternative (32,860 acres) would actually be in a suitable condition at one time, because allocations are based on a managed, long rotation condition. Even though 26,500 of suitable habitat are provided in wilderness, roadless areas and research natural areas, they tend to be concentrated and isolated from other habitat areas. Alternative No Change has a high risk of indirectly affecting populations of pileated woodpeckers on the Ochoco National Forest because of poor overall distribution, and because total acres outside wilderness, roadless areas and RNA's are insufficient to maintain viable breeding populations.

Alternative B-Modified is designed to provide this habitat at the minimum level (see Management Requirements, Appendix F), established at 18,000 acres of reproductive and 18,000 acres of feeding areas across the Forest (outside of wilderness, roadless areas, and RNA's). (Minimum levels are designed to provide some level of insurance against natural catastrophe and should not, therefore, be considered a "threshold" below which the population would suffer irreparable damage.) As in Alternative I, revised minimum direction for flexibility in distribution was applied, so that the "best" available old growth within any 12 to 13 thousand acre area was selected, in lieu of a rigid distribution pattern which was maintained for Alternatives E-Departure, A and I.

In addition, about 23,600 acres of suitable old growth are provided in wilderness, roadless areas and RNA's, but this tends to be concentrated and isolated. This alternative provides adequate long-term protection for maintaining species viability of old growth dependent species, but provides few additional options if habitat areas are destroyed by local catastrophe.

Alternative I (Preferred) was designed so that old growth was provided at the minimum level, but as in Alternative B-Modified, the "best" available old growth stand was selected within the minimum geographical area (12 to 13 thousand acres), in lieu of rigid distribution requirements. In addition, selected stands were maintained at higher acreages than required (300 acres), so that continuity of unique stands could be maintained. Also, specific mitigation measures designed to enhance movement between old growth blocks were designed into this alternative (see Mitigation Measures). In total, this alternative allocates 19,250 acres of old growth and an equal acreage of supplemental feeding areas, which is 1,250 acres above the minimum requirement. There is an additional 30,300 acres of old growth provided in unroaded, wilderness and Research Natural Areas, but again, these areas tend to be somewhat isolated. Even though optional habitat areas are not provided in this alternative as insurance against catastrophic events, additional mitigation measures and 1,250 additional allocated acres (equivalent to four reproductive old growth areas) above the minimum requirements are included.

The remaining alternatives (E-Departure, A, and C-Modified) all contain sufficient levels of old growth allocations (reproductive plus feeding areas), and exhibit a low risk of affecting viable populations of dependent species.
Biological Diversity
As an important element of biological diversity, old growth will be represented at different levels across the Forest over time. Table 4-15 displays acres of forested land by different successional stages for decades 1, 2 and 5 of the planning period (Stage VI representing old growth conditions). Alternative B-Modified (and probably No Change) results in the least acres of Stage VI at the fifth decade; Alternative C-Modified provides the most. The remaining alternatives (E-Departure, I and A) are all similar in terms of total acres remaining.

As discussed under Indirect Effects on Wildlife Habitat, the distribution of old growth (Stage VI) will also vary by alternative, with much of the old growth concentrated in wilderness, unroaded and research natural areas. None of the alternatives provide for an even distribution of acres and distance across the Forest over time.

Scenic Resources
Declining old growth does not necessarily equate to a decline in scenic resources on the Ochoco National Forest. Many open, parklike stands of ponderosa pine exist in current visual corridors, but have not been inventoried as “old growth” because official definitions (of old growth) preclude these particular stand conditions, even though tree ages in these stands average three hundred years and older (in many cases). Prime examples of these stand types occur in the Highway 26 Visual Corridor, but are not indicated in current (1988) old growth inventories (see Existing Old Growth Map - map packet). The alternatives provide various levels of land allocations to scenic resources (see Effects on Scenic Resources, this chapter). Management prescriptions for “retention” and “partial retention” call for long rotation stand management (200 to 300 years) to simulate old growth character as a visual resource, independent of official definitions. Additionally, “unique areas” are provided for with similar retention and partial retention objectives with the different alternatives. Direct comparisons of “big trees” for scenic resources, versus “old growth” are not possible, as the management objectives (and definitions) are substantially different.

Cumulative Effects
The cumulative effects of old growth habitat on the pileated woodpecker (management indicator species) were analyzed within an affected area which includes four National Forests in eastern Oregon (Ochoco, Wallowa Whitem, Malheur and Umatilla). Results of the analysis are summarized in Ochoco National Forest Memo, 1920 Land and Resource Management Planning - Wildlife Standards and Guidelines, April 23, 1982. A minimum legal requirement for maintenance of a viable population for this affected area was established at 500 birds (250 pairs). This number was derived from a formula found in Conservation Biology, Soul and Wilcox. Based on: 1) a 60 percent occupancy rate (derived from population ecology of pileated woodpeckers and consultation with Dr. Jack Ward Thomas); 2) a maximum five mile spacing requirement, and 3) acres of potential old growth available on each Forest, numbers of birds (pairs) and old growth acres were assigned on the basis of maintaining a genetically viable population as shown in Table 4-16.

It was affirmed at that time that all respective Forests would provide old growth habitat at minimum levels or higher.

In response to direction from Deputy Assistant Secretary of Agriculture Douglas MacCleery in March 1985, minimum requirements for wildlife in Region 6 were completely reassessed. The results are contained in “A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region,” USDA, Forest Service, June 1986, on file at the Ochoco National Forest. During this assessment, an analysis of risk of population viability was developed for major indicator species in Region 6. It was determined that the pileated woodpecker was not at high risk currently, even though it may be at risk in the future (15-50 years). Management direction was subsequently changed to provide for greater flexibility in application of habitat management, especially concerning distribution of habitat areas. Alternatives B-Modified and I have been updated to reflect the increased flexibility in mitigation measures (see Mitigation Measures, below and in Appendix F).

Alternative No Change provides for about 32,860 acres of "well distributed" old growth habitat, in addition to about 26,500 acres concentrated in wilderness, roadless areas and RNA's. But the 32,860 acre allocation was based on a managed stand condition, so in actuality, only about 1/3 of the allocated acres (approximately 10,950 acres) would actually be in a suitable habitat condition at any one time. As this equates to only about 60 percent of the total acreage needed to maintain minimum species viability, Alternative No Change has a relatively high risk of reducing species viability of pileated woodpeckers on the Ochoco National Forest, and therefore may have a cumulative effect on the population within the affected area. Distribution of habitat areas does not allow for movement of birds, and therefore reduces reproductive capacity and needed exchange of genetic material. The significance of this effect would greatly depend on habitat allocations of other Forests in the affected area, since the Ochoco's contribution to the total population requirements is only about 16 percent of the total needed for species viability. This holds true for all of the alternatives considered.

The remaining alternatives (B-Modified, E-Departure, I, A and C-Modified) provide old growth at levels that equal or exceed minimum acreages needed for maintenance of species viability. Also, as stated previously, minimum requirements were designed to provide some level of insurance against natural catastrophe, and do not represent a critical threshold for species survival. There is an unlikely probability that any of these alternatives would have a significant cumulative effect on the population of pileated woodpeckers within the affected area.

Mitigation Measures
Management requirements for old growth dependent wildlife species habitat are designed to provide some level of insurance against catastrophic event. Some specific components of the requirement (i.e. minimum defense territory, snag requirements) are based on well documented research data (Bull and Meslow, 1977), (Bull, 1975). Other components, such as dispersal distance requirements, are based on professional judgement (Philips and Robens, 1985).

As these management requirements are in fact designed to reduce the risk that land management activities may have on species viability, they in fact serve as mitigation measures for the proposed alternatives, with the exception of Alternative NC, which includes no policy mandated requirements as such. See Appendix F, Management Requirements, old growth dependent species.

An additional mitigation measure was applied specifically to Alternative I (preferred), primarily to reduce the risk associated with allocating old growth at relatively low levels across the Forest. Approximately 1,000 acres of riparian areas on 41 miles of primary Forest streams were identified as "connective habitat" during the land allocation process. The protected area on these streams was expanded from 100 to 200 feet on each side, in order to provide additional security for wildlife while travelling from original or primary habitat areas. According to Bull, 1988, "pileated woodpeckers dispersing to new territories are likely to use these travel lanes if surrounding areas are not forested."

It is not known whether old growth can be simulated over time through manipulation of stands. Specific characteristics, such as size and number of trees per acre, can be replicated with reasonable assurance, but proper size and distribution of both live and dead trees in the stand may not be achievable, given current knowledge and management practices. Based on historical perspective though, it is believed that future management will be at least partially successful in providing old growth from stands previously harvested.

Conflicts with Other Plans and Policies
None have been identified at this time.
Recreation

Direct Effects
Although some recreational activities such as camping can occur in any setting, many people choose different recreational settings for different recreation experiences. The Recreation Opportunity Spectrum (ROS) describes the different settings in terms of the recreation experiences they can offer (see Chapter 3 Affected Environment for a detailed discussion of ROS).

Vegetative manipulation, timber harvest, road construction, and access management are major activities that affect recreation settings. For example, road building and timber harvest increases access for motorized travel and firewood gathering, but at the same time affects the "naturalness" of an area and discourages those seeking a nonmotorized experience in a natural environment. The changes in recreational settings vary by alternative according to different levels of harvest and road construction within unroaded areas. Specific recreational activities (such as hunting and fishing) may be important components of different ROS settings; the effects on these are also discussed when appropriate.

Primitive Setting
There are no areas managed for primitive recreation opportunities, outside of designated wilderness areas, for any of the alternatives (see Effects on Wilderness, this chapter).

Semiprimitive, Nonmotorized Setting
Semiprimitive, nonmotorized recreation opportunities are directly dependent upon areas being maintained as unroaded and managed without use of motorized vehicles. Development of nonmotorized trails can increase use within a particular area, but the major limitation on supply occurs through the management allocation process.

Road building, timber harvest, and other vegetative manipulation eliminates the setting for semiprimitive nonmotorized recreation. Each alternative affects this setting to a different degree, based on acres allocated to unroaded conditions. Table 2-8, Chapter 2, Alternatives Considered displays acres remaining unroaded, plus projected RVD (Recreation Visitor Day) supply and demand over time. Table 4-17 displays a summary of RVD supply and demand projections for the various alternatives over the five decade planning period.

Alternative B-Modified reduces the semiprimitive, nonmotorized setting more than the other alternatives; it calls for road construction and timber harvest at a rapid rate, reducing the total unroaded acres to approximately 16 thousand acres by the end of the first decade. Only portions of Lookout Mountain, Deschutes Canyon/Steelhead Falls, and Silver Creek unroaded areas remain in a semiprimitive, nonmotorized condition. Only about one third of the demand for this setting can be provided in the first decade, despite trail development into these areas.

In Alternatives A and No Change, the area available for the semiprimitive, nonmotorized setting is reduced to approximately 29 thousand acres by the end of the first decade due to road construction and timber harvest. Lookout Mountain, Deschutes Canyon/Steelhead Falls, and Silver Creek would remain semiprimitive, nonmotorized throughout the planning horizon (5 decades). Projected demand for recreation opportunities in this setting cannot be met in the first decade with these alternatives. Lack of trail development into these areas in these alternatives restricts use to less than one half of the available area.

SPNM - Semiprimitive, Nonmotorized
RVD'S - Recreation Visitor Days

Alternative I (Preferred) maintains enough unroaded area to provide for the projected demand for this setting through the fourth decade by completing trail systems into all parts of the remaining areas. Projections of supply and demand are nearly equal by the fifth decade (demand exceeds supply by only .9 thousand RVD's; about two percent). Lookout Mountain, portions of Rock Creek/Cottonwood Creek and Deschutes Canyon/Steelhead Falls, and Silver Creek remain unroaded, providing a total of approximately thirty-six thousand acres of semiprimitive, nonmotorized setting.

Alternative E-Departure reduces total acres of unroaded areas to about thirty-five thousand by the end of the first decade, but seven thousand acres (Green Mountain unroaded area) are proposed for motorized recreation. Prescriptions for motorized recreation in this area (Green Mountain) do not eliminate options for future nonmotorized opportunities, but in the short term will conflict with the setting required for this use (semiprimitive, nonmotorized). Demand for the semiprimitive, nonmotorized setting is projected to surpass available supply by the second decade, in part due to the lack of trail development into remaining unroaded areas. By the fifth decade, projected demand exceeds supply by about 13 thousand RVD's (37 percent).

Alternative C-Modified provides semiprimitive, nonmotorized opportunities in excess of projected demand through the full planning period (5 decades). Approximately 57 thousand acres remain unroaded, but as in Alternative E-Departure, Green Mountain unroaded area is managed for motorized recreation, maintaining options for future nonmotorized opportunities. A net area of about 49 thousand acres is provided for semiprimitive, nonmotorized recreation with this alternative; this represents the maximum provided from any of the alternatives.

Semiprimitive, Motorized Setting
Semiprimitive motorized recreation opportunities are also dependent (as are semiprimitive nonmotorized) on maintaining unroaded areas on the Forest and Grassland. Even though some of the current unroaded areas (such as Rock Creek/Cottonwood Creek) are limited in terms of access and terrain for motorized use, development of improvements such as roads and trails could increase the availability for this setting. It is assumed (due to insufficient data) that only one unroaded area (Green Mountain) is suitable for a semiprimitive, motorized opportunity.

FOOTNOTE 1/Some development of Lookout Mountain for recreational purposes is planned, but is designed to maintain semiprimitive, nonmotorized characteristics.
Alternative E-Departure and C-Modified manage the Green Mountain unroaded area for semiprimitive, motorized opportunities throughout the planning horizon (5 decades). Table 2-8 (Chapter 2) shows that projected demand for this setting will increase dramatically, exceeding this supply by 11 thousand RVD's (260 percent) in the first decade and 18.1 thousand RVD's (360 percent) in the fifth decade.

The remaining alternatives (No Change, B-Modified, I, AND A) eliminate semiprimitive, motorized opportunities entirely. The demand for this setting is projected to increase to 18 thousand RVD's by the first decade and to 25.1 thousand RVD's by the fifth decade.

Roaded Recreation Setting
The roaded recreation setting is important to the majority of the Forest visitors. Access and natural-appearing surroundings combine to provide an ample supply of this opportunity with all of the alternatives (see Table 2-8, Chapter 2, for data on roaded recreation). Alternative C-Modified provides the least amount of this setting over time, but still exceeds demand by 605 thousand RVD's (215 percent) in the fifth decade. Alternative No Change provides the greatest opportunity for roaded recreation; supply exceeds demand by about 960 thousand RVD's (285 percent) in the fifth decade. The remaining alternatives (B-Modified, E-Departure, I, AND A) all provide more than sufficient roaded recreational opportunities throughout the planning horizon (5 decades).

Quality of the Roaded Recreation Setting
The roaded recreational setting is a broad category that encompasses a wide variety of opportunities for the Forest user. Scenic resources may range from heavily altered (Maximum Modification) to unaltered (Preservation), and access can vary from highly restricted (or even prohibited) to minimally restricted. Even though all of the alternatives are similar by providing a surplus of roaded recreational opportunities, they vary greatly by the quality of opportunities within this setting (see Effects on Scenic Resources and Effects on Transportation System, this chapter). In summary, the alternatives can be ranked according to the qualitative effect that they have on the roaded recreational setting as shown in Table 4-18.

Other important factors may affect the quality of the roaded recreation experience. Recreationists can expect to encounter difficult and dusty travel, and possibly safety problems during periods of heavy log hauling. Sights of recently logged areas, including stumps, slash, cul logs, fresh skid trails and landings will be encountered, especially during late spring, summer and fall. These effects are common to all alternatives, but may vary significantly as a result of planned timber harvest levels. It is reasonable to assume that the risk associated with these effects can be directly associated with timber outputs as shown in Table 4-19.

Trail System
Trail systems oriented to recreational uses are most desirable when traversing terrain that is naturally appearing, offering a variety of landscapes and difficulty. Depending on intensity of timber harvest and road construction, the scenic character of the area and the actual trail routes can be changed or lost resulting in displaced use, trail closures, trail relocations or reconstruction. Each alternative reflects...
different trail system proposals based on differences in unroaded areas being maintained and the differences in intensity of harvest outside of unroaded areas (see Table 2-8, Chapter 2, Alternatives Considered for planned trails by alternative).

Alternatives A and No Change include no addition to the trail system due to extensive even-aged management of timber stands. Maintenance of the existing routes would be difficult due to the harvest levels and the roading of unroaded areas for timber harvest.

Alternative E-Departure includes a moderate trail system based on the effects of increased use of even-aged harvest of pine stands. This demonstrates the need for concentrating the system in the unroaded areas and the main East-West Intertie and Summit Historic Route.

Alternative B-Modified includes more uneven-aged management of timber stands which offers more opportunities to develop and maintain trail systems. The harvest of Rock Creek/Cottonwood unroaded area and the lower portions of Lookout Mountain affect proposed and existing summer nonmotorized routes within these areas. Opportunities to develop motorized routes for summer travel, and snowmobile/cross-country ski routes for winter travel, may even be improved by allowing increased use of temporary roads and skid trails, and through extensive use of uneven-aged management.

Alternatives I and C-Modified include eventual construction of the total trail needs on the Forest and Grassland, most of this construction will occur in the first two decades. Primary unroaded areas, as well as unique recreational areas (such as Hammer Creek Area), are maintained in natural or near natural conditions and uneven-aged management of timber stands on the Forest is extensive, thus providing the necessary settings to justify additions to the trail system. As in Alternative B-Modified, opportunities to develop motorized routes for summer travel and snowmobile/cross-country ski routes for winter travel may even be improved by allowing increased use of temporary roads and skid trails, and through extensive use of uneven-aged management.

Big Game Hunting

Hunting opportunities vary primarily with game populations, but can also depend on quality factors such as remoteness and the challenge associated with hunting of unique animals that prefer habitat in wild and secluded areas provided by the Forest's unroaded and wilderness areas (e.g. multi-tined Rocky mountain elk). Populations of primary game animals on the Forest (elk and deer) react somewhat predictably to changes in habitat provided on the Forest and Grassland (see Appendix B, Section 6).

Overall populations of mule deer are expected to remain constant over the next five decades for all alternatives except B-Modified and No Change. This population is estimated at about 22,600 animals. For Alternative B-Modified, the population is predicted to remain constant for two to three decades, but then decline to about 17,200 animals by the fifth decade. This will also reduce a major hunting opportunity on the Forest, which is also assumed to be the number one recreation activity in terms of visitors days used. Alternative No Change is similar to A, but data is not available to make reasonable predictions on deer numbers. No significant negative effects are predicted for Alternative No Change; effects would probably be no worse than Alternative B-Modified.

Rocky mountain elk populations are estimated at 2,300 on the Forest today. As elk appear to be more sensitive than mule deer to changes in habitat, the populations vary more widely with the various alternatives. All alternatives except NC are predicted to increase populations of elk on the Forest over the first decade. As with mule deer, there is insufficient data to predict changes in elk populations with Alternative NC, but populations will probably be similar to Alternative A. In the long term (decades 2-5) populations of elk will begin to decline for all alternatives except C-Modified, but projections indicate that even with this decline, fifth decade populations will still be higher than today's numbers, except for Alternative B-Modified, which results in a rather dramatic decrease to 1700 elk by the fifth decade.
Pronghorn populations are estimated at about 590 animals on the Forest and between 70 and 160 animals on the Grassland. Hunting of pronghorn is not considered significant as compared to deer and elk, mainly due to the limited population. Opportunities for increasing populations are currently limited; the existing suitable habitat appears to be fully occupied, at least on the Forest. Management of pronghorn on the Grassland is an issue related to conflicts with livestock management and motorized recreation. Alternative I, B-Modified and C-Modified allocate areas for pronghorn management emphasis in order to resolve these issues, but significant increases in hunting visitor days are not predicted, despite this.

Recreation visitor days associated with hunting will tend to follow population trends of mule deer and elk over the planning period (see Table 2-8 Hunting Use-WFUD's, Chapter 2). Alternative C-Modified will probably produce the largest increase in hunting use over the long run, even though other alternatives (B-Modified, E-Departure, and A) show a larger increase in the short run, primarily due to more rapid changes in habitat conditions.

Fishing
Fishing opportunities are directly related to stream condition and the ability to produce a quality fishery. Each alternative improves different levels of streams in excellent condition, reflecting levels of activities that degrade streams, irrigation and scheduled improvement projects (see Effects on Water, and Effects on Wildlife and Fish, this chapter). Common to all alternatives (except No Change) is excellent riparian condition for all anadromous fish habitat, resulting in substantial increases in anadromous fisheries over the planning period; habitat for resident fish varies with each alternative. Alternatives C-Modified, I, and B-Modified offer the greatest opportunity for overall fishing as projects are scheduled to bring all streams to excellent conditions. In Alternatives E-Departure and A, investment levels in riparian restoration are limited to high priority areas, resulting in lower projected outputs of resident fisheries. As with hunting, recreational use associated with fishing is directly related to outputs of fish and increases over existing conditions with all alternatives. In contrast to hunting use, fishing and associated recreational activities continue to increase throughout the planning period for all alternatives (see Fish and Recreation outputs, Table 2-8, Chapter 2).

Indirect Effects
Providing recreational opportunities through specific land allocations to semiprimitive motorized and nonmotorized settings produces an indirect but significant effect on other resource uses.

Some effects are more appropriately described as foregone "opportunity costs" rather than as specific actions, as management for these settings reduces or eliminates more commodity-oriented endeavors such as timber harvest, grazing, mineral exploration, and even other recreational pursuits associated with a roaded setting. Appendix C describes specific effects on other resource uses as a result of semiprimitive allocations for individual unroaded areas. Appendix B (Section 7) discusses resource tradeoffs for combined unroaded allocations.

Areas managed for semiprimitive opportunities provide quality hunting experiences not found throughout more intensively managed, roaded areas. These islands of unroaded, nonmanipulated vegetation offer seclusion and escape for many wildlife species, providing a challenge for those hunters wishing to use backcountry skills in pursuit of elusive and, many times, large trophy animals.

Forest health is much more difficult to maintain in areas allocated for semiprimitive opportunities. Opportunities for using silvicultural techniques are limited due to accessibility problems. Options are mainly limited to prescribed fire and aerial application of chemicals. Recurring infestations of spruce budworm are a serious problem on the Ochoco National Forest, and unroaded areas provide islands of habitat for this and other insects and diseases which have increased dramatically as a result of many decades of fire exclusion.

See Effects on Unroaded, this chapter, for more detailed information on indirect effects of unroaded allocations.
Motorized recreational use (ATV and ORV) causes damage to other resources when users fail to obey laws and regulations or when the Forest fails to properly manage it. Soil erosion can be excessive in steep areas, or in areas with low vegetative cover. Riparian areas tend to receive higher resource damage than other areas because of the high level of access within them. Standards and guidelines (see Appendix D) are designed to limit this damage to within acceptable levels, but public trust and respect for the land is a necessary component of the overall management scheme to manage motorized use for the benefit of the users and other resources. See Effects on Soil, Wildlife and Water, this chapter, for more detailed discussions of motorized recreation on other environmental components. Also see Mitigation Measures, this section, for methods to reduce effects of motorized recreation on other resources.

Recreational facilities such as campgrounds, dispersed campsites, trailheads, and trails impact soils and watersheds by taking land out of production for construction purposes and by compacting and displacing soils in areas of heavy traffic. Alternatives C-Modified and I have more effects on these resources than the other alternatives, due to a higher level of planned construction and reconstruction of recreational facilities, and as a result of high levels of scheduled trail construction (see Table 2-8, Chapter 2 for display of recreational developments planned over the planning period).

Cumulative Effects
As unroaded areas continue to be developed for purposes other than backcountry recreation, people searching for these experiences will find fewer and smaller areas offering this opportunity. As a result, wilderness and the remaining unroaded areas may receive increasing use and overcrowding. This produces unacceptable conditions and undesirable use levels for wilderness and unroaded area experiences. The encounters with others become too frequent to allow for the recreation experiences sought. Use of dispersed sites and increases in numbers of dispersed sites is expected to occur as people discover the Forest and Grassland and search for a non-crowded recreation experience. People now utilizing the Deschutes National Forest may move east to avoid the crowds and developments occurring in that area.

Mitigation Measures
The National Recreation Strategy, developed to encourage partnerships and maintain quality recreational opportunities, has been incorporated into Alternatives C-Modified, I and B-Modified. This emphasis on quality outdoor recreation includes the mitigation of other resource activities on recreational opportunities as well as mitigating the impacts of recreation on other resources.

Measures designed to mitigate the effects of various activities are identified in the Standards, Guidelines, and Prescriptions in Appendix D. Some of the major mitigation measures are listed below:

To maintain semiprimitive recreation opportunities, unroaded areas are designated as special management areas and vehicles are restricted to protect the unroaded qualities.

Scenic corridors are designated and corridor plans will be developed to maintain the naturalness along specific roads and trails.

Trails that cross timber sales are managed, maintained and protected during harvests by sale layout and contract preparation and administration. Trails may be relocated to reduce impacts by harvest.

Road systems are designed and maintained to accommodate different types and levels of recreation traffic.

Developed sites are protected from mineral entry through the withdrawal procedures. These sites are also maintained, managed and protected during timber harvest through clauses in the timber contract. Areas where soil compaction is unacceptable will be rehabilitated and/or rested.

Cross-country ski opportunities away from snowmobiles may occur through the issuing of a Forest closure order prohibiting snowmobiles in certain areas.
Traffic controls can be initiated to restrict log haul on weekends and holidays to facilitate recreation traffic.

Roads can be closed after log haul to further protect wildlife habitat resulting in more nonmotorized recreation (hunting) opportunities.

Rockhounding areas can be withdrawn from being individually claimed to keep them available for general public use.

Timber sale areas can be left open for several seasons after harvest for people to gather firewood.

All vehicular use can be restricted on critical winter range during critical times by travel plan implementation.

Conflicts with Other Plans and Policies
None are known to exist.

Scenic Resources

Direct Effects
Effects on scenic quality are measured by the degree of change from the natural condition of an area. A landscape may appear natural or heavily altered depending on the extent of the management activities in the area. Timber harvest, vegetative manipulation projects, and road construction are the primary activities that affect the naturalness of an area.

Visual quality objectives (VQO) have been established for all Forest and Grassland areas based on the National Forest Visual Management System (VMS). The VMS process is briefly described in Chapter 3. These VQO’s are described as follows: Preservation, which allows no alteration of the landscape; Retention, which allows management activities that are not obvious to the casual observer; Partial Retention, which has management activities that are noticeable but do not dominate the landscape, and Modification/Maximum Modification where management activities are obvious and dominate the landscape. (The Forest’s visual resource inventory and analysis of the alternatives combined the Modification and Maximum Modification areas.)

Scenic corridors called viewsheds have been identified in the land areas seen from major highways, trails, heavily used recreation sites, lakes, and some streams. In the various alternatives, these viewsheds are treated differently based on the emphasis of the alternative. In alternatives E-Departure and B-Modified, where commodity production receives the highest emphasis, only the major viewsheds are managed to maintain their scenic qualities while the other viewsheds are managed for timber production. In alternative C-Modified, most of the inventoried viewsheds are managed to maintain the scenic quality as retention or partial retention corridors based on the recommended VQO.

In all of the alternatives, including the Current Direction alternative, the present naturalness of the Forest will continue to change toward a more heavily altered appearance. This will mean that in most of the Forest the large ponderosa pines will continue to disappear and the number of cleared openings and patches of young trees will increase. The Forest will look less natural.

The degree of this change varies between alternatives. Wilderness areas will be preserved in a natural condition. Areas maintained and managed for their unroaded condition, scenic river corridors and Research Natural Areas (RNA’s) will present a natural appearing scene. Areas managed for intensive timber and forage production will present a modified or heavily altered scene. Access routes through or to these various areas may receive special treatment to protect or enhance the view, depending on the amount and sensitivity of the traffic.
Table 4-20 displays the acreage and the percent of area identified for each visual quality objective by alternative.

1/ Preservation includes Wilderness and Research Natural Areas.
2/ Retention includes unroaded, old growth, developed recreation, enhanced riparian areas, and access corridors specifically managed for recreation VQO.
3/ Partial Retention includes maintained riparian areas and access corridors managed for partial retention VQO.
4/ Modification and Maximum Modification includes all other areas timber/rgange and areas for wildlife habitat improvement.

Alternative A and Alternative No Change
In general, the Forest lands outside of viewsheds, wilderness, Research Natural Areas, and the three managed unroaded areas will appear to be moderately to heavily altered. Most of the trees will be smaller than 24 inches in diameter. A mosaic pattern of harvest openings and patches of young trees of varying sizes in blocks of between 20 and 40 acres will dominate the landscape. At least for the next decade, the light colors and fine textures of replanted younger trees will contrast with the darker colors and courser textures of yet uncut older tree blocks. The large, ponderosa pines which have been a dominant visual element in the Ochoco Forest landscape will disappear, to be replaced by young, thicker stands of trees. State Highway 26, the Round Mountain Trail, and Forest Roads 16, 17, 27, 33, 41, 42, 43, and 58, will continue to appear natural. In these viewsheds, management activities will not be evident to most people after about one year from the time the activity has been completed. Fore-
Highway 26 visual corridor, on 9,000 acres along a couple of major routes, Bandit Springs, the upper 7,550 acres of Lookout Mountain, Silver Creek, Stein's Pillar, Squaw Creek, Hammer Creek, the wilderness areas and the Wild and Scenic Rivers, management activities will not be obvious. The north slope mixed conifer stands will appear heavily altered as clearcut areas will stand out due to the average timber harvesting and road construction.

Alternative C-Modified
In general the appearance of the Forest will be similar to the current situation; all major roads will be managed to protect and enhance the natural landscape. Views along Forest Roads 16, 17, 22, 27, 33, 38, 41, 42, 43, 47, and 58 should continue to appear natural. Approximately 40,000 acres of other secondary access viewsheds will offer a slightly altered landscape where management activities are evident but do not dominate the landscape. Large blocks of old growth and natural-appearing landscapes will be apparent in the wilderness areas, RNA's, and the 44,000 acres managed as unroaded. The 3,000-acre Bandit Springs cross-country ski area is managed to protect and enhance the natural old growth appearance of this landscape. The Forest area outside of the viewsheds and special management areas will appear moderate to heavily altered from timber harvests and projects to improve wildlife habitat. Seventy percent of the timbered area will be young tree stands.

Alternative E-Departure
In general, the Forest lands outside of the viewsheds, wilderness, RNA's, and the four managed unroaded areas will appear heavily altered in Alternative E-Departure. The large ponderosa pines which have been a dominant visual element in the landscape will be replaced by younger, thicker stands of trees. Eighty-eight percent of the timbered areas will be dominated by managed stands less than 100 years of age. State Highway 26 and the main route to Rager Ranger Station viewsheds will continue to appear natural. Management activities in these two viewsheds will not be evident to most people one year after the activity has been completed. The big-tree appearance will be maintained here also. Forest Roads 17, 22, 26, 27, 33, 41, 42, and 43 will be managed for partial retention, which means that management activities such as timber harvest will be noticeable, but will not dominate the view of the landscape. All other access routes will have no special visual management emphasis and management activities may dominate the scenery.

In addition to the viewsheds along these sensitive travel routes, the 3,000 acre Bandit Springs cross-country ski area and the special wide 7,000-acre scenic zone encompassing Crystal Creek, Walton Lake, Round Mountain, Lookout Mountain, Mt. Pisgah, and East Point will be managed to protect and enhance the old growth natural appearance. Most of the area remaining outside of these special management areas receives an intensive timber management emphasis which will dominate these landscapes.

Alternative I (Preferred)
The Forest and Grassland will offer natural-appearing scenery along all major travel routes in the Forest. Areas such as Steins Pillar, Hammer Creek, and Deep Creek will also maintain the scenic qualities associated with these areas. All of the Lookout Mountain unroaded area will provide unique natural scenery as will the major portion of Rock Creek/Cottonwood Areas, Bandit Springs Area, Squaw Creek, Silver Creek and the Wild and Scenic River Corridors. Uneven-age management in the pine stands will provide a more natural-appearing landscape in the pine areas across the General Forest. These areas will feature a smaller tree (20-inch diameter) average and evidence of more frequent entry.

Indirect Effects
Maintaining scenic viewsheds affects the quality of recreation opportunities and experiences. People prefer a natural appearing scenic environment for recreation activities. Alternatives that maintain the majority of the viewsheds such as C-Modified and Alternative I will meet the expectations of more recreationist by providing quality to the areas most frequently visited. Alternatives E-Departure and B-Modified maintain fewer viewsheds in the natural appearing condition and will be less acceptable to the recreating public.
Maintaining scenic viewsheds affects the intensity, location and manner in which management activities can be completed. Alternatives that maintain the viewshed corridors such as Alternative C-Modified and Alternative I will be most restrictive on resource management activities in these areas. Timber harvests will be reduced in these areas as well road construction. Locations of units and roads is limited. Prescribed fires must be carefully planned and executed to reduce visual impacts in these viewsheds. Other activities such as mining, utility lines, oil and gas explorations, wildlife habitat projects will have limits and restrictions to maintain viewsheds.

Cumulative Effects
The effects of natural and resource management activities on landscapes constantly change the scenic qualities of that landscape. As management activities become more evident, the naturalness of a particular area will be lost, and recreational opportunities will be less desirable, depending on the user’s objectives. The alternatives can be ranked according to the degree of negative change to the landscape and therefore the cumulative naturalness of the Forest.

Mitigation Measures
Landscapes can continue to appear natural by alteration of management activities to blend them into the landscape as designed in the visual retention prescription. Clearcut units can be positioned so they blend into the landscape. Roads can be designed to limit their visual effect on the landscape. Activities can be scheduled during periods of low public use, or when damage can be prevented, such as skidding over snow.

Intensities of management activities can be reduced so they are evident but do not dominate the landscape.

Unattractive views can be softened by feathering the effects, maintaining corridors between, planting vegetation and transplanting larger trees to screen the area.

Viewshed management plans can be developed and implemented that will protect, enhance and/or perpetuate the scenic values of the area.

Uneven-aged timber management can be implemented to retain a relatively unbroken canopy and diversity in sizes of trees in an area.

Harvest unit size can be reduced to lessen the visual impact to an area. Residue from timber harvests can be eliminated through various slash disposal techniques and fuelwood gathering.

Many other design techniques can be utilized to mitigate visual impacts of management activities. These are described in the National Forest Landscape Management Series (USDA Vol. 2, Chapter 6, 1973-1985).

Conflicts with Other Plans and Policies
None are known to exist.

Direct Effects
The direct effects of the alternatives include the following:

- Employment levels produced by the alternative’s mix of outputs.
- The amount of the Forest budget.
- The amount of 25 percent monies paid to the counties.

It can be seen that expenditures for salaries and for supplies vary less than contracting expenses. Alternative B-Modified provides the most support for local economies, and Alternative C-Modified the least.
Indirect Effects
The previously mentioned economic effects of the various alternatives would produce effects on the social fabric of the area. These social effects will be measured by four criteria, as follows.

- Effects on work-related lifestyle.
- Effects on leisure activities.
- Effects on community cohesion and community stability.
- Effects on women and minorities.

Effects on Work-Related Lifestyle
Six lifestyles were identified in the Socio-Economic Overview prepared for the Forest and Grassland (pp. 62-92). They are: Native Americans, farmers, loggers, millworkers, small town merchants, and government employees. These lifestyles are related to occupations, but are not limited to them.

In terms of county totals, the numbers and incomes of farmers and of government employees do not vary significantly by alternative. The Native American lifestyle is discussed in the "Women and Minorities" section. Employment levels for loggers, millworkers, and small town merchants will be discussed here.

For loggers, Alternative B-Modified would increase employment by 14 jobs, which is around four percent of total logging employment. This change is considered to be barely significant. Alternatives E-Departure, I, and A would increase employment for these sectors by one percent to three percent, while Alternative C-Modified would decrease employment by two percent. As discussed in the Cumulative Effects section, these changes and all employment changes may be affected by other factors.

For millworkers, the changes range from a three percent employment gain (Alternative B-Modified) to a three percent loss (Alternative C-Modified). None of these changes is considered to be significant. However, the remanufacturing industry will be affected by the Forest Plans of several Forests. This matter is discussed in the Cumulative Effects section.

Merchants benefit from any alternative. Their gain, as expressed in an increased number of employees, ranges from one percent (Alternative A) to four percent (Alternative E-Departure). Small town merchants, however, hire a smaller proportion of employees than do other businesses. Therefore, we consider that the merchants benefit more than these figures indicate.

Effects on Leisure Activities
Recreational activities are important to many central Oregonians. Some people have moved to central Oregon because of the recreation available here.

Alternative C-Modified would provide for the most recreation activities. Elk and fish are at the highest levels of any of the alternatives, as are opportunities for unroaded recreation. Landscapes appear most natural to the driver or hiker. Fuelwood gathering is the one activity which is at its lowest.

At the other end of the scale, Alternative A provides, in general, the least recreational opportunities. Unroaded areas and fish are at the lowest levels. Unlike the other alternatives, there is no construction of trails for hiking, ATV's, cross-country skiing, or snowmobiling.

Generally speaking, Alternative B-Modified provides the next lowest level of recreational opportunities. Unroaded areas and elk are at low levels. The scenery is the lowest of all the alternatives. However, fuelwood is at its highest; and trail construction and increased numbers of fish improve the picture.

Alternatives E-Departure and I provide an intermediate situation. Alternative I provides more unroaded areas, trails, and fish; while Alternative E-Departure offers slightly more elk plus a provision for a semiprimitive motorized area.

Effects on Community Cohesion and Community Stability
"Community Cohesion" is an estimation of whether a given alternative will tend to unify or polarize a community. While a diversity of opinions in a community is generally desirable, it is assumed that polarization of the community is harmful and that cohesion is beneficial. It is further assumed that polarization will be caused by the adoption of an
alternative which greatly favors one point of view over others. In contrast, the selection of an alternative that meets to some extent the desires of diverse participants is assumed to produce cohesion.

Judging by this criterion, Alternatives B-Modified and C-Modified would produce polarization. The public response to Alternative E-Departure, the Draft Preferred Alternative, included many negative comments about its "departure" harvest schedule. It is judged that the adoption of Alternative E-Departure would produce polarization. Under Alternative A, existing polarization would not diminish. Alternative I is the one alternative judged likely to promote some degree of community cohesion.

Community stability is judged by two factors.

- Continuity of the financial base -- the extent to which tax supported community services will be supported in the future; and
- Diversification of the community economy -- the extent to which diversification makes it possible for the community to "ride out" a downturn in one economic sector.

Continuity of the financial base is interpreted from the 25 percent monies and the total employment level. Alternative B-Modified meets this goal best. Alternative C-Modified, and Alternative E-Departure after the second decade, do not meet the goal well. Alternatives A and I meet the goal adequately.

Concerning diversification of the economy: Alternatives B-Modified and C-Modified meet the goal minimally. Alternative A is stronger, and Alternatives E-Departure and I perform the best.

Effects on Minorities and Women
The Native American Religious Freedom Act requires Federal agencies to evaluate their policies and procedures in consultation with Native American leaders in order to protect and preserve Native American religious sites and areas through cultural resource surveys and contact with the tribes. No conflicts were identified with the Tribes Comprehensive Plan. The Forest and Grassland are not recognized as having a significant impact on the resources or the socio-economic concerns for the Warm Springs Reservation.

Changes in employment and employment patterns may have effects on minorities and women. As employment in general increases or decreases, everyone, including minorities and women, will be affected. The question here is whether there are any disproportionate effects on minorities or women.

In the Forest Service, hiring of women and minorities is affected by the Equal Employment Opportunity (EEO) program. It is assumed that if the Federal workforce increases, women and minorities will benefit through the EEO program. Conversely, a decreased Federal workforce may reduce employment opportunities for minorities or women as for all potential employees. As shown in Table 4-9, projected workforce levels vary only slightly among the alternatives, with Alternative B-Modified having the highest number of employees and Alternative C-Modified the lowest. Overall, the difference among alternatives is small.

Another Federal provision relates to contracts set aside for disadvantaged minority contractors (8A contracts). As Federal budgets increase or decrease, the money available for such contracts will rise or fall. However, overall effects of the "8A" contracting in our area are small.

In employment in the private sector, there is no clear evidence that Forest decisions would disproportionately affect minorities. Women might be disproportionately affected by the selection of an alternative. Women's careers tend to be concentrated in clerical, trade and service fields, with significant numbers of women also employed in the mills (State of Oregon, 1984a and 1984b). Women are more likely than men to work part time, frequently in trade or service occupations. If these areas of employment are affected by a given alternative, women might be affected.

Alternative B-Modified would produce a slight increase (three percent) in mill employment which might increase full-time job opportunities for women. Alternative C-Modified would decrease mill employment by three percent and might decrease these job opportunities. No other alternative affects mill employment significantly.
The trade sector (see Table 4-22) is used as an indicator of part time employment. Alternative E-Departure produces the largest increase, a four percent gain. Alternatives B-Modified and I produce a three percent increase. Alternatives C-Modified (+2 percent) and A (+1 Percent) produce gains, but the increases are not as large as those created by the other alternatives. These alternatives all produce, in varying degrees, an increase in part time jobs which might employ women.

Cumulative Effects

The previous sections have examined the socio-economic effects of the Forest upon Crook and Harney counties, the Zone of Primary Influence. (Table 4-22 also includes Wheeler County in the totals, but the Wheeler County contribution is small.) But the Forest’s effect extends farther; and many other factors affect the Crook/Harney county region.

One million board feet of Ochoco NF ponderosa pine creates eleven jobs and an income of $220,000 (1987 dollars) within the two county area. But since 10 percent to 15 percent of the pine will be milled elsewhere, and some milled lumber will be remilled elsewhere, the total contribution to the Oregon economy is estimated to be fourteen jobs and a payroll of $290,000.

Other species are more likely to be milled outside the two county area. A harvest of one million board feet of “associated species” will create three jobs and $60,000 in income in Crook and Harney counties. Five jobs and $100,000 in income will be created statewide.

Therefore, when the Extended Area of Influence is considered, differences in timber harvest levels take on more important effects. The employment gains from Alternatives B-Modified, E-Departure, I, and A will be magnified. Likewise, the employment loss from Alternative C-Modified will be increased.

Just as the Ochoco National Forest creates effects in more distant counties, the decisions of other Forests affect local economics. Crook County in particular boasts a large remanufacturing industry. The plants process 120 MMBF of milled lumber each year.

Since 40 MMBF to 60 MMBF of this amount comes from the Ochoco NF, 60 MMBF to 80 MMBF originates elsewhere -- primarily on other eastside National Forests.

It would be desirable to estimate the future total ponderosa pine harvest for eastern Oregon. These figures are not easily obtained. However, Table 4-25 contains some figures for anticipated total harvests for the seven National Forests in eastern Oregon.

</tr>
</tbody>
</table>

1/ includes Deschutes, Fremont, Malheur, Ochoco, Umatilla, Wallowa-Whitman, and Winema National Forests.

It can be seen that total volume for these Forests is predicted to increase by 10 percent to 20 percent. The total ponderosa pine available for remilling may not share this rate of increase, however, for two reasons.

Ponderosa pine is decreasing as a percentage of the total harvest on the Ochoco NF and on some other Forests; and

The ponderosa pine which will be harvested will tend to have a smaller diameter and more defects than the pine harvested in the past.

Given these considerations, it is not clear whether the ponderosa pine available for remanufacturing will slightly increase, stay the same, or slightly decrease.

Because Crook County remanufactures do purchase material from a wide area, an increase in the Ochoco harvest might be compensated for by a decrease in the purchase of other material. Therefore, the increased employment projected for Alternatives B-Modified, E-Departure, I, and A might be diminished. Similarly, the decrease in harvest under Alternative C-Modified might result in a smaller decline in employment.
The timber industry can also be heavily influenced by national environmental, political, or economic factors -- and, increasingly, by international factors. Examples of such factors are the final classification of the spotted owl, a rise or fall in the Federal Reserve prime interest rate, or decisions regarding imports or exports of logs or lumber. The socio-economic effects from these quarters will affect and may even dominate the effects which are predicted above for the various alternatives.

Mitigation
It has been mentioned above that ponderosa pine will tend to be smaller and to have more defects in the future. For Alternative I, silvicultural prescriptions have been altered on parts of the Forest to yield a larger tree with fewer defects.

Other mitigation measures designed to improve future timber yields are discussed in the Timber section of this chapter.

Conflicts With Other Plans and Policies
The Crook County - Prineville Area Comprehensive Plan, issued in 1978, sets forth many objectives. Protection of the current timber industry is a primary topic, but concerns for grazing for livestock and wildlife, recreational opportunities, and environmental needs (especially protection of water and soil) are all mentioned. As an overall goal, the county plan states:

"It shall be the policy of the county to support forest land use and management decisions which maximize the present level of benefitting uses; specific emphasis shall be on timber production to sustain the existing forest products industry, forage production to maintain at least the existing levels of livestock and wildlife habitat, protection of water quantities and quality and to maintain existing dispersed recreation levels in coordination with the USFS planning and management programs." (p. 53)

Alternative C-Modified would conflict with the goal of "timber production to sustain the existing forest products industry." Or, conceivably, the phrase "existing forest products industry" could be interpreted to mean that the planned harvest level should match the 1977 harvest level. Every alternative would conflict with such an interpretation since the 1977 harvest level was 143 MMBF.

No conflicts are seen with plans of any other agencies or groups.

Soil

Direct Effects
Timber harvest and road construction have the greatest potential to affect the soil through compaction, displacement, or erosion. Concentrated grazing and recreation use may adversely affect soil especially in sensitive riparian zones. Intense fire may volatilize soil nutrients.

Effects of Timber Harvest
Due to the relatively gentle terrain on the Ochoco National Forest, tractor yarding is the most common method of timber harvest, especially on slopes under 30 percent. Multiple trips over the soil with a tractor or rubber-tired skidder can cause detrimental soil compaction and displacement. Fifty percent of the acres accessible to tractor harvest exhibit a high compaction hazard (SRI, 1977).
Soil compaction reduces site productivity by reducing the air space in the soil, creating a physical barrier to plant roots, and changing the infiltration and percolation rates of water into and through the soil. Displacement occurs when the fertile surface soil is removed or pushed aside, exposing the subsoil. Displacement can occur over large areas during machine site preparation or on smaller areas on skid trails and landings.

Machine piling of slash can triple the area of ground disturbed over that caused by timber harvest, greatly increasing soil damage caused by compaction, puddling and displacement. Dramatic growth reductions have been demonstrated on areas where surface soil has been pushed into windrows or piles along with stumps and logging debris. Since surface soil displacement or removal is a long-term, or nearly permanent, site disturbance, effects on nutrient cycling are significant. (Class 1976; Haines, et al, 1975).

The amount of soil compaction will depend on the number of acres affected by ground-based logging equipment (e.g. tractor or rubber tired skidder) and by the method of post-harvest site preparation. Cable yarding systems move logs to the landing by dragging or partially suspending the logs with cables. These systems cause less soil disturbance than tractor yarding and can be used where tractors are not suitable. Road density is usually less with cable systems since yarding can be done over longer distances with a stationary machine.

For each harvest entry, the extent of soil disturbance depends on the logging system and associated road network, terrain and soil factors, volume of timber removed, size of logs, weather, soil condition and skills of individual equipment operators. The most complex, expensive yarding systems are designed to operate in the steepest terrain and to have the least impact in terms of soil compaction and displacement; thus, careful practices in difficult, erosion-prone terrain may have soil erosion impacts comparable to poor practices carried out on naturally stable flat ground.

Historically, compacted bare soil has occurred (as shown in Table 4-26) from various logging systems and haul roads.

</table>

Management standards and guidelines allow no more than 20 percent of an area to be displaced or compacted; a Forest goal is to eventually have no more than 10 percent in such a condition, and the Forest has an aggressive program of skid trail designation and tillage of compacted soils (approximately 1,500 acres annually) in order to meet these standards over the long run. Rehabilitation of previously compacted soils will take at least 5 decades, as it will occur during subsequent timber sale entries. This is further complicated with management of existing stands (such as with overstory removal or uneven-aged management) because tillage is logistically very difficult; machinery for tilling also damages existing crop trees. The ideal time to till for compaction is during the regeneration phase of the rotation (e.g. clearcut or shelterwood). Destruction of existing crop trees in order to relieve compaction is done only under the most severe conditions, as the productivity lost from tree removal may outweigh the benefits of relieving the compaction.

Even with compliance with standards and guidelines (20 percent maximum compaction), overall acres of compaction on the Forest will increase in the short term as previously unentered timber stands are harvested. The Forest will only begin to reduce the acres when previously entered (and compacted)
areas are re-entered and rehabilitated. As this is predicted to take at least five decades, it emphasizes the need to maintain an aggressive rehab program. Because the ideal time to till for compaction is during stand regeneration (clearcut, shelterwood, etc., before new seedlings are established), those alternatives that provide for extensive acres of uneven-aged management maintain an "opportunity cost" because the tree stand is never cleared and replanted. Machinery of sufficient size to relieve compaction is also too large to maneuver around existing crop trees under most conditions encountered, therefore presenting conditions that may favor long term maintenance of compacted soils. Overall, the alternatives can be rated in terms how well they manage for compaction over time, based on rate of timber harvest, percent of tractor versus skyline logging, use of even-aged versus uneven-aged management, and total acres available for timber harvest.

Alternative A projects the best overall trend in reduction of soil compaction because of the high percentage of skyline acres scheduled for timber harvest and the small percentage of uneven-aged management. Alternative C-Modified calls for a high percentage of tractor logging, because the majority of steep ground areas are reserved for unroaded recreation and not available for timber harvest. It also provides for extensive use of uneven-aged management, therefore complicating efforts to rehabilitate existing compacted areas. Consequently, it has the worst overall trend in future management of compacted soils.

Effects of Road Construction and Reconstruction
Roads are the major nonpoint source of sedimentation. New road construction during the planning period will affect the soil resource by removing land from production and dedicating it to a portion of the transportation system.

Road construction activities cause the disturbance and removal of soil, which can result in soil erosion and increased sediment in streams. This effect varies by the amount of roads constructed, the season of construction, the types of soils, and the steepness of slope on which the roads are constructed. Maintenance of roads can also cause sedimentation in the streams as grading disturbs mineral soil and results in soil loss through erosion.

Roads constructed during the wet period of the year (November through May) will encourage surface runoff, erosion, and sedimentation. New roads are highly erodible during the first rains and/or snowmelt following construction.

Roads having high cutbanks produce more sediment than roads with low cutbanks. Freezing and thawing, heating and cooling, and raindrop action dislodge soil particles which ravel into drainage ditches and are transported to streams. Road construction on slopes exceeding 70 percent produces gravelly sidecast material that can bury downslope vegetation and create a doughy condition, resulting in reduced soil-site productivity. Sidecast can cause overloading of the fillslope and subsequent failures.

Improper compaction and logs and debris in fills can result in road failures. Improper location and inadequate numbers or sizes of drainage facilities can increase the incidence of road failures and road surface erosion.

Roads lacking adequate surfacing act as a transport mechanism delivering the bulk of the sediment to streams. In addition, roads with insufficient rock surfacing “pump” soil to the surface which erodes during winter use. The most critical conditions exist on roads constructed on soils high in clay.

Road reconstruction on the Forest is a source of sediment that occurs when an old road is cleared of protective vegetation.

Similar to new road construction exposed soils will tend to erode for one to several years after reconstruction.

Since most of the Forest’s transportation system is already in place, new construction does not vary significantly by alternative (see Table 2-8, Chapter 2).

</tbody>
</table>
The potential to increase sediment production lies mainly in roading currently unroaded areas since new road construction adds more sediment than existing roads and the unroaded areas have higher erosion hazard rates than surrounding areas. Examples of unroaded areas with 65 to 85 percent of the area exhibiting severe or greater erosion hazards are Rock Creek, Green Mountain, and Cottonwood. More than half of Lookout Mountain, Silver Creek, and Broadway unroaded areas exhibit severe erosion hazards.

Alternatives with the least impact on these unroaded areas are C-Modified and E-Departure. Alternative I has a moderate potential of impacting these sensitive unroaded areas, while Alternatives No Change, A, and B-Modified pose an increasing risk of soil loss from these areas (see Table 2-8, Chapter 2).

Effects of Grazing
Grazing allotments can be a source of soil compaction and erosion where livestock are concentrated, such as around water sources and riparian areas. Historical evidence indicates that excessive grazing over long periods of time, or grazing on soils that are too wet can lead to soil damage such as: 1) surface erosion, 2) soil compaction, 3) soil puddling, and 4) nutrient loss.

Cattle use can keep the surface (one to two inches) of soil layers compacted, but generally not any deeper (Alderfer & Robinson, 1947). Natural restoration through freezing-thawing and pioneering vegetation will generally correct, in a few seasons, the type of surface soil compaction done by livestock.

It can be assumed that as we expand the transitory range with more timber harvesting and increase the utilization of existing forage through water developments, additional grazing will follow and negative soil impacts will increase.

The number of Animal Unit Months (AUM’S) does not vary greatly among the alternatives (see Table 2-8, Chapter 2). With adoption of more restrictive utilization standards in riparian areas and range improvements designed to disperse livestock, soil compaction in riparian areas should be reduced.

Effects of Recreation
Recreational impacts on the soil resource have historically been minor on the Forest and Grassland but are increasing, especially with motorized use of All-Terrain Vehicles (ATV’s) and other Off-Road Vehicles (ORV’s); unregulated use of these has high potential for soil impacts, especially erosion in critical riparian areas. Concentrated recreational use will tend to compact soils and channel runoff. Overall dispersed recreational use will increase as access is provided into additional areas. Recreation use varies by alternative, Alternatives I and C-Modified (and to a lesser degree B-Modified) emphasize recreation strategies that include high levels of trail construction for nonmotorized and motorized, winter and summer use (see Table 2-8, Chapter 2). These three alternatives have equal levels of trail construction for All-Terrain Vehicle use and are, designed to better regulate existing use which is currently unregulated on a majority of the acreage on the Forest and Grassland. The impacts to soils in the trails themselves may increase, but better management for the off-trail areas would result and this facilitates monitoring.

Effects of Fire
The effects of fire on soil are highly variable depending on: (1) the intensity and duration of the fire, and (2) the transfer of heat in the soil (dependent on the physical properties of the soil affected). Significant beneficial effects of low to moderate intensity fires are (1) exposure of mineral soil/ash seed beds for natural tree regeneration, (2) improved nutrient cycling, and (3) reduced levels of some pathogenic microorganisms. Significant adverse effects of high-to extreme-intensity fire are (1) accelerated erosion (due to excessive mineral soil exposure and/or creation of hydrophobic conditions), (2) excessive nutrient volatilization (especially nitrogen and potassium), (3) loss of beneficial microorganisms, and (4) loss of organic matter for nutrient holding capacity of soil. (Boyer and Dell, 1980).

Under extreme compaction, air and water movement can be altered to the point that it affects the biological and chemical properties of the soil which ultimately affects the availability of plant nutrients.
Topsoil removal and intensive burning and cold soils can modify a soil source and create a nitrogen deficiency. Nutrient losses from fire management will be most significant on high elevation, volcanic ash soils. This is because nitrogen deficiencies are most common on colder soils (higher elevations) and on sites where topsoil has been displaced or altered through intense burning. This is most pronounced when a stand reaches crown closure—the period of greatest demand on soil nitrogen supply.

Although the total acreage of prescribed burning is large, including treatment of natural as well as activity fuels, only 20-30 percent of this area is likely to fall into the intensely burned category, or approximately 61,000 to 66,000 acres depending on the alternative. This is not a wide range and does not pose a high risk to the soil resource given the Forest’s commitment to fire suppression and fuels management.

Indirect Effects
Changes in soil characteristics will often affect water quality. An increase in soil compaction, erosion, or displacement can cause an increase in stream sedimentation. The effect of sedimentation on fish habitat will be discussed in greater detail in the water section (see Effects on Water, this chapter). Alternative No Change poses the greatest risk in the first decade; however, over time, Alternative B-Modified will likely have a greater impact. Approximately 50 percent of the runoff from the Forest is captured and stored in two reservoirs. Increased sedimentation could reduce the useful storage life of the Ochoco and Prineville reservoirs (Table 4-28).

The values in the table above are estimated to be about seven percent above background or natural levels. Whether this total amount of sediment is delivered each year to the reservoirs or is entrained in streambanks or channel gravels to be flushed into the reservoirs during major storm event is open to discussion. Overall the effects on reservoir storage is small.

Reduced site productivity caused by compaction, volatilization, or erosion can, in turn, reduce the growth rate of future stands and can influence the density and diversity of both cover and forage for wildlife. The actual reduction of site productivity is difficult to predict due to the interrelationship among stand stocking, genetic improvement, mitigation measures, length of line, natural recovery, and climate, among others. Though potential impacts to site productivity are real, they do not vary significantly by alternative.

Cumulative Effects
The cumulative effects of land management activities on adjacent and intermingled ownerships was considered. No measurable off-site effects on soil are anticipated. Compaction, the major effect on soil, is confined on-site. Soil erosion from adjacent ownerships may result in slight increases in stream sedimentation. Sedimentation of streams is discussed in more detail in the Water Effects section, this chapter.

Soil erosion and sedimentation in the headwaters of streams will affect the downstream segments of the drainages. Assuming more roads are constructed

TABLE 4-28
Annual Estimated Sediment Contribution
than are closed each year, sedimentation from road construction and maintenance will accumulate over time.

Alternatives I and C-Modified, which will close a large proportion of roads seasonally or yearlong, will have slightly less impact than the remaining alternatives.

As pointed out in Table 4-28, the contribution of sediment from the Forest is estimated to be approximately seven percent above background levels. It is unlikely this proportionally increased sedimentation will increase over time. However, the accumulation of sediment in both Ochoco and Prineville Reservoirs will have a cumulative effect on the storage capacity of the reservoirs over time, reducing their effective service life by an unknown number of years.

The effects of soil compaction following tractor harvest can last longer than 40 years (Power, 1974). Silvicultural prescriptions that require more than one entry, such as shelterwood cuts, can potentially compact a greater percentage of the area than harvest methods where only one entry is necessary. Salvage harvest is potentially the most damaging.

Local documentation on soil compaction exists from study of a heavy partial cut of old-growth ponderosa pine which removed most of the overstory from a stand of young pine on the Ochoco National Forest in 1961 (Big Summit R.D.). Soil compaction from logging equipment was readily measurable 16 years after cutting. Soil density in skid trails at depths of three and six inches averaged 18 percent higher than the densities in undisturbed soils. At the nine and twelve inch depths, skid trail density was nine percent greater than the density at the same depths in undisturbed soils. Growth of residual young pine trees related negatively to the intensity of soil compaction in the root zone. Moderately impacted trees showed a six percent reduction in growth rate and heavily impacted trees showed a twelve percent reduction over a 16-year period (Froehlich, 1979).

In another study supporting growth loss from compaction in the Coast Range of Oregon, the effects of skid roads kept soil heavily compacted 32 years after logging on 25 percent of the harvest area. An overall volume loss was 11.8 percent for the total area. (Wert & Thomas, 1981).

Recent research in progress reports statistically significant different soil bulk density, radial growth and tree height between lightly and heavily disturbed portions of harvest units. Growth was slower on heavily disturbed areas. Decreased growth relationships with increased soil bulk density is reported. (Geist & Seidel, 1984.)

Studies show that multiple entries have the potential to cumulatively reduce productivity more than single entries (Chambers, 1977).

Currently it is estimated that about 102,000 acres have been detrimentally compacted on the Forest. This is approximately 12 percent of the total acres. This value is expected to rise over the next two to four decades to between 18 and 20 percent under all alternatives. Peak flows were increased approximately 35 percent on a harvested drainage where disturbed areas, including roads, cut slopes, landings, etc., equalled 12 percent of the harvest area (Harr, et al, 1979). This situation may have an indirect cumulative effect on channel stability.

Finally, as more trees are harvested, chances are proportionately greater of removing more topsoil, cutting on colder sites, volatilizing more nitrogen through burning, and in compacting more soils, reducing tree root development. Loss of soil nutrients and organic matter through short rotations and high levels of tree utilization, plus complete slash disposal is another concern. But recent research from the Inland West (Harvey, et al.) concludes that “open grown, short rotation forests (forests with low competition, maximum soil volume per tree, using pioneer or seral species and a potential for understory symbiotic nitrogen fixers), with appropriate vegetation management seems a good biological approach to managing infertile, second growth forests with low organic matter reserves.” “Guiding (our) actions with the use of a reasonable biological perspective represents an opportunity to maintain or even improve harvested sites and their soils as a firm foundation for future forestry.”
Because soil productivity and growth losses from harvest activities may not always occur immediately, the effects of many of our activities must be considered as cumulative. Soil compaction created from harvesting may mean that a future stand to be regenerated in 100 years may need more time to achieve the outputs normally projected for 100 years. This has the potential of offsetting much of the gain to be expected from genetic tree improvement and silvicultural thinning. Alternatives I and C-Modified both have extended rotations on a majority of acres available for intensive timber management and exhibit the least potential for this cumulative, significant effect. Alternatives No Change, A, B-Modified, and E-Departure all have high potential for cumulative effects, because of significantly shorter rotations on a majority of harvestable acres. On the other hand, those alternatives that manage for long rotations commit the Forest to the use of large logging equipment into the future, one of the often unrecognized positive benefits associated with short rotation management is that significantly smaller yarding, skidding, and slash disposal equipment are adequate for log processing.

Mitigation Measures
Management of organic material as a source of future soil productivity is discussed in depth under Effects on Forest Residues, this chapter. In summary, specific levels of residues remaining after activities such as logging, precommercial thinning and slash treatments are prescribed for major forested species types, based on the most recent research available (Harvey, et al, 1987). Continuing research on soil management will be critical for ascertaining additional mitigation measures to be used in future forest management.

Alternatives with the most roads, especially new roads in present unroaded areas, will require the following kinds of mitigation:

- Special efforts should be made to minimize road standards by rolling the grade to conform to the topography, preferably at or near ridge crests and benches to minimize cuts and fills. On steep slopes, end hauling of excavated material will be done to prevent side cast waste which buries downslope vegetation. Eroding cut banks will be mulched, seeded and fertilized. Deep rooted species on cut banks are desired. To prevent loss of soil on cut slopes, stabilization efforts such as rounding off the upper two feet of the bank will prevent ravelling and sloughing of material into the ditch. Frequent culverts with energy dissipators on the outlets will be installed on steeper grades. Road rock should be spread before the wet season. These measures have been found to be very effective over a wide variety of situations on the Forest.

Additional mitigation measures aimed at reducing sediment yield consist of leaving unmerchantable material on the ground and limiting slash disposal to minimum levels needed to meet site preparation and slash disposal needs. Prescribed burning will often have some unavoidable effect on increased sediment if soil hydrophobic conditions occur from extremely hot burns. Much of this impact can be avoided (and is very effective) by burning when soils are moist, usually between May 15 and July 15.

Other forms of mitigation designed to offset effects of soil compaction and associated increased sedimentation follow.

For some soils, maximum compaction occurs at high soil moistures. Field operations can be done at times when soil moisture contents are lowest. Some studies have shown that compaction occurs over a wide range of soil moistures, especially on ash soils. The effectiveness of this measure will vary considerably.

Grass planting can accelerate the drying of a soil. Equipment usage can be restricted to snow pack or frozen ground conditions.

Controlled skid trails can be designated for ground based logging vehicles, including the following skid trail planning measures and considerations:

- Keep trails as narrow as possible (eight feet).
- Use no blades on tractors during skidding.
- Construct trails where possible without blading (the mashed-down brush and reproduction will inhibit compaction and erosion).
- Match machine size to the size of material removed will lessen soil compaction.

- Skidder operators should conscientiously minimize maneuvering that causes wide disturbance areas. Directional felling of trees toward or away from a trail to herringbone patterns helps reduce skidder maneuvering and load pivoting. This reduces the amount of soil compaction and bare soil exposed.

- Limb trees before skidding to decrease the amount of bare soil exposed.

- Season and weather conditions can affect soil and crop tree damage. Wet soils will result in increased root damage from skidding. Terminal shoots are tender and easily broken in June. Logging on snow will reduce root damage but care needs to be taken under freezing conditions to reduce breakage of stems made brittle by low temperatures.

- Machine plant shrubs on road cuts.

- Restoration on rocky soils is almost impossible.

- Mitigations, such as designated controlled skid road spacing of 100 feet, leads to 11 percent of an area in skid trails. Spacing of 150 feet lead to seven percent of an area in skid trail. In combination with haul roads and fuel treatments, 30 percent to 10 percent of an area in skid trails for tractor and cable harvests, respectively, is easily foreseeable.

- Tillage of compacted soils where compaction occurs. This is not feasible on rocky soils, but is very effective on a wide variety of soils and conditions.

- Rely on natural forces such as:

  - Freezing and thawing which tend to increase the porosity of compact soil through imbibition of water in soil pores during periods of freezing temperatures.

  - Shrinking and swelling in clayey soils. A swelling increases porosity while shrinkage causes cracks to open allowing for root penetration and water infiltration. Soils which shrink on drying often form dense layers. An example of such soils is found in the T3, T55, T7, and T8 land types (Paulson, Ochoco Soil Resource Inventory, 1977).

  - Decaying root materials increase soil porosity. Due to compaction occurring as a result of logging and slash disposal equipment, we can summarize some timber harvest mitigation built into the analysis for all alternatives, along with the Best Management Practices:

  - Compaction can be reduced by limiting equipment to designated skid trails during drier seasons of the year, or by use of other methods such as cable logging or nonmechanical slash disposal (burning). Some measures have been built into the planning process by requiring designated skid trails or cable logging and nonmechanical slash disposal on areas managed at or near maximum timber production. On other areas, machine use would be limited to when potential for compaction was in an acceptable level defined as a 15 percent increase in bulk density on 20 percent or less of area on residual soils, and a 20 percent increase in bulk density on 20 percent or less of area on volcanic ash soils. Some areas of existing compaction can be reduced by scarification, but this does not return the soil to original condition.

The following mitigations and Best Management Practices are very effective if proper monitoring and administration occurs:

- Cable logging on slopes greater than 30 percent reduces site disturbance by three times over tractor logging. The result is reduced erosion and displacement. On slopes greater than 30 percent, cable logging should ensure that logs have one-end suspension.

- Dryweather logging creates less damage to productivity than wet weather logging. Restricting activities during periods of high soil moisture has worked quite well on residual soils but will not be effective on ash soils, where traffic path controls should be used. Logging on frozen or snow-covered ground may also be a good opportunity.

- Landings should be kept as small as feasible and tilled, seeded and mulched.

- Contract administration may need to be increased to comply with objectives of Best Management Practices.
- Tillage to break up soil compaction along with water flow diversion and dispersion structures (i.e. waterbars) and seeding should be done to retard erosion.

- Monitor timber growth associated with different timber practices. Monitoring will indicate if practices need to be adjusted or more mitigation added.

- Cooperate with research agencies to install long term studies into this problem. Adopt new research results in revisions of this Plan.

- Maintenance of trails and rehabilitation of damaged areas will help to reduce the negative impacts associated with recreational pursuits, especially Off Road Vehicle use.

All of the mitigation measures/Best Management Practices (BMP's) discussed above are highly effective (90 percent or greater) at preventing or reducing impacts to soil resource values on the Forest. However, the degree and quality of implementation is highly variable, ranging from poor to excellent. Unexpected or unusually severe climatic events, availability of funding and manpower, knowledge and understanding of the BMP's by both operators and administrators, to name but a few, are reasons why many of these BMP's are often only 60 to 80 percent effective.

Conflicts with Other Plans and Policies

The Environmental Protection Agency (EPA) has certified The Oregon Forest Practices Act rules and regulations as best management practices (BMP's). The State of Oregon has compared Forest Service practices with these state practices and concluded that Forest Service practices meet or exceed state requirements. As state practices change, comparisons are made to ascertain whether Forest Service practices meet or exceed these changes. Monitoring and evaluation will determine the need for changes in BMP's and/or state standards. Local soil conservation groups, the irrigation district and the BLM have been actively informed, during the planning process, on matters potentially affecting their programs and have had the opportunity to submit into the Final Plan. There are no expected conflicts with other agencies' plans or policies.
Timber

Timber is a major component of the affected environment in central Oregon. Alternatives for management of the Ochoco National Forest will have significant effects on current and future inventories and growth of timber for existing and future generations of users (direct effects). Even though in the technical sense these are not in themselves environmental effects, local concern for current and future supplies of timber constitutes a need to disclose adjustments in timber harvest scheduling as an "environmental consequence."

Harvest activities associated with these alternatives will also affect the structure and species composition of timber stands in the future. In turn, timber harvest and related activities (including thinning, planting, slash treatment, and other cultural treatments) have significant effects on nearly all other components of the environment (indirect effects). Alternatives No Change, B-Modified, E-Departure, I, A, and C-Modified provide significantly different levels of timber production from the Ochoco National Forest (see Chapter 2). Increases or decreases from current programmed harvest levels can have significant and cumulative effects on both the socio-economic setting in central Oregon and on long-term productivity of timber and other forest resources.

Direct effects of the alternatives on timber are provided in detail in this section. Discussions revolve primarily around public issues, concerns and opportunities (ICO's) developed during early stages of the environmental analysis process. In summary these ICO's include:

Sustained Yield/Even-Flow and Departure;
Timber Supply and Allowable Sale Quantity (ASQ);
Uneven-aged Management; and
Ponderosa Pine Supply and Tree Size.

The indirect and possibly cumulative effects associated with timber include the long term changes that will occur to the "managed forest," as well as those on other environmental components. These other components or resources are only briefly described in this section, with extensive use of cross-referencing to other discussions on effects where more detailed information can be found. Soils, Water (including riparian), Biological Diversity, Fuelwood, Old Growth, and Socio-Economic are important environmental components that are significantly affected by timber harvest and related activities.

Direct Effects

Productive timber stands that are removed from intensive management (or scheduled for reduced intensity) to meet other resource objectives reduce the supply of harvestable timber, and therefore the long term sustained yield and ASQ. There are approximately 572 thousand acres of "forested land" on the Ochoco National Forest (see Chapter 3). Approximately 39.4 thousand acres have been withdrawn from consideration for timber production due to legislation, suitability, and regeneration difficulty, leaving a net of about 533 thousand acres as tentatively suitable. The six alternatives described in Chapter 2 allocate lands to various resource emphases (e.g. unroaded recreation, wildlife, riparian). Depending on the emphasis, intensities of timber production are adjusted down, which again reduces the long term sustained yield and ASQ from the Forest. Table 2-8, Chapter 2, displays long term sustained yield, ASQ, and other data relevant to understanding effects of the different alternatives on timber as an environmental component.

Growth and inventory of forest stands is measured in units of cubic foot volume because it is independent of numerous product requirements occurring
within a locale, region, or the nation as a whole. Board foot volume measurement varies with size of trees and is designed for certain product specifications and current technology. Young stands that have been regenerated cannot be measured in board foot or equivalent units of measurement, attempting to do so would underestimate the biological potential of timber producing lands and make future growth projections impossible. It is presently Forest Service Policy (FSM 1922.15) to use cubic foot volume as a measurement of long-term sustained yield, as well to regulate the amount of timber to be offered and sold as specified by the allowable timber sale quantity (ASQ), in order to respond to changing technology and product requirements projected for the future (RPA, '85).

Departures from the ASQ (in cubic feet) are allowed under certain circumstances (36 CFR 219.16), including those where implementation of the normal base sale schedule would cause a substantial adverse impact upon a community in the economic area in which a forest is located. By definition, departure requires a future decrease in the timber sale and harvest schedule to bring the ASQ in line with long-term sustained yield. Harvest levels are monitored and adjusted every ten years to insure that long-term sustained yield is not reduced. See Appendix B, Section 7 for further discussions on timber harvest projections. See Chapter 2 for discussions on “potential yield” of timber.

Local wood manufacturing facilities are currently tooled to process large diameter timber, even though some conversion to small log manufacturing has begun. Ponderosa pine is the species favored for local mills, and both primary and secondary manufacturing facilities are currently dependent on large pine (see Effects on Social and Economic, this chapter). Large, old growth ponderosa pine is a finite resource. Extremely long rotations or cutting cycles are required to grow the size and quality of wood favored by local industry and it is projected that current harvest levels of large, tight-grained ponderosa pine are not biologically sustainable for more than a few decades, especially within management requirements established for the Forest. Specific cultural techniques are available to simulate, as near as possible, both size and quality desired (see Mitigation Measures), but harvest reduction (from current levels) of large diameter pine is inevitable. This species (ponderosa pine) is also desirable for other reasons (including aesthetic), and conservation of old growth ponderosa for future generations is a public concern from both industrial and environmental perspectives (see Effects on Scenic Resources, this chapter). There will be a reduction in size and quality of timber produced with all alternatives. Large trees (18 inches in diameter or larger) are necessary for quality wood production with current technology. The alternatives presented in Chapter 2 provide varying levels of current and future quality wood, these levels are primarily a function of lands available for timber production, as well as extended rotations (or cutting cycles) designed to provide size and quality attributes.

Silvicultural systems (even- versus uneven-aged management) used on the Forest (especially ponderosa pine) affect future stand structure and species composition, forest health, harvest systems, slash disposal, productivity, forest succession, and numerous other factors associated with timber production. Silvicultural systems also affect public acceptance (or lack thereof) of intensive timber management on the Forest. Even-aged management (especially clearcutting) has been increasing on the forest over the last decade for numerous reasons (see Appendix E, Selection of Harvest Cutting Methods). Public concern has been instrumental in development of alternatives which include extensive use of uneven-aged management in stands biologically and logistically suitable.

Effects by Alternative

**Alternative No Change**

Alternative No Change provides the largest number of acres suitable for timber production (534 thousand acres), but has not been adjusted to reflect requirements of the National Forest Management Act of 1976. For this reason it is not directly comparable to the remaining alternatives, but instead provides a perspective for publics interested in pre-NFMA timber management on the Ochoco National Forest.
**Alternative B-Modified**

Alternative B-Modified allocates approximately 511 thousand acres of lands to some level of timber production (largest of remaining comparable alternatives). Intensity of timber management activities varies as follows:

- 484,000 acres - Full Yield
- 26,800 acres - 50 to 99 percent of Full Yield
- 0 acres - 1 to 49 percent of Full Yield

Alternative B-Modified also produces the highest timber outputs including long term sustained yield, ASQ, and board feet volume in pine for the first decade. This alternative also uses uneven-aged management as a primary silvicultural system on about 67.5 thousand acres during the first decade, second only to Alternative C-Modified. Additional use of uneven-aged management for this alternative was limited because of timber yield falldowns projected through the analysis process (see Appendix B).

This alternative will provide the most quality timber volume over 18 inches. This is because of the high harvest level and the inclusion of uneven-aged management with a target diameter of 20 inches. It has less volume over 24 inches than does "I" because it has much fewer acres in visual, and management for unique features where the objective is to produce trees larger than 24 inches.

**Alternative E-Departure**

Alternative E-Departure allocates approximately 495 thousand acres to some level of timber production. Intensity of timber management activities varies as follows:

- 0 acres - Full Yield
- 495,000 acres - 50 to 99 percent of Full Yield
- 1,800 acres - 1 to 49 percent of Full Yield

As a departure alternative, E-Departure produces timber outputs that decline from 20.6 million cubic feet per year in the first decade, to 19.7 million in the second decade, to 16.1 in the fifth decade, while maintaining a long term sustained yield of 19.3 million cubic feet. Production of ponderosa pine in the first decade is about 87 million board feet per year.

Alternative E-Departure uses uneven-aged management as a primary silvicultural system on only about four thousand acres, limited mainly to high visibility recreation areas.

This alternative produces the lowest volume of large, quality material. This is partly due to the low harvest level in the fifth decade, but more important is that this alternative emphasizes economic efficiency (Present Net Value [PNVI]) and all stands are harvested to maximize economic return which usually results in harvest before stands reach 18 inches in diameter. There is very little uneven-aged management planned in this alternative, and the only large material produced will be in areas planned for long rotations (recreation or other resource emphasis).

**Alternative I (Preferred)**

Alternative I allocates approximately 493.7 thousand acres of lands to some level of timber production (not significantly different than E-Departure). Intensity of timber management activities varies as follows:

- 0 acres - Full Yield
- 491,900 acres - 50 to 99 percent of Full Yield
- 1,800 acres - 1 to 49 percent of Full Yield

Alternative I maintains timber harvest (ASQ) at long term sustained yield levels of 19.0 million cubic feet per year. Production of ponderosa pine in the first decade is about 85 million board feet per year. This alternative uses uneven-aged management as a primary silvicultural system on about 62.2 thousand acres during the first decade, differing from Alternative B-Modified through use of longer cutting cycles in high visibility recreation areas, where larger diameter trees are desired.

This alternative produces the most volume in quality trees over 24 inches in diameter. This is because of the large acreage in visual and other management areas with emphasis on producing large trees, plus the emphasis on large trees in the General Forest Management Area. It is second to Alternative B-Modified in total volume in trees over 18 inches in diameter.
Alternative A

Alternative A reflects current direction and allocates approximately 488.6 thousand acres of lands to some level of timber production. Intensity of timber management activities varies as follows:

- Full Yield
  - 0 acres
  - 488,600 acres
- 50 to 99 percent of Full Yield
  - 0 acres
- 1 to 49 percent of Full Yield
  - 488,600 acres

Alternative A provides a timber harvest (ASQ) of 19.3 million cubic feet per year, or .2 million cubic feet per year below a long term sustained yield of 19.5 million cubic feet per year. About 90 million board feet per year of ponderosa pine is provided in the first decade. Only about 900 acres of uneven-aged management are used as a primary silvicultural system on the Forest, limited to campgrounds and other intensively used recreation facilities.

This alternative is third (between I and C-Modified) in terms of amount of large material available. Much of the large material would be from old growth areas, which in this alternative are managed on a rotating basis with long rotations. There is no emphasis on large material in this alternative.

Alternative C-Modified

Alternative C-Modified allocates 471.4 thousand acres of lands to some level of timber production (smallest acreage of all alternatives). Intensity of timber management activities varies as follows:

- Full Yield
  - 0 acres
  - 471,400 acres
- 50 to 99 percent of Full Yield
  - 0 acres
- 1 to 49 percent of Full Yield
  - 471,400 acres

Alternative C-Modified provides a timber harvest (ASQ) of 15.6 million cubic feet per year, equivalent to the long term sustained yield for this alternative. About 65 million board feet of ponderosa pine is provided during the first decade. Extensive use of uneven-aged management across the Forest is provided on about 96,400 acres during the first decade; cutting cycles vary significantly in order to provide large diameter trees in most visual corridors and other recreation use areas.

This alternative is next to last in terms of total large material produced. This is due mostly to the low total harvest level.

The expected harvest volume in the fifth decade by size class and alternative is shown in Table 4-29. This is also a close approximation of sizes to expect after the fifth decade and illustrates estimates of future availability of quality wood (greater than 18 inches in diameter).

Indirect Effects

Future Timber Stand Structure, Species Composition, and Size Class Diversity

The rate at which timber is harvested (particularly mature and overmature timber), plus the level of

MMCF - Million Cubic Feet
management intensity, has significant effects on future stand structure, distribution of size/age classes, species composition, productivity, and ultimately future harvest levels on the Ochoco National Forest. In those areas of the Forest allocated for long term production of timber, it is an objective to establish a "regulated forest" in which there are reasonable assurances of a "sustained yield" of timber products over the long term. Economic and administrative reasons are the basis for this objective; as long as the forest is well protected and cared for, it makes little difference biologically whether or not it is in a regulated condition (Davis, 1966). But both overcutting and undercutting of timber under a planned regulatory condition can create future deficits of both size and volume because such cutting controls the rate of new stand formation through regeneration. A regulated forest can be maintained with either even- or uneven-aged management (or a mix of the two).

The "regulated" Ochoco National Forest of the future will contain a variety of size classes and species of timber. Modeling techniques are not currently available to portray an accurate description of the forest by alternative, but estimates of future successional stages (found in Table 2-8, Chapter 2) provide some insight into the future forest. As can be seen, both young age classes (Stage I and II) and old growth age classes (Stage VI) will comprise the lowest percentage of total forested acres in future decades for all alternatives (except No Change for which data is unavailable). Stages III through V reflect timber stands in which sites are fully occupied and timber stands are growing at near maximum rates (assuming proper stand management). These stages comprise the largest percentage of total growing stock for all alternatives in future decades. Alternatives B-Modified, I and C-Modified may exhibit higher levels of diversity of stand structure due to a mix of both even- and uneven-aged management, but may also have higher percentages of white fir and Douglas-fir in younger age classes and growing stock due to successional pressure afforded through uneven-aged management. Alternatives E-Departure and A will probably exhibit lower levels of structural diversity due to even-aged management and associated harvest levels, but species composition of even-aged, younger stands (and future growingstock) will be primarily early successional species such as ponderosa pine, western larch and lodgepole pine.

Indirect Effects on Other Environmental Components

The volume of timber harvested today has significant effects on the economic structure and social fabric of the local community. Timber provides jobs both directly (through local timber manufacturing) and indirectly (through secondary support industries and services). These effects are also cumulative in that timber produced on the Forest is used in other communities within an area referred to as the "Extended Area Of Influence." Future timber supplies will affect the ability of primary manufacturers of timber products to compete in a market plagued with uncertainties, as well as the ability of local communities to finance local school and transportation systems. See Effects on Social and Economic, this chapter for analysis of timber harvest and other Forest resources on local communities.

Timber harvest affects almost all other environmental components existing on the Forest, some positively and some negatively. Timber harvest reduces old growth as a unique and dwindling resource on the Forest and in the nation as a whole. Timber harvest also changes (but not necessarily reduces) "biological diversity" of both plants and animals existing on the Forest. Effects on these two environmental components (old growth and biological diversity) can be cumulative; effects are discussed in detail in the relevant sections of this chapter (see Effects on Old Growth and Biological Diversity). Also see Effects on Soils, Water, Wildlife and Fish, Scenic Resources, Recreation, Air Quality, Cultural Resources, Forest Health, and Forest Residues.

Cumulative Effects

Cumulative effects of timber harvest on other environmental components are discussed under those relevant headings mentioned above (under indirect effects). In summary, the cumulative effects of the alternatives on timber relate primarily to social and economic issues and are discussed in detail under
Social and Economic Effects, this chapter. The cumulative effects on timber per se are reflected in projections of productivity and composition of future stands, which has been captured in calculations of current and future volume available for harvest (i.e. long term sustained yield and ASQ). It is assumed that application of proper silvicultural systems, including specific cultural treatments such as thinning and planting with genetically improved seedlings will increase future productivity of forest stands, and credit for this future productivity (Earned Harvest Effect [EHE]) is incorporated into harvest calculations for the various alternatives (see Appendix B, Description of the Analysis Process). Table 4-16 displays approximate adjustments to annual timber sale program quantities due to earned harvest effects for the various alternatives. It is presented in millions of board feet (rather than cubic feet) for clearer understanding by local concerned publics. These values have already been incorporated into ASQ and Timber Sale Program Quantity outputs displayed in Table 2-8, Chapter 2. Also see Socio-Economic Cumulative Effects, this chapter.

Mitigation Measures

Additional intensive timber management practices that result in future increases in productivity may be initiated during plan implementation, depending on staffing and budget levels on the Forest. Adjustments to the allowable sale quantity (ASQ) can be made as added earned harvest effects (Regional Policy 36 RF 219.13) as these practices are completed for some of the alternatives. These would be in addition to the earned harvest effect already incorporated into the alternatives, as discussed in Cumulative Effects, above. Table 4-31 displays approximate added earned harvest effects potentially available for each of the alternatives (in million board feet).

* Alternatives B MOD and A already include all potential earned harvest effects
** Earned harvest effect would vary each decade in order to reduce the decline of harvest over time (resulting from departure status)

Long-term management of timber stands which have an objective of maintaining high levels of wood production require careful scheduling and monitoring of silvicultural treatments, especially on “poor” sites, where delays of activities (such as precommercial and commercial thinning) may predispose stands to attacks by forest insects and disease. Fluctuations in forest staffing levels inhibit the agency (at times) from efficiently managing timber stands. All of the alternatives assume that some base level of organization is available to prepare and administer silvicultural activities. Increased budgets for monitoring and preparation of these activities have potential for increasing future productivity of timber stands, and therefore the supply of available timber for possible harvest.

Production of quality wood from second growth stands of timber will require skills and knowledge not yet fully available. The Ochoco National Forest has entered into administrative studies and has requested assistance from the Pacific Northwest Research Station to provide research on production of quality wood from ponderosa pine. This has substantial potential for mitigating the loss of future supplies of high quality wood for local manufacturing facilities. Standards and guidelines (Appendix D) have been developed to emphasize conservation
and production of quality ponderosa pine during timber sale preparation activities. Marking guides are to provide instructions for retention of high quality timber (when conditions are biologically suited), especially in uneven-aged management prescriptions. Allowances have been made for pruning, where it can be shown to be efficient and cost effective to do so. If pruning is done on a large scale, it should provide about the same percent of the volume in grade 3 or better as is provided today, about 15 percent. But the Forest will not provide the large 36-inch and greater fine grained material as is currently produced. If pruning is not done, it is estimated that less than five percent of the volume would be in grades 3 or better.

Conflicts with Other Plans and Policies
Alternatives I (Preferred), B-Modified, A and E-Departure will all meet the Oregon Department of Forestry timber goals for the Ochoco National Forest (see Conflicts with Other Federal, Regional, State and Local Plans, Including Indian Reservation Plans, this chapter).

Transportation

Effects on the transportation system from the implementation of land management alternatives are described in this chapter. A multitude of direct, indirect, and cumulative effects on various resources are associated with roads; these are discussed at length under respective environmental components in this chapter. Once constructed, the road system itself becomes a resource that alternative implementation affects. Significant interactions and their associated effects in this discussion are limited to those that affect the road system itself and its management.

The assumptions important to the following discussion are:
- The greatest potential for public use of roads would exist in the alternatives with the greatest mileage in the completed system. However, the mileage varies depending on the extent to which roads are closed or are not available for use by passenger cars due to design and maintenance levels.
- Road management objectives identify the need to close roads, and allow maximum public use of the road system consistent with resource protection, safety, and budgetary constraints.
- Arterial roads provide access to large areas and comprise the basic access network. Collector roads serve smaller areas and are usually connected to arterial roads. Local roads provide access to site specific areas and are constructed to serve a dominant use or resource.

Direct Effects
The activities that most affect the transportation system are road construction and road closure.

Road Construction
The majority of the arterial and collector road system is already established. Further construction of arterial or collector roads would be to provide access to unroaded areas, or to upgrade existing local roads to provide a safer and more efficient transportation system. The amount of arterial or collector road construction ranges from four miles under Alternatives E-Departure and C-Modified to 14 miles under Alternative B-Modified in the first decade.

Construction of additional local roads will account for the majority of the road construction. These roads are lower standard and intended for use by high clearance vehicles. They are primarily constructed to facilitate timber harvest. Some local roads which are unsafe, are causing resource damage due to poor location, or are poorly suited to current logging methods, will be replaced. All alternatives require new local road construction. The amount of
the construction reflects the number of acres harvested. Initial entry into an area for timber harvest generates the most local road construction.

Management of big game and other wildlife habitat affects the timing of road construction by affecting the scheduling and distribution of timber harvest. Delayed harvest of forest stands managed on long rotations to provide big game cover delay local road construction as well.

Road Management
Road closures on the Forest are yearlong or seasonal. Closures and restrictions are used to protect resources (soil and water), the investment, and safety of expected users. Closures would increase over the planning period for all alternatives. Seasonal closures are employed to maintain or improve habitat for big game. The number of closures in this category is directly related to the acreage allocated to big game management.

The Ochoco National Forest has a road closure program called the Green Dot System. This system is a result of a joint agreement with the Oregon State Department of Fish and Wildlife and the U.S.D.A. Forest Service under which National Forest roads may be closed in designated areas during big game hunting season. The purpose of the program is to enhance escape habitat and to improve hunt quality. A reflective green dot on a signpost is being used to identify open roads for hunters. Areas closed under this program are assumed to continue for all alternatives.

Effects by Alternatives
New system mileage and total miles needed for all alternatives are displayed in Table 4-32.

All alternatives show a substantial decrease in the annual rate of construction after the third decade, reflecting the decrease in first-entry harvest acres. The miles of roads open to passenger cars and high clearance vehicles by alternative is displayed in Table 2-8 in Chapter 2. The following alternative discussions do not include short-term road closures due to implementation of the Green Dot System.

Alternative B-Modified
During the first decade, approximately 246 miles will be added to the system. Ultimately, 931 miles will be constructed through the fifth decade. This amounts to 83 percent (1,122 miles) of the long-

The total mileage figures are for the completed system which occurs beyond the fifth decade. The total includes existing road mileage needed for management and approximate reductions due to the obliteration of unsafe or unneeded local roads.

4-76
term road construction needs. During the first decade, approximately 904 miles of road reconstruction will be required to serve user needs and resource management objectives.

During the first decade, there will be approximately 413 additional miles of seasonal and permanent road closures (see Chapter 3). Ultimately, through the fifth decade, 1,623 additional miles over the present time will be closed.

**Alternative E-Departure**

During the first decade, approximately 222 miles will be added to the system. Ultimately, 699 miles will be constructed through the fifth decade. This amounts to 91 percent (770 miles) of the long-term road construction needs. During the first decade, approximately 887 miles of road reconstruction will be required to serve user needs and resource management objectives.

During the first decade, there will be approximately 390 additional miles of seasonal and permanent road closures. Ultimately, through the fifth decade, 1,582 additional miles over the present will be closed (see Chapter 3).

**Alternative I (Preferred)**

During the first decade, approximately 179 miles will be added to the system. Ultimately, 750 miles will be constructed through the fifth decade. This amounts to 81 percent (924 miles) of the long-term road construction needs. During the first decade, approximately 878 miles of road reconstruction will be required to serve user needs and resource management objectives (see Chapter 3).

During the first decade, there will be approximately 1,058 additional miles of seasonal and permanent road closures. Ultimately, through the fifth decade, 1,685 additional miles over the present will be closed.

**Alternative A and Alternative No Change**

During the first decade, approximately 220 miles will be added to the system. Ultimately, 772 miles will be constructed through the fifth decade. This amounts to 94 percent (819 miles) of the long-term road construction needs. During the first decade, approximately 790 miles of road reconstruction will be required to serve user needs and resource management objectives.

During the first decade, there will be approximately 194 additional miles of seasonal and permanent road closures. Ultimately, through the fifth decade, 1,234 additional miles over the present will be closed (see Chapter 3).

**Alternative C-Modified**

During the first decade, approximately 189 miles will be added to the system. Ultimately, 633 miles will be constructed through the fifth decade. This amounts to 69 percent of the long-term (921 miles) road construction needs. During the first decade, approximately 887 miles of road reconstruction will be required to serve user needs and resource management objectives.

During the first decade, there will be approximately 1,020 additional miles of seasonal and permanent road closures. Ultimately, through the fifth decade, 2,724 additional miles over the present will be closed (see Chapter 3).

**Indirect Effects**

For all alternatives, the indirect effects are primarily those related to road maintenance. While these effects are essentially the same by alternative, they vary by the amount of construction, reconstruction, and the total system at the specific point in time. All system roads will be maintained to at least the basic custodial care required to maintain drainage, protect the road investment, and minimize damage to adjacent land and resources. This level is the normal prescription for roads that are closed to traffic. Higher levels of maintenance may be chosen to reflect greater use or for resource protection.

Roads normally deteriorate due to use and weather impacts. Livestock may cause damage to road cut and fill slopes. Timber management practices such as clearcutting increase water runoff, the increased runoff can result in the need for more extensive road drainage systems. This deterioration can be reduced through adequate maintenance or restriction of use. All alternatives have land allocations which attract vehicle use on existing roads, resulting in the need for recurring maintenance.
When excessive traffic wear resulting from deferred maintenance or storm damage has occurred, reconstruction may be required to provide a suitable facility.

User safety is an additional indirect effect. Regardless of maintenance levels, safety can be jeopardized by the volume and mix of traffic on certain roads.

Cumulative Effects
No significant adverse cumulative effects are expected to occur to the transportation system. Forest-wide standards and guidelines (Appendix D), as they apply to location, design, operation, and maintenance of the transportation system, assure that the road system will accommodate its intended use over time.

Cumulative effects of the transportation system on other resources (indirect), such as water, wildlife and soil, are possible and are discussed in detail under those respective headings of this chapter.

Mitigation Measures
The construction, reconstruction, maintenance, and management of Forest roads utilize many mitigation measures that derive from engineering requirements. Cost of mitigation measures to improve open roads for public use and measures necessary for resource protection are incorporated in all alternatives. The following activities are some of the measures taken to mitigate impacts:

- Outsloping road surfaces and adding culverts on ditched roads to keep water from concentrating.
- Rocking waterbars and drain dips to reduce erosion where water leaves the road.
- Diverting water onto undisturbed ground where sediment can be filtered out.
- Adding riprap at culvert outlets to stop erosion.
- Surfacing road travelways to reduce rutting and permit their use for log and firewood hauling when wet.
- Seeding cut and fill slopes, waste areas, debris burial sites, and unsurfaced roads to reduce erosion.
- Draining spring areas adjacent to roads to protect investment and accommodate permitted uses.
- Minimizing undercutting of cut slopes during ditch cleaning operations to reduce exposing bare soil.
- Reducing overall width of roads by designing travelways, turnouts and curve widening for only the projected use.
- Obliterating local roads no longer needed for management purposes and returning the land to productivity. Obliteration will temporarily increase soil movement but benefit soil and water resources by reducing erosion and sedimentation over the long term.
- Removing culverts likely to be blocked during periods of long-term nonuse (yearlong closures) to mitigate soil and water impacts and investment loss. A short-term consequence on the water quality will occur when replacing the culverts during later entries.

The cost of many of these measures increases as roading and timber harvest occur on steep slopes and sensitive soils.

Prohibiting noncommercial traffic on weekdays and commercial traffic on weekends, gating and signing during commercial operations and rescheduling some outputs to other areas to minimize traffic are examples of traffic management techniques which can be effectively used to mitigate safety conflicts between commercial and recreational uses and eliminate the need for reconstruction.

Restrictions on use of the Forest's road system can have a strong influence on the public's perception of the Forest's management. Increasing public understanding of the selected road management strategy will increase acceptance and avert potential conflicts. Information may be posted on signs in the Forest and/or on visitor maps.

Additional mitigation measures can be found in Appendix D, this FEIS.
Conflicts with Other Plans and Policies
No conflict is seen with other plans and policies regarding the transportation system. The Forest cooperates with State, County and other Federal agencies in meeting transportation objectives. Rights-of-way and easements across Forest land for roads are granted to individuals, companies, and government agencies, subject to need and environmental restrictions.

The Forest may also negotiate with the counties to acquire jurisdiction on county roads where the proportion of Forest Service-related traffic is high. The jurisdiction will allow the Forest Service to have full responsibility for traffic operations and maintenance.

Unroaded Areas
This section discusses the effects on those unroaded areas inventoried for potential wilderness during the Congressionally mandated Roadless Area Reviews and Evaluations (RARE I and RARE II). The Oregon Wilderness Act of 1984 considered these same inventoried areas, designating three areas Wilderness, one area as “further study” and released the remaining areas for management to be determined by the Forest Plan. The effects of different management strategies on each of the unroaded areas vary by alternatives, with the exception of the Broadway area in which vegetative manipulation has occurred. Further analysis of the unroaded areas does not include the Broadway area. Those alternatives aimed at vegetative manipulation and roading eliminate future management as unroaded areas, and forgo future options of these areas being designated as Wilderness. Those alternatives that maintain undeveloped conditions provide options for evaluating Wilderness values in future planning efforts.

Direct Effects
A detailed description and analysis of the effects of the alternatives on individual unroaded areas is contained in Appendix C, Roadless Area Evaluation.

Table 4-33 displays the different management strategies for each unroaded area by alternative. Seven options are considered for the future management of the six unroaded areas.

1. SPNM - Maintain the area’s unroaded character for semiprimitive, nonmotorized recreation.
2. SPM - Maintain the area’s unroaded character for semiprimitive, motorized recreation.
3. W - Recommend the area, or portion thereof, for inclusion in the wilderness system.
4. BG - Manage the area to meet big-game habitat objectives. This would include some timber harvest and related road construction to create proper cover/forage ratios and improve the habitat for big game species.
5. G/F - Develop the area for timber/forage production and construct the transportation system that will facilitate the area’s future management.
6. RNA - Protect the area for research purposes as a Research Natural Area.
7. WS - Manage the area consistent with Wild and Scenic River designation.

4-80
Direct Effects Common to All Alternatives
The major direct effect of developmental activities in unroaded areas is the reduction of the total area available for unroaded activities. Another consequence of management activities is the reduction of a particular quality associated with a specific unroaded area. Most of the unroaded areas on the Ochoco National Forest have common characteristics; they provide semiprimitive motorized and nonmotorized recreation experiences, add to the overall scenic quality of the Forest, and provide relatively large areas of secure habitat for many wildlife species. Vegetation and plant community types are similar. The exception to this is Deschutes Canyon, which is located at lower elevations in the high desert, and contains large areas of grass and shrub dominated plant communities.

Alternative A and Alternative No Change
Timber harvest roads and other vegetative manipulation activities would reduce the unroaded acreage to 28,450 acres. Lookout Mountain, Deschutes Canyon, and a portion of Silver Creek would be managed under an unroaded prescription. The qualities associated with Cottonwood, Rock Creek, and Green Mountain would be reduced or eliminated as they would be developed and managed for big game production; entry and development into these areas will likely occur in the first and second decade. Individuals desiring a semiprimitive, nonmotorized recreation experience would use the remaining unroaded areas or wilderness areas on or outside the Forest.

Alternative B-Modified
The lower 8,110 acres of Lookout Mountain, all of Cottonwood, Rock Creek, Green Mountain and half of Silver Creek would be allocated to a timber/forage emphasis; development for these purposes would occur at a rapid rate, probably within the first decade. A portion of Deschutes Canyon, Silver Creek, and the upper 7,550 acres of Lookout Mountain will remain unroaded, a total of 15,750 acres.

Alternative C-Modified
This alternative would maintain a relatively large acreage (46,500 acres) in an unroaded, semiprimitive condition. In addition, Deschutes Canyon/Steelhead Falls Wilderness Study Area (9,350 acres) would be recommended as wilderness. The remaining portions of Cottonwood (40 acres), Rock Creek (2,080 acres), and Silver Creek (3,390 acres) would be developed and managed with a big game emphasis. Development of these areas would begin immediately upon selection of a preferred alternative and approval of the Plan. This alternative would have very little negative impact on individuals currently using the existing unroaded areas.

Alternatives E-Departure
This alternative would reduce the total Forest unroaded area by 24,800 acres. Cottonwood, most of Rock Creek, a portion of Silver Creek, and a small portion of Lookout Mountain would be retained as unroaded with a semiprimitive, nonmotorized emphasis, for a total of 27,315 acres. In addition, 2,500 acres of Deschutes Canyon would be recommended for wilderness. A portion of Silver Creek (845 acres) would be managed as a Research Natural Area; the Green Mountain area (7,000 acres) would be managed for semiprimitive, motorized recreation. Very little displacement of users would occur as a result of this alternative because the qualities of each unroaded area are retained in a semiprimitive condition. Lookout Mountain would be most affected because it is becoming increasingly popular for primitive hunting experiences, hiking, horseback riding, cross-country skiing, snowmobiling, and mountain biking. Areas allocated for purposes of development would probably be entered in the first decade.

Alternative I (Preferred)
This alternative would retain 7,550 of Lookout Mountain, 3,110 acres of Silver Creek, and 11,820 acres of Rock Creek/Cottonwood Creek as unroaded. In addition, 5,140 acres of the Deschutes Canyon/Steelhead Fall Wilderness Study Area would be allocated to Squaw Creek, a 7,840 acre Squaw Creek Management Area for SPNM recreation opportunities. A total of 35,460 acres would be maintained as unroaded. The lower Rock Creek/Cottonwood areas
would be affected by helicopter logging. The effects of harvest preclude this area from semiprimitive recreation opportunities; timber harvest would dominate the landscape. Portions of the upper Rock Creek/Cottonwood Creek Area (56,250 acres) would be harvested by conventional methods. Roads would be constructed; skyline and tractor skidding would dominate the landscape. These areas would not be available for unroaded recreation and this precludes future options for wilderness designation. The potential to disturb sensitive soils and have negative impacts on the anadromous fisheries of Rock Creek/Cottonwood Creek would be increased. Development in these areas would probably occur during the first decade.

In summary, Table 4-34 displays the total acres remaining unroaded at the end of the first, second and fifth decades. It can be assumed that entry into all of the areas reallocated to development will occur at a relatively rapid rate, probably during the first decade. The exception to this is Lookout Mountain (Alternative I only); any development to the lower section will occur at a slower rate conducive to management area objectives, in cooperation with major user groups and in coordination with the Pacific Northwest Experiment Station.

Indirect Effects
The effect of maintaining unroaded areas restricts activities such as road building, timber harvest, and summer motorized recreation. Without vegetative manipulation, including timber harvest, these areas would eventually reach climax successional conditions. Natural fuels will build up increasing the risk and severity of fires. The unmanaged timber stands will not have the vigor of managed stands, increasing susceptibility to insects and disease. Even though mining activities are not excluded from unroaded areas, the location and development of the minerals resource is hindered by lack of access and the added expense of special operation requirements. The indirect effect on the economy is discussed in the Recreation section of this chapter. Alternative C-Modified, which maintains the most unroaded areas, would affect these activities the most; Alternative B-Modified would open the majority of the unroaded areas to development and have the least effect.

Alternatively, retention of unroaded areas has a positive effect on maintaining the old growth habitat for a variety of wildlife species, protecting watershed and soils resources, and providing natural scenery. These unroaded areas provide for security of big game as well as challenging hunting and viewing opportunities. Trophy game animals are associated with these areas. Alternatives C-Modified and I provide the greatest positive effect on these resources.

Cumulative Effects
Each time an unroaded area is developed on the Ochoco National Forest there is a cumulative impact, this action contributes to an overall reduction in unroaded acres from the local, regional or national perspective. It not only affects unroaded areas in terms of the amount of semiprimitive environment available, but also affects wilderness and unroaded use throughout the region. These effects result in shifts in either current or future demand for this resource to alternate areas that may create crowding. Even though unroaded and wilderness areas may provide two different kinds of experience for users, there is a common denominator; the environment is in a natural state, unaltered by human activities. Future options also remain open when unroaded areas remain unroaded.

Cumulatively, the reductions in unroaded areas would be greatest in Alternative B-Modified, followed by Alternatives No Change, A, E-Departure, I and C-Modified.

Mitigation Measures
Trail system management in remaining unroaded areas can increase the total carrying capacity by redistributing visitor use. This increase in use is brought about by opening areas that were not previously accessible. This measure has only limited value; eventually the total carrying capacity can be exceeded.
Limited unscheduled timber harvest is planned in the lower portions of Lookout Mountain to improve timber stand conditions for recreational purposes. The low-standard roads that may be needed to complete these projects will be closed to summer motorized use and can be narrowed to provide access for horseback riding, hiking, and mountain biking.

Fire implementation plans and projects may be developed to lessen the potential wildfire effects, while creating some diversity within the areas.

Access for mining will be limited to that necessary for the current stage of development. It will be designed to fit into the land with as little impact as possible to the unroaded character of the area. Mining activity must be justified by an economic analysis based on potential quality and quantity of the material being mined.

The only mitigation for the loss of unroaded areas is not to schedule roads or timber harvest in those areas. Alternative I mitigates development within the Rock Creek/Cottonwood areas by maintaining some of the area as unroaded and by utilizing helicopter logging. Trail systems developed through these areas will need to be protected and possibly relocated to offer viable recreation opportunities into the remaining unroaded areas.

Conflicts with Other Plans and Policies

The Jefferson County Comprehensive Plan does not support the creation of additional Wilderness within the bounds of Jefferson County. Consequently, a conflict occurs with Alternatives C-Modified and E-Departure, which allow for wilderness recommendation for all or portions of the Deschutes Canyon/Steelhead Falls Area. No other conflicts arise with any of the proposed management strategies for the unroaded areas of the Ochoco National Forest.

Water

This section includes Riparian Areas, Wetlands and Floodplains.

The condition of riparian areas, wetlands and floodplains on the Forest reflects in large measure the condition of the whole watershed where they exist, from Class IV tributary headwaters to Class I main drainages. Water quality, quantity, and timing of runoff in this system are the product of the interaction of soils, vegetation, climate and management activities that affect each watershed. Nowhere within a watershed are management activities and the water resource more closely related than in riparian areas.

Direct Effects

Timber management, the transportation system, livestock grazing, and fire may all result in significant consequences to the water resource.

Water Quality

Timber

Timber management activities, including timber harvest, slash treatments, and site preparation, affect the water resource through the alteration or destruction of vegetation, the compaction or disturbance of mineral soil (see Effects on Soils, this chapter), and changes in sediment yield and tem-
perature (Fredriksen and Harr, 1979, Hewlett and Doss, 1984). The potential for impact becomes greater on steeper slopes or on more erosive soils. Removal of streamside vegetation has a direct effect on water temperature with potential for increased temperatures during summer months (Brown and Krygier, 1967), and for lower temperatures in winter. Increased ice formation can result in stream bank damage (Chamberlin, 1982; Swanson, 1980). Increased water temperatures also reduce the amount of oxygen that can be dissolved in water (Ruttner, 1963). At higher temperatures the more rapid decomposition of organic debris (needles, leaves, branches) in streams may reduce dissolved oxygen below critical levels for fish (Berry, 1975). Higher stream temperatures in combination with increased availability of nutrients and sunlight are often responsible for the formation of nuisance blooms of algae (Likens, et al, 1970). Within currently degraded stream reaches on the Forest, water temperatures will often exceed 80 degrees F. on warm sunny days.

Alternative No Change has the greatest overall effect on vegetation and soil in the first decade (see Table 2-8, Chapter 2). However, over the course of the first five decades, Alternative B-Modified treats 13 percent (100,000 acres) more than any other alternative. Alternative E-Departure treats the fewest acres over the same period of time. Alternative I treats the fewest acres in the first decade, but over five decades its effects are very similar to Alternatives No Change, A and C-Modified.

**Transportation System**

Although road effects are difficult to separate from timber harvest effects, it is generally agreed that roads account for the majority of severe sediment problems and are often the links between sediment source areas (skid trails, landings, cutspiles) and stream channels (Harr, 1976; Houpt, 1959; Kidd and Megahan, 1972, Ric, 1979; Stone, 1973). Roads paralleling streams may reduce shade on some sites by as much as 43 percent (Thomas, 1979; Skeesick and Steward 1981). Roads constructed adjacent to streams produce up to twice the amount of sediment as that from mid-slope or ridge top roads (Anderson, 1974; Wooldridge, 1980). Substandard roads left open after logging for recreation or other use can become chronic sources of erosion and sediment (Anderson, et al. 1976). Maintenance operations themselves (clearing ditches, reshaping cutspiles, regrading road surfaces) can prolong recovery and significantly increase erosion and sedimentation (Bullard, 1963).

The major portion of the transportation system on the Forest has been completed. Approximately 5,000 miles of road have been constructed (See Chapter 3, Affected Environment). Many roads built decades ago paralleled drainages, severely degrading the character of riparian areas through compaction of soils and elimination of a large portion of the narrow band of riparian vegetation. The proposed alternatives vary by only 1.4 percent in the total miles of open and maintained roads in the first decade. By the 5th decade, the maximum difference is only six percent. Although the differences between alternatives are small, the overall impact of the road system, especially the indirect and cumulative effects of sediment and runoff, are extensive.

**Livestock Grazing**

Removal of vegetation and compaction (especially of moist riparian soils) by grazing animals can reduce infiltration and increase the potential for overland flow. These impacts on the riparian area can in turn lead to changes in sedimentation, peak flows, and channel morphology (Anderson et al, 1976; Blackburn, 1983; Gebheardt and Johnson, 1981; Lusby, 1970; Platts, 1981; Wilott and Pullar, 1984).

Forage use by grazing animals can be 25 to 60 percent higher on streambanks in riparian areas than on adjoining uplands (Nelson and Platts 1985). This concentrated use can lead to compaction in the surface one to two inches of soil, especially in moist riparian areas (Alderfer and Robinson, 1947). Removal of streamside vegetation through over-grazing has a direct effect on stream temperature, especially on sites where coniferous shade is lacking.
or is insufficient and where grasses and shrubs provide a large proportion of the effective shade. Livestock use does not vary significantly among the alternatives (Table 2-8, Chapter 2). However, new, more stringent forage utilization standards combined with structural improvements designed to draw livestock away from riparian areas should help to reduce grazing impacts in all alternatives (see Mitigation Measures, this section).

Impacts to the chemical quality of water are quite variable and difficult to monitor, but increases in organic matter and bacteria occur as a result of grazing (Francis and Schepers, 1982; Skinner, et al, 1974).

**Fire**

Wildfire effects on water quality come about primarily through increased sedimentation and mass soil movement following the destruction of vegetation and exposure of mineral soil to increased runoff (Helvey, 1980). The flushing of ash deposits into streams may alter the concentration of some chemical elements, but this effect on water quality is not well understood (Swanson, 1980). In addition, the loss of vegetation in riparian areas exposes the water surface to increased solar radiation which directly affects water temperature (Helvey, et al, 1976).

The negative effects of wildfire on water quality may be increased as a result of measures taken to bring a fire under control (Barney and Steels, 1983), or through salvage operations following a major fire (Bottom et al, 1985, Cornish and Mackay, 1982).

Wilderness, unroaded areas, Research Natural Areas and old growth units tend toward long term stable vegetation. In this environment, erosion and sedimentation could be expected to remain at low levels and water quality would be high. However, such areas would not be immune to disturbance by wildfire, insect attack or other natural disasters (Anderson, et al, 1976). Such catastrophic events may result in a one time major impact to water quality.

Prescribed burning has the potential to affect riparian areas and the water resource directly through the destruction of vegetation and changes in the character of some soils causing them to become water repellent or hydrophobic. Wildfires, although they have potential for great impact, are not a planned event and their effects are difficult to predict. The amount of prescribed burning planned to treat both natural fuels and activity fuels does not vary significantly among any of the alternatives.

**Other Direct Effects**

Mining activities can affect water quality by exposing spoils piles to erosion, thereby increasing the potential for sedimentation, or through the leaching of chemicals to a stream course from spoils piles or treatment processes.

Off-road vehicle (ORV) use has the potential to affect water quality primarily through the destruction of vegetation, and compaction and rutting of road surfaces. The ultimate impact on water quality is determined by such factors as season and amount of use, soil type, terrain, vegetation and the likelihood of sediment from areas reaching a watercourse (Payne et al, 1983, Sparrow and others 1978; Webb et al, 1978).

**Alternatives B-Modified, I and C-Modified** propose the construction of 190 miles of all terrain vehicle (ATV) trails in the first two decades.

**Water Quantity and Runoff Timing**

Figure 4-1 displays the effect of the various alternatives on the potential annual volume of runoff leaving the Forest for decades one, three, and five. The range is two percent above to 3.5 percent below the existing level of runoff based on a current annual harvest. This range may be exceeded on a localized basis in individual watersheds. Optimum distribution of harvest among all watersheds should serve to mitigate this potential problem (see cumulative effects discussion).
Currently there is some debate over the effects of runoff (both annual and peak flow), and the role played by sediment delivery in determining channel stability (Galbraith 1973, Megahan 1979, Rice 1980). Recent research has focused on the potential of rain-on-snow events in causing increased channel damaging peak flows (Harr 1975). Since at the present time there is no quantified relationship between annual runoff and peak flows, Figure 4-1 should be looked on as a relative indicator of potential changes in peak flow and as a source of energy available to more sediment from disturbed areas into stream channels. Increases above the existing level of annual runoff could be expected to decrease stability on marginally stable stream channels, while decreases in runoff could be expected to have the opposite effect (Alternatives I and C-Modified).

Openings in the Forest accumulate more snow than contiguous forested areas (Hoover and Leab 1967; Smith 1974; Golding and Swanson 1978; Haupt 1979). Spring melt rates in these openings are higher and begin two to four weeks sooner (Haupt 1979, Chamberlin 1982; Kattelmann, et al, 1983, Troendle 1983). Snow melt and runoff generally progress from lower elevations to higher elevations as sun angle and temperatures increase. Creating additional openings at higher elevations will increase the melt rate at these elevations. If these flows become synchronized with runoff from lower elevations the potential for increased downstream peak flow is increased (Christner 1981). Increased peak flows have the potential to destabilize stream channels and slow recovery of streams that are moving toward a more stable condition. Natural attenuation of flows as they move downstream works to mask this effect. Research studies have not detected significant changes in peak flows where logging has been conducted without severe soil disturbance (Ellison, 1981; Harr 1976). See Effects on Soils, this Chapter.

Evaluation of the proposed Forest alternatives based on their effects on timing of runoff is difficult. The potential for synchronization of flows in conjunction with soil disturbance increases with increasing rates of timber harvest. Late season low flows will not likely be affected by any of the alternatives because of shallow soils and low summer rainfall.

No accurate estimate of the effects of grazing by alternative on water quantity or timing is possible. Measurable impacts would most likely be site specific and as such could be addressed through mitigation.

Indirect Effects
Indirect effects are often difficult to separate from direct effects; they interact with almost every aspect of the water/riparian resource, and they are some of the most important impacts to be dealt with by land managers.

The ultimate effect on water quality is determined by how much sediment reaches a watercourse and the value placed on the use of that water, e.g. fish production, irrigation, recreational or domestic use (Forest Service Policy 2526-1). Sediment can smother fish eggs and fry, smother and scour stream bottom plants and aquatic organisms that anchor the food chain, cloud water, abrade fish gills, and reduce visual appeal of waters used for recreation. Sedimentation also increases the cost of treating water destined for human use. Filling in of reservoirs is another cost of sedimentation. In this case, estimates of the amount of sediment contributed by each of the alternatives is less than seven percent above natural or background levels (see Effects on Soils, and Wildlife and Fish, this Chapter).

Cumulative Effects
Cumulative effects are the sum total of individually minor but collectively significant actions taking place over a period of time. Approximately half of the over 800 miles of Class I and II streams and adjacent
riparian areas (on the Forest) are in an unacceptable condition in that they do not meet management requirements for temperature and turbidity. This provides strong evidence that these drainages have suffered the cumulative effects of past road construction, timber harvest, and grazing.

Research indicates that measurable changes in runoff occur when 20-30 percent of a drainage is in a cutover condition (Brown, et al, 1974; Rich and Thompson 1984; and Troendle and Leaf 1980). Water quality, water quantity, and runoff timing may all be affected. These changes may be negative and often are cumulative.

Preliminary analysis of FORPLAN runs indicated that if unconstrained, over 90 percent of the timber harvest in the first decade of the Plan would be scheduled on the high value, extensively roaded ponderosa pine stands located in drainages with predominantly south and southwest aspects.

Further analysis showed that up to 70 percent of the acres in some drainages would be treated in the first decade. This would result in over 40 percent of a drainage being in an equivalent harvest (EHA) condition, a situation judged to have potentially unacceptable impacts on water quality. In addition, in the second decade, the harvest would shift to the steeper, mixed conifer drainages characterized by more erosive soils and high value anadromous fishery streams, further exacerbating potential watershed damage.

The Forest Service Manual directs that where prescribed cutting methods may be detrimental to watershed conditions, including water quality, limits be set on the timing of operations and the percent of watershed coverage per entry (FSM 2405.13, 3b).

To assess the effect of proposed rates of harvest by alternative, threshold values were established for each of the 24 major watersheds on the Forest. These threshold values were chosen to reflect the ability of each drainage to absorb disturbance, both natural and human-caused and to recover in a reasonable period of time without long-term damage to channel stability or water quality. Threshold values range from 25 to 35 percent and take into consideration channel condition, soils, roads, livestock use, fishery values etc. The weighted acreage for all watersheds on the Forest is 30.1 percent. In other words, up to 30.1 percent of the Forest can be in an equivalent harvest area (EHA) condition without exceeding the natural ability of a watershed to absorb impacts without unacceptable damage.

An analysis of the proposed alternatives for potential cumulative effects indicates that only Alternative No Change (which exhibits an EHA of 32.2 percent) has a high risk of causing long-term impacts to watersheds (Table 2-8, Table 4-35). The degree of risk is determined by the probability of experiencing a major storm event (10 to 25 year) during that period when a watershed is hydrologically sensitive. In the case of Alternative No Change, there is a

* The Forest EHA Threshold (30.1) will be exceeded
likely chance that a 10 percent chance storm event will occur on one or more watersheds on the Forest in the next decade with long term effects on channel stability, the riparian zone, and water quality.

A ten percent chance storm event is a ten percent chance of flooding in any given year.

Mitigation Measures
The National Forest Management Act (NFMA) of 1976 requires that timber will be harvested from National Forest System lands only where watershed conditions will not be irreversibly damaged by changes in water temperature and deposits of sediment. The following mitigation measures are proposed to meet this direction.

Mitigation includes a range of actions aimed at reducing the impacts of management activities, and includes: best management practices (BMP's), structural and nonstructural improvements, dispersion, and monitoring. Other relevant mitigation measures can be found in Effects on Soils, this chapter.

Best Management Practices (BMP's)
BMP's encompass a broad range of measures designed to mitigate on-site or site-specific impacts by correcting a recognized problem. Mitigation measures common to all alternatives are contained in Appendix G. These measures, including buffer strips along streams, use of designated skid trails, specific criteria for stream crossings, etc., are designed to achieve a high rate of success (90 percent or greater). However, the degree and quality of implementation is highly variable, ranging from poor to excellent. Unexpected or unusually severe climatic events, availability of funding and staffing, knowledge and understanding of the BMP's by operators and administrators are reasons why many of these BMP's are often only 60 to 80 percent effective.

Improvements in the degree and quality of BMP implementation would be the most effective measure for mitigating some of the potential risk/impact of managing above Forest threshold value as in Alternative NC.

Mitigation after the fact is often not as effective in reducing impacts to the water resource as reducing or controlling the initial amount of impact. Examples include: mitigation of soil compaction through ripping and tillage is seldom as effective in maintaining the hydrologic properties of a soil as is the use of designated skid trails to control the amount of an area impacted during management activities. Development of self maintaining roads, though more costly in the initial design and construction stages, often provide significant advantages over time in reducing overall impacts on water quality and runoff. With this in mind, every effort should be made to select BMP’s which avoid or prevent a problem rather than attempting to correct a problem after the damage has occurred.

Structural and Nonstructural Improvements
Structural and nonstructural improvements are more site specific than BMP's. They are designed to improve productivity, stability or diversity of an area in order to increase its ability to absorb impacts. Examples include: water developments, salt block placement and grass seeding designed to draw grazing animals away from riparian areas, fencing or herding to reduce pressure on sensitive areas; altering the grazing system or changing from cattle to sheep to achieve specific end results. Structural and nonstructural improvement measures also include installing log weirs for improved fish passage, planting willow and alder to improve streamside shade or managing beaver populations to rehabilitate degraded watersheds.

A detailed watershed improvement schedule will be applied to all alternatives. Alternatives B-Modified, I and C-Modified will contain improvements designed to bring all streams/riparian areas to an excellent condition. Alternative E-Departure has a fairly aggressive improvement schedule although only 19 of the 24 watersheds on the Forest will be managed for excellent conditions. A less aggressive schedule is proposed in Alternatives A and C-Modified with 7 of 24 and 22 of 24 watersheds respectively, managed for excellent conditions, but at a slower pace (see Table 2-8, Chapter 2).
Dispersion of Timber Harvest and Grazing Activities

Each of the alternatives includes constraints on the amount and location of timber harvest over time. The goal of this harvest dispersion is to desynchronize the arrival of individual effects of activities at some critical point downstream (Rice 1981). The farther downstream the effects of logging or road construction occur, the more the effects of that synchronization will be reduced, so long as channel sensitivity is constant. The extent of these effects, such as increased runoff or sediment from disturbed sites, will vary in seriousness, predictability and controllability.

More stringent forage utilization standards, combined with structural improvements designed to draw livestock away from riparian areas, should help to reduce grazing impacts in all alternatives.

Monitoring

Monitoring serves as a check on the effectiveness of mitigation measures. It identifies necessary adjustments in the level and type of mitigation required to meet management requirements.

The cumulative effects process described above will be employed at the project/watershed level to assess risk and to assure optimum distribution of harvest affects among watersheds.

Conflicts with Other Plans and Policies

There are no known conflicts with the management plans of adjacent landowners or agencies. Throughout the planning process, the Forest has been in contact with the Oregon State Forestry Department, Oregon Department of Fish and Wildlife, local soil conservation agencies, county planners and the Bureau of Land Management.

Wild and Scenic Rivers

The Oregon Omnibus Wild and Scenic Rivers Act of 1988 designated the Deschutes River, the Crooked River, and the North Fork of the Crooked River as Wild and Scenic. The Wild and Scenic Rivers Act defines three classes of rivers: wild, scenic, and recreational. Wild river areas are those rivers, or sections of rivers, that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America. Scenic river areas are those rivers, or sections of rivers, that are free of impoundments, with shorelines or watersheds still largely primitive and natural appearing. Limited access by roads may occur in places. Recreational river areas retain natural, free flowing characteristics, but shorelines may show evidence of some agricultural or forestry uses, past water diversions, or existing minor improvements or diversions. The river segments that have been designated are further described as follows:

Deschutes River - The portion of the Deschutes River that flows through the Crooked River National Grassland has been designated as scenic. This wild and scenic river area is to be managed by the Bureau of Land Management.

Crooked River - The portion of the Crooked River that flows through the Crooked River National Grassland has been designated as recreational. This wild and scenic river area is to be managed by the Bureau of Land Management.

4-89
North Fork of the Crooked River - The portion of the North Fork of the Crooked River that flows through the Ochoco National Forest has been designated in three segments. The first segment, from the river source to where the river enters the Big Summit Prairie has been designated as recreational. The second segment, from where the river exits the Big Summit Prairie to the confluence of Deep Creek, has been designated as recreational. The third segment, from the confluence of Deep Creek to the Ochoco National Forest boundary, has been designated as scenic. The portion of this river, between segments one and two, that flows through the Big Summit Prairie (private land), has no official designation under the Oregon Wild and Scenic Rivers Bill.

Lower Squaw Creek has been determined to be eligible and suitable for designation as a "scenic river" in the Wild and Scenic River system. A 7.5 mile segment of the creek, 1370 acres, from the Grassland boundary to its confluence with the Deschutes River, would be recommended for designation. This recommendation would be a preliminary recommendation that would receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. Congress has reserved the authority to make final decisions on designation of rivers as part of the Wild and Scenic Rivers System.

Direct Effects
The corridors of designated Wild and Scenic Rivers are protected in all alternatives. The effects of the alternative on Wild and Scenic Rivers will not change. Lower Squaw Creek, which would be recommended for designation in Alternatives B-Modified and I, would be protected for its scenic river qualities in those alternatives. Protection is afforded through inclusion in the Squaw Creek Management Area.

Livestock grazing along the segments of rivers designated for Wild and Scenic Status affects water quality as well as the presence and quality of the riparian vegetation. Timber harvest within the corridor would be planned to protect and enhance the qualities of these river corridors. Harvest adjacent to the corridor could affect the quality, timing and quantity of water in the rivers. Harvest might also temporarily disrupt the access to and serenity of the area. This could vary by alternatives based on the intensity of harvest. Uneven-aged management would be emphasized over even-aged management practices and the impacts of harvest over time would be reduced.

Indirect Effects
Legislative designation of areas to the Wild and Scenic River System does establish management emphasis and precludes other alternative land uses or allocations not in harmony with the management objectives for wild, scenic or recreation rivers.

Cumulative Effects
The "outstanding/remarkable" attributes of the designated Wild and Scenic Rivers are not expected to significantly change as a result of management activities programmed within any of the alternatives.

Both timber harvest and recreation use can have a cumulative effect on the Wild and Scenic River resource. The Forest and Grassland seek to implement management practices designed to protect the character of the Wild and Scenic River corridors for all the alternatives.

Mitigation Measures
The management of the designated sections of Wild and Scenic Rivers will be developed in management plans by 1991, which will be tiered to the Forest and Grassland Plans. All outstanding/remarkable features will be protected through mitigation of other resource projects. The Lower Squaw Creek area which would be recommended for inclusion in the Wild and Scenic River System, in Alternatives B-Modified and I, would be managed to protect those values key to the recommendation.
Conflicts with Other Plans and Policies

No conflicts are anticipated with the plans and policies of other agencies. Management of those Wild and Scenic River segments which transgress Forest, Grassland and BLM administered lands will be coordinated between agencies.

Wilderness

The Oregon Wilderness Act of 1984 designated Black Canyon, Bridge Creek, and Mill Creek as Wilderness Areas on the Ochoco National Forest. The fate of the Deschutes Canyon/Steelhead Falls unroaded area was left to be determined through Forest Planning. This section discusses the effects that are incident on these areas and how the effects vary by alternative.

Direct Effects

There are a number of activities that have a direct effect on wilderness but these effects do not vary between alternatives. Valid mining activities will continue to affect the wilderness by the use of motorized vehicles and equipment, access routes and associated ground disturbances. Livestock grazing and associated approved improvements and approved use of mechanized and motorized equipment to maintain the improvements can detract from the wilderness experience.

Recreation use in wilderness could vary by alternative depending on how much of the unroaded areas outside wilderness becomes developed for other resource concerns. In alternatives B-Modified and A, as the unroaded areas become developed and no longer available for the semiprimitive nonmotorized recreation experience, more people will be displaced into wilderness for the more primitive recreation opportunities. The sites and sounds of forest industrial operations may detract from the user's wilderness experience along access routes to a wilderness area. This effect would be most extreme under Alternatives B-Modified and E-Departure. These effects could detract from the experience of those seeking the wilderness experience.

The amounts of wilderness acres vary by alternative due to the different management strategies for the Deschutes River/Steelhead Falls Wilderness Study Area. The wilderness qualities of this study area are protected in all alternatives, but to different degrees. Degree of protection depends on where motorized activities in conjunction with grazing are allowed. Alternative C-Modified recommends all of the areas (10,000 acres) that minimally meet wilderness standards for wilderness designation. This area contains some nonconforming features, such as roads and powerlines. Alternative E-Departure recommended only the pristine canyon area of 2,500 acres of Grassland and 2,660 acres of BLM be recommended for wilderness. Alternatives A and No Change protect the full study area as a semiprimitive nonmotorized recreation area but do not recommend wilderness. Alternative I manages over 5,100 acres of the study area as part of the 7,840 acre Squaw Creek Management Area. This area will be managed for unroaded semiprimitive nonmotorized recreation opportunities. The main access road dividing the area will be closed seasonally to protect wintering deer herds, and should have little impact on summer canyon use except at the ford of Squaw Creek.
Indirect Effects
Alternative C-Modified, which recommends acres of the Deschutes Canyon/Steelhead Falls roadless area to wilderness, will limit grazing and cause a decrease in livestock use due to the inability to transport water daily by motor vehicle. None of the other alternatives would affect grazing in the area recommended. E-Departure recommended excluded areas needing motorized water transportation.

Mining is affected by wilderness; no new claims will be allowed and existing claims are closely monitored. Only motorized and mechanized equipment that is absolutely necessary for the mining will be allowed.

Recreation is affected by wilderness since no facilities other than those needed to access trails will be developed. Limits of acceptable change are established to monitor the effects of use in the wilderness and to change recreation use patterns when limits are exceeded. No mountain biking, hang gliding, or other mechanized-motorized recreation can occur.

A fire management plan will be developed for each wilderness area that establishes prescription criteria for managing fires as a natural part of the environment. Some natural ignitions may be allowed to burn unless significant resource damage is expected, in which case the fire will be declared a wildfire and suppression action will go into effect. Suppression actions will be designed to minimize human impacts on wilderness.

Fire management strategy in wilderness is designed to protect or enhance wilderness resource values. Where analysis has shown that the wilderness ecosystem has been significantly altered from its natural state due to fire exclusion and that the probability of lightning ignition returning it to its natural state is low, scheduled ignitions will be considered.

Additionally, the timber resource may be affected by wilderness designation. Because wilderness vegetation remains unmanaged, tree vigor will decline and forest pests such as the spruce budworm may reach outbreak levels. Infestations may then spread beyond wilderness boundaries into forest zones dedicated to multiple use management. This effect would be minimal in the Deschutes Canyon/Steelhead Falls area where grass and shrub vegetation comprise the dominant plant communities.

Cumulative Effects
Some nonconforming features, improvements, and conditions currently exist in the wilderness. Additional nonconforming conditions may legally be necessary for the development of prior existing valid mining claims. These developments create additional unnatural conditions that cumulatively may be detrimental to the wilderness resource. In addition, progressive trail development may have cumulative effects on the supply of primitive recreation experiences.

As unroaded areas outside wilderness become developed for other resource management objectives, recreational use of the wilderness will increase. The increased number of wilderness users could exceed the capacity to provide a primitive experience and conditions could occur that exceed the limits of acceptable change.

Mitigation Measures
All management of wilderness is guided by the Wilderness Act of 1964 which strongly directs management toward pure untrammeled wilderness. The Act also allows some prior existing rights to continue. Such operations will be permitted with provisions to protect wilderness values as much as practical. The use of motorized and/or mechanized vehicles for these excepted activities will be scheduled to minimize conflicts with wilderness values and wilderness users as much as possible. Ground disturbing activities will be bonded to ensure restoration/reclamation of the area will be completed in a timely manner. Nonconforming features will be removed when feasible.

Conflicts with Other Plans and Policies
The Jefferson County Comprehensive Plan does not support the creation of additional Wilderness within the bounds of Jefferson County. Consequently, a conflict occurs with Alternatives C-Modified and E-Departure which allows for wilderness recommendation for all or portions of the Deschutes Canyon/
Steelhead Falls Area. No other conflicts arise with any of the proposed management strategies for the unroaded areas of the Ochoco National Forest.

Wildlife and Fish

Direct Effects
Management indicator species were selected to simplify the evaluation of impacts on terrestrial vertebrate species with different habitat requirements. Theoretically, the effects on the selected species represent the effects on other wildlife species with similar habitat requirements. Under no alternative would management indicator species populations and their habitats be adversely affected to the point where minimum viable populations could not be maintained (see Appendix F, Management Requirements).

Effects by Alternative on Elk Populations and Habitat
Timber harvest affects the spatial relationships of cover and foraging areas as well as the ratio and juxtapositioning of each that occurs over an area. The amount, type, and interspersion of forage, water, and cover (habitat components) can result in effects on big game and other wildlife habitat and use.

Cover is an important component of elk habitat. It is utilized by big game in part to modify climatic effects on body temperatures, which results in increased metabolic efficiency (Beall, 1974; Edgerton and McConnell, 1976; Leckenby, 1984), and for security. Timber management and applied silviculture practices can influence habitat through changes in cover quality and quantity (cover/forage ratio) and associated road densities.

Timber harvest utilizing clearcutting and shelterwood temporarily eliminates or alters cover. Thinning practices may reduce the quality of the cover. Timber management may also have positive effects on the quality and quantity of cover; e.g., harvesting of stands that do not provide cover and reforesting the sites with stands adequate to provide improved tree stocking and canopy closures; and in some cases managing to defer or reduce harvests in stands recognized to be important for providing cover.

All alternatives have an effect on cover from timber harvest and management. Standards and guidelines have been developed (Appendix D) that control the cover requirements and amounts in various management areas to meet habitat effectiveness objectives for elk.

Roads affect elk habitat by directly removing habitat area. Vehicular traffic also decreases the effectiveness of adjacent roaded habitat (Pederson, 1978). Studies have demonstrated that elk use increases proportionately as distance from roads increases (Hershey and Leege, 1976; Perry and Overly, 1977; Pederson, 1978, Long, 1980), and increased road densities reduce habitat effectiveness (Hershey and Leege, 1976; Lyon, 1979). Generally it is the associated traffic, not the roads themselves which discourage use by big game (Hershey and Leege, 1976; Perry and Overly, 1977).

A model was used to predict the influence of forest management on elk and habitat effectiveness. Table 2-8, Chapter 2, shows the model results/elk numbers for each alternative. It is a biologically based model dealing with habitat effectiveness for elk. It was designed to estimate effectiveness on a scale of 0 to 180, with 180 representing the highest potential and 0 representing the least desirable situation. It is a relative measure of effectiveness only and does not consider all factors that could influence the actual population. Some of the additional factors may include: effects of hunting, predators, disease, yearly changes in weather, forage production, competition with other animals, and reproductive rates.
To make the results of the model easier to interpret, the effectiveness index was translated into number of animals. This was done by estimating the density of animals that could be supported on an area if the habitat were maintained at optimum effectiveness. For the Ochoco National Forest this was an average of nine elk per square mile. The habitat effectiveness value of 180 translated to this possible density of elk. Lower values translate to proportionally lower densities. The numbers are not necessarily projections of actual elk populations but provide basis for relative comparisons between alternatives. As noted above, many additional factors would have to be considered in order to predict actual populations.

It is also important to note that present elk populations may not be the direct result of factors that are used in the habitat effectiveness model. The current population in an area can be limited by availability of winter range on private land, by hunting pressure, or by any of the other factors discussed above. In this case, habitat effectiveness may change, but still have no influence on the number of elk. Thus, the numbers shown in tables and graphs represent modeled projections only and cannot account for factors outside the model. It is important to understand this in order to relate how the effect of forest management on the elk population was predicted (see Table 4-36).

**Effects of Livestock Grazing on Big Game**

Livestock grazing can affect big game habitat through competition for forage. An analysis was made to determine the amount of forage produced on the Forest and identify if significant competition for forage potentially existed Forest-wide. The model showed that, theoretically, an abundance of forage remained in all alternatives after the needs of both big game and livestock had been met. This assumed, however, that animals were evenly distributed throughout the Forest. Localized conflict could occur in areas of high animal concentrations or in particular habitats. Conflicts between elk and cattle were not quantifiable at the Forest planning level, but will be considered and evaluated on an allotment plan basis when each plan is updated.

**Effects on Deer Populations**

Deer numbers have been projected to remain constant at an estimated 22,600 animals during the first two decades for all alternatives. Even though the habitat is capable of supporting higher deer populations during this time frame, the Oregon Department of Fish and Wildlife intentions are to keep the population at current levels. They feel deer winter range carrying capacities, which are mostly outside the Forest, have been reached. In the third decade, it is predicted deer populations may begin to decline for Alternative B-Modified. This is a result of reduced habitat caused by intensive timber management activities. All other alternatives remain constant through the fifth decade (see Table 2-8, Chapter 2).

* Although the NC Alternative was not actually evaluated for elk production using the model, elk numbers are expected to be quite similar to those shown for B MOD. The reasons for the similarity are due to the similar effects that both alternatives would have on habitat effectiveness.
before it has a chance to get old and coarse, then leaving the regrowth for big game, increases quality of winter forage. Livestock browsing on shrub winter ranges, however, decreases the value of these areas for wintering big game, as does heavy use on grass ranges, thus resulting in displacement of winter big game and/or reduction in carrying capacity of big game winter ranges.

Effects of Alternatives on Threatened, Endangered, and Sensitive Species
The bald eagle and peregrine falcon are the only two Federally listed threatened and endangered species known to occur on the Forest. The bald eagle uses parts of the Forest for winter roosting and feeding. Infrequent sightings of the peregrine indicate migrating individuals; no nest sites have been found. Under each alternative, their habitats, either known or when found in the future, will be managed to meet the intent of the recovery plans for both species. Conservation measures for the bald eagle include road closures in and around their roosting sites, supplemental feeding stations near winter roosting areas, and allocations for protection of known roosting sites. Consultation procedures with the U. S. Fish and Wildlife Service for threatened and endangered species will be carried out as required under the Endangered Species Act. All alternatives equally protect eagle and falcon habitat as required by law.

Sensitive wildlife species, listed in “Rare, Threatened and Endangered Plants and Animals of Oregon,” 1985, and the Regional Forester’s list (FSM 2670), that are known or suspected to occur on the Forest or Grassland are Swainson’s hawk and the wolverine. The Swainson’s hawk is known to use primarily juniper for nesting purposes. Juniper is located along the Forest fringes and on the Grassland. None of the alternatives are anticipated to reduce nesting habitat below existing levels.

The wolverine, classified by the State of Oregon as a threatened species, has had sightings reported in recent years (Utzinger, 1985). Because of their large home range and habitat requirements, alternatives such as C-Modified, with less roading and less intensively managed acres, would favor wolverine more than commodity-oriented alternatives.

Three additional species (Cooper’s hawk, golden eagle, and prairie falcon) are considered species that require special consideration because of their nesting habitat requirements. The Cooper’s hawk utilizes young, dense stands of ponderosa pine. Alternatives which include precommercial thinning on these stands could have effect on nesting opportunities for this species. The prairie falcon and golden eagle are primarily cliff nesters. All alternatives will control management activities that might disrupt the nesting cycle.

Effects by Alternatives on Pileated Woodpeckers
The pileated woodpecker is a management indicator species for old growth habitat. It serves as the surrogate for a guild of species which require old growth forest for habitat. There are constraints on management activities in areas allocated to old growth (see Appendix D). The major consequence of the alternatives on old growth dependent wildlife species will be the amount of old growth allocated in any alternative. Acreage currently in an old growth habitat condition, estimated to be 93,800 acres, declines in all alternatives as stands are entered for timber harvest. Alternative C-Modified would retain the most old growth, whereas No Change and B-Modified have the least remaining after five decades. See the Old Growth section of this chapter for more detail on effects by alternative on old growth dependent species, and Appendix F.

Effects by Alternative on Primary Cavity Excavators
The alternatives and their objectives, as described in Chapter 2, provide different levels of snags for primary cavity excavator habitat. Table 2-8, Chapter 2, displays the estimated percent of maximum potential population by alternative. The 100-percent level occurs when the number, size, and spatial distribution of snags are not limiting to the population. The habitat levels depicted represent an average for all the management areas in each alternative. However, for each alternative, snag levels vary by management area, generally ranging from 40 to 80 percent, except wilderness, unroaded areas, and other less intensively timber managed lands, which provide 100-percent levels.
Snag levels are unknown for Alternative No Change because data is unavailable for it. However, it is estimated to be about the same as Alternative A (46-52 percent of potential). This is a moderate level of habitat.

Snag levels for alternatives E-Departure and I are also both moderate (E-Departure 46-55 percent; and I 47-54 percent).

Alternative C-Modified has a potentially higher level of habitat, at 51-69 percent of the potential population.

Alternative B-Modified provides a low level of habitat starting at 43 percent and dropping to 33 percent of potential by the fifth decade. This is above the NFMA management requirement level of 20 percent of the potential population, as such it should maintain a viable populations of primary cavity excavators, but at much lower population levels than the other alternatives above.

The common flicker was identified as a specific primary cavity excavator (indicator species) to represent juniper old growth habitat. It is probably the only avian species capable of creating cavities in juniper (Thomas, 1979). It is not anticipated that juniper habitat will become a limiting factor in any alternative. However, due to the fact that juniper cutting and burning will be done for deer habitat, range improvement, and fuelwood cutting, Alternatives I and B-Modified have identified stands of juniper on the Grassland to be retained undisturbed for old growth juniper characteristics. Fifteen stands of juniper, for a total of 740 acres, are identified in both of those alternatives. No juniper stands are protected in the other alternatives, nor on the National Forest in any alternative.

Effects by Alternative on Rainbow and Brook Trout
Rainbow and brook trout are treated as indicator species for riparian habitat. It is assumed that if requirements for rainbow trout are adequately met, the aquatic system will also be suitable for steelhead spawning.

Timber harvest, road construction, livestock grazing, recreation, fire, and watershed structural improvements all affect riparian habitat, which affects fisheries. Discussion of the effects of alternatives on riparian condition are given under the water section of this chapter.

In this respect, resident trout numbers would vary somewhat by alternative (see Chapter 2, Table 2-8). Alternatives No Change and A have two riparian prescriptions (see Chapter 2 and Appendix D for a discussion of riparian prescriptions) with 17 watersheds going to a fair condition class and seven watersheds going to an excellent condition class. Fish numbers are lower in these two alternatives because of the seventeen watersheds being maintained in fair condition.

Alternative E-Departure has 17 watersheds going to excellent prescription and seven going to a fair prescription. Fish numbers are higher than in alternatives NC and A because of fewer watersheds being maintained in fair condition. Cottonwood Creek and Rock Creek unroaded tributaries of the John Day are planned for development.

Alternatives B-Modified, C-Modified and I have all watersheds being managed under an excellent riparian prescription and, therefore, are predicted to provide the highest resident trout numbers.

Effects by Alternative on Anadromous Fish
All alternatives are assumed to have the same effect on steelhead populations (see Chapter 2, Table 2-8). This is because in all alternatives, the watersheds with anadromous fish are all priority streams for riparian improvement to excellent condition. It is recognized, however, that alternatives which have greater levels of industrial and commodity management activity pose greater risk and higher cost for maintaining or improving anadromous fish spawning habitat. Therefore, Alternatives No Change, A, B-Modified, and E-Departure favor fisheries the least, Alternative I is better relatively speaking, and C-Modified, the best in respect to the six alternatives treated.
Indirect Effects

Increases or decreases in wildlife and fish populations have indirect effects on activities and businesses related to hunting, fishing and wildlife viewing recreation opportunities. See Table 2-8, Chapter 2 for estimations of recreation use by alternative. Also see the Recreation section of this chapter.

Wildlife and fish populations affect social and economic considerations. The requirements incorporated into alternatives to produce higher levels of wildlife populations can limit timber management which decreases jobs in that sector. At the same time, recreation related jobs and services may be increased. Central Oregon lifestyles relate indirectly to fish and wildlife populations. For further discussion of social and economic considerations, see the Social and Economic section, this Chapter and Appendix B.

Providing habitat that results in large populations of free-ranging big game animals results in conflicts with farms and ranches, damaging crops and fences, and competing with domestic stock when animals drift or migrate off public lands onto private lands in winter.

Cumulative Effects

Continuing and widespread management activities, timber management practices applied uniformly over the Forest, improved access and increased human presence contribute to reduced habitat effectiveness for wildlife, increase stress at critical periods, and increase hunter access. When considered in total over time these effects can be cumulative and impact wildland resources through reductions in certain wildlife populations, habitat loss and reduced diversity. Alternatives such as E-Departure, B-Modified, A and No Change, which promote intensive development and utilization of resources, are thought to be more likely follow a scenario of this kind.

Conversely, large acreages of undeveloped and inaccessible land increase the risk of epidemic insect outbreaks, wildfire or other natural catastrophe which may result in significant long term economic and habitat loss. The utilization argument is to manage wildland resources to prevent this kind of catastrophic loss of resource and impacts, and thus better maintain a sustained level and of fish and wildlife production over time. Alternative C-Modified would represent the least intensive management (for commodity resources) over time.

Other practices on the Forest can have cumulative effects, e.g. salvage and firewood cutting have impacted the snag habitat over time on the Forest; clearing of vegetation, silviculture activities and roads alter timing, flows and sediment for streams, thus potentially affecting fish habitat over time; and, cumulative effects of past management practices are reflected in condition of riparian areas in places.

Mitigation Measures

Mitigation measures are intended to minimize or eliminate potential conflicts or adverse effects of implementation. Mitigation measures have been developed through interdisciplinary efforts and incorporated into the Plans at different levels in several different ways.

The standards and guidelines (Appendix D) and management area prescriptions in Chapter 2, are a fundamental and integral part of these measures, and as such they are a basic and essential part of the analysis. These apply to such things as road closures which are utilized to reduce harassment of big game, especially during critical periods. Road closures have been found to be very effective for mitigating loss of other big game habitat components, and are accomplished by either physically restricting access or by the “green-dot system,” which provides for seasonal road closures during the hunting season. In addition to benefitting big game, road closures can be employed to restrict access for firewood cutters, which helps insure planned snag density levels are maintained. Practices which may be employed to improve or maintain wildlife habitat and timing of activities can be a way to mitigate adverse effects, such as during raptor nesting and big game calving/fawning periods. Restoration practices such as woody debris placement, channel and erosion structures, planting, seeding and fencing, and improved grazing systems and road design are also mitigation measures which have been found to be very effective.
The allocations (see Chapter 2) play an important role in mitigation by the separation of incompatible uses, impacts and conflicts. Allocations relate to protection of riparian areas, old growth, unroaded areas, wildernesses and others which, when viewed in total across the Forest or Grassland, contribute to the habitat mosaic and diversity. This is probably the most effective method for mitigating forest-wide impacts to wildlife and fish resources.

National Forest Management Act (NFMA) requirements were incorporated into the planning process and are reflected in the allocations and standards and guidelines (see Appendix B and Appendix F). These requirements assure that in all cases adequate habitat is provided to maintain viable populations of wildlife.

"General Water Quality Best Management Practices" (USDA Forest Service, Pacific Northwest Region, November 1988. 86p) are incorporated by reference under requirements of Section 319 of the Clean Water Act. The BMP’s assure water quality requirements, and hence fish habitat, are protected.

Mitigation measures are developed at the site specific project level of planning, and projects are “tiered” to other planning levels above. Project level application controls what actually occurs on the ground.

Conflicts with Other Plans and Policies
None are known to exist.

The Relationship Between Short-term Uses of Man's Environment and the Maintenance and Enhancement of Long-term Productivity

From the perspective that each generation is trustee of the environment for succeeding generations, an objective of this plan is to provide for the proper and continued development of resources in a manner that maintains economic stability, yet retains local natural heritages, such as wildlife habitat, outdoor recreation opportunities, water quality, scenic qualities and open range. The preferred alternative emphasizes a balanced mix of uses and also attempts to provide for the protection of other resources (soil, water, wildlife habitat, aesthetics) over the long term.

While the plan proposes short term harvest of timber, sustaining or improving long term productivity is planned through intensive forest management practices (e.g. reforestation, thinnings). Lands identified as unsuitable for sustained timber yield management have been allocated for soil, watershed or wildlife habitat protection. Dispersion of timber harvest activity, retention of old growth and protection of riparian areas have all been planned in order to prevent impairment of long term land and resource productivity.

Construction of roads, mechanical slash piling, and logskidding are examples of activities that are short-term uses, but can reduce long term vegetation productivity on specific places where they occur.
Increases in road densities, improvements in access, subsequent increases in human presence and continuing and ongoing expansion of management activities proposed herein have the potential in the short term to create effects that could cumulatively affect long term productivity of wildlife habitats, aquatic systems and local socio-economic developments.

The allocation of land to uses other than timber production may affect timber supply in the short term, but it retains future management options and does not rule out the possibility of future harvest in the event of emergency or change.

Irreversible and Irretrievable Commitments of Resources Associated with the Preferred Alternative (I)

This plan deals with both developed and undeveloped (roadless) lands. Lands where road systems, plantations, thinnings and structures are established represent an economic commitment. These investments represent “sunk funds” from an economic standpoint, and are not retrievable; nor do they necessarily have any liquidity over the planning period.

The specific acres, estimated to be one percent of the total Forest and Grassland area, on which permanent roads and facilities are constructed constitute an irretrievable, and for all practical purposes irreversible, loss of soil vegetation productivity and unaltered landscape.

Continued avoidance of cultural resource sites (as opposed to evaluation/mitigation/clearance) tends to undermine efforts to acquire data which would expedite future site evaluations. Data recovery projects ultimately enhance the Forest’s ability to manage its cultural resources. Data recovery efforts represent, in essence, the scientific and controlled destruction of a cultural resource site. Once undertaken, the effects of data recovery are irreversible; this mitigation measure represents an irretrievable commitment to the resource.

Use of rock for road surfacing and construction purposes, estimated to be 147,850 cubic yards annually on the Forest and Grassland, is an irreversible commitment of a resource, but is not considered critical because of the abundant availability of good quality rock in this locale.

Undeveloped or unroaded areas once allocated for development will, in a relatively short time, no longer be suitable for wilderness classification. Wilderness designation is considered a permanent commitment. Congress could reverse this designation but this is extremely unlikely.

In the case of lands already intensively developed by roading, a high degree of irreversibility exists. With undeveloped lands, frequently a wide range of management options exists.

Dasmann, et. al., in Ecological Principles for Economic Development, 1973, (pp. 22-23), recognized six broad development levels for lands, each representing a progressively greater commitment of resources. The development levels are:

1) The land can be left in a completely natural state and reserved for scientific study, educational use, wilderness, watershed protection and its contribution to landscape stability.

2) It may be used as a park, refuge or reserve with the natural scene remaining largely undisturbed to serve as a setting for outdoor recreation and attraction of tourism.

3) It might be used for limited harvest of its wild vegetation or animal life, but maintained for the most part in a wild state, serving to maintain landscape stability, support certain kinds of scientific or educational uses, provide for some recreation and tourism and yield certain commodities from its wild populations.
4) It can be used for more intensive utilization of its wild products as in forest production, pasture for domestic stock, recreation, or intensive wildlife production. In this case, its value as a wild area for scientific study diminishes, but it gains usefulness for other kinds of scientific and educational uses. Its value for some tourism and outdoor recreation diminishes, but is not necessarily lost. Its role in landscape and watershed stability is changed, but may be maintained at a relatively high level.

5) The wild vegetation and animal life having been removed in part, it can be intensively utilized for the cultivation of planted tree crops, pastures or farming crops.

6) The wild vegetation and animal life having been almost completely removed, it can be used for intensive urban, industrial or transportation purposes.

Using these development levels, Tables 4-37, 4-38 and 4-39 display the extent of irreversibility proposed by the preferred alternative (I).

So long as the first three choices are taken, the option remains open to change to any of the others. In the fourth choice, the options for restoring the land to any of the first three levels are reduced, but not eliminated. Lands allocated to development are likely to approach the fifth level. This would largely prohibit any shift to the lower level on those acres.

With the resource allocations proposed in the preferred alternative, 19 percent of the lands will be managed in categories of “low or moderate” irreversibility, 80 percent will be managed for intensive timber and range production or “moderately high” irreversibility, and one percent will be committed to roads and administrative sites which represent “high” irreversibility.

Unavoidable Environmental Effects Associated with the Preferred Alternative (I)

Air Quality

Prescribed fire use will contribute to total suspended particulates (TSP) in the atmosphere, and will result in a temporary increase in haze and localized impairment of visibility. The FEIS on Managing Competing and Unwanted Vegetation (U.S.D.A. Forest Service, 1988) provides a detailed investigation into the effects of smoke on human health. The following is a summary of that investigation pertinent to this FEIS.

Short term effects due to high level exposures immediately adjacent to prescribed fires or wildfires include "...eye irritation, coughing, and shortness of breath in moderate-to-heavy smoke..." This type of exposure is generally experienced only by forest workers since the general public is not normally involved in such activities.

Documentation of adverse effects from long-term exposure to wildland fire smoke is virtually nonexistent. Forest workers are at some risk of such low-level exposure contributing to such health effects as emphysema or lung cancer. Long-term effects from even lower levels of smoke experienced by the public-at-large are less well known. Individuals with chronic lung disease or other respiratory ailments may experience additional irritation from the infrequent episodes of stagnated smoky air masses.

There are a number of potentially toxic components known to exist in wildland smoke. However, the levels experienced under normal conditions and exposures are well below any levels known to cause harmful effects on humans. Some of the more common are carbon monox-

1/ Total acres less roads
ide, carbon dioxide, carbon particles, and trace amounts of a number of chemicals that may enter the lungs on the surface of particulate matter. Close to 90 percent of the particulate matter is small enough (less than 2.5 microns diameter) to penetrate deeply into the lungs.

Some of the components (polycyclic aromatic hydrocarbons) are known carcinogens under exposures much higher than that documented from wildland smoke. Other components, such as the aldehydes, are acute irritants. These are most likely to affect forest workers who receive high exposures at burn sites.

Because of the regional scope of visibility effects and problems, Region 6 of the Forest Service has been conducting cumulative effects analysis on TSP production through subregional analysis of emissions (for example, Eastern Oregon). The FEIS for Managing Competing and Unwanted Vegetation (U.S.D.A. Forest Service, 1988) contains the latest information on this continuing analysis. In that analysis, the Ochoco National Forest contributed approximately 15 percent of the emissions from Forest Service sources in Eastern Oregon. The Eastern Oregon subregion is projected to reduce emissions by 23 percent under the selected alternative in the Vegetation Management Plan. The Ochoco National Forest and Crooked River National Grasslands will contribute to that reduction in all of the Alternatives in this FEIS.

The projected reductions in emissions for the preferred alternative should continue to widen the gap between probable exposures and any possible health effects; chronic or acute.

**Biological Diversity**

Forest vegetation will be altered in respect to species composition, stand structure and age. With the exception of about 10 percent retained in old growth, RNA's and wilderness, existing mature forest on suitable lands will be subject to management treatments, including harvesting of mixed conifer timber stands and, where feasible, replacement with more economically or silviculturally desirable species (primarily ponderosa pine). Other management treatments include overstory removal of old-growth ponderosa pine from multi-storied stands, resulting in reduction in basal area, and removal of less desirable species in densely forested areas by thinnings. Intensively managed or regulated forests may provide less habitat for species dependent on old growth forest, snags and down material; less species diversity and habitat diversity; and fewer scenic settings.

**Cultural Resources**

Current procedures cannot insure that all cultural resource sites will be located. Some sites could be inadvertently destroyed or damaged. Such impacts are unavoidable pending advances in inventory techniques.

**Forage and Livestock Use**

The direction in the Plans to improve riparian conditions may initially result in increased costs in grazing management; e.g., in installation of improvements (fencing and water developments), herding and transport to control stock distribution and use and possible slight reductions in stocking levels.

**Recreation**

With the exception of the areas designated wilderness (4 percent), or allocated to roadless management (4 percent), opportunities for primitive recreation, solitude, and recreation in natural settings unaltered by man will decrease over time.

**Social and Economic**

Levels of commodity and amenity resources provided by the Forest and Grassland may decrease over time in response to changing conditions and legal requirements. Decreases in timber harvest levels
or amenity resources may have direct socio-economic effects on local communities, governments and businesses in terms of socio-economic variables such as occupational lifestyles, leisure, attitudes, beliefs, values and community institutions.

Forest users will encounter more controls and restrictions as management intensity, resource competition and human population continue to increase over time.

Wildlife and Fish

Increased road densities (and access), and ongoing expansion of management activities can result in reduction of wildlife security. Physiological stress in wildlife species may therefore result in altered behavior and productivity. This is likely to change attitudes and experiences of hunters over time.

Other Specifically Required Disclosures

Effects on Consumers, Civil Rights, Minority Groups, and Women

Federal and State Human Resource Programs, Civil Rights and Minorities

The Forest and Grassland will continue to participate in these programs in accordance with laws, administrative opportunities and economic availability of programs. Minorities or economically disadvantaged groups should not be adversely affected by the preferred alternative (I).

Alternatives involving reduced recreational attractions and fewer government jobs could have an effect on employment of women. Fewer recreation opportunities may mean local merchants benefit less, and are less apt to hire people for low wage jobs traditionally held by women in this locale.

Effects on Prime Farmland, Rangeland, and Forest Land

All the proposed actions in alternatives are consistent with the intent of the Secretary of Agriculture direction (FSH 1909.15) for protecting and managing prime lands.
Effects on Prime Farmland, Rangeland, and Forest Land

All the proposed actions in alternatives are consistent with the intent of the Secretary of Agriculture direction (FSH 1909.15) for protecting and managing prime lands.

Effects on Wetlands and Floodplains

Consideration for floodplain management, as required by Executive Order 11988, and protection of wetlands, Executive Order 11990, are incorporated into all alternatives by virtue of the respective executive orders.

Effects on Threatened and Endangered Species, and Critical Habitat

The only Federally listed species which occasionally are observed on the Forest and Grassland are the peregrine falcon and bald eagle. Neither is a known permanent resident in the area, even though roosting sites for both bald and golden eagles are known to exist and have received legally required protection under all of the alternatives.

All Federally listed species are protected in all alternatives regardless of the management direction that may apply to the area where they are found (see Effects on Wildlife and Fish, this chapter, for more thorough discussion on threatened and endangered species).

Natural or Depletable Resource Requirements (including energy), and Conservation Potential of the Alternatives and Mitigation Measures

Methods to estimate the impacts of various management activities on energy resources have been outlined by Schwarzbart and Schmitz (1982). Prestructured energy coefficients in terms of British Thermal Units (BTU's) applicable to resource management activities in the Pacific Northwest are provided in the above source.

Analyses conducted on other National Forests in the course of environmental impact assessment and forest planning indicate, without exception, that the energy required to implement alternatives is more than the energy produced. The range that planned National Forest activities' energy consumption exceeds energy yields has been shown to be in the magnitude of two to six billion BTU's/decade. The amount of energy deficit per alternative as a general rule is directly proportional to timber harvest volumes projected. Alternatives providing maximum timber yields generally require intensified timber cultural activities and more road construction and maintenance, both being spread across a greater land area. Therefore, efforts to maximize timber production or commodity production under current states of technology lead to proportionally greater amounts of energy consumption.

Activities on the Forest and Grassland which may have a positive net energy balance are firewood gathering and forage production. Generally, all other activities consume more energy than they produce.

Effects of the Alternatives on Urban Quality, Historic and Cultural Resources, and the Design of the Built Environment Including the Re-use and Conservation Potential of Various Alternatives and Mitigation Measures

4-105
This FEIS deals with wildland resources and as such does not directly affect urban quality, or historic or cultural resources within an urban environment.

Conflicts with other Federal, Regional, State, and Local Plans (including Indian Reservation Plans)

County Plans

Regulations require Forests to coordinate with other public planning efforts (36 CFR 219.7) during the planning process. Accordingly, comprehensive plans for the six counties and the Warm Springs Reservation were reviewed.

The Crook County - Prineville Area Comprehensive Plan, issued in 1978, sets forth many objectives. Protection of the current timber industry is a primary topic, but concerns about grazing for livestock and wildlife, recreational opportunities, and environmental needs (especially protection of water and soil) are all mentioned. As an overall goal, the county plan states:

"It shall be the policy of the county to support forest land use and management decisions which maximize the present level of benefitting uses; specific emphasis shall be on timber production to sustain the existing forest products industry, forage production to maintain at least the existing levels of livestock and wildlife habitat, protection of water quantities and quality and to maintain existing dispersed recreation level in coordination with the USFS planning and management programs" (p. 53).

If Alternative C-Modified was selected, it might be perceived as conflicting with the goal "to sustain the county forest products industry." Conversely, Alternative B-Modified might be judged as not being entirely compatible with the goal to protect wildlife, soil and water. Alternative I (Preferred) would appear to be consistent with the county's overall goal.

The Deschutes County Year 2000 Comprehensive Plan, issued in 1979, makes no mention of the Ochoco National Forest or the Crooked River National Grassland. Its general emphasis on the importance of timber, or tourism, and of multiple resource management is similar to the concerns of the other counties. No conflict is anticipated with the Deschutes County plan.

The 1969 Grant County plan expresses concern about the timber harvest level from Federally-owned lands, but makes no policy statement regarding desirable harvest levels. Other concerns include the quantity and quality of forage, the quantity of water, the desirability of increasing recreation, and the importance of multiple use. No conflict is foreseen with the objectives of this 1969 plan.

The Harney County Comprehensive Plan (1979) discusses the importance of National Forest land (the Ochoco and the Malheur) as sources of timber, grazing, recreation, fish and wildlife, and water. The plan supports the adoption of the preferred alternative in the Forest Service "Silvies-Malheur Unit Plan." This implies support for a mixture of uses similar to the Forest's present management.

The Jefferson County Comprehensive Plan, adopted in 1981, refers to the Crooked River National Grassland, but not to the Ochoco National Forest. The present management of the Grassland is supported. Except for the statement, "The County does not support the creation of additional Wilderness Areas inside Jefferson County" (p. 145), there do not appear to be conflicts with the Jefferson County plan.

A Wheeler County Comprehensive Plan was adopted in 1980. It examines concerns such as the supply of timber, forage, recreation, and water, but sets no official objectives. No conflicts are foreseen between Wheeler County policies and the effects of any alternative.
Warm Springs Indian Reservation Comprehensive Plan
The Warm Springs Indian Reservation Comprehensive Plan contains no references to the Forest or the Grassland. In the planning process, a number of meetings were held with representatives of the Confederated Tribes of the Warm Springs Reservation. Concerns expressed included availability of access to the Forest and Grassland, being able to gather plant materials, support of prescribed burning, protection of archaeological sites, and the general availability of Forest and Grassland resources. Except for the level of prescribed burning, none of these concerns vary among alternatives, and no conflict is currently anticipated between these desires and the preferred alternatives.

Oregon State Forestry Program Projections
The Oregon State Forestry Department has developed a Forestry Program for Oregon (FPFO). This program is the guiding policy for the State Board of Forestry in reviewing forestry matters in the State of Oregon. Key to this program for the Ochoco National Forest are the output levels assigned to the various land “owners” (state, private, industrial, federal) required to accomplish the coordinated programs envisioned.

The State Board of Forestry Forest Program for Oregon target levels related to timber production must not be confused with the State of Oregon objectives reflected in the Governor’s response nor the State Alternative prepared for the Forest Plan Objectives guiding the Governor’s response include concerns for Oregon’s forest environment, wildlife protection, jobs, and timber production. An equitable balance among these often conflicting resources is the principal goal.

Table 4-40 displays a comparison of timber outputs from the preferred alternative (I) with the FPFO objectives, sales, harvest, and alternatives.

Other Resource Plan Comparisons
Oregon State Air Quality Implementation Plan
Depending on cumulative effects in conjunction with neighboring prescribed burning, the smoke particulate emissions from the Forest may conflict with the Oregon State Implementation Plan (SIP) concerning air quality.

</table>

1/ The potential yield is the net chargeable volume from the current Timber Management Plan and is not directly comparable to Forest Plan TSPQ (Timber Sale Program Quantity). TSPQ includes volume that will be up for sale but which is chargeable against the allowable sale quantity.
Emissions from prescribed burning can have significant short-term adverse effects on visibility in and around wilderness areas. There are legal requirements to preserve or enhance visibility quality in designated Class I Areas (Clean Air Act, 1977). The closest Class I Area downwind of the Forest is the Strawberry Wilderness on the Malheur NF. Under certain weather conditions, smoke from the Forest and Grassland may affect visibility in the Strawberry Wilderness.

Oregon Outdoor Recreation Plans
Alternatives not including the East-West Trail as a part of the Forest-wide trail system are in conflict with Oregon Outdoor Recreation plans and the State of Oregon Trail Advisory Group plans. All final alternatives except the No Change include the Summit Historic Trail, which also may serve as an East-West cross state trail.

Establishment of Pacific Northwest System of Research Natural Areas
The proposed RNA's provide some of the plant associations and conditions identified in *Research Natural Area Needs in the Pacific Northwest* (Dyrness et al. 1975). The five areas represent a portion of many areas reviewed and are the ones identified as best representing the needed cells (basic units in a natural area system). The preferred alternative (I) recommends all five of the areas for RNA designation.

Oregon State Water Quality Standards
Analysis of the effects of the various alternatives on dispersion of harvest activities indicates that potential conflicts may occur between final Alternative NC in the first decade and the ability of the Forest to meet State water quality guidelines for turbidity and temperature (DEQ, 1980).

Oregon Department of Fish and Game Objectives
There has been little conflict regarding projected deer population levels because populations in all alternatives are maintained at the levels presently desired by Oregon Department of Fish and Wildlife (ODFW) through the fifth decade.

Based on the Habitat Capability Index predictive model, population numbers for elk may, depending on the alternative, exceed or fall below the proposed ODFW planning benchmarks. The preferred Alternative I, however, is in accord with ODFW's recent benchmark of 2,600 for elk. ODFW's population benchmark for elk has been in flux. The benchmark for elk when planning was originally initiated in the early 1980's was 1,250, as compared to 2,600 now. There have been ongoing discussions between ODFW, the Forest Service, local land owners, and sportsmen's groups on the appropriate elk population objective; the population objective has yet to be determined.

Federal Regulations Governing Toxic and Hazardous Materials
Activities that may occur on the Forest or Grassland involving the use or disposal of hazardous or toxic materials are required in all alternatives to meet all State and Federal laws and provisions.

Utility and Transportation Corridors
All alternatives recognize State and County road corridors. The Western Region Corridor Study (1986) information has been consulted and appropriate utility corridors recognized. No alternatives result in any conflict with movement of power throughout the area.
List of Preparers
List of Preparers

The following is a list of Forest Interdisciplinary Team (IDT) and Forest Planning core team members who developed the Ochoco National Forest Plan, Crooked River National Grassland Plan, and Final Environmental Impact Statement. Their qualifications (position, education, and experience) are provided.

Numerous other Forest Service employees contributed to the completion of these documents through assignments to the Forest Supervisor’s Office, by providing needed information, or by assuming the duties of co-workers who were deeply involved in the planning effort.

Anderson, Bruce P.

Forest Hydrologist
Education: M.S. in Water Resources Management; University of Wisconsin.
M.S. in Botany (use biological indicators of water quality), University of Wisconsin.
Experience: Nine years of professional experience. Two years as a U.S. Peace Corps Volunteer - research hydrologist. Seven years with U.S.D.A. Forest Service including one and one-half years as a hydrologic technician and forest planning team member on the Siskiyou National Forest and five and one-half years as Forest Hydrologist on the Ochoco National Forest.

Carlson, Ann L.

Writer/Editor
Education: B.A. English Literature/ Writing, Oregon State University, 1979.

Carter, Bernie E.

Wildlife and Watershed Staff
Education: B.S., M.S (Wildlife Management); Oregon State University.
Experience: District Biologist, Umatilla National Forest; Asst. Wildlife, Range and Watershed Staff, Winema National Forest; Asst. Wildlife and Watershed Staff, Wallowa-Whitman National Forest; District Ranger, Fremont National Forest; Wildlife and Watershed Staff, Ochoco National Forest, plus I.D. team member on development of two Land Management Unit plans besides present planning efforts; experience in land management planning, 5 years.
Cissel, John H.

**Operations Research Analyst/Economist**

Education: B.S. Forestry, Michigan State University, 1978; M.S. dual title in Operations Research - Forestry, the Pennsylvania State University, 1981.

Clagg, Harry

**Fire Planner, Assistant Fire and Recreation Staff**

Education: B.S. Forest Management, Colorado State University, 1974. M.S. Fire Ecology, Colorado State University, 1975

Experience: Fire ecology studies, Rocky Mountain National Park, 2 years; Presale Planning Forester, Greenville District, Plumas National Forest, 3 years; Fire Management Officer, Republic District, Colville National Forest, 5 years; Assistant Fire and Recreation Staff, Fire Planner, Ochoco National Forest, 1 year.

Courtright, Craig V.

**Planning Team Leader**

Education: B.S. in Forest Science, California State University - Humboldt, Graduate studies in Forest Ecology and Silviculture, Oregon State University, 1972-1972; Silviculture Certification, Utah State University, 1976.

Experience: Seventeen years experience in 5 Regions on 6 National Forests, 5 Ranger Districts. Includes a breadth of experience in all resource areas at the Ranger District and National Forest level. Experience includes assignments ranging from technical work as a silviculturist to line officer responsibility while a District Ranger on the Tongass National Forest in Alaska. Breadth of experience includes 1-1/2 years in National Forest planning.

Cuddy, Paul

**Operations Research Analyst/Economist**

Erickson, Frank S.

Writer/Editor
Education: BS in Journalism, University of Utah, 1970.

Forsman, Richard T.

Assistant Range Staff
Education: B.S. in Wildlife Biology with a minor in Range Management, Oregon State University, 1976.

Experience: Thirteen years of professional experience with the Forest Service as Range Conservationist and Wildlife Biologist.

Hain, Gordon

Recreation Planner
Education: B.S. in Forestry, University of Georgia, 1965.

Layser, Earle F.

Forest Planning Staff Officer
Education: B.S. Forest Sciences, University of Montana, Missoula 1965.

Experience: Fifteen years USDA Forest Service on two Ranger Districts, four National Forests, and five Regions - Forester, Forest Staff, Regional Staff, and District Ranger. Two years USDI BLM - Plant Ecologist/Resources Specialist, 3 years Private consultant - NEPA, Permit Acquisition, Minerals development, Natural Resources Management.

Linkenhoker, Chris

Assistant Forest Planner

Owens, Dave

Forester, Silviculturist
Silviculture Institute IV, 1982.

Experience: District Silviculturist and Timber Sale Planner on the Ochoco National Forest, Prineville District; District Silviculturist, Umatilla N.F.; Post Sale Forester, Fremont N.F.; Forester in Sale Administration and Project Supervisor, Coconino N.F., Region 3; Forestry Technician, Fire Management, Cleveland N.F., Region 5.

Tout, Deborah S.

Lands and Minerals Assistant
Education: B.S. in Geology, Syracuse University, New York.

Experience: Seven years professional experience as geologist on the Ochoco, Gifford Pinchot, and Umpqua N.F.'s, one and a half years as Civil Engineering Technician on the Umpqua N.F.
Tubbs, Darryl K.

**Transportation Systems Manager**

Experience: Worked in surveys and hydraulics for Corps of Engineers, St. Louis, Montana, 1 year; Assistant Zone Engineer, Superior National Forest, 2 years; Transportation Planner, Malheur National Forest, 2 years; Transportation Planning and Interdisciplinary Team Member, Ochoco National Forest, 9 years.

Wood, Donald C.

**Forest Silviculturist**

Experience: Post Forestry, Fort Leonard Wood, Missouri, 1 year; Forester on Randle District of Gifford Pinchot National Forest, 5 years; Land Exchange, Gifford Pinchot National Forest, 2 years; District Silviculturist, Hebo District, Siuslaw National Forest, 8 years, Forest Silviculturist on Ochoco National Forest, 8 years.

Worrall, William H.

**Computer Specialist**

Experience: Have worked on the Ochoco NF since 1983, doing computer programming, economic analysis, computer mapping, space management and desktop publishing.

GLOSSARY

These definitions apply to Forest Service land management and planning. Meanings may differ when used in another context. Some definitions were shortened, paraphrased or adapted to fit local conditions. Definitions of other terms used in resource management but not included in this glossary may be found in the following publications:

ACCEPTABLE RIPARIAN CONDITION - A shady, brushy riparian condition with frequent amounts of tall overstory conifer trees and shorter hardwoods of alder, willow and aspen; the site has the potential to produce conifers and/or hardwood species. Moderately gentle bank slopes containing moderate to high plant densities, thick root masses, embedded angular boulders and old logs characterize these areas. Frequent channel scouring and deposition will largely be replaced by mossy aquatic growth on assorted sizes of tightly packed rocks.

ACRE EQUIVALENT - Used to adjust actual acres of habitat improvement or improvement structures to reflect overall habitat benefits derived. It reflects the zone of influence of the habitat improvement for the target species. For example, a single water development for upland game birds has an acre equivalent of 160, whereas a single water structure for big game has a value of 640 because it has a larger zone of influence for the more mobile big-game animals.

ACRE FOOT (ACF) - A unit for measuring a volume of water. Quantity of water required to cover 1 acre (43,560 square feet) to a depth of 1 foot.

ACRES OF DEGRADED WATERSHED CONDITION - represents existing soil/watershed areas which are degraded and contributing to loss in site productivity and/or creating water quality deterioration when hazardous events occur. The Soil/Water Restoration Inventory (1979) for the Ochoco National Forest (located at the Ranger District Offices) delineates these areas.

ACTIVITY - Actions, measures, or treatments that are undertaken that directly or indirectly produce, enhance, or maintain forest and rangeland outputs or achieve administrative or environmental quality objectives. Forest Service activity definitions, codes, and units of measure are contained in the Management Information Handbook (FSM 1309.11.).

ADVISORY COUNCIL ON HISTORIC PRESERVATION (ACHP) - An independent advisory body established by the National Historic Preservation Act of 1966. The mission of the Council is to advise the President and Congress on national historic preservation policies, to encourage private and public interest in historic preservation, and to review and comment on Federal undertakings that might have an effect on properties listed on or eligible for the National Register of Historic Places.
ALL-TERRAIN VEHICLE (ATV) - An abbreviation whose initials stand for All-Terrain Vehicle, which is any motorized off-highway vehicle 50 inches or less in width. ATV's usually have a dry weight of 600 pounds or less, traveling on three or more low pressure tires and having a seat designed to be straddled by the operator.

AIRSHED - A geographical area that, because of topography, meteorology, and climate, shares the same air.

ALLOTMENT - see Range Allotment.

ALLOWABLE SALE QUANTITY (ASQ) - (Comparable to programmed allowable harvest used in previous plans). The quantity of timber that may be sold from the area of suitable land covered by the forest plan for a time period specified by the plan. This allowable sale quantity (ASQ) is usually expressed on an annual basis as the "average annual allowable sale quantity" (FSM 1900).

ALL-TERRAIN VEHICLE (ATV) - Any motorized, off-highway vehicle 50 inches or less in width, having a dry weight of 600 pounds or less that travels on three or more low pressure tires with a seat designed to be straddled by the operator. Low-pressure tires are 6 inches or more in width and designed for use on wheel rim diameters of 12 inches or less, utilizing an operating pressure of 10 pounds per square inch (psi) or less as recommended by the vehicle manufacturer.

ALTERNATIVE - One of several policies, plans, or projects proposed for decision making.

AMENITY - An object, feature, quality, or experience that gives pleasure or is pleasing to the mind or senses. Amenity value is typically used in land-use planning to describe those resource properties for which market values (or noncash values) are not or cannot be established, such as hiking or scenic viewing.

ANADROMOUS FISH - Those species of fish that mature in the sea and migrate into streams to spawn. Salmon, steelhead, and searun cutthroat trout are examples.

ANALYSIS AREA - An area of land (not necessarily contiguous) which for FORPLAN analysis purposes has homogeneous timber management costs and vegetative responses to timber management activities.

ANALYSIS OF THE MANAGEMENT SITUATION (AMS) - A step required under the National Forest Management Act in which the Forest determines its ability to supply goods and services to meet society's demand for them.

ANIMAL UNIT (AU) - An animal unit is a 1,000 pound mature cow, or its equivalent based on an average daily forage consumption of 26 pounds dry matter per day.

ANIMAL UNIT MONTH (AUM) - The amount of forage required by an animal unit for one month.

ANNUAL PROGRAMMED HARVEST - That part of the potential timber yield that is scheduled for harvest in a specific year.

APPROPRIATE SUPPRESSION RESPONSE - The kind, amount, and timing of suppression action on a wildfire which most efficiently meets fire management direction under current and expected burning conditions. The action may be from prompt control to confinement (See definitions for confine, contain, and control.)

AQUEOUS - Of, relating to, or resembling water.

ARCHAEOLOGY - The scientific study of the physical characteristics of cultural resources in order to describe and explain former ways of life.

ARTERIAL ROAD - Roads comprising the basic access network for National Forest System administrative and management activities. These roads serve all resource elements to a substantial extent, and maintenance is not normally determined by the activities of any one element. They provide service to large land areas and usually connect with public highways or other Forest arterial roads to form an integrated network of primary...
travel routes The location and standards are often determined by a demand for maximum mobility and travel efficiency rather than by a specific resource management service. Usually they are developed and operated for long-term land and resource management purposes and constant service.

Bacillus thuringiensis (B.t.) - A biological agent used to initiate insecticidal treatments of the western spruce budworm populations

BACKGROUND - The visible terrain beyond the foreground and middleground where individual trees are not visible, but are blended into the total fabric of the stand (See "Foreground" and "Middleground.")

BASALT - A dark gray to black, fine-grained igneous rock.

BENCHMARK - An analysis of the supply potential of a particular resource, or of a set of resources subject to specific management objectives or constraints.

BENEFIT COST RATIO - An economic indicator of efficiency, computed by dividing total priced benefits by priced costs. Usually both benefits and costs are discounted so that the ratio reflects efficiency in terms of the present value of future benefits and costs.

BEST MANAGEMENT PRACTICES (BMP) - A specific activity, measure, course of action, or treatment.

BIG GAME (BG) - Those species of large mammals normally managed for sport hunting, generally elk, deer, and antelope

BIOLOGICAL DIVERSITY - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan.

BIOLOGICAL POTENTIAL - The maximum possible output of a given resource limited only by its inherent physical and biological characteristics.

BOARD FOOT - A unit of timber measurement equaling the amount of wood contained in an unfinished board 1 inch thick, 12 inches long, and 12 inches wide.

*Board foot volume measurement varies with size of trees and is designed for certain product specifications and current technology. Young stands that have been regenerated cannot be measured in board foot or equivalent units of measurement, attempting to do so would underestimate the biological potential of timber producing lands and make future growth estimates impossible. See cubic foot

BRECCIA - A rock made up of highly angular coarse fragments.

BROADCAST BURN - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for reduction of fuel hazard or as silvicultural treatment, or both.

CANOPY CLOSURE - The progressive reduction of space between crowns as they spread laterally, increasing the canopy density.

CAPABILITY - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices and at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils, and geology, as well as on the application of management practices, such as silviculture or protection from fire, insects, and disease.
CAPITAL INVESTMENT COST - Costs generally associated with construction such as trails, roads, and physical structures for range, recreation, and fish and wildlife. Other major functions include reforestation, timber stand improvement and prescribed burning.

CAVITY - The hollow excavated in trees by birds or other natural phenomena, used for roosting and reproduction by many birds and mammals.

CINNABAR - A mineral (HgS) which is the principal ore of mercury.

CLEARCUTTING - The harvesting in one cut of all trees on an area for the purpose of creating a new, even-aged stand. The area harvested may be a patch, strip, or stand large enough to be mapped or recorded as a separate class in planning for sustained yield.

COLLECTOR ROAD - Roads that serve smaller land areas than a Forest arterial road, and usually connected to a Forest arterial or public highway. Collect traffic from Forest local roads and/or terminal facilities. The location and standard are influenced by both long-term multiresource service needs, as well as travel efficiency. May be operated for either constant or intermittent service, depending on land use and resource management objectives for the area served by the facility.

COMMERCIAL FOREST LAND (CFL) - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; and (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvesting.

COMMERCIAL THINNING - A cut in a stand under rotation age designed to remove excess merchantable trees. The objective is to place the growth capability of the site on the remaining leave trees.

COMMODITY - A transportable resource product with commercial value; all resource products that are articles of commerce.

COMMON VARIETY MINERAL - Saleable minerals.

COMMUNITY COHESION - The degree of unity and cooperation evident in a community as it defines problems and attempts to resolve them.

COMMUNITY STABILITY - A community's capacity to handle change without major hardships or disruptions to component groups or institutions. Measurement of community stability requires identification of the type and rate of proposed change and an assessment of the community's capacity to accommodate that level of change.

COMPACTION, SOIL - The packing together of soil particles by forces exerted at the soil surface, resulting in increased soil density.

CONCERN - A point, matter, or question raised by management that must be addressed in the planning process.

CONFINE - To limit fire spread within a predetermined area principally by use of natural or preconstructed barriers or environmental conditions. Suppression action may be minimal and limited to surveillance under appropriate conditions.

CONSTANT SERVICE - A road developed and operated for continuous or annual recurrent service.

CONTAIN - To surround a fire, and any spot fires therefrom, with control lines as needed, which can reasonably be expected to check the fire's spread under prevailing and predicted conditions.
CONTROL - To complete the control line around a fire, any spot fires therfrom, and any interior islands to be saved; burn out any unburned area adjacent to the fire side of the control line; and cool down all hot spots that are immediate threats to the control line, until the line can reasonably be expected to hold under foreseeable conditions.

CONVERSION PERIOD - A transition period during which an unregulated forest structure is converted to a regulated one. When regulated, the forest will have a distribution of stand age and size classes, providing approximately equal periodic harvests.

CORD - A unit of volume measurement containing 128 cubic feet of solid wood. Generally a stack of round or split wood measuring 4 feet wide by 4 feet high by 8 feet long.

CORRIDOR - A linear strip of land identified for the present or future location of transportation or utility rights-of-way within its boundaries.

COST EFFICIENCY - The usefulness of specified inputs (costs) to produce specified outputs (benefits). In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values, but are achieved at specified levels in the least cost manner. Cost efficiency is usually measured using present net value, although use of benefit-cost ratios and rates-of-return may be appropriate.

COVER/FORAGE RATIO - The ratio, in percent, of the amount of area in cover condition to that area in non-cover or forage condition; the criteria by which potential deer and elk use of an area is judged.

COVER - Vegetation used by wildlife for protection from predators, to ameliorate conditions of weather, or in which to reproduce.

CUBIC FOOT - In timber management a volume measured as a 1 foot cube of solid wood.

*CULMINATION OF MEAN ANNUAL INCREMENT (CMAI) - The age at which a stand of trees no longer increases in average annual growth.

CULTURAL RESOURCES - The remains of sites, structures, or objects used by humans in the past--historical or archaeological.

CULTURAL RESOURCES - Physical remains of districts, sites, structures, buildings, networks, or objects used by humans in the past. They may be historic, prehistoric, archaeological, or architectural in nature. Cultural resources are land based and are nonrenewable.

CUMULATIVE EFFECTS - The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

CURRENT DIRECTION - The direction contained within the following plans that has guided the recent management of the Forest and Grassland:

1. Ochoco-Crooked River Planning Unit Land Management Plan, 1979
DATA - Any recorded measurements, facts, evidence, or observations reduced to written, graphical, tabular, or computer forms.

DATA RECOVERY - Collection of information through any of a variety of techniques (e.g., photography, mapping, archaeological excavation) conducted for purposes of No Adverse Effect or mitigating Adverse Effect. Data collection is designed to recover representative data from a cultural resource prior to its disturbance or destruction.

DBH - Diameter at breast height. Diameter of a tree 4 feet 6 inches above the ground.

DECISION CRITERIA - Essentially the rules or standards used to evaluate alternatives. They are measurements or indicators that are designed to assist a decisionmaker in identifying a preferred choice from an array of possible alternatives.

DECISION VARIABLE - A component of an alternative in which input costs, outputs and benefits are identified and used for analysis and decision making.

DEMAND - The amount of goods or services that will be consumed if offered over a given range of prices at a particular point in time.

DEMOGRAPHIC - Pertaining to the study of the characteristics of human populations, such as size, growth, density, distribution, and vital statistics.

DEPARTURE (DEP) - Timber harvest schedule which deviates from the principle of nondeclining even flow by exhibiting a planned decrease in the timber sale and harvest schedule in the future. A departure is characterized as a temporary increase over the base sale schedule without impairing the Forest's long-term sustained-yield.

DETERMINATION OF ELIGIBILITY - Formal determination by the Keeper of the National Register, Department of Interor, as to whether or not a cultural resource is eligible for listing on the National Register of Historic Places.

DETERMINATION OF EFFECT - Determination of the effect (No Effect, No Adverse Effect, Adverse Effect) a proposed undertaking will have on cultural resources listed on or eligible for the National Register of Historic Places. Requires consultation with the State Historic Preservation Officer and may require review by or consultation with the Advisory Council on Historic Preservation.

DEVELOPED RECREATION - Recreation that requires facilities that, in turn, result in concentrated use of an area. Examples of recreation areas are campgrounds and ski areas; facilities in these areas might include roads, parking lots, picnic tables, toilets, drinking water, ski lifts, and buildings.

DISCOUNT RATE - The interest rate used in plan formulation and evaluation for discounting future benefits and computing costs, or otherwise converting benefits to a common time basis.

DISPERSED RECREATION - A general term referring to recreation use outside a developed recreation site; this includes activities such as scenic driving, hunting, backpacking, and recreation in primitive environments.

DISPERSION - To disperse the effects of timber harvest by distributing harvest units more or less uniformly throughout a drainage so that increased runoff and sediment from disturbed sites will be buffered by lower levels of runoff and sediment production from surrounding undisturbed lands.
DISTRICT - See Ranger District.

DIVERSITY - The distribution and abundance of different plant and animal communities and species within the area.

DRAFT ENVIRONMENTAL IMPACT STATEMENT (DEIS) - The version of the statement of environmental effects required for major Federal actions under Section 102 of the National Environmental Policy Act (NEPA) and released to the public and other agencies for review and comment. It is a formal document which must follow the requirements of NEPA, the Council on Environmental Quality (CEQ) Guidelines, and directives of the agency responsible for the project proposal.

EARNED HARVEST EFFECT (EHE) - An increase in the present harvest based on the expectation of increased yields in the future resulting from management practices such as planting genetically-improved stock and thinning.

ECONOMIC EFFICIENCY - See cost efficiency.

ECOSYSTEM - The interacting system of a biological community and its nonliving environment.

EDGE - The place where plant communities meet or where successional stages or vegetative conditions within plant communities come together. It often contains organisms from both communities as well as those restricted to the interface area. The number of species present is often greater than the surrounding communities.

EFFECTS - Environmental consequences as a result of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and are later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems. Effects and impacts as used in the FEIS are synonymous. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic quality, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial (40 CFR 1508.8).

ELIGIBLE - Cultural properties that meet the criteria for listing on the National Register of Historic Places.

EMPIRICAL YIELD TABLE - A table reflecting the existing standing timber volumes today and how they would grow in the future, under various timber management regimes.

ENDANGERED SPECIES - Any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range. Plant or animal species identified by the Secretary of the Interior as endangered in accordance with the 1973 Endangered Species Act.

ENDEMIC - A taxonomic category (e.g., genus, species, variety) whose natural occurrence is confined to a certain region and whose distribution is relatively limited.

ENDEMIC ORGANISM - A taxonomic category (e.g., genus, species, variety) whose natural occurrence is confined to a certain region and whose distribution is relatively limited.

ENHANCE - To improve, reinforce, enrich or strengthen the existing condition, value, or beauty of a resource.

ENHANCEMENT - Interpret cultural resources for the public benefit. Cooperate with museums, universities, and other recognized institutions, agencies, and knowledgeable persons in planning and constructing cultural resource exhibits involving National Forest System cultural resources. Coordinate these efforts with
interpretive Services people (FSM 2390). Enhancement efforts may include the full range of interpretive techniques. Because enhancement may affect the resource, comply with regulations set forth in FSM 2366. In all cases consider a determination of beneficial effect (FSM 2366.26).

ENVIRONMENT - The sum of all external conditions and influence affecting the life, development, and survival of an organism.

ENVIRONMENTAL ANALYSIS - An analysis of alternative actions and their predictable short- and long-term environmental effects, incorporating the physical, biological, economic, social, and environmental design arts and their interactions.

ENVIRONMENTAL ASSESSMENT (EA) - A concise public document required by the regulations implementing the National Environmental Policy Act.

EPIDEMIC - An outbreak of sudden rapid spread, growth, or development.

EPITHERMAL MINERAL DEPOSIT - A deposit formed in rocks of shallow depth from low-temperature hydrothermal solutions.

EQUIVALENT CLEARCUT AREA (ECA) - That area which when harvested under any of the various silvicultural regimes produces hydrological effects similar to one acre of clearcut.

EQUIVALENT HARVEST AREA (EHA) - The same as Equivalent Clearcut Area (ECA).

EROSION - The processes whereby earthy or rocky materials are worn away, loosened, dissolved and removed from any part of the earth’s surface.

EVAPOTRANSPERSION - Process by which water moves from the soil to the atmosphere by evaporation from the soil or transpiration through plants.

EVEN-AGED MANAGEMENT - The application of a combination of actions that results in the creation of stands in which trees of essentially the same age grow together. Managed even-aged forests are characterized by a distribution of stands of varying ages (and, therefore, tree sizes) throughout the forest area. The difference in age between trees forming the main canopy level of a stand usually does not exceed 20 percent of the age of the stand at harvest rotation age. Regeneration in a particular stand is obtained during a short period at or near the time that a stand has reached the desired age or size for regeneration and is harvested. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands.

EXCELLENT RIPARIAN CONDITIONS - An extremely shady and brushy riparian condition with an abundance of tall overstory conifer trees and shorter hardwoods of alder, willow and aspen will be present; the site has the potential to produce conifer and/or hardwood species. Gentle bank slopes, high plant densities, thick root masses, embedded angular boulders and old logs characterize these areas. Channel scouring will be minimized with deposition replaced by mossy aquatic growth on assorted sizes of tightly packed rocks.

F

FAULT A fracture or fracture zone along which there has been displacement of the sides relative to one another parallel to the fracture.

FAWNING AREAS - areas used regularly by female deer for fawning (and maintaining fawns for their first few days or weeks); optimum fawning habitat includes low shrubs or small trees under a tree overstory of about 50-percent closure, usually located on slopes of less than 15 percent where vegetation is succulent and plentiful in June and potable water is available within 183 meters (600 feet).

FINAL ENVIRONMENTAL IMPACT STATEMENT (FEIS) - The final version of the statement of environmental effects required for major Federal actions under Section 102 of the National Environmental Policy Act (NEPA). It is a revision of the Draft Environmental Impact Statement to include public and agency responses to the
draft. It is a formal document which must meet legal requirements and is the document used as a basis for judicial decisions concerning compliance with NEPA.

**FIRE HAZARD REDUCTION** - The treatment of fuels and residues, which reduces the potential fire's rate of spread or intensity.

**FIRE MANAGEMENT EFFECTIVENESS INDEX (FMEI)** - A number derived by totaling the cost of a fire protection organization and fire suppression cost with the net value change and dividing that figure by 1000 acres.

**FIREWOOD** - Wood, either round, split or sawn, and burned primarily for heating purposes.

**FISCAL YEAR (FY)** - October 1st to September 30th.

**FLOODPLAIN** - The lowland and relatively flat areas adjoining inland and coastal waters (including debris cones and flood-prone areas of offshore islands) including, at a minimum, those areas subject to a one-percent or greater chance of flooding in any given year (100-year recurrence).

**FORAGE (LIVESTOCK)** - All grass and grass-like plants.

**FORAGE (WILDLIFE)** - All browse and herbacious food that is available to wildlife for grazing.

**FORBS**

1. Any herbaceous plant other than those in the Gramineae (true grasses), Cyperaceae (sedges) and Juncaceae (rushes) families - i.e., any non-grass-like plant having little or no woody material on it.

2. A palatable, broad-leaved, flowering herb whose stem (above ground) does not become woody and persistent.

**FOREGROUND** - A term used in scenic management to describe the stand of trees immediately adjacent to a high-value scenic area, recreation facility, or forest highway. (See "Background" or "Middleground.")

**FOREST AND RANGELAND RENEWABLE RESOURCES PLANNING ACT OF 1974 (RPA)** - An Act requiring the preparation of a program for the management of the National Forests' renewable resources and of Land and Resource Management Plans for units of the National Forest System. It also requires a continuing inventory of all forest, rangelands, and renewable resources nation-wide.

**FOREST DEVELOPMENT ROADS (FDR)** - Roads that are part of the Forest transportation system, which includes all existing and planned roads, as well as other special and terminal facilities designed as Forest development transportation facilities.

**FOREST HEALTH** - A condition where biotic and abiotic influences on the Forest (i.e. insects, diseases, atmospheric deposition, silvicultural treatments, harvesting practices) do not threaten management objectives either now or in the future.

**FOREST INVENTORY PLAN** - A plan, based on known cultural and environmental information, that delineates areas of varying degrees of suspected cultural resource potential.

**FOREST PLAN** - The National Forest Land and Resource Management Plan (Forest Plan) guides all natural resource management activities and establishes management standards and guidelines for the Forest. It describes resource management practices, levels of resource production and management, and the availability and suitability of lands for resource management. It is prepared under the implementing regulations and requirements of NFMA.

**FORESTRY PROGRAM FOR OREGON (FPFO)** - A comprehensive forest management program developed by the State of Oregon for all forest lands in the state regardless of ownership.
FOREST STANDARD - A performance criterion indicating acceptable norms or specifications that actions must meet to maintain the minimum conditions for a particular resource. This type of standard applies to all areas of the Forest regardless of the other management area direction applied.

FOREST SUPERVISOR - The official responsible for administering the National Forest System lands in a Forest Service administrative unit. He or she reports to the Regional Forester.

FORPLAN - The forest planning model. A linear programming software package used to analyze planning decisions regarding land use patterns, capital investment, and timber harvest scheduling.

FUEL BREAK - A strategically located strip of land, usually 100 to 500 feet wide, that has been altered by removal of flammable vegetation so that fires burning into it can be more readily extinguished.

FUELS - Anything within the Forest that will burn. Usually live and dead woody vegetation (e.g., grass, shrubs, trees).

FUEL TREATMENT - The rearrangement or disposal of fuels to reduce the fire hazard.

G

GEOMORPHIC - Of, or pertaining to, the form of the earth, or its solid surface features.

GEOTHERMAL - Of, or pertaining to, the heat of the earth's interior.

GOAL - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad, general terms and is timeless in that it has no specific date by which it is to be completed. Goal statements form the principal basis from which objectives are developed.

GOODS AND SERVICES - The various outputs, including on-site uses, produced from forest and rangeland resources.

GRAZING - Consumption of range or pasture forage by animals.

GRAZING SEASON - 1. A period of grazing to obtain optimum use of the forage resource. 2. On public lands an established period for which grazing permits are issued.

GREEN DOT SYSTEM - A seasonal vehicular management program which visually indicates travel routes open to public use; roads not identified by the green dot, and cross-country travel, are closed to public use during the designated time period.

GROUND WATER - Water in a saturated zone of a geologic stratum.

GROUP SELECTION - A modification of the selection system in which trees are removed in small groups at a time.

GUIDELINE - An indication or outline of policy or conduct that is not a mandatory requirement (as opposed to a standard, which is mandatory).

H

HABITAT - The sum total of environmental conditions of a specific place occupied by a wildlife or plant species or a population of such species.

HABITAT CAPABILITY INDEX (HCI) - A process used to determine habitat capability for big game by evaluating thermal cover and road density.
HABITAT DIVERSITY INDEX - A number that indicates the relative degree of diversity in habitat forest wide.

HABITAT EFFECTIVENESS (HE) - A combination of both quantity and quality of habitat, including both natural and introduced factors, which produces a specific habitat condition that either limits or generates habitat use by a wildlife species.

HARVEST CUTTING METHOD - The combination of management practices used to manipulate forest vegetation resulting in forests of distinctive form and character. Harvest cutting methods are classified as even-aged and uneven-aged.

HEAP LEACH - A mineral extraction process in which a solution (commonly cyanide solution) percolates through a pile (heap) of ore, dissolving the metal being extracted. The solution is collected after it percolates through the heap, and the metal is recovered from the solution. This is a common extraction process for low-grade deposits of gold, copper, and silver.

HERBACEOUS - Having little or no woody tissue and persisting usually for a single growing season.

HIGH CLEARANCE VEHICLES - Motorized vehicles that can drive over minor obstacles because of their elevated frame.

HISTORIC - Refers to the period of time for which there are written records (after European contact). In Region 6, the historic era begins at roughly 1800 A.D., with the first explorers who kept journals.

HYDROLOGIC - Pertaining to the quantity, quality, and timing of water yield from forested lands.

HYDROPHOBIC - Lacking affinity for water.

HYDROTHERMAL - An adjective applied to heated or hot aqueous-rich solutions, to the process in which they are concerned, and to the rocks, ore deposits, and alteration products produced by them.

IGNEOUS ROCK - Rock formed by the crystallization of once molten material called lava or magma.

IMPLAN - A Forest Service input-output model that is an economic model which predicts the behavior of an economy as certain portions of the economy are altered.

IMPROVED ROAD - A constructed or maintained vehicle way for the use of highway-type vehicles having more than two wheels.

INDICATOR SPECIES - A plant or animal species so highly adapted to a particular kind of environment that its mere presence is sufficient indication that specific conditions are also present. (W-W DEIS).

INTEGRATED PEST MANAGEMENT (IMP) - A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are studied and weighed. The information considered in selecting appropriate strategies includes the impact of the unregulated pest population on various resource values, alternative regulatory tactics and strategies, and benefit/cost estimates for these alternative strategies. Regulatory strategies are based on sound silvicultural practices and ecology of the pest-host system and consist of a combination of tactics such as timber stand improvement plus selective use of pesticides. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable.

INTENSIVE FOREST MANAGEMENT - A high investment level of timber management that envisions initial harvest, regeneration with genetically improved stock, control of competing vegetation, fill-in planting, pre-commercial thinning as needed for stocking control, one or more commercial thinnings, and final harvest.

INTERDISCIPLINARY TEAM - A group of individuals with different training assembled to solve a problem or perform a task.
INTERMINGLED OWNERSHIPS - Lands within the National Forest boundaries or surrounded by National Forest lands that are owned by private interests or other government agencies. Because of early land grants, these lands frequently are in checkerboard ownership patterns.

INTERMITTENT SERVICE - A road developed and operated for periodic service and closed between periods of use.

INTERPRETATION - Educational activity which aims to reveal meaning and relationships of the natural and cultural environment through first-hand experience.

IRRETRIEVABLE - Applies to losses of production, harvest, or use of renewable natural resources. For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible.

IRREVERSIBLE - Applies primarily to the use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long periods. Irreversible also includes loss of future options.

ISSUE - A point, matter, or question of public discussion or interest to be addressed or decided through the planning process.

JASPEROID - Agate, jasper, or thundereggs.

KNUTSON - VANDENBERG ACT OF 1924 (K-V) - An act that allows for the use of receipts for National Forest timber to reforest, to conduct stand improvement work or to perform improvement projects for other resources on the area where timber was harvested.

LAND ALLOCATION - The decision to use land for various resource management objectives in order to best satisfy the planning process issues, concerns, and opportunities, and meet assigned forest output targets.

LAND EXCHANGE - The conveyance of non-Federal land or interest in the land to the United States in exchange for National Forest System land or interest in the land.

LANDLINE LOCATION - Location of Forest property boundaries.

LIFESTYLE - A characteristic way of living which may be an individual variant within the cultural mainstream or may be an individual expression of a subculture.

LEASABLE MINERALS - Generally include minerals such as oil, gas, oil shale, coal, potassium, sodium, phosphates, sulphur, and geothermal.

LOCAL ROADS - Local roads are usually one-lane roads constructed to serve a dominant use or resource. Local roads do not access large land areas since they are more site specific than arterial and collector roads.

LOCATABLE MINERALS - These resources include gold, silver, lead, copper, and mercury, which are mined and processed for metals, and some uncommon nonmetals.
LOGGING SYSTEMS -

Tractor Logging - A system of log transportation in which logs are pulled from the woods to a landing by means of a crawler tractor, skidder, or similar ground-based equipment.

High-Lead Logging - A system of cable logging in which the working lines are elevated at the landing area by a rigged wooden tree or portable steel spar.

Skyline Logging - A system of cable logging in which all or part of the weight of the logs is supported during yarding by a suspended cable.

Balloon Logging - A system of cable logging in which the weight of the logs is counteracted by the lift provided by a lighter-than-air balloon.

Helicopter Logging - A system of transporting logs from the woods to a landing as an external load on a helicopter.

LONG-TERM EFFECTS - Those effects which will be significant beyond the RPA planning horizon of 50 years.

LONG-TERM SUSTAINED-YIELD TIMBER CAPACITY (LTSYC) - The highest uniform wood yield from lands being managed for timber production that may be sustained under a specified management intensity consistent with multiple-use objectives.

M - The Roman numeral for 1000.

MBF - One thousand board feet. Lumber or timber measurement.

MM - Million

MANAGED STAND - A stand of trees in which stocking level control is applied to achieve maximum growth.

MANAGED YIELD TABLE - A table showing, for a given species (or species mix) on a given site, the progressive development of a managed stand at periodic intervals covering the greater part of its useful life. It usually includes average diameter, basal area, number of trees, standing volume, and harvest volumes for a specific timber management regime.

MANAGEMENT AREA (MA) - A unit of land allocated to emphasize a particular resource, based on the capability of the area.

MANAGEMENT CONCERN - An issue, problem or a condition which constrains the range of management practices identified by the Forest Service in the planning process.

MANAGEMENT DIRECTION - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them.

MANAGEMENT INDICATOR SPECIES (MIS) - A wildlife species whose presence in a certain location or situation at a given population level indicates a particular environmental condition. Population changes are believed to indicate effects of management activities on a number of other wildlife species.

MANAGEMENT INTENSITY - A management practice or combination of management practices and associated costs designed to obtain different levels of goods and services.

MANAGEMENT PRESCRIPTION - Management practices selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives.
MANAGEMENT REQUIREMENT (MR) - Standards for resource protection, vegetation manipulation, silvicultural practices, even-aged management, riparian areas, soil and water and diversity, to be met in accomplishing National Forest System goals and objectives. (See 36 CFR 219.27)

MARGINAL COMPONENT - The portion of the commercial forest land on which it is presently not feasible (economically or technologically) to manage for timber crops but on which it may be possible in the future.

MASS-WASTING - A general term for a variety of processes by which large masses of earth material are moved by gravity either slowly or quickly from one place to another. (Dictionary of Geological Terms). Also mass movement.

MAXIMUM MODIFICATION - See "Scenic quality Objectives.*

MEAN ANNUAL INCREMENT (MAI) - The total increment up to a given age divided by that age.

MEMORANDUM OF AGREEMENT (MOA) - A three-party agreement (responsible Forest Service Official, State Historic Preservation Officer, Executive Director of the Advisory Council on Historic Preservation) which documents an agreed-upon plan to mitigate a proposed project's adverse effect upon cultural resources listed on or eligible for the National Register of Historic Places.

METAMORPHIC ROCK - Rocks changed by heat and pressure causing recrystallization and loss of original characteristics

MIDDLEGROUND - The visible terrain beyond the foreground where individual trees are still visible, but do not stand out distinctly from the stand (See "Foreground" and "Background.")

MINERAL DEVELOPMENT - The activities and facilities associated with extracting a proven mineral deposit

MINERAL ENTRY - Filing a mining claim on public land to obtain the right to any minerals it may contain.

MINERAL EXPLORATION - The search for valuable minerals on lands open to mineral entry.

MINERAL RESERVE - That portion of a mineral resource from which a mineral commodity can be economically and legally extracted.

MINERAL RESOURCE - A concentration of naturally occurring solid, liquid, or gaseous materials in or on the Earth's crust in such a form that economic extraction of a mineral resource is currently or potentially feasible (BLM Manual 3031).

MINIMUM VIABLE POPULATION (MVP) - The low end of the viable population range

MITIGATION - To moderate the force or intensity of environmental effects. To lessen or minimize an Adverse Effect upon a cultural resource listed on or eligible for the National Register of Historic Places. The two categories of mitigation most often used are project modification and data recovery.

MIXED CONIFER (MC) - A stand of coniferous trees with a mixture of species. Ponderosa pine will usually make up 25 percent to 75 percent of the species composition.

MODIFICATION - See "Scenic Quality Objectives.*

MONITORING - A process of collecting significant data from defined sources to identify departures or deviations from expected plan outputs

MOUNTAIN PINE BEETLE - A small insect (1/8 - 5/8 inch) that bores into the tree's cambium and deposits its eggs. Larvae emerge from the eggs and feed upon the cambel layer and thus disrupt the tree's translocation of food. Frequent attacks on the host tree result in the tree's mortality
MORTALITY - The volume of sound wood dying from natural causes during a specified period.

MULTIPLE-AGED STANDS - An intermediate form of stand structure between even-/ and uneven-aged stands. These stands generally have two or three distinct tree canopy levels occurring within a single stand.

MULTIPLE USE - The management of all the various renewable surface resources of the National Forest System so that they are utilized in the combination that will best meet the needs of the American people; making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in use to conform to changing needs and conditions, that some lands will be used for less than all of the resources, and harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land, with consideration being given to the relative values of the various resources, and not necessarily the combination of uses that will give the greatest dollar return or the greatest unit output.

NATIONAL ENVIRONMENTAL POLICY ACT OF 1969 (NEPA) - An act declaring a National policy to encourage productive harmony between man and his environment, to promote efforts which will prevent or eliminate damage to the environment and the biosphere and stimulate the health and welfare of man, to enrich the understanding of the ecological systems and natural resources important to the Nation and to establish a Council on Environmental Quality.

NATIONAL FOREST FUND (NFF) - An account that includes all receipts (to the U.S. Treasury) from proclaimed National Forests for timber, grazing, land use, power, minerals, and user fees.

NATIONAL FOREST MANAGEMENT ACT (NFMA) - A law passed in 1976 that amends the Forest and Rangeland Renewable Resources Planning Act and requires the preparation of Forest plans.

NATIONAL FOREST SYSTEM (NFS) LAND - Federal lands that have been designated by Executive order or statute as National Forests, National Grasslands, or Purchase Units, and other lands under the administration of the Forest Service, including Experimental Areas and Bankhead-Jones Title III lands.

NATIONAL RECREATION TRAILS - Trails designated by the Secretary of the Interior or the Secretary of Agriculture as part of the national system of trails authorized by the National Trails System Act. National Recreation Trails provide a variety of outdoor recreation uses in or reasonably accessible to urban areas.

NATIONAL REGISTER OF HISTORIC PLACES - A register of cultural resources of national, state, or local significance, maintained by the Department of the Interior.

NATIONAL WILD AND SCENIC RIVER SYSTEM - Rivers with outstanding scenic, recreational, geological, fish and wildlife, historic, cultural, or other similar values designed by Congress under the Wild and Scenic Rivers Act for preservation of their free-flowing condition.

NET PUBLIC BENEFIT - An expression used to signify the overall long-term value to the Nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index.

NO ACTION ALTERNATIVE (Alternative A) - The most likely condition expected to exist in the future if current management direction were to continue unchanged.

NONCOMMERCIAL SPECIES - Species that have no economic values at this time nor anticipated timber value within the near future.

NONDECLINING EVEN FLOW - A policy governing the volume of timber removed from a National Forest, which states that the volume planned for removal in each succeeding decade will equal or exceed that volume planned for removal in the previous decade.
NONFOREST LAND - Land that has never supported forests and lands formerly forested but now developed for such nonforest uses as crops, improved pasture, etc.

NONMARKET - (Noncash economic benefits). Products derived from National Forest resources that do not have a well-established market value, for example, wilderness, wildlife.

NONPRICED OUTPUTS - Outputs for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value commensurate with the market values associated with the priced outputs.

NONSTRUCTURAL RANGE IMPROVEMENT - Practices and treatments undertaken to improve range not involving construction of improvements (e.g., seeding, fertilizing, or prescribed burning).

OBJECTIVE - A concise, time-specific statement of measurable planned results that respond to pre-established goals. An objective forms the basis for further planning to define the precise steps to be taken and the resources to be used in achieving identified goals.

OBLITERATE - The action needed to close an unneeded road and return the land to production.

OFF-HIGHWAY TRAVEL MANAGEMENT OBJECTIVES - These objectives relate to the recreation opportunities for off-highway use on areas and trails on National Forest lands. The objectives, which include off-highway travel criteria, are developed from management area direction and access management objectives.

OFF-ROAD or OFF-HIGHWAY VEHICLES (ORV's or OHV's) - Any vehicle, including ATV's, which is restricted by law from operating on public roads reserved for general motor vehicle traffic.

OLD GROWTH STAND - An old-growth stand is defined as any stand of trees 10 acres or greater generally containing the following characteristics: 1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage, 2) stands will usually contain a multilayered canopy and trees of several age classes; 3) standing dead trees and down material are present; and 4) evidence of man's activities may be present, but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand.

OPERATION AND MAINTENANCE COSTS - Costs associated with operating and maintaining facilities, program management, and support costs associated with management of other resources.

ORE - A mineral deposit which can be extracted at a profit.

ORV CLOSURE - An administration order closing a land area to specified types of off-road vehicle travel yearlong.

ORV RESTRICTION - An administrative order restricting a land area to specified types of off-road vehicle travel during specific seasons or conditions.

OUTPUT - The goods, end products, or services that are purchased, consumed, or used directly by people. Goods, services, products, and concerns produced by activities that are measurable and capable of being used to determine the effectiveness of programs and activities in meeting objectives. A broad term for describing any result, product, or service that a process or activity actually produces.

OVERMATURE - The stage at which a tree declines in vigor and soundness, for example, height growth has usually stopped and probability of mortality is high.
OVERSTORY - The portion of trees in a forest which forms the upper most layer of foliage.

OVERSTORY REMOVAL - A type of harvest which is designed to remove all of the trees in the overstory. The objective is to release the acceptably stocked understory.

OVERVIEW - A report, based primarily on archival research, that organizes and summarizes cultural resource information from a particular National Forest or geographic area.

PACIFIC NORTHWEST REGION - A Forest Service organizational unit consisting of all the National Forests in Oregon and Washington.

PARTIAL CUT - Any cutting other than a clearcut. This may include thinning, selection shelterwood or an overstory removal.

PARTIAL RETENTION - See "Scenic Quality Objectives."

PERMITTED GRAZING - Use of a National Forest range allotment under the terms of a grazing permit.

PERSONS-AT-ONE-TIME (PAOT) - The number of people in an area or using a facility at the same time. Generally used as "maximum PAOT" to indicate the capacity of an area or facility to support peak usage within established user density standards and without degradation to biophysical resources.

PHYSIOGRAPHIC - Pertaining to physical geography.

PHYSIOGRAPHIC PROVINCE - Region of similar structure and climate that has had a unified geomorphic cycle.

PLANNING HORIZON - The overall time period considered in the planning process that spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions which would influence the planning decisions.

PLANNING PERIOD - Generally one decade. The time interval within the planning horizon that is used to show incremental changes to yields, costs, effects, and benefits.

PLANNING RECORDS - A system that records decisions and activities that result from the process of developing a forest plan, revision, or significant amendment.

PLANT ASSOCIATION - Climax plant community type

PLANT COMMUNITIES - A homogeneous unit in respect to the number and relationship of plants in the tree, shrub, and ground cover strata.

POTENTIAL YIELD - The maximum, perpetual, sustained-yield harvest attainable through intensive forestry on regulated areas considering the productivity of the land, conventional logging technology, standard cultural treatments, and interrelationships with other resource uses and the environment.

PRECOMMERCIAL THINNING - The practice of removing some of the trees less than merchantable size from a stand so that the remaining trees will grow faster.

PREHISTORIC - Relating to the period of time before written records (prior to European contact). In Region 6, before 1800 A.D., or before the advent of written records.

PRESCRIBED BURNING - Use of fire in forest management for hazard reduction and vegetative manipulation.
PRESCRIBED FIRE - A wildland fire burning under specified conditions which will accomplish certain planned objectives. The fire may result from either planned or unplanned ignitions. Plans for use of unplanned ignitions for this purpose must be approved by the Regional Forester.

PRESENT NET VALUE (PNV) - The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are assigned and the total discounted costs of managing the planning area.

PRESERVATION - See "Scenic Quality Objectives."

PRIMARY CAVITY EXCAVATOR - An animal that excavates a cavity in wood for nesting or roosting.

PRIME FARMLAND - All land which qualifies for rating as Class I or as Class II in the U.S. Soil Conservation Service land use capability classification.

PRIMITIVE ROADS - Roads constructed with no regard for grade control or designed drainage, sometimes by merely repeated driving over an area. These roads are single lane, usually with native surfacing and sometimes passable with 4-wheel drive vehicles only, especially in wet weather.

PROGRAMMED ALLOWABLE HARVEST - That part of the potential yield scheduled for harvest in a specific year. It is based on demand, funding, management needs and multiple use considerations and, as a consequence, may vary over time.

PUMICE - A volcanic glass full of cavities and very light in weight.

PYROCLASTIC ROCK - A rock consisting of unreworked solid material explosively or aerially ejected from a volcanic vent.

PUBLIC ISSUE - A subject or question of widespread public interest relating to management of National Forest System.

PUBLIC PARTICIPATION - Meetings, conferences, seminars, workshops, tours, written comments, responses to survey questionnaires, and similar activities designed and held to obtain comments from the public about Forest Service planning.

PURCHASER CREDIT - Credit earned by the purchaser of a National Forest timber sale by construction of contract-specified roads. Earned purchaser credit may be used by the purchaser as payment for National Forest timber removed.

RANGE ALLOTMENT - A designated area available for livestock grazing upon which a specified number, kind of livestock and season of use may be grazed under a term grazing permit. The basic land unit used to facilitate management of the range resource on National Forest System and associated lands administered by the Forest Service.

RANGE CONDITION - The state or health of the range vegetation and soil to produce a stable biotic community based on the composition, density, and vigor of the vegetation and the physical characteristics of the soil. Condition is expressed as satisfactory or unsatisfactory.

RANGE IMPROVEMENT - Any structure or nonstructural improvement to facilitate management of rangelands or livestock.

RANGELAND - Land where the vegetation is predominantly grasses, grass-like plants, forbs, or shrubs suitable for livestock grazing and browsing.
RANGE MANAGEMENT - The art and science of planning and directing range use to obtain sustained maximum animal production, consistent with perpetuation of the natural resource.

RANGER DISTRICT - Administrative subdivisions of the Forest supervised by a District Ranger who reports to the Forest Supervisor.

RARE II - See Roadless Area Review and Evaluation II.

REAL DOLLAR VALUE - A monetary value which compensates for the effects of inflation.

RECONSTRUCTION - Road or trail construction activities which take place on an existing road or trail and raise the standard of the road or trail. This can include relocation of the facility in a completely new location.

RECREATION CAPACITY - The number of people that can take advantage of the supply of a recreation opportunity during an established use period without substantially diminishing the quality of the recreation experience of the biophysical resources.

RECREATION INFORMATION MANAGEMENT (RIM) - A computer oriented system for the organization and management of information concerning recreation use, occupancy, and management of National Forest land.

RECREATION OPPORTUNITY SPECTRUM (ROS) - Land delineations that identify a variety of recreation experience opportunities categorized into six classes on a continuum from primitive to urban. Each class is defined in terms of the degree to which it satisfies certain recreation experience needs, based on the extent to which the natural environment has been modified, the type of facilities provided, the degree of outdoor skills needed to enjoy the area, and the relative density of recreation use. The six classes are:

1. **Primitive** - Area is characterized by an essentially unmodified natural environment of fairly large size. Interaction between users is very low and evidence of other users is minimal. The area is managed to be essentially free from evidence of human-induced restrictions and controls. Motorized use within the area is not permitted.

2. **Semiprimitive Nonmotorized (SPNM)** - Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Interaction between users is low, but there is often evidence of other uses. The area is managed in such a way that minimum on-site controls and restrictions may be present, but would be subtle. Motorized recreation use is not permitted, but local roads used for other resource management activities may be present on a limited basis. Use of such roads is restricted to minimize impacts on recreational experience opportunities.

3. **Semiprimitive Motorized (SPM)** - Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present, but would be subtle. Motorized recreation use of local primitive or collector roads with predominantly natural surfaces and trails suitable for motor bikes is permitted.

4. **Roaded Natural (RN)** - Area is characterized by predominantly natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidence usually harmonizes with the natural environment. Interaction between users may be moderate to high, with evidence of other users prevalent. Resource modification and utilization practices are evident, but harmonize with the natural environment. Conventional motorized use is allowed and incorporated into construction standards and design of facilities.

5. **Rural (R)** - Area is characterized by a natural environment that has been substantially modified by development of structures, vegetative manipulation, or pastoral agricultural development. Resource modification and utilization practices may be used to enhance specific recreation activities and to maintain vegetative cover and soil. Sights and sounds of humans are readily
evident, and the interaction between users is often moderate to high. A considerable number of facilities are designed for use by a large number of people. Facilities are often provided for special activities. Moderate user densities are present away from developed sites. Facilities for intensified motorized use and parking are available.

6. **Urban** - Area is characterized by a substantially urbanized environment, although the background may have natural-appearing elements. Renewable resource modification and utilization practices are often used to enhance specific recreation activities. Vegetative cover is often exotic and manicured. Sights and sounds of humans are predominant on site. Large numbers of users can be expected both on site and in nearby areas. Facilities for highly intensified motor use and parking are available with forms of mass transit often available to carry people throughout the site.

**RECREATION VISITOR DAY (RVD)** - A measure of recreational use of an area. One recreation visitor day consists of 12 hours of recreation use of a site or area. Recreation visitor days are used as a recreation production or output capacity measure.

**RECREATION WILDERNESS SPECTRUM (RWS)** - This is associated with the recreation opportunity spectrum (ROS), a system used to classify or differentiate areas within wilderness to provide for a variety of management possibilities and wilderness opportunities. The objective of all classifications is to provide wilderness opportunities but to different degrees; from pristine to the semiprimitive transition.

**REFORESTATION** - The natural or artificial restocking of an area usually to produce timber and other wood products, but also to protect watersheds, prevent soil erosion, and improve wildlife, recreation and other natural resources. Natural reforestation includes site preparation to reduce competing vegetation and provide a mineral seed bed for seed provided by seed trees. Artificial reforestation is the planting of seedlings, cuttings or seeds by hand or mechanical means and may include site preparation.

**REGENERATION CUT** - The removal of trees intended for the purpose of assisting regeneration already present or to make regeneration of the stand possible.

**REGION** - The standard administrative unit of the Forest Service administered by a Regional Forester.

**REGIONAL FORESTER** - The official responsible for administering a single Region and preparing a Regional Guide.

**REGIONAL GUIDE** - The plan developed to meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974, as amended, that guides all natural resource management activities and establishes management standards and guidelines for the National Forest System lands of a given region. It also disaggregates the RPA objectives assigned to the Region and to the Forest within that region.

**REGULATIONS** - Generally refers to the Code of Federal Regulations, Title 36, Chapter II, which covers management of the Forest Service.

**REHABILITATION** - Actions taken to protect or enhance site productivity, water quality, or other values for a short period of time.

**RESEARCH NATURAL AREAS (RNA’s)** - An area set aside by the Forest Service to preserve a representative sample of an ecological community; primarily for scientific and educational purposes. Commercial exploitation is not allowed and general public use is discouraged.

**RESOURCE** - An aspect of human environment which renders possible or facilitates the satisfaction of human wants and the attainment of social objectives.

**RESOURCE VALUES** - The tangible and intangible worth of forest resources.

**RESPONSIBLE LINE OFFICER** - The Forest Service employee who has the authority to select and/or carry out a specific planning action.
RESTORATION - The long-term placement of land back into its natural condition or state of productivity.

RETENTION - A scenic quality objective which means human activities are not evident to the casual forest visitor.

REVEGETATION - The re-establishment and development of a plant cover. This may take place naturally through the reproductive processes of the existing flora or artificially through the direct action of man - reforestation or range reseeding.

RIGHT-OF-WAY - The right to pass through another person's land as obtained by condemnation or purchase.

RIM - See Recreation Information Management.

RIPARIAN AREAS - The riparian ecosystem (area) is that land, next to water, where plants that are dependent on a perpetual source of water occur. Riparian sites include fluvial surfaces such as streambanks, active channel shelves, active floodplains, and overflow channels.

RIPRAP - A structure built of broken rock or other material used for protecting exposed soil from erosion along stream channels or road ditches.

ROAD DENSITY - The number of road miles per square mile of land area.

ROADLESS AREA - An area of undeveloped Federal land within which there are no improved roads maintained for travel by means of motorized vehicles intended for highway use.

ROADLESS AREA REVIEW AND EVALUATION (RARE II) - A comprehensive process directed by the Secretary of Agriculture to identify roadless and undeveloped land areas in the National Forest system and to determine their uses for either wilderness or other resource management and development, and to determine areas that would require further planning to make such a decision.

ROADLESS ISLANDS - A roadless area that is surrounded by permanent waters, or that is markedly distinguished from surrounding lands by topographical or ecological factors such as precipices, canyons, thickets, or swamps.

ROAD MANAGEMENT OBJECTIVES - Road management objectives establish the intended purpose of an individual road based on management area direction and access management objectives. Road management objectives contain design criteria, operation criteria, and maintenance criteria.

ROS - See Recreation Opportunity Spectrum.

ROTATION AGE - The age of a stand when regeneration harvest occurs.

RPA - Forest and Rangeland Renewable Resources Planning Act of 1974.

ROCKHOUND - An amateur rock and mineral collector.

RVD - See Recreation Visitor Day.

SALEABLE MINERALS - Saleable minerals include common varieties of sand, stone, gravel, pumice, pumicite, cinders, and clay. In general, these minerals are of wide-spread occurrence and are of relatively low unit value. They are generally used for construction materials and for road building purposes. Saleable minerals, which have some property giving them distinct and special value, remain locatable. Before a deposit can be sold, a determination of "common variety" must be made by minerals staff and legal counsel.
SALVAGE HARVEST - Removal of dead or dying trees resulting from insect and disease epidemics or wildfire

SANITATION HARVEST - Removal of dead or dying trees to prevent spread of insects or disease.

SAWTIMBER - Trees that will yield logs suitable in size and quality for the production of dimension lumber.

SCENIC QUALITY OBJECTIVES - Categories of acceptable landscape alteration measured in degrees of deviation from the natural-appearing landscape.

1. *Preservation* - Ecological change only.
2. *Retention* - Human activities are not evident to the casual Forest visitor.
3. *Partial Retention* - Human activity may be evident, but must remain subordinate to the characteristic landscape.
4. *Modification* - Human activity may dominate the characteristic landscape, but must, at the same time, follow naturally established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.
5. *Maximum Modification* - Human activity may dominate the characteristic landscape, but should appear as a natural occurrence when viewed as background.

SCENIC RESOURCE - The composite of basic terrain, geologic features, water features, vegetative patterns, and land-use effects that typify a land unit and influence the visual appeal the unit may have for visitors.

SCOPING - Determination of the significant issues to be addressed in an EIS.

SEDIMENT - Solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface either above or below sea level.

SEDIMENTARY ROCK - A rock made up of sediment.

SEED CUT - Removal of mature trees near rotation age in a shelterwood harvest to permanently open the stand and prepare the site for regeneration from the seed trees left for that purpose.

SEEDLING/SAPLING - A forest successional stage in which trees less than five inches in diameter are the predominant vegetation.

SELECTION CUTTING - The annual or periodic removal of trees (particularly the mature), individually or in small groups from an uneven-aged forest to achieve the balance among diameter classes needed for sustained yields, and in order to realize the yield, and establish a new crop of irregular constitution. NOTE: The improvement of the Forest is a primary consideration.

SELECTION SYSTEM - A silviculture system in which trees in an uneven-aged stand are removed individually, here and there, from a large area each year in order to achieve a balance among diameter classes needed for sustained yield by selection cutting - ideally over a whole forest or working circle, but from practical considerations almost always over the annual coups of cutting series; regeneration mainly natural and crop ideally all-aged.

SENSITIVE SPECIES - Plant or animal species which are susceptible or vulnerable to activity impacts or habitat alterations. Those species that are recognized by the Regional Forester as needing special management to prevent placement on Federal or State lists.

SERAL - A plant and animal community which is transitional in stage of succession, being either short- or long-term. If left alone, the seral stage will pass, and another plant and animal community will replace it.
SHELTERWOOD HARVEST - Silvicultural system used to harvest mature trees at rotation age in a series of preparatory, seed and removal cuts designed to regenerate a new even-aged crop under the shelter of the old crop.

SHORT-TERM EFFECTS - For timber management planning, those effects which will not be significant beyond the RPA planning horizon of 50 years; for DEQ water quality, short-term effects are defined as two days or less. Generally, short-term effects are within the planning period.

SIGNIFICANT - Meeting the criteria for inclusion on the National Register of Historic Places (same as eligible).

SILVICULTURAL SYSTEM - A management process whereby forests are tended, harvested, and replaced, resulting in a forest of distinctive form. Systems are classified according to the method of carrying out the fellings that remove the mature crop and provide for regeneration and according to the type of forest thereby produced.

SILVICULTURE - The science and art of growing and tending crops of forest trees to attain the desired level of marketable and unmarketable products.

SITE INDEX - A measure of the relative productive capacity of an area for growing wood. Measurement of site index is based on height of the dominant trees in a stand at a given age.

SITE PREPARATION - Removing unwanted vegetation and debris from a site and preparing the soil before reforestation.

SITE PRODUCTIVITY - Production capability of specific areas of land.

SKYLINE LOGGING - A system of cable logging in which all or part of the weight of the logs is supported during yarding by a suspended cable.

SLASH - Debris left after logging, pruning, thinning, or brush cutting, and large accumulations of debris resulting from windstorms. It includes logs, bark, branches, and stumps.

SMOLT HABITAT CAPABILITY INDEX (SHCI) - Smolt refers to the life history stage of anadromous salmonids in which physiological changes are taking place to adapt them for ocean survival and they are either migrating or will shortly migrate seaward. The three levels associated with this index are:

1. Existing SHC - The number of smolt being produced at the present time with existing escapement levels in existing freshwater habitat.

2. Potential SHC - The number of smolt that are capable of being produced assuming there is sufficient adult escapement to fully seed existing freshwater habitat.

3. Potential SHC with Full Enhancement - The number of smolt that are capable of being produced, assuming sufficient capital investments have been made to maximize the freshwater habitats and there is sufficient adult escapement to fully seed the existing and enhanced habitat.

SNAG - A nonliving standing tree. The interior of the snag may be sound or rotted.

SNAG LEVEL - The number of snags per unit of area by d.b.h. class selected as a management goal; the level is predicted on the theoretical number of snags per unit of area by diameter class needed to support nesting populations of woodpeckers at a selected density.

SOCIOECONOMIC - Pertaining to, or signifying the combination or interaction of, social and economic factors.
SOIL EROSION - The detachment and movement of soil from the land surface by wind, water, or gravity.

SOIL COMPACTION - Increase in soil bulk density

SOIL PRODUCTIVITY - The capacity of a soil, in its normal environment, to produce a specific plant or sequence of plants under a specific system of management.

SOIL RESOURCE INVENTORY (SRI) - An inventory of the soil resource based on landform, vegetative characteristics, soil characteristics, and management potentials

SPECIAL COMPONENT - The portion of the commercial forest land that needs special treatment of the timber resource to achieve other resource objectives (e.g., old growth, streamside protection, or visual corridors)

SPECIAL USE PERMITS - Permits and granting of easements (excluding road permits and highway easements) authorizing the occupancy and use of land.

STAND - An aggregation of trees occupying a specific area and sufficiently uniform in composition, age arrangement, and condition as to be distinguishable from the forest in adjoining areas.

STANDARD - Performance criteria indicating acceptable norms or specifications that actions must meet. A principle requiring a specific level of attainment, a rule to measure against

STANDARD COMPONENT - The portion of the commercial forest land on which crops of industrial wood can be grown and harvested with adequate protection of the forest resources under the usual provisions of the timber sale contract.

STATE HISTORIC PRESERVATION OFFICER (SHPO) - An official appointed by the Governor of each State to direct implementation of the National Historic Preservation Act of 1966 and subsequent regulations and Executive Order. Responsibilities include: State-wide cultural resource inventory, development of a State Historic Preservation Plan, review of National Register of Historic Places nominations, administration of Federal historic preservation grants, and review of Federal undertakings which might affect cultural resources listed on or eligible for the National Register of Historic Places.

STOCKING - The degree of occupancy of land by trees as measured by basal area or number of trees and as compared to a stocking standard; that is, the basal area or number of trees required to fully use the growth potential of the land.

STOCKING LEVEL CONTROL - The process of maintaining the desirable number of trees to achieve optimum growth and management.

STREAMFLOW - The discharge of water from a watershed that occurs in a natural stream channel

STRUCTURAL RANGE IMPROVEMENT - Improvement requiring construction or installation to improve the range, facilitate management, or control distribution and movement of livestock

SUITABILITY - The appropriateness of applying certain resource management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices.

SUITABLE TIMBER LAND - Forested lands that are available for timber management because they have not been withdrawn because of Law or Regulation, where irreversible damage would not occur, and where regeneration can be assured.

SUMMER RANGE - A portion of the total range on which big game animals normally find food and cover during summer months.
SUNK FUNDS - Monies already invested.

SUPPRESSION - The action of extinguishing or confining a fire.

SUSTAINED YIELD - The achievement and maintenance in perpetuity of a periodic output of the renewable resources without impairment of the productivity of the land.

TARGETS - Objectives assigned to the Forest by the Regional Plan.

TECTONIC - Of, pertaining to, or designating the rock structure and external forms resulting from the deformation of the earth's crust.

TEMPORARY ROADS - Temporary roads are low-level roads constructed for a single purpose and short-term use. Once use of the road has been completed, it is obliterated, and the land it occupied is returned to production.

THERMAL COVER - Cover used by animals to lessen the effects of weather; for elk the types of cover are:

- **Summer Range** - A stand of coniferous trees at least 40 feet tall with an average crown closure of 40 percent or more.

- **Winter Range** - A stand of coniferous trees 10 feet or more tall with an average crown closure of 40 percent or more.

THINNING - The practice of removing some of the trees in a stand so that the remaining trees will grow faster due to reduced competition for nutrients, water, and sunlight. Thinning may be done at two different stages:

1. **Commercial thinning** - Removing trees that have reached sufficient size to be manufactured into a product.

2. **Precommercial thinning** - Removing trees that are too small to make a merchantable product

THREATENED SPECIES - Any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range and which has been designated in the Federal Register by the Secretary of the Interior as a threatened species.

THRESHOLD - The point or level of activity beyond which an undesirable set of responses begins to take place within a given resource system.

TIERING - Refers to the coverage of general matters in broad environmental impact statements (such as national program or policy statements) with subsequent narrower statements or environmental analyses (such as regional or basin wide program statements or ultimately site-specified statements), incorporating by reference the general discussions and concentrating solely on the issues specific to the statement in question.

TIMBER - A general term for the major woody growth of vegetation in a forest area.

TIMBER CLASSIFICATION - Forested land is classified under each of the land management alternatives according to how it relates to the management of the timber resource. The following are definitions of timber classifications used for this purpose.

1. **Nonforest** - Land that has never supported forests and land formerly forested where use for timber production is precluded by development or other uses.

2. **Forest** - Land at least 10-percent stocked (based on crown cover) by forest trees of any size, or formerly having had such tree cover and not currently developed for nonforest use.
3 **Suitable** - Land to be managed for timber production on a regulated basis

4 **Unsuitable** - Forest land withdrawn from timber utilization by statute or administrative regulation (for example, wilderness), or identified as not appropriate for timber production in the Forest planning process

5 **Commercial Forest** - Forest land tentatively suitable for the production of continuous crops of timber and that has not been withdrawn

**TIMBER PRODUCTION** - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees to be cut into logs, bolts, or other round sections for industrial or consumer use. The term "timber production" does not include production of fuelwood.

**TIMBER SALE PROGRAM QUANTITY** - This includes all volume expected to be offered for sale. This includes "green" material, salvage, firewood and miscellaneous products. This is used to measure attainment of RPA budgeted target.

**TIMBER STAND IMPROVEMENT (TSI)** - Management activities conducted in an immature stand to accelerate diameter growth and improve the form of the trees that remain

**TOLERANCE** - The ability of a tree to grow satisfactorily in the shade of, and in competition with, other trees.

**TONS OF SUSPENDED PARTICULATES** - A measure of the amount of solid material contributed to the airshed by smoke.

**TRAILHEAD** - The parking, signing, and other facilities available at the terminus of a trail

**TRAIL VEHICLE** - Vehicles designed for trail use that are 40 inches wide or less, such as bicycles, snowmobiles, trail bikes, trail scooters, and all-terrain vehicles

**TRANSITORY RANGE** - Land that is suitable for grazing use of a nonenduring or temporary nature over a period of time. For example, on particular disturbed lands, grass may remain in the area for a period of time before being replaced by trees or shrubs not suitable for forage

**TRANSPORTATION SYSTEM** - All existing and planned roads and trails needed to access the Forest.

**TUFF** - A rock formed of compacted volcanic fragments, generally smaller than 4mm in diameter.

**UNDERSTORY VEGETATION** - Grass, small trees, shrubs, and other plants found beneath the overstory (the trees comprising the forest).

**UNEVEN-AGED MANAGEMENT** - The application of a combination of actions needed to simultaneously maintain continuous high-forest cover, recurring regeneration of desirable species, and the orderly growth and development of trees through a range of diameter or age classes to provide a sustained yield of forest products. Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes. Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection.

**UNIT PLANS** - Land management plans prepared for multiple use management of land and resources on portions (units) of the National Forests, which do not necessarily fully incorporate NFMA requirements. "Units" do not always follow National Forest boundaries and, in some cases, include parts of two or more National Forests.

**UNPLANNED IGNITION** - A fire started at random by either natural or human causes, or a deliberate incendiary fire
UNREGULATED - Timber land not managed on a sustained yield basis, such as administrative sites, campgrounds, and experimental forests.

UTILITY AND TRANSMISSION CORRIDOR - A strip of land designated for the transportation of energy, commodities, and communications by railroad, State highway, electrical power transmission (69 KV or above), oil and gas and coal slurry pipelines 10 inches in diameter and larger, and telecommunication cable and electronic sites for interstate use. Transportation of minor amounts of power for short distances, such as short feeder lines from small power projects including geothermal or wind, or to serve customer subservice substations along the line, are not to be treated within the Forest Plan effort.

UTILIZATION STANDARDS - Standards guiding the use and removal of timber, which is measured in terms of diameter at breast height (d.b.h.), top diameter inside the bark (top d i.b.), and percent 'soundness' of the wood.

VIABLE POPULATION - The number of individuals of a species required to ensure the long-term existence of the species in natural, self-sustaining populations adequately distributed throughout their region.

VIEWSHED - The total landscape seen or potentially seen from all or a logical part of a travel route, use area, or water body.

WATERSHED - The area that contributes water to a drainage or stream.

WETLANDS - Areas that are inundated by surface water or groundwater with a frequency sufficient to support, and under normal circumstances does or would support, a prevalence of vegetation or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction (Executive Order 11990).

WILD AND SCENIC RIVERS - Those rivers or sections of rivers designated as such by congressional actions under the 1968 Wild and Scenic Rivers Act, as wild, scenic, or recreational by an act of the Legislature of the State or States through which they flow. Wild and scenic rivers may be classified and administered under one or more of the following categories:

1. Wild River Areas - Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.

2. Scenic River Areas - Those rivers or sections of rivers that are free of impoundments, with watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

3. Recreational River Areas - Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

WILDERNESS - Areas designated by congressional action under the 1964 Wilderness Act. Wilderness is defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation. Wilderness areas are protected and managed to preserve their natural conditions, which generally appear to have been affected primarily by the forces of nature, with the imprint of human activity substantially unnoticeable; have outstanding opportunities for solitude or for a primitive and confined type of recreation; include at least 5,000 acres or are of sufficient size to make practical their preservation, enjoyment, and use in an unimpaired condition, and may contain features of scientific, educational, scenic, or historical value as well as ecologic and geologic interest.
WILDERNESS ACT - Establishes a National Wilderness Preservation System to be composed of Federally-owned areas designated by Congress, administered for use and enjoyment as Wilderness, the preservation of their wilderness character, and for the gathering and dissemination of information regarding their use and enjoyment as Wilderness.

WILDERNESS RESOURCE SPECTRUM (WRS) - Classification used to further divide a wilderness into zones based on degrees of primitiveness. Areas of the Ochoco Wilderness will be managed under two classes of the WRS system:

1. *Primitive* - characterized by an essentially unmodified environment. Concentration of users is low and evidence of human use is minimal. The area is managed to be essentially free from evidence of human-induced restrictions and controls.

2. *Semiprimitive* - characterized by a predominately unmodified natural environment of moderate size. The concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present, but are subtle.

WILDFIRE - Any wildland fire that is not a prescribed fire. All wildfires require suppression.

WILDLIFE - All nondomesticated mammals, birds, reptiles, and amphibians living in a natural environment, including both game species and nongame species. Animals or their progeny, which once were domesticated but escaped captivity and are running wild (i.e., feral animals), such as horses, burros, and hogs, are not considered wildlife.

WILDLIFE AND FISH USER DAY (WFUD) - One WFUD consists of 12 hours of recreation that is the result of fish or wildlife.

WILDLIFE HABITAT DIVERSITY - The distribution and abundance of different plant and animal communities and species within a specific area.

WINTER RANGE - A range, usually at lower elevation, used by big game during the winter months; usually smaller and better-defined than summer ranges.

WITHDRAWAL - The withholding of an area of Federal land from settlement, sale, location, or entry, under some or all of the general land laws for the purpose of limiting activities under those laws in order to maintain other public values in the area.

WORKING GROUP - Comprises those parts of a forest that have generally the same growth potential and management opportunities.

YARDING - The moving of logs from the stump where cut to a central concentration area or landing.

ZONE OF INFLUENCE - The geographic area where most, but not all, of the direct social and economic effects of the Forest and Grassland's management occur.

Appendix A

Issues, Concerns, and Opportunities
Appendix A

Issues, Concerns, and Opportunities

Introduction

This appendix covers the major steps taken to identify public issues, management concerns and resource opportunities considered during the planning process. The appendix is organized into five sections: 1) the process used to identify the issues, concerns and opportunities, 2) contacts and consultations with others, 3) the criteria used to screen the issues down to the few selected to be addressed in the Environmental Impact Statement (EIS), 4) changes in the issues between the Draft and Final EIS, and 5) a discussion of the issues and how they were used to formulate alternatives.

Issue Identification

During the Fall of 1980, the Forest began to identify the principal issues to be addressed in the Draft Forest Plan. The Forest Management Team (Forest Supervisor, District Rangers, and Forest Staff Officers) decided to try a fresh approach, without a rehash of old issues from former Unit Plans. The previous issues were reviewed but not established as a base.

The Management Team agreed to utilize interest groups as a starting point. Individuals representing key interests of conservationists, recreationists, sportsmen, ranchers, timber industry, and government agencies were invited to identify preliminary issues that could be expanded or refined by a broader audience. These key interest groups met with the Forest Interdisciplinary Planning Team (ID Team) at six meetings held during the period of September 27 to October 2, 1980. A total of 56 people attended these meetings.

From the meetings, 125 preliminary issues, concerns, and opportunities (ICO’s) were identified. The ID Team then consolidated these ICO’s into 60 issues and submitted this list to the public along with a request for response. A total of 338 copies were mailed to addresses on the Forest’s mailing list, 450 copies were distributed from our offices, and another 2,000 were distributed through bulk mailings to the rural areas around Burns and Prineville, Oregon.

In addition, public involvement was requested through various news media. Newspapers, radio, and television participated as listed below:

The ID Team also conducted six public meetings to gather additional public comment. These meetings were in Prineville (two meetings) 11/12/80, Dayville 11/13/80, Paulina 11/13/80, and Burns (two meetings) 11/24/80. Five other meetings were held for Forest Service employees.
Response from mailings and attendance at the meetings was as follows:

Mailing Responses - 164
Attendance at Public Meetings - 52
Attendance at Forest Service Employee Meetings - 121

The ID Team used the information that was gathered to consolidate the issues into resource or land use topics. Seventeen issues were developed from this exercise. Comments that were not clearly represented in these 17 issues were also evaluated by the ID Team.

In January 1981, these 17 issues were submitted to the public for verification and ranking by intensity. Ranking the issues was useful initially, however, the rankings were later dropped when they no longer proved meaningful in developing the alternatives. The 17 issues were condensed to 14 as a result of the analysis of the public responses. These 14 issues are listed below.

1. What should be the level of timber production?
2. How can activities on the Forest and Grassland benefit social and economic wants and needs of local communities?
3. What is the appropriate level of livestock grazing and intensity of range management?
4. How should riparian areas be managed to meet various resource needs?
5. What road system should be provided to meet public, commercial and administrative access needs?
6. Should habitat be provided for increased populations of big game?
7. How much roadless recreation opportunity should be provided?
8. Should the Forest and Grassland limit the emphasis placed on visual resources to those areas of high scenic value?
9. How much old growth habitat should be provided?
10. To what extent should off-road vehicle use be controlled?
11. To what extent should firewood be provided to meet demand?
12. How much habitat should be provided for wildlife species dependent on dead trees?
13. To what extent should the Forest and Grassland provide for an expanded trail system?
14. To what extent should the Forest provide for winter sports activities?

The interdisciplinary team developed alternative management strategies based on these issues. As the alternatives were developed two of these issues were removed from the preceding list. They were the off-road vehicle use issue and the trail issue (numbers 10 and 13).

The off-road vehicle use issue, as initially identified in the public involvement process, was primarily an issue on the Crooked River National Grassland. It appeared at the time that the issue could be negotiated at the local level, outside the Forest and Grassland Plans. During the validation effort between the Draft and the Final, the public and agency interest in ORV use has increased. The Henderson Flat area on the Grassland continues to be a controversial area. In addition, some of the local citizenry has voiced concern over resource damage by ORV’s on other areas of the Forest and Grassland.

The trail issue was also dropped as a separate issue. As the proposed trail system is closely tied with the allocation of roadless areas, the two issues were closely related. On those trails (existing or proposed) not part of the roadless area allocation issue, only minor resource interactions were identified, with little affect to the overall management of the Forest and Grassland.

In April 1984, three public meetings were held to update the issues and acquire additional information on unroaded areas. The meetings were held in Prineville (on April 2, 3, and 4) with 29 people attending.
After those meetings, the Forest continued to use a variety of activities to keep its employees and the local communities informed of the planning process. We published periodic articles and special editions in our Forest and Grassland report. We prepared and distributed a Forest Plan Report. During the summer and fall of 1985 we had multi-resource media coverage, providing information and education on Forest management. Through a networking process, each Management Team member has been contacting key individuals in our local communities and informally discussing Forest management and the planning effort.

The Proposed Land and Resource Management Plan and the Draft Environmental Impact Statement were published in September, 1986. Notice was published in the Federal Register on September 12, 1986. During the 90-day public review period, 1,125 copies of the Draft Plan and EIS were distributed. The Forest announced the availability of these documents through seven news releases and three Forest Plan reports. Office hours were extended at the Supervisor's Office in Prineville. The Forest held six public meetings and 25 organizational, individual or agency meetings. Radio and television interviews, fliers, newspaper articles, and displays at the Jefferson, Harney and Crook County Fairs were also used to inform the public of publication.

A number of interest groups were active during the DEIS comment period. Of particular note was the level of activity by timber industry, the Central Oregon Economic Development Council and a coalition of eight environmental groups. Two additional groups were actively involved in expressing opinions about the management of Lookout Mountain: snowmobile organizations and the retirement community. The activities of these groups appeared to play a significant role in soliciting additional public comment, and in many cases, appear to have been a major source of information from which these comments were generated.

During the 90-day public review period, 2,154 comments were received. The results of the public comment period for the DEIS are thoroughly discussed in Appendix I of this FEIS. The substantive comments received on the DEIS did result in the development of a new alternative, Alternative I. In addition, Alternatives B and C were modified.

A Supplement to the DEIS was prepared in response to two appeals that took issue with some of the methods used in Forest planning by the National Forest in the Pacific Northwest. The appellant was concerned with how the "No Action" Alternative was described, and the methods used to address Forest planning management requirements. The Supplement described a new alternative, Alternative NC (no change), and analyzed alternative levels of management requirements. The SEIS was published in October, 1988, and the 90-day public review period ended January 17, 1989. The Forest received nearly 200 letters in response to the Supplement. The results of the public response period for the Supplement are also discussed in Appendix I of this FEIS.

Significant steps were employed during the last 3 months of final document preparation to insure that direction in the Final Plan responded accurately to comments received on the Draft. Meetings were held, and contacts made with selected groups, individuals, agencies and political leaders in order to:

Validate public responses received during the process.

Insure that we correctly interpreted what was said.

Insure that we did not miss something or overlook stumbling blocks towards successful implementation.

Set the stage for implementation of the Plan.

This networking followed our efforts in seeking broad public review of our draft documents. During this time, 39 meetings have been held with more than 289 citizens, and 69 interest groups or agencies.

In response to this effort, when appropriate, adjustments were made to the final planning documents. This was intended to strengthen the Plan and build a base of support for effective implementation.
During public review of the Draft Plan, the issues of uneven age management and growing large diameter ponderosa pine trees were brought to the forefront. To promote public information and education on these issues in a contemporary fashion, a video entitled “Ponderosa Pine Management in Central Oregon” was developed. Presentations were given to local civic clubs, interest group meetings, and the media.

Consultation with Others

Several agencies and Native American Tribes were involved in the initial issue development process. The most active of these agencies were the Oregon Department of Forestry, Oregon Department of Fish and Wildlife, and the Bureau of Land Management. These contacts provided the identification of agency concerns that could be dealt with in the plan, provided information useful in the analysis, and allowed the coordination of management and planning efforts.

Reviews of other agency plans, which could affect the Forest and Grassland Plans, were undertaken by the Forest. The following plans were examined:

- County Plans from Crook County, Deschutes County, Grant County, Harney County, Jefferson County, and Wheeler County.
- State Plans from the Oregon Forestry Department, Parks and Recreation Division, State Comprehensive Outdoor Recreation Plan, Department of Fish and Wildlife, and the Oregon Recreation Trail System.
- Bureau of Land Management Plans, including the Brothers Grazing Management Program, Wilderness Study Proposals, and the John Day Area Plan were studied.
- Also reviewed were plans for the Warm Springs Reservation and the Central Oregon Economic Development Plan for fiscal years 1984 and 1985.

The review of these plans did not identify any unknown issues. The goals of those agency plans were included in at least one of the alternatives developed by the Ochoco National Forest.

Interest groups involved in the development of issues, concerns, and opportunities were assembled periodically to keep them apprised of progress and to acquire additional information or feedback from them. The groups are:

- Conservationists - Local members of the Oregon Natural Resource Council were contacted. These contacts included, as a principal contact, the Central Oregon Conservationists. This group also included the Blue Mountain Resource Alliance, the Grant County Conservationists, and the Central Oregon Chapter of the Sierra Club.
- Recreationists & Sportsmen - Included are the Ochoco Snow Sports Club, the Oregon State Snowmobile Association, the Nordic Club, the Oregon Hunter's Association, and the Ochoco Elk Hunters.
- Ranchers - The Crook County Stockmen's Association was the organization most frequently contacted. The Grey Butte Grazing Association, in their link to the management of the Grassland, was the only organized adjacent landowner group frequently involved in plan development.
- Industry - Industry representatives from the local mills often participated. They were joined by representatives from the Northwest Pine Association and the Western Forest Industry Association. The Association of Oregon Loggers also was involved.
- Government Agencies - The Forest contacted Crook, Harney and Jefferson Counties, the Governor's Office, Congressman Smith and Senator Packwood.
The Screening Process

The preliminary issue, concern and opportunity comments were screened and consolidated in two separate operations. The first process involved the 125 comments received from the interest groups previously identified. These ICO’s were run through a set of screens. First, it was determined if the ICO could be immediately resolved by either the Forest Supervisor or District Rangers. Second, the determination was made whether or not the Forest could and should address each of the ICO’s through the planning process. Some suggestions were beyond the scope of this planning effort and comments of this nature were screened out of the potential issues, but were shared with the Forest Management Team. The third screen was the resolvability of the ICO. If the suggested issue was not considered resolvable in the forest planning process, it was referred to the management team for action outside the forest planning process, and dropped as a planning issue. Next, issue statements that were potentially part of a larger issue were identified. For example, the amount of timber available to the local mills could be considered a part of the larger issue of the level of timber harvest which should be provided from the Forest. These issue components were retained and dealt with throughout the planning process.

The second process was to take the tentative issues that passed through the screening process and consolidate them into like comments by resource groupings. These consolidations were then written by the ID Team into terms that would best reflect the contents of those groups. These steps reduced the 125 comments to 60 comments which were submitted to the general public for their comments.

This second set of categorized comments was then evaluated using the following steps:

1. Evaluate Issues and Concerns

   Is it already required in the planning regulations?

   Can it be dealt with by the responsible official without going through the planning process?

   Is it a prior decision which can’t be reversed?

   Is it outside of Forest Service jurisdiction?

   Should it be dealt with at some other planning level?

   Does it involve land use allocation?

   Is it operational in nature, a standard, guideline, or budgetary?

   What is the source? From public or management?

   Are there common or similar aspects?

   Categorize comments by 1) production of outputs, 2) use of resources, 3) a management practice or prescription, and 4) management performance or policy.

2. Determine Action to be Taken on Issues and Concerns

   Consider in the planning process.

   Transfer to management for action outside the Forest planning process.

   Determine to be irrelevant.

   Each action was justified and documented.

3. Take Action

   Consider in planning process: develop as an issue or concern, or deal with as a planning or process criteria.

   Refer to management for appropriate action or response.

   Determine to be irrelevant.

The management concerns were then compared with the public issues and incorporated with the issues, or classified into various non-issue categories, such as: administrative decisions, planning criteria, opinions, items required by Federal regulation, items outside the scope of the planning process, items outside of Forest jurisdiction, statements, practices to be shown in prescriptions, and items that are part of the planning process.
The results of the screening process are on the following pages. Three categories are used to identify how the issues and concerns were screened after categorization by resource. The list represents those issues and concerns that were not eliminated, referred, or resolved through the interdisciplinary team's screening process. Many of the issues were similar; an issue statement may be representative of many comments.

How Were the Issues Developed in the Public Involvement Process Handled?

Disposition of Issues by Category

1The initials I, C, or O denote whether an issue evolved from a public issue (I), a management concern (C), or an opportunity (O)

Issue #1, Timber Supply and Forest Management

Deferred outside of Plan
Consider re-use of tomahawk in treating thinning slash for firewood availability. (O)
Administer timber sales so as to insure fences will be left intact or repaired promptly. (I)

Treated Same in all Alternatives
Sophisticated logging methods are not always needed. Analyze entire process to ensure continuity of implementation, end product, and follow-through. (I)

Make reforestation a high priority. (C)
Do not conduct precommercial thinning except for mistletoe and insect control. (I)
Stop wasting natural resources, such as wood products. (I)
Protect tree seedlings from animal damage. (C)

Treated Differently by Alternatives
Make more land available for timber production and harvest. (I)
Utilize all available timber mortality in a timely manner. (I)
Depart from non-declining even-flow timber harvest. (I)
Use silviculture practices, such as fertilization and planting of different species, to produce greater timber volume. (I)
Provide more timber products. (I)
Reduce the acreage of forest land available for timber harvest allocated to old growth. (I)
Eliminate burning as a slash treatment method. (I)
Need more intensive timber management (enhance timber and other resources in balanced silviculture practices). (I)
Launch an intensive reforestation program for future needs. (I)
Should clearcutting be practiced on the Ochoco? (I)
Do not create management areas with no programmed harvest. (I)
Clean up logging slash. This would soften the impact and create less animosity toward timber harvesting. (I/O)
We need some intermediate types of harvest and roadless combinations. (I/C)
We are getting good regrowth, but we're cutting trees down faster than regrowth is occurring. (I)
**Issue #2, Social and Economic Wants and Needs of Local Communities**

Deferred Outside of Plan  
People too far from Central Oregon may set plan priorities. (I)

Treated Same in All Alternatives  
Analyze cost/benefit of producing timber and quantify effects on habitat and dispersed recreation. (I)

Treated Differently by Alternatives  
Correct the disparity between economic considerations given one resource vs. another. (C)
Improve the social and economic condition of the local communities. (C)
Maximize economic and social benefits to locally dependent communities. (I)
Recognize community development needs and opportunities: a) increase employment, b) recognize social impacts of decision made, c) increase National Forest receipts to the County in real dollars, d) provide equitable distribution in employment increases or decreases, e) display impacts of actions on other lands and resources in the community. (C)
Too many dollars are taken out of the system by unroaded allocations. We need the payments to counties generated by returns from receipts for use on local roads and for schools. (I)
Emphasize uses that produce a dollar return vs. those that do not. (I)

Larch should be more available to permittees for fence posts. (I)
Don’t use Special Use permits that create an economic impact on the grazing permittee. (I)
Skid trails supporting adequate grass should not be re-used for new entries. (I)

**Treated Same in All Alternatives**  
None

**Treated Differently by Alternatives**  
Provide both a maximum and consistent supply of forage. (I)
Stop repeated timber harvest entries in the same specific areas which result in adverse economic impacts on the grazing permittee. (I)
Visual and riparian management objectives are too restrictive on grazing livestock. (I)
Reduce grazing restrictions to improve utilization and palatability of forage for livestock and wildlife. (I)
Utilize more range improvement practices to obtain better range conditions. (C)
Reduce the use of grazing systems which cause economic impacts on the rancher. (I)
Provide more range improvements to manage the range, to meet resource management directions for all resources (riparian, etc.), and still maintain stock numbers. (I/C)
Develop more water systems. (I)
Overgrazing is creating erosion. (I)
Reduce cattle grazing (I)
Whenever range improvements are carried out, commensurate animal unit months (AUM’s) should be made available. (I)
Assignment of other areas to wilderness would reduce forage production over the long haul. (I)

**Issue #3, Livestock Grazing and Allotment Management**

Deferred Outside of Plan  
Livestock grazing should not be allowed on the Forest. (I)
More knowledge and information is needed regarding grazing seasons and distribution with associated effects on resources. (I)
**Issue #4, Riparian Area Management**

**Deferred Outside of Plan**

Livestock enclosures of creeks (e.g. Silver Creek) have not encouraged riparian recovery. (I)

Repair damage to rockhound sites to prevent erosion. (I)

**Treated Same in All Alternatives**

All soils on slopes over 30 percent should not be lumped into one category of being highly erodible. (C)

**Treated Differently by Alternatives**

Provide the greatest balance of water quality and quantity. (I)

Maintain riparian habitat which is healthy and improve current degraded riparian habitat associated with streams, springs, intermittent streams, etc. (I)

Accomplish recovery of riparian communities by 1990. (I)

Harvest timber in a manner to reduce stream channel damage from high spring runoff and to increase summer flows. (C)

Do not use fences to restrict cattle grazing in riparian areas. (I)

Place more emphasis on enforcing existing regulations pertaining to soil, water, and wildlife resources. (I)

Allow no more enclosures of riparian areas until results of riparian recovery are proven in existing closures. (I)

Do not construct any more riparian enclosures. (I)

More restrictions are needed concerning tractor and rubber tired skidder logging on wet soils. (C)

Keep logging disturbance to a minimum, such as reusing same skid roads. (C)

---

**Issue #5, Transportation System**

**Deferred Outside of Plan**

Do not construct any roads across private land without permanent public access. (I)

Close roads which connect Forest lands with deeded land. (I)

Bicycling could be a significant recreational activity on the Ochoco. Consideration should be given to this potential in road design, construction and reconstruction. (I/O)

Private owners should not close access to roads built with public money. (I)

Involve public in decision to close roads, and inform public before roads are closed. (I)

Off-road vehicle use should be stopped when it creates erosion or occurs on fragile terrain. (I)

**Treated Same in All Alternatives**

Roads should be constructed to the lowest standard (length and width) which allows protection of other resources. (I)

Do not pave roads. (I)

Off-road vehicles should be permitted for resource administration only. (I)

**Treated Differently by Alternatives**

More roads are needed to provide intensive use of all resources (C)

Too much money is being spent on high standard road construction (I)

Too many roads (I)

Well-known established roads should not be closed to vehicular access; roads which have been closed should be reopened. (I)

Keep existing roads and rockhounding areas open for access by motor vehicles and the public. (I)

Whenever possible, use gates for closing roads instead of tearing up roads. (I)
species. Others note that grazing increases are dependent upon new water developments away from existing riparian areas which help to disperse use and reduce riparian damage. The public felt the Forest needed to show site potentials for willows and cottonwoods and to implement activities for the protection of various plant communities. Some stated that the Ochoco National Forest needs to stop planting "tough" poor nutrient grass for riparian protection.

The Oregon Department of Fish and Wildlife stated that the information on livestock grazing was not sufficient in the EIS. They wanted more information on the management systems, condition and trend, actual use and improvement programs to evaluate effects of the grazing program.

The Columbia River Inter-Tribal Fish Commission felt that when management strategies and integrity fail to protect riparian areas, fencing will be used. They ask how many miles of fence will be needed to protect riparian areas. The Commission also questioned the record of compliance of cattlemen in moving their herds as frequently as is required.

The U.S. Environmental Protection Agency stated that in prioritizing the development of Forest level plans, it would encourage making the allotment management plan one of the first. This is because it will have a direct bearing on riparian areas, water quality, and the protection of beneficial uses.

Response:
The Draft EIS did not do a good job of covering the environmental consequences of livestock use on the Forest and Grassland. This area has received much more attention in Chapter 4 of the FEIS. Additional work has been done on identifying needed improvements in riparian areas in Chapter 4. Watersheds have been prioritized for improvement and allotment management plans scheduled for updating. Schedules are included in the Final Plan to show these priorities, as well as schedules to show the projects and work necessary to meet riparian prescriptions.

An evaluation was done for the final plan to estimate total miles of fence and water developments to implement the riparian prescription. These figures are included in Chapter 2 of the FEIS, Table 2-8, Range Improvements. Potential for individual stream reaches to support willows, cottonwoods and other deciduous shrub and tree species will be determined on a site-specific basis in individual allotment management plans using riparian plant community guides published by the Pacific Northwest Forest and Range Experiment Station.

Erosion control seed mixes used on road cut and fill slopes commonly contain several species of grasses. Often one or two of these species are not as palatable as others to wildlife and livestock. The emphasis in these instances is on using species that establish quickly to hold the soil in place and which won’t be immediately consumed by livestock and wildlife.

Standards and Guidelines have been developed in the Preferred Alternative I to identify and protect threatened and endangered species and sensitive plants.

0500-02.3 Grazing Effects

Two letters discussed the issue of threatened and endangered plants affected by grazing. Some comments were that affected threatened, endangered or unique plants need to be addressed better by the Ochoco National Forest, or that the Forest should plant grass so it will be available during peak season use. This, according to respondents, would allow natural threatened and endangered species to develop and remain strong and disease resistant.

Response:
Chapter 4 of the FEIS evaluates the effects of grazing by domestic livestock on threatened, endangered and sensitive plant species.

Standards and Guidelines have been developed in the FEIS alternatives to identify and protect sensitive plant species. Forage utilization standards in the Final LRMP will allow good plant vigor and high levels of plant species diversity.
@0500-03 Raise Grazing Fees

Eighty-four responses, including those of the EPA and the CRITFC, commented on the fee aspect of the grazing program.

Some stated that the Ochoco National Forest is operating a cattle grazing give-away program and that it is undercharging cattlemen for the use of publicly owned land. Some also remarked that the Forest Service is operating a program which costs more than it returns to the Treasury. These respondents felt that the permittees should pay the full costs of administration of the grazing program.

The Environmental Protection Agency felt that the increased costs in grazing management area should not be included in “environmental” effects, but that these costs should be discussed as an economic issue.

The Columbia River Inter-Tribal Fish Commission stated that the Ochoco National Forest should consider the factors that are involved in the trade-off between Range and Timber management. The Commission also asked why the most productive lands were allocated solely to range.

Response:

The issue of grazing fees is outside the scope of the Forest planning process. The grazing fee formula was set by Congress, and in 1985 the base level was set by executive order. Legislation would be required to change the grazing fees. Even though the returns the Forest Service gets in the form of grazing fees do not cover the cost of administration of the range program, the economic benefits of the program are realized in the local economy.

The allocation of management areas in the DEIS and Draft Plan was misunderstood. Timber/range emphasis was not intended to be exclusive use. The FEIS and Final LRMP have changed this Management Area to General Forest (Ochoco National Forest) and General Forage (Crooked River National Grassland); these are both multiple use areas.

@0500-04 Management

Six comments dealt with the issue of specific grazing management systems.

Some comments were that the Ochoco National Forest failed to fully disclose specific grazing management systems, and that issues and concerns need to be discussed on an allotment-by-allotment basis. One reviewer felt the Rock Creek allotment was not covered adequately in the proposed plan. In addition, some stated that the Forest Service needs to include ranchers in the management picture and display present and future grazing conditions.

Response:

Specific grazing management systems will not be outlined in the FEIS or Plan. Those decisions are made in the individual allotment management plans in consultation with the affected permittee. They are site-specific and require on-the-ground analysis. No matter what grazing system is employed, each allotment will be monitored to make sure it is meeting all resource objectives such as riparian area recovery and wildlife habitat objectives.

@0500-05 Utilization Rates and AUM’s

There were 18 comments that discussed implementation of the plan and utilization levels for grazing.

Some felt that the Ochoco National Forest needs to show the effects of implementation of and utilization levels for the proposed plan in regard to the range land. Others stated that the Ochoco should include maps showing allotment AUMs and a discussion of the implementation process.

In addition, some felt that the Ochoco National Forest should manage all areas with 40-80% utilization levels and that the Forest should adhere to the AMP schedule. Many felt all fences should be shown on allotment maps and cattle should be removed from the Forest by October 15, 1989.
Response:
Increases and reductions in permitted AUMs are generally handled through the allotment management planning (AMP) process. This is an allotment-specific planning process involving interdisciplinary team approval and directly involving the affected livestock permittee(s). Resource objectives are outlined, a grazing system designed, various range improvements planned, and a monitoring plan developed. This is all done through the NEPA process. A schedule for updating allotment management plans will be in Appendix A of the Final Plans.

Forage utilization standards are in Chapters 4 of the Final Plans and are separated for riparian areas and upland areas. Utilization standards are set to allow prescribed use of forage but prevent overuse that would degrade the forage resource or other resources. Utilization is measured in areas preferred by livestock because those are the areas where overuse and resultant resource damage would occur if livestock were not removed after prescribed use.

Utilization standards are incorporated into allotment management plans which become a part of the grazing permit. Compliances with the grazing permit is normally handled by close coordination between the permittee and Forest Officer, but if violations occur, action is taken against the permittee. Forage use by domestic livestock is a legitimate use of National Forest Lands as mandated in the Multiple Use Sustained Yield Act and will continue.

0500-05.1 Utilization Rates and AUM's

There were 21 letters, including one from the Columbia River Inter-Tribal Fish Commission, which had comments on the range of alternatives and AUM's. Some of the comments were that the Ochoco National Forest needs to show an adequate range of alternatives and range of AUMs in alternatives. Some requested information on the availability of range to livestock, as well as data on increase or decrease on an allotment-by-allotment basis. Some recommended that the Forest consider using sealed bids and enlarging alternatives for foraging.

The Columbia River Inter-Tribal Fish Commission stated that as the overstory is removed and the understory thinned, the forested rangelands will be found more frequently in fair and good forage condition class. The Commission questioned whether it is necessary to thin old growth timber stands to thinned tree farms just to provide grazing. CRITFC also noted that the Forest Service stated that range utilization standards will not exceed an average of 50% on meadows, and less than 30% on slopes and asked if this is a new standard or if it has been used before. They also question why, if it has been used before, the ranges are still in predominantly poor to fair condition.

Response:
The FEIS contains alternatives that show a range of AUMs from approximately 73,000 to 80,000. These estimates were based on timber harvest levels with resultant availability of transitory forage and on investments in structural and non-structured range improvements that make previously unusable areas available for forage use. Allotment-specific analyses were done to determine riparian improvement needs and estimates on what range improvements would be necessary to make those improvements. The Ochoco's analysis indicates it can meet the resource objectives of each alternative and produce the AUM outputs indicated. It was not considered necessary to arbitrarily reduce AUMs to show a broader range of outputs in AUMs.

Forage utilization standards have been changed in the Final Plan and EIS and are now based on whether range is in satisfactory or unsatisfactory condition and on management intensity levels. Old growth timber stands are not proposed to be thinned to improve forage condition classes under the stands. New plant community guides and forage condition guides are due to be published for the Ochoco National Forest in 1990.

@0500-06 Wild Horses

Fourteen letters commented on the issue of wild horses on rangeland.
Many thought that the Ochoco National Forest should not promote or allocate rangeland for the management of wild horses. Many felt that horses compete for rangeland with big game and that they are adversely affecting the environment. In addition, some stated that the cost of controlling wild horses is wasted funds, or that there are no “true” wild horses on the ONF or CRNG.

One respondent felt the holding pen at Big Summit is inadequate, that the horses were improperly fed straw, and that at least one had died while held there.

Response:
The Wild Horses and Burros Protection Act was passed by Congress in 1971. The law spells out very specific requirements for dealing with wild horses. The horses on the Ochoco National Forest meet the definition of wild horses in the 1971 Act, and as such are managed as required by the law. The Wild Horse Management Plan (Forest Plan, Appendix G) sets the herd size based on the carrying capacity of the area.

The corral used to hold wild horses between the time they are captured and the time they are transported to the wild horse facility near Burns, Oregon, is of pole construction and has been built with the safety of the horses in mind. Horses are fed while being kept in the facility, and to the agency’s knowledge, no horse has ever died while in the facility.

@0500-07 Decrease Grazing

One hundred twenty-eight public responses, including the one from the Oregon Department of Fish and Wildlife, commented on the current levels of grazing.

Some felt the Ochoco National Forest should consider reducing or maintaining current levels of grazing as a viable issue. Some felt that since the overgrazing of the 40’s and 50’s, the land has been trying to heal, and perhaps the Forest needs to justify the appropriateness of grazing by analyzing the adverse environmental impacts. These impacts need to be justified by NEPA standards, according to some.

Also, some felt that by reducing grazing, the Forest will improve water quality and quantity. They felt that, by reducing AUM’s, taking fences down and phasing grazing out in 10-15 years, the Forest Service would improve riparian areas immensely.

The Oregon Department of Fish and Wildlife (ODFW) stated that they cannot support any increase in the Forest grazing program. ODFW stated that it is difficult to justify continuation of the Forest grazing program, considering the standards and guidelines in the proposed plan.

Response:
Domestic livestock grazing on the Ochoco National Forest is and has been an important part of the local grazing economy. It can also be a means for managing vegetation, e.g., reduction of vegetative competition in tree plantations and fuels reduction to reduce wildfire hazard.

Overuse of many riparian areas and some upland sites has occurred in the past and is dealt with in the Final Plans by specific utilization standards (see Utilization Standards, Chapter 4, Section 2 and 3). Monitoring (Plans, Chapter 5) will assure utilization standards are being met.

AUM levels by alternatives in the FEIS vary due to the amount of investment in structural range improvements and the level of timber harvest. Some structural range improvements are designed to make forage available in areas where it is presently not available, due to distance from water sources or livestock distribution patterns. This can increase the overall level of AUM’s available while still not exceeding utilization guidelines. Other structural range improvements are designed to control livestock use, such as many riparian areas. This will allow forage use to acceptable levels and restrict any further use. This kind of intensive grazing management, when properly done, can increase the amount of AUM’s available, while at the same time not rehabilitating degraded riparian areas.

Timber harvest opens the tree canopy, allowing more sun to reach the forest floor, which may in some cases produce more forage. This potential increase in forage production is termed “transitory”
because it will be available for a period of time and then will decrease as the forest canopy closes. The level of timber harvest in an alternative determines how much transitory forage may be available over time. Transitory forage can increase the overall amount of AUM's potentially available.

Alternative C in the FEIS shows fewer AUM's than are presently permitted (FEIS, Chapter II). This is because Alternative C invests very little money in structural range improvements and has a reduced timber harvest level, which doesn't provide much transitory forage. Also, the emphasis of this alternative is for less grazing. All the other alternatives in the FEIS show either more AUM's than are presently permitted or the same level as at present due to investments in structural range improvements and timber harvest levels with resulting transitory forage production.

@0500-08 Stop Grazing on the Forest

There were 52 letters that supported stopping livestock grazing on the Ochoco National Forest. Many felt that livestock grazing should not be permitted on the Forest, and that grazing is destructive to native plant species. Also, they felt that livestock use compacts the soil and reduces plant diversity. Some claim that a decrease in livestock grazing would reduce undesirable and exotic plants, upland degradation and noxious weed invasion. Therefore, many felt, there should be a no grazing alternative and/or a ten-year ban on livestock grazing.

Response:
The alternatives displayed in the FEIS have a range of AUM outputs. There is not, however, an alternative that eliminates livestock grazing from the Ochoco National Forest and Crooked River National Grassland, nor were there alternatives that eliminated other uses from the Forest or Grassland. Livestock grazing has been a traditional and important use of the Forest and Grassland, and is one of the uses specifically mentioned in the Multiple Use Act of 1960. When properly administered, livestock use can be compatible with other resource values and uses. The environmental consequences of grazing are outlined in Chapter 4 of the FEIS; livestock use of the Forest and Grassland contribute to the social and economic well being of local communities.

@0500-09 Prohibit Grazing in Certain Areas

Ten letters commented on grazing in sensitive areas. The public respondents indicated that they feel the Forest Service should manage the Forest for the public, not just for livestock owners who use it for grazing. Some felt that the Forest Service should remove all livestock from the Forest. If this is not possible, some stated, then the Forest should keep cattle on grasslands, and keep cattle away from poor/fair condition areas for at least five years. Additionally, some respondents recommended removing cattle from wildlife winter range, riparian and shallow soil areas, and recreational areas.

Response:
The riparian prescription in the preferred Alternative I is designed to improve riparian areas. Individual allotment management plans will outline whether this will require livestock exclusion (short term or long term) or whether more intensive management systems and additional range improvements will be needed to meet the riparian improvement objectives.

Utilization standards in Chapter 4 of the Final Plans have utilization levels that vary depending on whether or not the area is in satisfactory condition. Areas that are not in satisfactory condition will have use levels adjusted down so they can recuperate. In some cases, there will be total exclusion for enough time to allow recuperation of areas in less than satisfactory condition.

Almost all of the developed recreation sites on the Forest and Grassland are fenced to exclude livestock. Those that are not fenced will be if conflicts arise between recreationists and livestock.
Section 4(d) (4) (2) of the Wilderness Act states that grazing in wilderness areas, if established prior to designation of the area as wilderness, "shall be permitted to continue subject to such reasonable regulations as are deemed necessary by the Secretary of Agriculture." It was stressed that there would be no curtailment of grazing permits or privileges in an area simply because it is designated as wilderness. As stated in Forest Service regulations (36 CFR 293.7), grazing in wildernesses ordinarily will be controlled under the general regulations governing grazing of livestock on National Forests. This includes the establishment of normal range allotments and allotment management plans. Under the direction of Preferred Alternative I, livestock grazing in Wilderness will continue.

Livestock use of big game winter range will be controlled in the individual allotment management plans. Monitoring of use will be done and spring and fall green-up will be reserved for big game in some cases. Grazing systems will be developed that leave adequate forage for wintering big game.

Subject Area 550 Native/Introduced Plants

@0550-01 Introduced Plants

Two comments were received from respondents who were concerned that the Forest Service plants introduced grass species for erosion control and some range improvement projects. It was felt that the introduced grass species grow tall and tough and are not good forage species.

Response:
Species of grass that are not native to the immediate area are sometimes used for erosion control purposes on road cut and fill slopes and other disturbed areas. The reasons are two-fold: some introduced species are easier to establish, and species that are not highly palatable are not grazed heavily. There is no more large scale range improvement seeding using non-native grass species planned on the Ochoco National Forest or Crooked River National Grassland.

The Forest conducts a program in cooperation with local extension agencies to control noxious weeds.

@0550-02 Management

One comment was received from a respondent who feels that while the Ochoco N.F. has not a single botanist on its staff and has had only one major botanical study conducted, it continues to destroy natural plant communities and to propose further destruction.

Response:
The Ochoco N.F. does not employ a botanist per se, but does employ on a shared basis a forest ecologist who is an expert on plant communities and species. In addition, the Forest employs range conservationists, foresters, and wildlife biologists who are versed in basic plant taxonomy and botany. The Forest also consults with the Native Plant Society and other local interest groups in these matters. Chapter 4 of the FEIS analyzes the effects of various programs on plant communities.

0550-02.1 Management

One comment was received from a respondent who was concerned that grazing may often destroy beneficial and increasingly rare plants in favor of other species.

Response:
Proper grazing and management practices generally should not result in this. Some of the impacts of grazing in the Blue Mountains seen today are a result of practices that took place at the turn of the century. Chapter 4 of the FEIS analyzes the effects of grazing on sensitive plant species.
0550-02.2 Management

One comment was received from a respondent who felt that Forest Service management was increasing brush and juniper to the detriment of grass, which causes deer and antelope to go to private land to feed.

Response:
The alternatives in the FEIS provide different allocations of land for big game emphasis. Big game winter range is to be managed to provide a cover forage ratio for wildlife needs. This will not, however, change the fact that some traditional big game winter range is off the National Forest and Grassland; and under winter conditions, big game may end up on the private lands at lower elevations.
Subject Area 600
Research Natural Areas

@0600-01 Silver Creek

A letter was received from the Department of the Interior suggesting that it would be helpful to include a description of the features of proposed RNA's. The USDI also noted that Silver Creek RNA is a name already used by the BLM and that the RNA cell need may have already been met.

Response:
Appendix E of the DEIS had a description of each proposed RNA and the plant communities they represent. An establishment report is scheduled to be prepared for each Research Natural Area and will give additional detailed information on plant communities and features.

The BLM in Burns does have an existing RNA called Silver Creek RNA. It is on the same creek as the one proposed in the FEIS but further downstream. The two areas represent different “cells” (plant communities). The FEIS describes Silver Creek RNA in FEIS Chapter 3, and Forest Plan Chapter 4.

@0600-02 Management

Twenty-nine comments were received from respondents who felt that RNA’s should be open to ORV/ATV use and all forms of winter and summer recreation.

Response:
For some areas ORV/ATV use is incompatible, for example, Research Natural Areas (RNA’s) are sites on which natural features and processes are preserved in as nearly an undisturbed state as possible for scientific and educational purposes. RNA’s serve as a standard or baseline for comparison with areas influenced by man, as tracts for ecological and environmental study, and as reserves to protect typical as well as rare and endangered organisms. Motorized recreation is incompatible with these goals and objectives. Non-motorized recreation use is not generally prohibited but it is also not encouraged. If non-motorized recreation use increased to a level where it negatively affected the value of the area as a RNA, it could be restricted.

0600-02.1 Management

Forty-six comments were received from respondents who were not in favor of designating any new RNA’s. Some felt they were totally unnecessary or were just on excuse for more mini-wildernesses. Others felt the ONF had proposed too many acres as RNA’s.

Response:
Research Natural Areas are a nation-wide, multi-governmental agency program designed to preserve representative samples of a wide spectrum of ecosystems. They are preserved in as nearly an undisturbed state as possible for scientific and educational purposes. They are also important for preserving genetic pools, biological diversity, and as baseline areas for monitoring Forest Plans. They are not tied to the Wilderness Act in any way and their purposes are different from those of Wilderness.

The size of RNA’s can vary considerably. They can be only a few acres but the average minimum size is usually 300 acres. It all depends on how many acres of undisturbed site are available and how many acres it takes to encompass the target vegetation types. All the proposals in the DEIS were field inventoried and the boundaries recommended by Forest Service ecologists trained in the RNA program.

0600-02.2 Management

One comment was received stating that over-the-snow machines should be specifically prohibited in the RNA’s and that the only new trails that should be built in RNA’s should be to conduct research.
Response:
Snowmobiles are not allowed in RNA's. These two concerns are covered in the management area prescriptions in FEIS Appendix D, and Chapters 4 of the Plans.

0600-02.3 Management

Two comments were received from respondents who felt that RNA's should be fenced to exclude livestock.

Response:
Livestock grazing is generally not allowed in RNA's unless it is part of the particular RNA's charter or research purpose. Therefore, RNA's will be fenced to exclude livestock where necessary. Exceptions would be those areas like the Island on the Grassland which is inaccessible to livestock due to topography, or as mentioned above.

0600-02.4 Management

A comment was received from one respondent stating that he was aware of another potential RNA that has not been designated.

Response:
The RNA program is dynamic. Other RNA's can be added at a later date. Forest ecologists will be made aware of this additional potential RNA and will review its chances for addition to the program if it meets the needs of an unfilled cell.

@0600-03 Plan Comments

Twenty-nine comments were received from respondents who were in favor of the RNA's as proposed in the Preferred Alternative of the DEIS.

Response:
The alternatives in the FEIS contain a range of acres proposed for RNA's including the proposal in the DEIS Preferred Alternative. Preferred Alternative I's proposal for RNA's is the same as Alternative E-Departure.

0600-03.1 Plan Comments

Three comments were received from respondents who felt there should be more RNA's. One respondent stated that additional RNA's, including The Island, should be added.

Response:
The idea behind the RNA program is to have one for each ecosystem or unique flora, fauna, or geology system represented on the Forest and Grassland. Forest Service ecologists as well as other scientists have inventoried the Ochoco N.F. and CRNG and identified the potential RNA's as outlined in the various alternatives in the FEIS. These are the areas that meet the needs of the RNA program. If other areas are found in the future that meet the need of a cell in the program they can be added.

0600-03.2 Plan Comments

A comment was received from one respondent stating that the plant community description for option A of Haystack Butte RNA proposal was left out in Appendix E of the DEIS.

Response:
The plant communities for option A were inadvertently left out. Major vegetation types for the Haystack Butte proposal are described in FEIS Chapter 3.

0600-03.3 Plan Comments

The Pacific Northwest Research Station noted that in the description for the Island, mention was made of 39 acres of CRNG and 160 acres of BLM land, and that this was the first place the EIS/Plan distinguished between the two acreages; elsewhere, it appeared that the 199 acres is all National Grassland.
Response:
The above statement is correct. We have attempted to clarify this in the FEIS. In the interim, the Island has also been designated as a national landmark by the Department of the Interior.

Subject Area 700 Timber Resource

@0700-01 Harvest Levels (General), Alternatives B,B+,C,E

There were 670 letters with comments on the timber harvest level. These comments ranged from “don’t cut anything” through “maintain existing harvest levels” to “increase ASQ.” There were comments requesting higher levels of old growth, visual resources, recreation, and firewood on the Forest.

Many of the comments related to the available timber base requesting either a decrease or an increase in the amount of land available for harvest.

Sixty-four respondents indicated a preference for the harvest level prescribed in a specific alternative.

The Harney County Farm Bureau recommended that harvest should not be increased even temporarily unless such an increase could be sustained.

The Crook County Courthouse desires that the ONF maintain or increase the amount of land managed for timber.

Some commented that timber harvest levels above the established sustained yield are in conflict with NFMA regulations.

The Columbia River Inter-Tribal Fish Commission noted that the timber base has declined 14 percent from 1973 to 1982 and asks how harvest levels can be maintained.

Many comments related to the harvest level were from those who preferred a specific alternative. Fifty respondents preferred the harvest level of Alternative B or B-plus (a modification of “B” proposed by industry). Thirteen indicated a preference for the levels in Alternative C. One person Preferred Alternative E.

Response:
The analysis in the FEIS explored a range of timber harvest levels from 13.9 to 24.4 MMCF (82-144 MMBF). The major factors affecting this level are: land allocations (described as Management Areas), the existing timber inventory and expected growth rates. In the long run growth is much more important than inventory. Since the forest is a dynamic system, the scheduling model is also dynamic and considers both growth and mortality by timber types to take advantage of both existing inventory and potential growth to make the best use of forest potential.

The Forest cannot maintain its current harvest level and still provide the other values (wildlife, scenic value, recreation use, etc.) that many people expect from the forest. In fact, any timber harvest level has both positive and negative effects on other resources. The economy was an important issue but was weighed against other values in selecting a final alternative.

These comments were carefully considered in developing the new Alternative. Some changes that have taken place since the DEIS to help address these concerns are:

1. The application of uneven-aged management on about 100-120 thousand acres of the ONF. This will make areas more acceptable visually for recreationists and still provide a moderate level of timber production.

2. Increased emphasis on a quality product (larger pine). This reduces the frequency of regeneration cutting and leaves more big trees in the forest.

3. Addition of the Summit Trail Corridor and other management areas, which will be managed to maintain unique qualities.
4. Parts of Lookout Mountain and the Rock Creek/Cottonwood Roadless area will be managed for recreation and wildlife. This may involve some timber harvesting to maintain forest health. Other changes are described in the summary and elsewhere in the FEIS. These changes should help maintain a sustained timber supply, reduce some of the negative impacts, and provide an equitable balance of uses.

See Chapters 4 of the Plans for more information on Old Growth, Firewood, Recreation, etc. Also see response to board foot/cubic foot issue in the Record of Decision and FEIS Chapter 4.

The harvest level at Snow Mountain stays much more constant with uneven-aged management than it did with the alternatives displayed in the DEIS. The ONF is also working with the Malheur National Forest to develop a combined schedule for the Burns Area that will avoid abrupt changes in harvest levels in this area.

0700-01.1 Departure

Four letters were received with comments favoring departure harvest. The common feeling was that the lowest level of timber harvest could be increased with more intensive management.

There were 304 letters containing comments opposed to a departure alternative, favoring sustained yield instead. Some felt that departure is short-sighted and that future drastic reductions in the harvest would disrupt the economy. Others believed that departure harvest would result in an irretrievable loss of resources and cause severe ecological damage due to erosion.

Still others noted that departure violates NFMA regulations.

The Office of the State Economist pointed out that the short-term gain will not outweigh long-term costs of departure.

Response:

A new alternative, Alternative I (see FEIS Chapter 2), has been developed. The proposed harvest has been changed from the Departure in the DEIS to a sustained yield even-flow harvest schedule. Reasons for changing were based on response to the DEIS, which favored the long-term good of the forest and local community stability. With increased intensity of management or by decreasing the level of departure, there is some opportunity to make a departure more acceptable. However, a sustained yield even-flow timber harvest schedule was selected based on public input and a further review of the consequences. The ONF has explored ways of maintaining the harvest closer to the present level and will use a gradual transition within the first decade of the plan to reduce ASQ to the planned level of 19.3 MMCF (115 MMBF). See FEIS Chapters 2 and 4 for further discussion. The major negative impact of this decision will be to reduce the dollar returns to the U.S. treasury in the first few decades.

Alternative I calls for even-flow for the ONF on a decade by decade basis. There will be fluctuations in timber sale from year to year based on budget and economic conditions. Harvest by district will be determined administratively considering biological, administrative, and social impacts. Sustained yield by species is not intended nor is it practical. Harvest levels will consider local economies as discussed under the reply to the ponderosa pine issue in this appendix, but timber condition and Forest Health (Chapter 4 of Forest Plan) will be the primary consideration in determining the species mix.

@0700-02 Species Mix

0700-02.1 Ponderosa Pine Management

Many respondents were concerned about the volume of ponderosa pine sold in the timber sale program. There were also concerns for management of other species.
The inherent value of ponderosa pine was one such concern. Enhanced harvest and regeneration of pine were desired by many respondents. There was also concern regarding substitution for ponderosa pine by inferior species. In addition, some respondents brought up the need for studies as to replacement of pine stands after harvest by juniper and sagebrush.

The Oregon State Forester comments that a steady supply of ponderosa is critical to the economy of central Oregon and is opposed to any proposition of large changes in the species mix, especially a reduction in ponderosa pine.

A related concern is the display of outputs in terms of cubic feet instead of board feet. The discrepancy between the Resource Protection Act document, which displays timber outputs in board feet, and the DEIS, which uses cubic feet, is questioned.

Response:

The Ochoco considered a range of ponderosa pine harvest levels in the first decade from 65 MMBF in Alternative C to 95 MMBF in Alternative B-Modified. The harvest level of ponderosa pine is a critical item to the local economy and also is currently the major contributor to forest receipts from timber sales. Short term (next 5 decades) harvest level of pine depends on land allocation, harvest schedule, and existing volume. The existing volume of pine is based on the 1982 inventory adjusted for harvesting to the end of FY88. Sampling error was less than five percent for the inventory. See FEIS Chapter 3 for volume by species group. Chapter 4 of the Draft Plans shows a reduction of 14 percent in total volume and 18 percent in pine volume between 1973 and 1982. The long term level (beyond five decades) depends mostly on management strategy. The existing volume does not allow a continued sale of historical levels (FEIS Chapters 2 and 4) of ponderosa pine. The addition of uneven-aged management helps to even out the sale of ponderosa pine over the next five decades but at a level below that of the previous decade. To maintain future harvest levels of ponderosa pine requires the harvest of stands with other species now so that they can be regenerated with new stands of pine. The Forest strategy is to manage future stands with a larger component of pine than occurs on most existing stands, with the intent of creating a species mix closer to what was here before fire protection (prior to 1930). This is particularly true in the mixed conifer types. There is no plan to remove pine overstory when the only understory is Douglas-fir or white fir. See Standard and Guidelines in Chapter 4 of Plan - Timber for specific direction. Reforestation efforts have been very successful and encroachment of juniper and sage brush has not been a problem. See FEIS Chapter 2 for proposed harvest level in ponderosa pine by decade.

For the Plan, the volume growth of trees and annual harvest level has been calculated in cubic feet. This is a measure of sound wood volume in a tree.

Much confusion is created when attempting to convert cubic feet to board feet, or when estimating long term growth in terms of board feet. Board feet, when referring to standing trees, is not a measurement but an estimate of an end product. There are several rules for doing this and different rules can result in considerably different estimates. In addition there can be large differences in estimated volume of a tree based on the length of logs it is bucked into. There is also considerable difference in the ratio of sound wood to estimated board foot volume for different size trees. For these and other reasons most research is done in cubic feet as are all yield tables for forest plans. For these reasons, cubic feet has been used to control or project timber harvest levels. Harvest can drop on a board foot basis while remaining stable on a cubic foot basis. An estimate of board foot volume is shown for the first decade only.

The inventory reduction of 14 percent (shown in FEIS Appendix E) is what was expected from the previous plan. The standing inventory in expected to decrease for the next five to ten decades as overmature stands are replaced by younger stands. This will be accompanied by an increase in growth until an equilibrium is reached. See "Timber" in FEIS Chapter 4 for more discussion of this.
0700-02.2 Genetic Diversity

Six respondents expressed the need to maintain old growth as a reservoir for genetic diversity.

Response:
Diversity is a major concern of the forest. There were several new management areas added since the draft to recognize more unique situations on the forest. The direction for management on the general forest has been changed to favor more uneven-aged management and longer rotations. Even-aged harvest units will be limited in size and distribution, resulting in greater diversity in stand age and structure than proposed in the DEIS. There are also about 60,000 acres in riparian and recreation areas that will have stands with extended rotation (150 to 300 years), and about 85,000 acres with no timber harvesting in designated old growth, RNA’s, wilderness, and roadless areas. See Chapter 4 of the Forest Plan for exact acres and description of each area. These areas serve as genetic reservoirs.

The Forest has about 2,800 trees in the tree improvement program. Each major tree species is represented in this program. Progeny from these trees have been planted in seed orchards and evaluation plantations. This is intended to improve the genetic base as well as preserve a wide genetic base for future plantations. There is a significant number of natural trees in regenerated areas to further expand the genetic base. The genetic base on future timber stands will be at least as diverse as existing stands and in many areas more diverse.

@0700-03 Timber/Livestock Issues

Twenty-four letters were received with comments concerning the relationship between timber and grazing.

Some felt that both timber and grazing should be deemphasized in the interests of wildlife, recreation and scenic values. Others were of the opinion that proper grazing and timber practices were compatible and acceptable uses of the forest. Still others felt that grazing and timber should be dealt with separately (e.g. timber should be favored over grazing, or slash if harvest prohibits cattle use).

There were also several comments urging the seeding of domestic grasses after harvest to control erosion and provide grazing.

Response:
There is a generally favorable relationship between timber harvesting and grazing as any removal of trees tends to increase forage production. Generally it was conflicts with other values such as water quality, old growth, and recreation experience that limited timber harvesting or grazing. The forest attempted to create a proper balance among uses as described in Chapter 4 of the Forest Plan. Emphasis has been given to water quality (enhance prescription used for all riparian areas) and unique scenic values, such as Stein’s Pillar, in Alternative I. Areas available for timber production and grazing will be managed as intensively as is economically feasible.

Areas of conflict between timber and grazing are in slash disposal, grass seeding, and protection. See the Timber section of FEIS Chapter 4 for more discussion. Slash disposal guidelines were developed to provide protection from wildfires, and provide down woody material to insure future productivity. See Chapter 4, Forest Plan, Standards and Guidelines for Woody Biomass for details. This should allow cattle access to most harvest areas but there will be some slash and large down material left on the site. Grass seeding will generally not be done except for erosion control as it competes with tree seedlings and prevents the return of native species. Tree seedlings will be protected from livestock where necessary by temporary exclusion or individual tree barriers.

@0700-04 Data Analysis

Seven letters, including the responses from the Oregon State Forester, the Oregon Director of Economic Development, and the Columbia River Inter-Tribal Fish Commission, had comments dealing with yield tables as used in the DEIS.
There were some questions as to the reliability of current inventories and harvest levels compared to levels on previous tables.

Some respondents felt that the plans for genetic gains are not practical on low sites on the Ochoco National Forest.

Growth rates of mature pine vs. second growth were also questioned. The CRITFC felt that the drop in potential yields is due mostly to a change in the managed yield tables. They also stated that the South-Central Oregon/Northern California variant prognosis model may have been more appropriate to reassess the accuracy of the Ochoco managed yield tables for stands similar to those on the Deschutes.

The Oregon Director of Economic Development does not support reducing the acreage available for full yield management.

Response:

Yield tables were developed as described in Appendix B, with more detail available in “Existing and Managed Yield Tables for the Ochoco N.F.,” an unpublished document available at the Ochoco National Forest Supervisor’s Office in Planning Records. The 1982 inventory was done to an accuracy standard of more than ninety-five percent. Volumes for each model component were projected forward to 1994 (midpoint of first decade) and acres by model component have been adjusted for timber sold since the inventory. This inventory was within one percent of the projected inventory, based on 1972 inventory, with adjustments for growth and cutting. The ONF has a very high degree of confidence in the inventory volume and the existing yield tables which were developed from inventory information. The inventory data was also used to calibrate the growth model used for developing managed yields. The Blue Mountain variant was used to develop the basic yield tables as SORNEC was not available at that time. Uneven-aged yield tables were developed later and SORNEC was used. Some standard tables were compared between the two variants and there was little net difference so basic tables were not redone. Since growth rates for yield tables are based on existing stands, the effects of mortality from insects and disease, and growth effects of compaction are included in the tables, but the final impact of each cannot be separated.

These yield tables show less net growth than does research or the previous yield tables. That is because these are Forest specific yield tables that show the best estimate of what can actually be produced on given sites with technologies available. This makes allowance for islands of nonproductive land within timber stands, trees left for snags, and local site productivity. Research that was done on Pringle Falls and in the Cascades was done on higher or better sites and uniform stands where there were no inclusions of low or nonforest sites. Consequently research yields are higher than what would be expected on the average site on the Ochoco N.F. A common set of yield tables developed for the Blue Mt. Forests was used for the 1980 Plan. The ONF is on the drier end of this group so sites and expected yields are lower than the average for the four Forests. Informal comparison between existing stands and projected growth was compared and results were similar. A separate inventory of managed stands is planned with the next inventory which should give a better basis to compare and adjust yields. A sensitivity analysis has been completed since the draft was prepared. In that analysis, all managed yields were increased by 20 percent, and this resulted in less than a two percent increase in ASQ. This shows that existing volume and S&G, such as watershed constraints, are the primary controlling factors and a major change in managed yield tables have little effect on ASQ. Growth on immature stands (Forest Plan Appendix G) is less than mature stands at present because most of the immature trees are not yet merchantable but projected growth of immature stands is several times that of the mature stand. See Table 4-3 (Annual Growth by Age and Timber Type) for more details.

Genetics gain is incorporated into the managed yield tables that call for planting (note: planting is not planned on low site pine types). The genetics program is already in place and forest has been using plantings from selected trees for several years so this is not a new level of investment to be made. The Tree Improvement Plan is available at the Supervisor’s office for more information.
0700-04.1 Data and Table Errors

Seven respondents pointed out inaccuracies, inadequacies, or discrepancies in the documents. Among the respondents were the Environmental Protection Agency, the Oregon Department of Fish and Wildlife, and the Oregon State Forester.

The following errors were commented on:

- Table 2-8 of the DEIS shows incorrect value for current ASQ.
- Graphs on pages 35 and 39 do not agree.
- Table 2-8 should show volume for each decade.
- Table 3-25 on Page 89 of DEIS is in error.
- Table 3-25 of DEIS does not agree with Table 4-1 of Proposed Plan.
- Sale program data incorrect in appendix A of Proposed Plan.
- Table S-2 and harvest level of 89 MMBF for E-Departure in year 2030 is in error.

Response:

Tables have been corrected in the final documents. The graph on Page 35 was changed so MMBF is no longer shown. The long-term Sustained Yield Capacity was not calculated in board feet, nor can it be calculated with the current data in the model. The Crooked River Grassland acres are no longer included in these tables which should also improve readability. Table 2-8 did not show volume by decade as it would have complicated the table. This information by selected decades is available on Table S-8 of the FEIS Summary. A new sale schedule is shown in Appendix A of the Forest Plan. Contact the Supervisor's or District office for more details on specific timber sales.

Table S-2 (now Table S-8) has been revised to display the new alternatives and Alternative I shows a much higher harvest level in the fifth decade than did alternative E-Departure. This change is due mostly to maintaining an even-flow and the emphasis on producing larger trees in Alternative I.

@0700-05 Reforestation

Thirty-seven letters contained comments on reforestation, among them the responses from CRITFC, ODFW, the Oregon State Forester, and Crook County.

Most comments, including those of Crook County, favored placing a growing emphasis on reforestation in the future. Some respondents recommended planting species most adaptable to a particular area and increased research on super trees.

Others suggested mechanical site preparation to favor naturals. A preference was indicated for auger planting over slit planting, and for protecting snags from fire during site preparation. There were also concerns that burned areas are not being reforested.

While many respondents have been impressed by reforestation efforts, some felt that recent favorable growing conditions have made silviculturists overly optimistic. Others were opposed to intensive practices such as fertilization or spraying. Concerns about nutrient cycles and gene pool reserve were not adequately addressed for some respondents.

To some, planting and maintaining tree plantations did not seem economically justified.

The Oregon State Forester noted that the stocking standard of 50 to 75 trees is lower than State of Oregon standards.

ODFW recommends that standards for reforestation in big game management areas should be driven by cover needs rather than harvest needs.

CRITFC stated that the certification process appears to take six years instead of the mandatory five (site preparation within two years of harvest; planting within one year after site preparation; certification three years after planting). The council also questioned the status of a stand if it cannot be certified as revegetated.

Response:

Most of these concerns are covered in the Forest Wide Standards and Guidelines in Chapter 4 of the Plan for Timber, Diversity, and Forest Residue. Site
specific decisions on planting method, spacing, planting tools, etc., are made to comply with the Standards and Guidelines and objectives for each Management Area. These are project level decisions. Some projects such as fertilization, spraying, pruning, etc., will require additional environmental analysis and documentation. The minimum stocking standard was designed to meet the requirements of NFMA Sec. 4. This is not the recommended level that is normally obtained. It should also be noted that this standard is for trees 4.5 feet tall, not two-year-old seedlings as is the case with Oregon's requirements. Planting may be done if stocking exceeds the minimum level and if the expense is justified to meet the management objective for a particular Management Area. The planting program on the ONF has been very successful with an average survival after three years of about seventy percent. The areas requiring replanting have been less than five percent. Survival is generally better in clearcuts than in areas with residual overstory.

@0700-06 Below Cost Sales

Three letters, including one from the Columbia River Inter-Tribal Fish Commission, had comments regarding deficit or below cost timber sales. All the respondents were opposed to deficit sales. It was urged that every timber sale make a profit, or at the very least recover costs.

CRITFC voiced concerns that the Forest Service will respond to the below-cost sale controversy by shortchanging mitigation needs to artificially improve its timber sale balance sheet. The council also noted that high-value ponderosa pine old growth has kept most timber sales out of the deficit category, but questions sales in the next decade or two if the old growth is removed.

Response:
The current timber sale program has a positive return, and is expected to in the future. See Table 3-30 of the FEIS. Also, the Timber Sale Program Information System (TSPIRS) reports are available at the Forest Supervisor's office. It is not the intent of this Plan or Forest Regulations that all sales produce a net return to the government. Examples where sales may be deficit, or below cost, are: beetle killed lodgepole, where remaining merchantable trees are removed and slash is disposed of, and the area is reforested; or sales in campgrounds to remove hazard trees. In each case the sale may be deficit but it is the least-cost way of meeting the management objectives for an area. Economics were considered in developing harvest schedule and selecting intensity of management. It was also considered in determining boundaries of management areas such as Rock Creek/Cottonwood Unroaded and Helicopter.

@0700-07 Land Suitability/Allocations

Nineteen comments dealt with management and identification of land unsuitable for timber production. Most had questions concerning methods and guidelines used to classify land as unsuitable. A map and analysis of unsuitable lands was not included in the DEIS, and some desired one.

There were also questions regarding present management of unsuitable land. Some, including the Columbia River Inter-Tribal Fish Commission, questioned the amount of land classified as unsuitable -- only 0.47 percent of the forest.

One reviewer suggested that timber land which becomes unsuitable be traded for lands reserved for recreation.

Response:
The NFMA provides direction for identifying lands to be classed as unsuitable for timber production. The reasons for being classed unsuitable are described in Chapter 3 of the FEIS. No timber harvesting is planned on unsuitable land. Unsuitable land was identified on areas as small as two and one half acres if they could be identified on aerial photos. These were ground sampled and other areas identified based on field experience and soil inventory.
About 11,130 acres have been identified as unsuita-
able because of regeneration difficulty. Much of the
most arid land has been classified as non-forest.

The reforestation first-time success has been greater
than 90 percent, and the lower sites have not been
the most difficult to reforest. There are several
examples of successful plantations on burns on low
sites. So there is very high probability that lands
identified as suitable can be reforested within five
years.

The economics of timber harvesting and the ability
to reforest is discussed under timber suitability in
Chapter 4 of the FEIS. The Ochoco has one of the
most economically efficient timber programs in the
nation, based on recent Timber Sale Reporting System
reports. Thus, while the cost of timber management
and harvesting was not a limitation on timber har-
vest throughout most of the forest, it was a major
consideration in developing management direction
for the unroaded areas.

**0700-07.1 Allocations**

Four letters, including those from ODFW, the Ore-
gon State Economist, and the Director of Economic
Development, had comments concerning acres
available for timber harvest and in full productivity.

The Oregon Department of Fish and Wildlife pointed
out that the proposed plan allocated 547,072 acres
to General Forest, which is 52,000 more than the
suitable timber base.

Other reviewers, including the Oregon State Econo-
mist and the Director for Economic Development,
question the implications of the reduction in land in
full productivity from 423,000 to 262,500 acres.

**Response:**

There is some confusion concerning acres of gen-
eral forest. When this refers to land allocation as in
Table 2-2 in DEIS, it refers to gross acres which
include nonforest land such as meadows, water, etc.
within the general allocation. Other places, such as
DEIS Table S-2, "Lands with Timber Yield Reduc-
tion," refer to suitable timber acres only. This is
made more clear in the new Plan which displays both
gross acres in a management area and the net acres
of forest land.

The acres in full productivity are based on land
allocations and the management intensity from the
selected FORPLAN run. All lands allocated to
General Forest are available for full productivity,
but there are a variety of yield tables and related
cultural practices available. A maximum economic
return function (See Appendix B for more explana-
tion) was used for Alternative I and also the Plan.
This selects the combination of treatments that is
most cost effective such as some natural regeneration
and not thinning every available acre. This
results in about one MMCF (4 to 5 MMBF) less
ASQ than would a maximum timber function.

**0700-07.2 Lowsite Pine Lands**

Two letters were received with comments concern-
ing management of low site pine lands. The Colum-
bia River Inter-Tribal Fish Commission questioned
the Ochoco plan to harvest on sites producing 20
cubic feet or less, pointing out that other forests
prohibit this practice.

Others requested a map of unsuitable areas and a
summary by district of plant community types for
pine stands.

**Response:**

There are about 21,000 acres typed as low site pine
and about 12,000 of these are classified as suitable.
(Note: NFMA does not include productivity as a
criteria for suitability.) These are generally nearly
flat ground with good access and high value pine
species. The management as shown in the Standards
and Guidelines will insure continued productivity
and a positive economic return. Mature trees will
only be removed where there is existing regenera-
tion. Type mapping was done at a four-inch-to-the-
mile scale and producing maps at this scale is not
practical. Maps are available at forest offices. See
FEIS Chapter 3 for acres of low site land by district.
The ONF does not have a summary of land class by
community type. Also see response to suitability.
@0700-08 Harvest Methods

Fourteen letters had comments concerning logging systems. Most respondents were concerned about environmental impacts and suggested helicopter logging, balloon logging, or the use of large rubber-tired skidders to reduce compaction. Some recommended that no logging occur in riparian zones or near trails.

Others felt that the timber companies should do a better job of cleanup after harvest operations.

Response:
Providing areas for specific logging systems was not identified as a specific concern. However, the logging system does play an important part in many of the other issues such as riparian areas, recreation, and protection of the soil and water resource. Generally, the selection of the logging system is a project-level decision based on the Standards and Guidelines for the specific Management Area. The Plan has been revised since the Draft Plan to include Management Areas that emphasize logging systems that require little or no roadings such as helicopter or skyline logging. See Chapter 4 of the Plan for specific direction for each management area.

Timber purchasers are required to remove all equipment and debris from any site of operations. Disposal of woody debris from logging is disposed of based on contract requirements. These requirements vary from site to site depending upon such factors as fire hazard, disposal costs, and the need for down woody material for soil productivity or wildlife needs.

See responses to biological diversity and forest residues comments for more information.

@0700-09 Thinning Practices

There were 18 letters with comments on silvicultural practices, among them letters from the Oregon Department of Fish and Wildlife, the Columbia River Inter-Tribal Fish Commission, and Grant County.

Many respondents, including Grant County, felt that thinning was not sufficiently emphasized. They believe that thinning will increase the growth rate and that thinning along roads will decrease vehicle/big game accidents.

Others believe that thinning defeats its own purpose and that unthinned islands should be left to provide cover. Some felt that a percentage of each sale should be left in an unaltered state.

Some felt that intensive management and new technologies should be utilized to raise the harvest level to the maximum, while others believe the Ochoco is a fragile desert unsuited to tree farming.

ODFW suggests that, under Standards and Guidelines, a screen of understory vegetation should be left along the edge of natural openings and along roads.

CRITFC asks how much projected yield depends on precommercial thinning.

Response:
Chapter 4 of the Forest Plan describes management activities appropriate to each management area. All cost-effective silviculture treatments are planned that are compatible with a specific area’s management objectives. There is a section in Chapter 4 - Forest Health that describes appropriate action to be taken in each Management Area to protect it from insect and disease. This recognizes that high levels of damage are acceptable in some areas such as old growth. The selection of specific treatments will be based on project level analyses along with direction from the Plan and may also include an Environmental Analysis. See Chapter 4 of the Forest Plan for planned treatment by decade.

@0700-10 Even- and Uneven-Aged Management

Five-hundred thirty-four letters were received with comments regarding harvest methods, particularly the impacts of clearcutting on harvest levels and other resources.
Some respondents, including Crook County, were opposed to clearcutting and felt that selective logging would result in a healthier forest ecosystem. Soil integrity and wildlife habitat were mentioned as possibly being harmed by even-aged management.

Others were opposed to clearcutting for aesthetic reasons, or because they felt recreation suffers from clearcutting practices.

Some respondents favored clearcutting for diseased or defective trees, or for a certain species of tree such as white fir, but not ponderosa pine.

Still others favored clearcutting everywhere, expressing a desire to see the forest shift toward even-aged management.

The Oregon State Forester stated that frequency of entry is greater with selective logging and that this may contribute to more soil damage than clearcutting, depending on soil characteristics.

Response:

The Forest has reviewed the policy on even-aged management including clearcutting, and has provided standards and guidelines to encourage uneven-aged management where appropriate (see FEIS Chapter 4, Environmental Impacts, FEIS Appendix D, Standards and Guidelines, and FEIS Appendix E, Selection of Harvest Cutting Methods). New yield tables were also developed that include more intensive uneven-aged management than was used in the draft. The planned acres of clearcutting per decade have been reduced from 14,400 in E-dep alternative to 8,700 in Alternative I, and no clearcutting is planned in pine types unless no other alternative exists due to the presence of mistletoe or disease.

There are many situations where clearcutting or some form of even-aged management is the only reasonable way to continue to grow timber. Some of these are areas with root rots, dwarf mistletoe, excessive fuel buildups and areas with white fir as the major species. The on-site decision of cutting method will be made by qualified district personnel based on the Standards and Guidelines in Chapter 4 of the Plan (see Timber and Forest Health). Clearcutting and other types of even-aged management are acceptable cutting methods under NFMA. See Appendix E for discussion of selection of harvest methods. For impacts of harvesting on a specific resource, see Chapter 4 of FEIS.

A further review was done of management in existing roadless areas, and some areas will have timber harvesting with little or no roaded and uneven-aged management will be emphasized where appropriate. See specific direction in Chapter 4 of the Plan. Harvest unit size and shape will meet direction in Chapter 4.

There is very little intermingling of National Forest land with other federal agencies so harvesting policy on the ONF should not have major impacts on other agencies.

@0700-11 Salvage Program

Forty-five letters were received with comments related to the timber salvage program. Among the respondents commenting on this subject were the Oregon State Forester, Crook County Courthouse, Prineville City Council, CRITFC, and ODFW.

CRITFC stated that salvage should be counted toward satisfying long-term sustained yield (LTSY) volume.

Crook County Courthouse recommended development of a creditable system for salvage of bug-killed or blown-down trees.

Prineville City Council suggested management of the salvage program for maximum timber production.

The Oregon State Forester urged aggressive harvest of scattered ponderosa pine.

ODFW noted that impacts of salvage are extensive on snag levels and large woody debris.

Other reviewers requested more firewood be made available through the salvage program. Some recommended small sales as a more efficient method of salvage. Still others felt that salvage should be limited to catastrophic events.
Response:
Salvage is part of the timber resource issue. The salvage program can conflict with snag needs (Chapter 4 FEIS). All material not required for snags is generally available for harvest. See Forest Standards and Guidelines under the Timber and the Wildlife sections for specific direction. The size of sale and whether it should be used for firewood or sawlogs is an administrative decision to be made on a site-specific basis. See appropriate District Ranger for specific concerns.

@0700-12 Multiple Use Management

0700-12.1 Timber and Recreation
Six individuals expressed concerns about conflicts between timber harvest levels or practices and recreation. Most respondents felt that recreation and harvest are compatible, but that harvest should be considered more important than recreation. Some felt that scenic qualities can be enhanced by proper harvest procedures.

There was apparently some confusion over acres available for timber harvest. Some commented that 780,000 acres was not acceptable.

Response:
Alternative I was designed to balance uses between timber harvest level and recreation use as directed in the Multiple Use Act and NFMA. A change to more selective cutting and large diameter stands at final harvest are two changes that were made in response to public comment to help resolve this issue.

There were not 780,000 acres planned for timber harvesting in the draft plan. The general forest terminology may have been confusing as the management area “General Forest” included both timber and non-timber lands on both the ONF and the Crooked River Grasslands. In most instances the acres are gross acres (timber and non-timber). The planned distribution of timber land is displayed in Chapter 4 of the Proposed Forest Plan which shows a total of 495,006 acres available for some timber harvesting and 314,738 acres in general forest. See Chapter 4 of the Plan, for acres planned for timber harvesting in the proposed action.

0700-12.2 Timber and Wildlife
There were nine letters with comments concerning possible conflicts between timber management and wildlife.

Opinions on this subject were unusually polarized. Some respondents felt that logging destroys wildlife habitat, that all old-growth harvest should be stopped, and snags should be maintained at the 100 percent level.

Others expressed a desire for less big-game allocation. They felt that harvest enhances the availability of forage for deer and elk, and that roadless areas should all be open to harvest. These respondents felt that protected old growth stands should not exceed three percent of the total, or that a certain amount of old growth needs to be harvested to sustain harvest levels.

Response:
The land allocations in the Forest Plan were developed according to NFMA standards and multiple use and sustained yield principles. The location and total acres in big game emphasis has also been changed as a result of comments and coordination with the State Fish and Game Department. A mix of timber and wildlife emphases have been provided to maximize net public benefit for both timber harvest and wildlife. Specific management goals, objectives, standards and guidelines can be found in Chapter 4 of the Forest Plan.

The NFMA (Sec. 6, g) requires the forest to “provide for diversity of plant and animal communities...”. The preservation of old growth is intended to help meet this requirement. Areas have been designated as old growth to meet the needs of old growth...
dependent species. Attempts have been made to limit the impact on timber harvest levels by designating old growth which occurs in areas which would have high levels resource protection in any case instead of designating areas that could be in General Forest. The Old Growth designated acreage in each alternative is shown in FEIS Table 2-8.

Areas planned for old growth have also been reviewed and are described in Chapter 4 of the Plan and areas are shown on map. The relationship between the timber program and wildlife is very complex. See Chapter 4 of the FEIS for effects of timber program on wildlife.

@0700-13 Timber Production

0700-13.1 Rotation Length

There were nine comments concerning rotation length and the methods used to decide when to harvest a tree or stand.

Some feel the forest is a crop, to be harvested when ready. For some this meant "mature or diseased." For others, a more tangible figure, such as 12 inches in diameter, was the indicator to cut.

Response:

There is not a common agreement as to when a tree or stand is "mature." A definition of maturity in "Terminology of Forest Science, Technology, Practice, & Products" is: "The stage at which a tree or stand best fulfills the purpose for which it was maintained." NFMA limits final harvest to stands that have culminated in average annual growth. This usually occurs on the Ochoco National Forest after a stand age of 70 years. It was recognized that there is a local demand for larger material, and further analysis was done to compare economics, timber yields and effects on other resources if longer rotations were used (see appendix B, sections 2 and 7). In Alternative I, the General Forest Management Area provides for an average merchantable stand size of 18" DBH before final harvest for ponderosa pine stands rather than the minimum rotation age from culmination of mean annual increment which could occur on trees as small as 12" DBH. The exceptions to this are when earlier harvesting is needed to meet some resource need other than timber, or where stands are threatened by insect or disease damage.

Stands with trees smaller than 18 inches DBH may be harvested during commercial thinnings. On the Ochoco National Forest, stands which are not thinned are vulnerable to insect attack because individual trees in a fully stocked stand grow very slowly. Thinning redistributes the growth potential of the site so the remaining trees grow faster and are generally healthier.

With uneven-aged management, both regeneration cutting and thinning take place on a stand during the same harvest operation.

0700-13.1 Growth

Eight letters were received with comments on growth rates. Most felt that harvest should not exceed growth but should remain at a level slightly less than the growth rate.

Response:

The current growth on all timber lands is 14.6 MMCF or 79.7 MMBF from Appendix E of the Proposed Plan. This will change in the future depending on alternative as shown on Table 2-8 of the FEIS. Growth in cubic feet is displayed here by alternative for year 2030 and the Long Term Sustained Yield Capacity. Similar values are shown for Alternative I. The FORPLAN model is used as a tool to help schedule harvest so that the maximum level of harvest can be maintained within limits set by the standards and guidelines. As a general rule, the younger the trees in a stand, the faster the growth, so as volume accumulates on a stand the rate of growth decreases. A mature stand therefore will have high
volume but little growth, and a very young stand will have a high rate of growth but little volume. Part of the scheduling problem in managing the forest is to bring these into a proper balance. On the Ochoco N.F., growth rates will increase through time as mature trees are replaced with younger trees. See Chapter 4, of the FEIS. During this time the inventory will decrease.

0700-13.2 Fiber vs. Sawlogs

Ten letters were received with comments concerning fiber or quality sawlogs.

Some reviewers felt that rotation length is too short. They believe that increasing rotation length will enhance the quality of timber products.

Others request that the Ochoco National Forest be managed for mature ponderosa pine only.

Still others want the value evaluated by species rather than by total wood fiber.

Response:
The analysis process that was used to determine harvest levels and product size considered size and species (ponderosa pine and others). Alternative I had an objective of maximizing PNV while meeting management objectives. Longer rotations were considered and are required in many management areas, but to require 200 year or longer rotation ages would result in a 40 to 50 percent reduction in harvest level. As a result of responses to the draft, the objective on General Forest has been revised to include an emphasis on the production of quality pine on General Forest. See Standards and Guidelines for General Forest in Chapter 4 of the Plan. This results in longer rotations and larger trees at final harvest. Pine and other seral species will be emphasized on most of the Management Areas where timber harvesting is permitted. Mixed conifer along with all other sites will be managed as intensively as is economically practical.

@0700-14 Specifics

0700-14.1 Catastrophic Conditions

CRITFC asked what constitutes a catastrophic condition and how the ONF will compensate if a high level of catastrophic damage occurs each decade.

Response:
A catastrophic condition is when the mortality or damage in a decade exceeds the level planned. It is possible, but not likely, that the salvage level would be near but not over ten percent for several decades. Whenever a catastrophic event occurs that has the potential of effecting future harvest levels, then new FORPLAN runs would be made and a new harvest schedule developed. It is also planned to reinventory at ten-year intervals and recalculate the harvest schedule based on current information. This would ensure corrections for changes in tree mortality or damage.

0700-14.2 Idlewood Burn

There was one comment about the growth rate of an area reforested on the Malheur National Forest in the late 1940's or early 1950's. The area was the Idlewood burn, and the respondent stated that the trees are now only eight or nine inches in diameter.

Response:
Your observation of eight to nine inch trees in 50 years is similar to the managed yield table which predicts nine to 10 inch trees in 50 years, and 18 inch trees in 120 years.

0700-14.3 Sold Sales

One respondent mentioned commitments to timber sales made prior to the DEIS that are incompatible with the Land Management Plan. The person asked
for direction in the EIS addressing mitigation of prior commitments.

Response:
The Plan does not change history. Each situation will be reviewed based on direction for each Management Area (M.A.). If the existing condition is not compatible with goals for a M.A., than corrective action may be taken depending on feasibility and funding.

@0700-15 Timber Economics

0700-15.1 Budget
Fourteen letters were received which had comments concerning the budgeting and financing of forest operations.

Some respondents stated that the ONF budget is too commodity-oriented, and that the allowable cut was set by Congress based on economic and political pressures.

Others were opposed to public-subsidized harvest operations and felt that the timber industry should bear the full cost of logging, or that the ONF should charge more for timber sales.

The Columbia River Inter-Tribal Fish Commission asked if the forest reduced prices as an incentive for harvesting old growth.

Some respondents expressed the feeling that the forest should favor local remanufactures when allocating timber sales, or that cutting circles should be established.

Other concerns included: the desire for set-price salvage sales without bidding, more coordination between the Forest Service and BLM, and the need for more qualified personnel to mark and lay out timber sales.

Response:
The Forest, through the Regional and Washington Offices, provides information to Congress as to the harvest potential from the Forest based on the current Forest Plan, but decisions made in this plan do not constrain or restrict Congress’ ability to set budget or outputs. Congress may vary harvest levels from year to year but historically this has been based on the planned harvest level. Congress is influenced by many factors in making its decision, as is the ONF in developing its proposed action. Congress also establishes the laws governing sale of timber and other products so, this is not an issue to be decided by this FEIS.

The Forest attempts to hire well qualified people and see that they have proper training and supervision to do their jobs, but the regulations governing these decisions are outside the scope of this Plan.

All timber is appraised using standard appraisal procedures (see Forest Service Manual 2430, available at Forest Offices). No arbitrary adjustments are made. However, the appraisal process does consider logging and other costs, so areas with high costs (such as cable logging or very small volumes) will have lower stumpage than a typical sale.

0700-15.2 Demand and Supply
Twelve letters were received with comments dealing with demand and supply of timber. The letter from the Oregon State Forester questioned the statements in the draft that claim local supply affects stumpage price. He also feels that more analysis of assumptions used in demand curves (Appendix B) is needed.

The Oregon State Economic Development Department disagrees with the prediction that demand will drop after the first decade.

Other respondents expressed the need for a model to forecast stumpage values and for better analysis of timber volume available from state, private, and other forest sources.

Still others pointed out that no reference was made to volume under contract.

The equation between local installed mill capacity and demand was labelled inaccurate by some.
Finally, some respondents believed the last-five-year average cut is the best measure of demand.

Response:
The harvest level as shown in Table III-29 of DEIS is not a good indicator of local demand as this was during the worst recession in the timber industry in recent history. The current harvest level (1986-88) is much higher than the 1975-1984 level and is probably a closer reflection of demand. The harvest level from “The Forest Program For Oregon,” shown in FEIS Chapter 4, is lower than the planned harvest level in Alternative I (see FEIS Summary).

Volume under contract has been removed from the inventory by the acres adjustment for sold sales so it is no longer considered in calculating future harvest. This does supply an important source of guaranteed supply of timber for the purchaser. Currently the volume under contract is about two years worth of sales.

See Chapter 3 of FEIS for further details.

@0700-16 Management Practices

0700-16.1 Utilization

There were two letters with concerns about the effects of utilization standards on outputs. One concern is that projected outputs in the DEIS do not reflect the practices which actually take place. It was felt that the amount of timber actually taken out as usable products is much smaller than that in the EIS.

Another respondent indicated that better utilization of logging residue would reduce the demand for old growth timber.

Response:
A utilization standard of a four inch DIB top and a seven inch DBH was projected for future decades. This is two inches smaller than is presently required. This amounts to about one percent more volume for an 18 inch DBH tree than with a six inch DIB. The Ochoco believes having larger quantities of small material available will be a reasonable utilization standard.

For more information concerning utilization standards, refer to the Pacific Northwest Region Plan, available at the Ochoco National Forest Supervisor’s Office.

Subject Area 750
Firewood

@0750-01 Firewood

Two-hundred forty-seven respondents felt that firewood is a desirable by-product that should not go unused or be burned up in slash piles. They also felt it helps to clean up the Forest and provides income to local communities.

Some of the reviewers, among them the Crook County Soil and Water Conservation District, felt that the allotments should at least stay the same if not increase. They also wanted the Forest to allow more time for woodcutting and to make the wood more available.

Many people indicated that the general public should be allowed to cut larch for firewood. They also felt that the Forest should stop loggers from selling logging truck loads as fuelwood.

Some noted that there was a problem with the way fuelwood demand is displayed. They felt that the amount sold probably exceeds what is cut.

A few respondents felt that selective cutting would be more beneficial for firewood. They also felt that the Forest needs to educate the public on how to use smaller green fuelwood material.

One person indicated that the amount of firewood available should be reduced.
Response:
Availability of fuelwood is an issue that concerned many people. However, what is acceptable fuelwood has not been defined so it has not been inventoried. Estimates of fuelwood that will be available by alternative (Table 2-8 of FEIS) were based on typical volume of cull material left after logging and the normal mortality that would occur in the vicinity of roads. There is also a small amount from juniper and precommercial thinning. So, the level of timber harvest has the greatest influence on availability and quality of fuelwood. Demand is equally hard to determine as it is based on accessibility and quality of available wood compared to cost of alternative sources of wood or other forms of heat.

Chapter 4 of the Plan has been rewritten to provide standards and guidelines for managing fuelwood. This attempts to make all wood that is not utilized for commercial sawlogs available for fuelwood cutting except were it conflicts with the management direction of a specific Management Area. Some items that have precedence over fuelwood cutting are snag requirements and road closures for big game habitat. Also, a timber purchaser has the right to all timber included in a contract and can process or sell those logs as desired, except for export restrictions, so a purchaser can sell logs for fuelwood. It is very possible that as demand and price for fuelwood increases, more logs will be sold for fuelwood.

The free use of fuelwood was under enabling legislation that allowed giving wood to settlers who were dependent on National Forests for fuel. There are several other legislative acts concerning disposal of forest products. The Region and Forest has considerable discretion on how this will be done. This policy is in the 2400 section of the Manual which is available at the Supervisor’s or District offices. With the current demand for fuelwood, most is sold. This allows the recovery of some administrative costs plus collection of money for slash disposal, reforestation, and erosion control. But some free use material is still available. See local district for availability.

Subject Area 800 Water

@0800-01 Watershed

Four letters, among them the responses from the EPA and the Oregon State Forester, had comments on watershed management.

One respondent stated that in Table 4-6 and on page 43 of the Draft Plan, the water yield values have no real purpose. The reviewer states that this line should reflect a measured output of the Plan’s objectives, such as number of restored miles of fish habitat or riparian areas resulting from changes in the timing, quantity, or quality of runoff due to improved watershed conditions. In addition, this person suggested that the Mountain Creek Watershed and Bear, Badger, and Willow Creeks should all be considered highly sensitive due to the presence of anadromous fish.

Another respondent asked how goals and objectives for watershed management are being met.

EPA noted that DEIS Table II-11 is apparently missing two watersheds; the agency stated that they understand there are 24 major watersheds on the Forest and Grassland (22 on the Forest and two on the Grassland), but that two seem to be missing from the table.

The EPA also stated that the streams on the Ochoco range in condition from poor to good in relation to their natural potential, and that the Forest should practice management on a stream-by-stream basis to address individual problems or concerns. The Environmental Protection Agency also noted that Cottonwood, Black Canyon, and Wind Creek drainages are not mapped in the DEIS, and asked if these drainages are part of larger drainages; and if so, which ones EPA further stated that an area analysis would be appropriate for all watersheds in which development is planned near important aquatic resources.

And finally, the EPA requested a statement in the FEIS concerning the one existing instance of domestic use of surface water occurring on the Forest.
To ensure protection of current and future drinking water supplies, the agency requested information on location, size, source, and municipality served, as well as any instances of waterborne disease occurrences and pertinent water quality monitoring information.

The Oregon State Forester noted an apparent discrepancy in the documents. The Forester noted that Appendix B states that watershed harvest dispersion constraints will be between 17 and 23 percent, but that Appendix H lists these figures at 25 and 35 percent, respectively. The Forester asked which set of figures is correct, and what the rationale is supporting these constraints when the Deschutes National Forest satisfied this minimum management requirement with a 58 percent constraint.

Response:
Project level analysis is currently being used on the Forest at the project level, and is part of the NEPA process.

The Final Plan displays a corrected watershed map showing 26 watershed divisions, 24 on the Forest and 2 on the Grassland. The Ochoco regrets any confusion this error may have caused.

Cottonwood, Black Canyon and Wind Creek drainages are included within the watershed identified as John Day tributaries (see FEIS Chapter 3).

Management of the uplands in a watershed will be addressed chiefly through application of a cumulative effects model which measures the rate of harvest activity against a threshold based on watershed sensitivity.

Watershed harvest dispersion constraints (FEIS Appendix B) refer to regeneration (clearcut) harvest limitations (17-23 percent) and overstory removal limitations (50-67 percent) which were employed in FORPLAN modeling to address the concern of the model planning unusually high levels of harvest in certain drainages (see Chapters 3 and 4, FEIS). The values given in Appendix H of the Draft LRMP are watershed threshold values employed to assure a more optimum dispersion of harvest activity/effect over space and time. These threshold values are also employed in risk analysis at the project level.

A further discussion of watershed threshold values and their use can be found in the Supplement to the Draft Environmental Impact Statement for the Ochoco National Forest in the discussion of Management Requirements for Water Quality, and Appendix F.

The watershed threshold values given in Appendix H of the DEIS and Appendix F of the FEIS are specific for each watershed and range from 25 to 35 percent. The Forest weighted average threshold value is 30.1 percent, which means that 30.1 percent of the Forest could be in a harvested condition at any point in time without exceeding the ability of streams on the Forest to absorb and recover from the effects of management activities and natural storm events without long-term impact.

The harvest dispersion constraints and watershed threshold values referred to above could be expected to differ considerably from those used on other Forests (e.g. the Deschutes NF) due to differences in soils, watershed condition, and management practices that have affected the landscape over the past several decades.

The Forest Plan is built around a process designed to assure that goals and conditions are being met. See chapter 5, Implementation, of the Final LRMP.

The FEIS will include the information on domestic water supply use in Chapter 3.

@0800-02 Upstream Impoundments

Four reviewers commented on upstream impoundments. Three of the participants felt that upstream impoundments could and should be used to improve water quality, game habitat, riparian areas and recreation. They recommended the program be expanded and stated that the Forest would benefit from approximately 200,000 acre-feet of usable water.

The other respondent felt that nature should be allowed to take its course along streams but stated
that upstream impoundments seemed to be beneficial from all aspects.

Response:
Forest experience with upstream or headwater impoundments has not been encouraging. They are expensive to construct and maintain and to provide an increased streamflow of just one cubic ft/sec. requires the storage and release of nearly two acre ft./day. More effective from a cost efficiency standpoint as well as providing better fish and wildlife habitat is the improvement of riparian areas which is a key element of the proposed Forest Plan.

@0800-03 Timber/Grazing Effects

Two letters were received with comments on timber and grazing effects on runoff. The reviewers expressed concern that, once the overstory vegetation is removed, whether by timber harvest or livestock grazing, water flow patterns are likely to change, adversely affecting watercourses both on and downstream from the Forest. The respondents were particularly concerned about spring runoff, and felt the DEIS inadequately dealt with this aspect of water management.

Those responding suggested that grazing practices will have to be drastically altered to protect the Forest from heavy snowpack runoffs.

Response:
It is recognized that timber harvest has the potential to affect the quality, quantity and timing of runoff (see Chapter 4, FEIS). However, analysis of the various alternatives indicates they would affect the amount of runoff by less than 5 percent; in fact, several alternatives would actually decrease total runoff. One area of concern remains - the distribution or dispersion of harvest by watershed across the Forest. In order to assure an optimum dispersion of harvest effects, a model was developed to track harvest activities (cumulative effects) over time and area. Watershed thresholds were established to reflect the natural ability of each watershed to absorb impacts (both natural and human caused) without suffering long term loss of resource values (or causing downstream problems). This model will be utilized to monitor harvest effects and changes in watershed (including riparian areas) condition over time.

For more information on the use of this model please refer to Chapter 3 and Appendix F of the FEIS.

@0800-04 Data/Analysis

One reviewer stated that the water yield values in Table IV-6 of the DEIS have no real value, and that the line should reflect a measured output of the Plan's objectives.

The U.S. Fish and Wildlife Service suggested that the statement in the Draft should address the range of yields from water wells and estimate the usage of ground water on the Forest.

Response:
Water yield values given in DEIS Table IV-6 were developed during the planning process as a possible tool in the development and evaluation of alternatives. Ultimately it was found that total water yield was not significantly affected by the alternatives developed. The values are presented in Table 2-8 of the FEIS, as it was felt this information might be of value to some members of the public. The information requested on yields from wells has been included in WATER, Chapter 3, FEIS.

@0800-05 Monitoring

The EPA stated that Water Management Practices should refer to the Monitoring Plan so as to describe the methods used for the attainment of goals and objectives.

Response:
The FEIS refers to the monitoring plan to show how goals will be reached. See Chapters 5 of the Final Plans.
One respondent commented on the hazards of flood erosion. The comment was made that the ONF is already at the maximum runoff allowed by the state, and that Federal Regulation 36 CFR 219.27 directs the Forest to minimize hazards from flood erosion and similar impacts to streams and wetlands.

Response:
State regulations do not cover maximum water runoff. However, Federal regulations (36 CFR 219.27) do require the Forest Service to minimize hazards from flood erosion and Forest Service policy (FSM 2520 Amend. 48 and FSM R-6 Supp. 37) reflects this shared concern.

The wording "36 CFR 219.27--minimize hazards from flood erosion and similar impacts to streams and wetlands" is now included in the FEIS Forest-wide Standards and Guidelines (see Appendix D).

There were sixteen comments on water quality.

The majority of the respondents were concerned that the Ochoco National Forest's DEIS failed to acknowledge and comply with State of Oregon and Federal water quality standards. Among those with this comment were the Oregon DEQ, the Environmental Protection Agency, the Columbia River Inter-Tribal Fish Commission, ODFW, and the Oregon Water Resource Department.

The DEQ further stated that there are no state water quality standards for riparian zone condition, as stated in the DEIS Table V-3.

ODFW asked, in addition to the above comment, what was meant in the DEIS by "significant degradation of water quality."

The CRITFC asked whether the Forest anticipates continuing management practices on those drainages where standards are being violated, and if so, on what legal basis the Forest justifies those activities that increase or perpetuate those violations.

The EPA also stated that the Plan and DEIS should have referenced the Oregon Forest Practices Act and Rules and indicated how they would be complied with.

Some respondents noted that violations of water quality standards are mentioned in the DEIS, but that only general guidelines are given for their correction. The reviewers requested more specific standards be given for the areas with seasonal violations.

Several participants in the public review process stated that reduction in shade has caused a rise in sedimentation and temperature, causing some streams to fall below water quality standards. Others felt that Forest management activities have had a negligible effect compared to natural processes.

Some stated that since there are very few areas where 50-75 percent shade is obtainable on the Ochoco, and shade appears to be increasing slightly, the Forest should keep the shade standards as they are at present.

One respondent stated that the standard for stream temperature in the DEIS fails to describe what temperature is to be maintained. Another reviewer asked what state water quality standards for temperature refer to--average daily values, daily highs, etc.

Response:
Concerns focusing on the water resource issue (quality, quantity and timing) are shared by the Forest. Of primary importance are temperature and sedimentation (turbidity). The Watershed Improvement Schedule is designed to correct a large measure of problems dealing with water temperature and sedimentation by bringing all riparian areas up to an excellent condition (see response to Riparian comments, 0450-02). Sedimentation problems of the upland watershed level will be mitigated by dispersing harvest activities optimally over the entire Forest, by applying appropriate Standards and Guidelines, and by applying best management practices (BMP's) to deal with site specific situations and problems. Forest Service policy makes allowances for short term deviations from water quality standards (FSM 2526-6). However, it is ultimately the...
task of Forest Service personnel, through project planning and administration, to keep any short-term impacts from becoming long-term cumulative effects in violation of state standards. Future activities with the potential to affect the water resource will be monitored and problem areas or activities identified and brought into compliance.

With regard to shade requirements for Forest streams, please refer to Chapter 4 of the FEIS. The pertinent section states; "The requirements for shade along streams will generally correspond to provisions for more than 80 percent of the surface shaded. Where this is unattainable, 100 percent of the potential for shade is the standard."

These shade requirements are necessary in order for the Forest to comply with State Water Quality Standards as directed by the Clean Water Act (Public Law 95-217).

The State of Oregon Water Quality Standards with which the Forest must comply under regulations of The Clean Water Act, are maximum values; though "management activities will include objectives for reducing temperatures to levels that will improve fish habitat capability" (DEIS Appendix D-59).

The Forest Plan FEIS makes reference to the Memorandum of Understanding between the Department of Environmental Quality, State of Oregon, and the Forest Service, United States Department of Agriculture. Under this agreement, the Forest Service recognizes the State's lead in water quality management, cooperates with and gives assistance to State or designated area wide planning agencies, acts in compliance with the Forest Practices Act, and coordinates with EPA (see 208 of the Federal Water Pollution Control Act).

The fact that approximately 50 percent of the streams on the Forest do not meet state water quality standards for temperature and turbidity is an indication to some that many of the watersheds are suffering the cumulative effects of past management activities including: road construction, timber harvest, and grazing. While it is recognized that our understanding of how management activities affect watershed outputs (including sediment) is only just becoming clear, it is wise policy to proceed with caution in situations where risks of long term resource values are high.

As a matter of explanation, harvest threshold values serve as benchmarks reflecting watershed condition or sensitivity (see FEIS Chapter 4, and Appendix F) against which the Forest is able to monitor the rate of harvest activity to determine the level of risk of incurring long term impacts to watershed condition and water quality. "Exceeding a threshold value does not, in itself, limit management options on the Forest. It does, however, indicate the need to undertake other specific mitigation measures to offset potential reduction in site productivity or long-term impairment of water quality" (DEIS p. 133). In order to meet management requirements for water quality, the Forest must assure optimum harvest dispersion, initiate the rigorous application of Best Management Practices, schedule an extensive program of Riparian Improvements, and monitor activities carefully to assure resource objectives are met. All of these elements are key factors in the FEIS.

Finally, it should be pointed out that increased timber harvest (or even harvest at current levels) does not produce the highest present net value, due in part to overall higher mitigation costs. Identifying the level at which the Forest is able to produce a wide range of resource outputs (timber, water, recreation, etc.) and still maintain a viable, functional ecosystem is the basis of multiple resource management.

Two nonpoint source pollution parameters, water temperature and suspended sediment, are the major determinants of water quality on the Forest. Higher water temperatures encourage the growth of certain nuisance organisms such as bacteria, algae and fungi, that in turn affect the levels of dissolved oxygen, pH, and turbidity, while producing undesirable tastes and odors. The amount of shading in riparian areas determines the extent streams are warmed by solar radiation. The riparian prescription (Final Land and Resource Management Plan, Chapter 4) contains the water temperature standards and the amount of shade necessary to meet those stan-
Standards. Special riparian area alternatives for meeting shade requirements were not examined individually because their effect on PNV would be less than one percent.

Sediment yield is largely determined by the amount and erodibility of exposed soil in a watershed. Timber harvest activities, including road construction, slash treatment and site preparation, not only affect the amount of exposed soil, but also alter the timing and quantity of water leaving a watershed. Following harvest activities, watersheds become more hydrologically sensitive for a period of time, with storm events producing more rapid and extreme responses. This greater sensitivity to storm events results in more energy being available to transport sediment to stream channels. Thus the primary effort in maintaining water quality is directed at the timber harvest program and its effect on sediment production in a watershed over time. Other water quality parameters will be monitored on a project basis as needed.

Table 5-3 (Plans Chapters 5) has been changed to reflect new wording: “Any degraded riparian areas found to be adversely affecting water quality will be improved to assure that the water quality meets state water quality standards.”

“Significant degradation of water quality” is taken to mean any water quality parameter that does not meet stated Oregon water quality standards.

On the Forest, there are two primary water quality parameters: temperature (as it is affected by shade) and sediment (both in transport as suspended sediment or turbidity, as well as entrained in streambed gravels).

State of Oregon Water Quality Standards for temperature refer to point-in-time maximum values.

@0800-08 Best Management Practices

Three respondents commented on best management practices (BMP’s).

One reviewer stated that BMP’s are not used for a number of reasons, and that the DEIS should address how implementation of a new Management Plan will “magically” change actual practices into “best” practices.

Another suggested that the Forest attempt to meet “optimal” management requirements rather than minimum management requirements.

The EPA stated that the DEIS should have more fully explained selection of BMP’s for a particular activity, and how uncertainty was factored into those selections.

Response:
The element that has the potential to bring about the actual implementation of effective Best Management Practices is the monitoring plan. Monitoring closes the circle between the Environmental Assessment process and project implementation. Monitoring tells the Forest how well it is doing and is vital in bringing about change in how the Forest Service plans and carries out management activities.

@0800-09 Equivalent Clearcut Area

Nine reviewers commented on equivalent clearcut area (ECA) or equivalent harvest area (EHA) (the two are used interchangeably in the Plan/FEIS documents).

Some remarked that they had serious concerns about watershed ECA and its use; they stated that they were not aware of any research on how reliable ECA calculations used in the DEIS were.

Several respondents stated that Table 3-II in the DEIS was suspect because it implied that some watersheds are capable of withstanding abuse while others are not. Others felt that “watershed sensitivities” in the table were poorly defined and should have been included in the glossary.
Some felt discussion of ECA was double-talk to justify cutting more than the threshold value of 30.1 percent. They asked if the ECA includes the present system of roads, extent of compacted sites, grazing, mining, or the orientation of a clearcut, commenting that a clearcut on a slope into a stream is more destructive than one on a flat area.

CRITFC and the Oregon DEQ asked what criteria are used to derive ECA values, and how ECA values are determined and implemented for a specific watershed.

One person said that the meaning of Table 4-16 (ECA) was not clear. The reviewer asked that labels or legends be added to the text to explain the values in the table.

Some respondents felt that the limitations on the amount of area harvested in watersheds should be reduced or the Forest Service should get the legal authority to control harvest schedules. These reviewers pointed out that two or more sales within a single watershed, each harvesting near maximum ECA, could cut out in one year, adversely affecting water quality. They stated that the Forest Service is gambling with soil and water resources.

Response:

The concept of watershed sensitivity is discussed in Chapter 4 of the FEIS and in Appendices E and G. Watershed sensitivity ratings are based on a number of factors including: soil type, channel condition and fishery values. These ratings reflect the existing physical condition of the watershed and its susceptibility to damage from human activities and/or natural events. Sensitivity levels were established to work within the natural ability of a watershed to recover from the impacts of human activities and natural events with no long-term resource damage. These sensitivity ratings will be evaluated over the life of the Forest Plan and will be readjusted as necessary in the future.

The fact that two or more timber sales, sold at different times, could cut out within a short period of time with possible negative impacts to the watershed is a recognized problem. However, new timber sale contract regulations shorten the period in which harvest must take place and require a higher bond to encourage earlier harvest. Also, the cumulative effect model used by the Forest has the ability to evaluate this situation and its effect on ECA for various alternatives during the planning process, in time for corrective action to be taken to mitigate or avoid potentially damaging situations.

Equivalent Clearcut Area (ECA) calculations are a method of keeping track of a range of harvest activities, including: clearcut, overstory removal, thinning and uneven-aged management. As part of the cumulative effects (CE) model, ECA yields a picture of the rate of timber harvest or vegetative management over time. Other more static elements, e.g. roads, grazing, stream channel condition, soils, fishery values, and slope, figure into the development of watershed sensitivity levels reflecting the physical condition of a particular watershed (see chapter 3, FEIS, and Appendix E and G). Watersheds have a natural ability to absorb impacts, natural or human caused, up to a certain level or threshold. Above this threshold, longer term damage to watershed resources may occur.

For each sensitivity level assigned to a watershed on the Forest, a harvest threshold value was established. When ECA is plotted against this threshold value a cumulative effects analysis of the rate of harvest activity against watershed conditions is made possible. Should a condition arise when the ECA exceeds the threshold value, it is an indication that watershed values may be at risk and that steps should be taken to reduce this risk either through mitigation or rescheduling of harvest activities (FSM 2405.13).

Additional uses for this cumulative effects analysis include assuring an optimum dispersion of harvest effects on watersheds on a District or the whole Forest. Also, cumulative effects analysis provides a benchmark, management activities versus watershed condition, which can be evaluated against in the future for purposes of monitoring the effectiveness of management prescriptions and best management practices.

Reference to Table IV-16 is made on page 133 of the DEIS. The table has been corrected in the FEIS to make it more readable.
Subject Area 820 Soil

@0820-01 Compaction

Three letters were received with comments on soil compaction. CRITFC remarked on the DEIS statements that no more than twenty percent of an activity area can be compacted to a degree which degrades vegetative productivity, that cable logging is estimated to increase soil bulk density on ten percent of an activity area and tractor logging on thirty percent; and that it was previously stated that a Forest-wide average of twenty percent soil compaction would be allowed for activities. From this, CRITFC infers that, if this degree of compaction constitutes the predicted compaction level, then with a twenty percent threshold of variability from the predicted level, compaction would have to affect twenty-four percent of the activity area before action would be taken.

One reviewer asked whether compaction caused by partial cutting can't be largely offset by equipment modification, and how much has been done in this area such as requiring the use of large-rubber-tired skidding devices, managing placement of skid roads, etc.

The other respondent suggested that soil effects should receive the highest priority throughout project planning and implementation, and that emphasis should be placed on prevention of compaction and displacement in relatively undisturbed areas.

Response:

The soil management guideline (Plan, Chapter 4) which states that, "no more than 20 percent of an activity area can be compacted or displaced to a degree which degrades vegetative productivity," refers to a point in time one year after the activity has taken place; and may include mitigation such as ripping and tilling to bring compaction levels with the 20 percent guideline. This is an average value and includes a 20 percent variability factor meaning some sites may be at 16 percent while others will be at 24 percent.

Equipment modification along with use of designated skid trails or logging on snow, are all techniques that are being explored to reduce soil compaction damage. However, each method has its drawbacks and limitations.

The Forest agrees that soil should receive high priority during project planning and implementation. See Chapter 4 of the FEIS for the discussion on environmental consequences.

@0820-02 Productivity

One respondent stated that, until such time as better information becomes available on lost soil productivity, the following ECA thresholds should be used: high, ten percent; medium, twenty percent; and low, twenty-five percent.

Response:

At this point in time the watershed threshold (EHA or ECA) values provide the Forest with a benchmark against which it can evaluate the risk or effects of harvest and management activities. These threshold values will be monitored against effects on the ground, and can be raised or lowered in the future to assure resource values are protected.

@0820-03 Sedimentation

Eight letters, among them the response of CRITFC, had comments on sedimentation.

One person stated that the Transportation section of Riparian Management, PLRMP ("Road drainage will be designed and maintained to eliminate any influx of road sediment runoff directly into riparian areas"), is not realistic. The comment is made that many roads are located in draw bottoms, and the only place the roads can drain is into the riparian zone.

Another respondent stated that the low soil/water values in DEIS Table B-VIII-7 and elsewhere do not reflect the true value of the Forest's soil resource.
Another reviewer requested that a value be assigned to potable water with relatively steady seasonal flow and low suspended sediments. This person felt the entire Forest Plan showed a bias by not recognizing that water may be as valuable an output as timber.

One participant stated that the value of sedimentation should be based on how much money must be spent to remove it from spawning beds.

CRITFC asked what the effects of different amounts of road building, cattle grazing, and mining on sedimentation are. The Council also requested that the methodology for calculations of sediment production and delivery to stream channels be made more clear in the final documents, and should include formulas and references.

Response:
The wording in the Final LRMP has been changed to read “directly into stream channels.”

The Forest shares a strong concern for maintaining soil productivity and water quality values. Forest-wide Standards and Guidelines contain a number of criteria designed to protect soil and water. The best management practices (BMP’s) described in Chapters 2 and 4 of the FEIS (also Appendix G) have also been developed to assure soil and water resources are maintained.

The soil and water values used in the economic analysis of the various alternatives were taken directly from the 1985 RPA program assessment, and have been designated for use in the planning process. The value assigned to sediment reduction (i.e. reduced soil erosion) of $6.00/metric ton and maintaining water quality of $0.20/acre ft. (FEIS Appendix B, Section 4) are considered by many to be unrealistically low.

Any land management plan is a blend of resource values and outputs involving tradeoffs between a range of objectives. It is felt that by adhering to the standards and guidelines and management prescriptions that resource values will be adequately protected.

Sediment production is closely tied to timber harvest, since it is the only real variable from among the range of alternatives. Roads, generally recognized as the major source of sediment, change little from alternative to alternative. More stringent grazing utilization standards will be applied to all alternatives for riparian areas. The Forest has no data from which to make estimates on sediment production from grazing or mining. The process for calculating sediment production and delivery to stream channels is available in the Planning Record, which is on file in the Supervisor’s Office.

@0820-04 Specifics

Two letters had specific comments on soils. The EPA asked where on the Forest the high-clay soils are located. The other respondent stated that if logging could benefit a particular site, balloon or helicopter logging might be used to protect fragile soils.

Response:
The FEIS contains a description of the location of the high-clay soils (see FEIS Chapter 3). For the most part, they are located on southern exposures as buried soils on north and east exposures. For a detailed description of the location of clay soils, there are copies of the Forest Soil Resource Inventory available at the Supervisor’s Office.

Alternative logging methods, including the use of helicopters, are viable options and have been used in the past to protect and minimize effects on other resources (see also Plan, Chapter 4, mitigation measures for soil).

@0820-05 Plan Comments

One respondent asked why soil loss is considered an output (Table IV-6 and elsewhere in the DEIS and PLRMP).
Response:
The soil loss values given in FEIS Table 2-8 provide relative comparisons of erosion levels. They are not looked upon as a positive output.

@0820-06 Erosion

Eight responses were received containing remarks on erosion. Among the letters were those from ODFW and CRITFC.

Several of the respondents registered opposition to clearcutting, stating that this practice is very conducive to erosion and destructive to the environment. Some commented that the Forest Service is directed by Federal regulations to minimize erosion impacts. Others said there is nothing wrong with clearcutting as long as it does no harm to the environment, and that in fact the practice creates wildlife and livestock forage, however, they agreed that clearcutting in the wrong areas can harm streams through erosion.

Most of the comments pertained to ground cover and its relationship to erosion prevention. ODFW stated that the standard for ground cover in riparian areas should be 80 percent. CRITFC asked how it was established that 40 to 60 percent ground cover will be sufficient to prevent significant erosion, and on which streams flowing through grazing allotments does ground cover exceed 60 percent.

Others stated that 60 percent should be specified in the FEIS as the minimum basal ground cover area to effect proper infiltration of precipitation. One reviewer mentioned the requirement in the 1897 Organic Act to provide favorable conditions of streamflow, and stated that the amount of vegetation needed for precipitation infiltration was not alluded to anywhere in the Plan.

One respondent blamed neither logging nor livestock for erosion. This person stated that the vast majority of erosion occurring on the Ochoco in the past 23 years took place in February of 1979 as a result of storms and runoff.

Response:
The Forest has reviewed ground cover standards and feels the range given (FEIS Appendix D) is adequate to maintain soil productivity in riparian areas (see FSM 9/83 R-6 Supp 45--effective ground cover by erosion hazard class).

Standards for maintaining soil and vegetation in a condition which promote infiltration of precipitation (i.e. reduced compaction and surface erosion) are contained in the Final Plan, Chapter 4 (soil management in riparian areas).

The wording “36 CFR 219.27--minimize hazards from flood erosion and similar impacts to streams and wetlands” has been included in the FEIS Forest-wide Standards and Guidelines.

Removal of vegetation from the Forest, namely timber harvest, reduces evaporation transpiration. As a result, soil moisture values are higher in clearcuts than under adjacent stands of mature timber. This is the reasoning that is used to calculate the changes in runoff predicted in FEIS Chapter 4. Increased timber harvest yields greater runoff; though overall differences are less than five percent.

Although clearcutting appears more destructive, soil damage is concentrated and because of this is often easier to correct; e.g. reducing the compaction damage from heavy equipment through tilling. On the other hand, partial cuts or salvage logging must cover large areas of land with many miles of skid trails. The choice is between concentrated impact (with clearcutting) or extensive impact to the land with other forms of harvest. Which method is better or worse overall often depends on site characteristics and stand condition.

The majority of degraded stream reaches on the Forest are the result of the cumulative effects of a number of activities (including road construction, timber harvest, grazing, etc.) that have taken place over the last several decades, and are seldom the result of a single activity. The cumulative effects model in use on the Forest analyzes the risk of entering watersheds at various levels of management in conjunction with a major storm event.
Subject Area 830 Air

@0830-01 Air

Eleven letters, among them the responses of the Environmental Protection Agency, the Oregon Department of Environmental Quality, and the Oregon State Forester, had comments on air quality. Most, including the agencies mentioned above, were concerned about the detrimental effects of prescribed fire and slash burning on air quality. The agencies all referred to the Oregon State Implementation Plan (SIP) and asked if the Ochoco was in compliance with it.

DEQ and others expressed concerns over the amount of Total Suspended Particulates (TSP) from prescribed fire. Most respondents expressed a desire to see prescribed fire used less frequently. Some suggested that all slash and debris be ground back into the soil.

Long-term effects of air pollution, such as acid rain and health effects, were addressed by some. The EPA stated that smoke from woodstoves causes serious winter air pollution.

The State Forester noted that the DEIS failed to state that prescribed fire reduces fuels buildup and the risk of wildfire. The letter from the Forester also made the statement that forest smoke will originate in the Ochoco whether prescribed fire occurs or not.

The DEQ commented that if projected annual and daily air pollution emissions do not exceed those of the baseline period (1977-78), then this issue should not be analyzed further.

Response:

The Forest is concerned about the health and discomfort impacts of smoke. Prescribed fire is conducted in accordance with State Smoke and Visibility Plans to avoid and minimize these impacts on the public. Although currently outside the jurisdiction of State Smoke and Visibility Plans, this Forest abides by the spirit of these plans in continuing to reduce emissions from our activities. The recently completed Environmental Impact Statement (EIS) on Managing Competing and Unwanted Vegetation emphasizes human health issues. The Forest incorporates this more comprehensive guidance on public health concerns in the FEIS and Forest Plan. Improvements in smoke abatement technology will be utilized as they develop.

Since the adoption of the Oregon SIP, the Forest has been in full compliance with the regulations on protection of visibility and the goals of reducing smoke emissions. The FEIS Appendix D and Forest Plan Chapter 4 have been updated to reflect the newly approved SIP.

During the 1977-78 baseline period, the Ochoco National Forest's share of the Bend-Madras Basin TSP load was 9,200 tons. From current levels of around 13,000 tons it should continue to drop to approximately 9,000 tons by the fifth decade. For this reason it was decided that further analysis of this issue was not needed.

While most of the draft alternatives did in fact show an increase in TSP in the first couple of decades due to increased harvest levels, none of the alternatives proposed a level out of line from that of the baseline period. The range of expected TSP production is well within the range of error of the estimates.

Statewide, TSP emissions from Forest Service prescribed burning are being reduced. This reduction occurs because many forests are burning fewer acres and most forests are burning a smaller percentage of forest residues by employing tested and proven techniques to reduce emissions. See Chapter 4 of the Forest Plan for details on mitigation techniques employed on this Forest.

The DEIS did fail to mention that prescribed fire is one tool used to assist in preventing uncontrollable wildfire. That oversight has been corrected in Chapter 4 of the FEIS.
Subject Area 900 Land Status

@0900-01 Land Ownership Adjustment and Exchange

There were four comments concerning Land Status. One respondent stated that the Forest Service should recommend the acquisition of lands by exchange or purchase with willing private landowners to produce a consolidated block of Federal land.

Another felt that the Forest Service should not use condemnation or exert pressure on landowners to acquire private inholdings.

Still another opinion was that land ownership adjustments should give a high priority to riparian areas, lands adjacent to wilderness, and lands along inventoried Wild and Scenic Rivers.

Finally, one reviewer stated that the lands designated for exchange in the proposed Steelhead Falls Wilderness Area should be identified for acquisition.

Response:

The Ochoco National Forest and Crooked River National Grassland goal is to achieve the land ownership pattern that best supports resource needs and reduces administrative costs. The Ochoco will acquire or dispose of lands only when it is clearly in the public interest. Changes in land ownership should reduce administration and protection costs or improve resource conservation and production.

Land exchanges are the most common method of land ownership adjustment, and most land exchanges in which the Ochoco participates are actually initiated by the private landowner. The purchase of a piece of property will be considered only when the possibilities of exchange, donation, or the acquisition of a partial interest have been exhausted. Condemnation will be used only when all other methods of acquisition fail and the property is required for the protection, administration or utilization of National Forest land.

The Ochoco has not identified any lands for possible purchase or condemnation.

Lands within the Ochoco National Forest have been grouped into the following ownership categories:

1. Areas where Congress has directed the Forest Service to retain Federal lands and to acquire non-Federal lands for a designated purpose. Scenic Rivers fall into this category.

2. Areas where National Forest ownership is necessary to meet management objectives. Federally owned lands will be retained, and non-Federal lands will be acquired as the opportunity or need arises. Riparian areas and lands with wilderness values fall into this category.

3. Lands allocated for commodity production, where the lands would be managed to provide similar types of output regardless of ownership. Federal lands may be retained, or they may be used to acquire lands in Categories 1 and 2. However, lands in this category will not be disposed of if that would result in a breach in a solid block of Federally owned land. Private lands within this category may be acquired in order to consolidate Federal ownership.

4. Small, isolated blocks of National Forest land which do not contain special features, and which are expensive and difficult to manage. These lands will be used to acquire lands in Categories 1, 2 and 3. Disposal of Category 4 lands will have priority over the disposal of lands in Category 3.

5. Areas where more intensive study and planning are necessary to determine the optimum land ownership patterns. Federal lands in Cove-Palisades State Park are included in this category.

Refer to the Standards and Guidelines Section of Chapters 4 of the Final Plans, to FEIS Chapter 4, to Appendix G of the Grassland Plan, and Appendix D of the Forest Plan for more detailed information.
Subject Area 920
Special Land Uses

@0920-01 Utility Corridors
There were four letters with comments on Special Land Uses. Among them were the responses of the US Department of the Interior, the Oregon Department of Energy, and the Bonneville Power Administration of the US Department of Energy.

One respondent stated that the DEIS failed to address the environmental consequences of visual impacts resulting from transmission systems. The Oregon Department of Energy commented that the DEIS should address the effects by alternative on siting of transmission lines and pipelines.

The US Department of the Interior and BPA recommended that existing and planned utility corridors be designated and addressed as required by Section 503 of the Federal Land Policy and Management Act of 1976.

Response:
The Proposed Land and Resource Management Plan has been modified to identify an allocation for utility corridors (Utility Corridors Management Area, Chapter 4, Grassland Plan) This management area will provide for limited additional facilities. No further corridors are planned. This is true in all alternatives.

A proposed transmission line would cross private land only within the Forest boundary. Because the National Forest would have no legal jurisdiction over this corridor, it is not designated as a management area.

Electric transmission lines involve large, negative visual impacts. For technical reasons, these lines cannot be buried. The natural gas transmission line is buried.

Refer to Chapters 3 and 4 of the FEIS for more information.

@0920-02 Guides
One person noted that the Plan allows for a commercial guiding and outfitting concern in the Black Canyon Wilderness, and requested information on setting up such a venture.

Another stated that commercial outfitters and their attendant stock animals should be carefully regulated and monitored on Forest lands, particularly in Wilderness Areas. This respondent felt that preservation of natural resources should take precedence over commercial uses of the forest.

Response:
Outfitter/guide permits will be awarded in the Black Canyon Wilderness only when the permitted activity will meet the management objective of providing a wilderness experience. If an application for an outfitter/guide is received, the activity will be analyzed through the NEPA process to determine whether a permit should be issued.

If a permit is issued, the outfitter/guide will be required to comply with certain restrictions, as identified in the analysis to maintain wilderness qualities and objectives. Refer to Chapter 4 of the Plan, Standards and Guidelines, for use restrictions.

Subject Area 930 Energy

@0930-01 Leasing
Four letters were received with comments on energy leasing.

One respondent suggested that all National Forest lands be withdrawn from appropriation under the energy leasing laws.

Another wanted leasing prohibited in areas allocated to old growth, SPNM recreation, or areas considered for Wild and Scenic River or Wilderness classification.
Still another respondent was unhappy that 80 percent of the Forest was proposed for oil and gas lease availability, stating that many areas not in wilderness have uses incompatible with oil and gas leasing.

Finally, one respondent suggested that a general overview of constraints on oil and gas leasing would prepare the public and managers for issues which activation of the leases will initiate.

Response:
The Forest Service recognizes the importance of responsible energy development to the nation’s economy and security. The Ochoco National Forest seeks to facilitate the environmentally sound development of oil and gas resources.

On the Ochoco National Forest, wilderness areas are the only areas withdrawn from mineral leasing. In other areas, stipulations are attached to leases to assure that development will be compatible with other resource values.

The most restrictive stipulation requires “no surface occupancy.” When a lease is issued with this stipulation, no road building, seismic testing, drilling, pipeline construction, or any other use of the surface is allowed. However, oil, gas or geothermal deposits below an area leased with a “no surface occupancy” stipulation may be tapped by directional drilling from outside the restricted area. The management areas on the Ochoco where the “no surface occupancy” stipulation will be attached to all leases include old growth, roadless areas, Scenic Rivers and the North Fork Crooked River Wilderness Study Area.

Other, less restrictive, stipulations are also attached to mineral leases. For example, a seasonal use stipulation may be used to protect wildlife during critical times of the year. A setback stipulation may be used to keep operations and facilities away from roosting or nesting sites.

In addition, lessees and operators are responsible for the proper rehabilitation of disturbed lands. Even after a lease has been issued, operations will not be allowed until a surface use plan has been approved. The surface use plan must describe in detail the technical aspects of the proposed activity, the location and magnitude of any potential surface disturbance, and the rehabilitation measures that will follow the activity. To insure that rehabilitation work is performed, a bond based on the cost of that work will be required before any surface-disturbing activities are approved.

The Standards and Guidelines Section of Chapter 4 in the Final Plan lists the lease stipulations required for each management area. Chapter 4 of the FEIS, Environmental Consequences, also discusses the effects of oil and gas development.

@0930-02 Data Incorrect

The Oregon Department of Energy and DOGAMI commented on energy potential on the Ochoco.

The Department of Energy disagreed with the conclusion in the DEIS that 90 percent of Ochoco lands are prospectively valuable for oil and gas resources, citing what that agency calls a lack of conclusive data in the draft.

DOGAMI contradicted the statement in the draft that the Forest and Grassland have no known geothermal resources. The letter stated that DOGAMI's geothermal maps show a warm water spring on the Forest.

Response:
A mineral potential report was prepared for the Final Plan. This report classifies approximately 54 percent of the Grassland and 92 percent of the Forest as prospectively valuable for oil and gas, based on USGS information.

The report also classifies all of the Grassland and Forest as favorable for the discovery of thermal water suitable for direct heat applications. This classification is based on a Oregon Department of Geology and Mineral Resources report which shows a warm water spring on the Snow Mountain District.
Subject Area 940
Minerals

@0940-01 Plan Comments

Letters from the U.S. Department of the Interior, the EPA, the Oregon Department of Geology and Mineral Industries (DOGAMI), and the U.S. Bureau of Mines were received with requests for more information to be included in the EIS.

The EPA requested that a list of mining claims classified as lode or placer mines be added.

The Department of the Interior wanted information concerning mineral development and production, the value of past production, and projected mineral demand. USDI and the Bureau of Mines recommended the following information be added to the documents: a discussion of how minerals are affected by each alternative; a list of current mineral withdrawals and acres involved; definitions of access restrictions for locatable minerals; and mineral potential for locatable and leasable minerals, including a detailed discussion of the mineral potential of each roadless area. Along with DOGAMI, USDI recommended that a mineral potential map and mineral inventory be added. DOGAMI also noted that jasperoid being mined may be an indicator of a hot spring gold mine.

DOGAMI and the EPA stated that the potential environmental impacts of mining on water quality and cultural resources should be discussed under mineral exploration.

The EPA also commented that the process through which operating plans are approved or disapproved in sensitive areas should be described.

Response:

Two mineral potential reports, one covering the Grassland and one covering the Forest, were written to be used as input to the final Plans. The presence of jasperoids (agate, jasper or thundereggs) was one of the criteria used to determine mineral potential.

A computerized list of mining claims is maintained and updated quarterly at the Regional Office. This list classifies each claim as lode, placer, tunnel or mill site. The reports and list of claims are available for review at the Supervisor’s Office.

Mineral development and production, mineral potential, past production, current mineral withdrawals, access restrictions, and the process used to approve or modify operating plans are discussed in Chapter 3, “Affected Environment” of the FEIS. The mineral potential of each roadless area is discussed in Appendix C of the FEIS. The environmental effects of mining on water quality and cultural resources are discussed in the minerals section of Chapter 4, “Environmental Consequences” of the FEIS.

The FEIS does not identify new sources of mineral resources or predict future demand for minerals. Rather, it defines broad areas favorable for the occurrence of mineral deposits. Ultimately, the exact nature, extent and location of any new resources will be determined by industry through self-initiation under the 1872 Mining Laws.

0940-01.1 Plan Comments

The USDI stated that Federal law gives claimants the statutory right to develop their mining claims, and that the Forest Service has the responsibility to accommodate mineral development on lands open to mineral development.

DOGAMI felt that a bias against mineral production was evident in the draft Plan. The agency stated that a different set of standards was used for minerals than for other resources. The example given was the fact that dollar values were placed on campers using the forest, but none was given for mineral exploration.

DOGAMI also felt that the planning team had a minimal background in geology and mineral resources, because there were no geologists or minerals personnel listed as preparers in the draft.
Response:
It is true that Federal law gives claimants the statutory right to develop their mining claims. The Forest’s goal for minerals and energy is to “provide for and facilitate the exploration, development and production of mineral and energy resources in coordination with other resource objectives, environmental considerations and mining and leasing laws.” The Forest will respect the rights of mining claimants and will accommodate mineral development on the Forest.

The evident bias against mining in the Proposed Plan and DEIS is unfortunate. A geologist was included on the interdisciplinary team which prepared the Final Plan and FEIS. The geologist used available references to prepare two mineral reports which were used as input to the Plan. These reports are listed in the references and are available for review at the Supervisor’s Office.

In the Final Plan, a dollar value was placed on mineral leasing. A value was not placed on locatable mineral exploration and development. It was decided that such values cannot be accurately predicted because the discovery and development of mineral resources will be initiated by industry under the 1872 Mining Laws. A value was not placed on mineral materials because almost all mineral material produced is used on Forest Service roads or provided free of charge to other government agencies.

0940-01.2 Plan Comments
The EPA letter contained the comment that mining will be allowed on 80-90 percent of the Forest and questioned the statement in the draft that mining would have a “minor effect on the water resource.” The EPA stated that many small mines could have a large cumulative effect, particularly if road building increased due to mining projects.

Another respondent commented on the statement in Chapter IV of the DEIS which says, “The level of control (of mining activities) depends on the mineral potential of the scenic and riparian areas.” The reviewer asked if this indicated that ecological balance can be purchased if the mineral potential is great enough.

Response:
Mining can have a negative impact on the environment. Reasonable and practical measures aimed at minimizing or mitigating these impacts are included in operating plans. In addition, when it is appropriate to do so, operating plans are used to limit impacts until it is certain that valuable minerals are present at a site. However, this is not meant as an indication that ecological balance can be purchased if the mineral potential is great enough, but rather as recognition of the balance between the statutory rights of a mining claimant and the need to protect the environment.

Although mining is allowed on 95 percent of the Forest, it is concentrated on approximately 10 percent of the land (the areas with moderate or high mineral potential). Most mining on the Ochoco National Forest is lode (hard rock) mining, which generally has less effect on water quality than placer mining. Any predicted impact on water quality is addressed in the operating plan. At present levels of activity, mining has a minor cumulative effect. Increased levels of activity would require a new analysis of environmental effects.

Refer to Chapter 3 of the FEIS, “Affected Environment,” for a discussion of operating plans and to Chapter 4 of the FEIS, “Environmental Consequences,” for a discussion of the environmental impacts of mining.

0940-02 Monitoring Requirements
The EPA recommended that the plan include water quality monitoring requirements for sites with the potential to affect water quality.

The Columbia River Inter-Tribal Fish Commission noted that management plans for mineral development include reclamation requirements, but stated there is no indication of monitoring required of the
mining company, and asked if monitoring is the sole responsibility of the Ochoco. CRITFC also asked what the Forest-wide goal for reclamation consists of, and whether it implies restoration to natural appearance.

Response:
The Plan requires that water quality be monitored before, during and after selected projects. As appropriate, mining activities will be selected for this water quality monitoring. In addition, water quality will be monitored as part of minerals activities monitoring. Refer to Chapter 5 of the Plans, “Implementation of the Plan,” for monitoring requirements.

The degree to which reclamation can restore the landscape to its original appearance depends on the type and size of development. For this reason, reclamation is addressed on a case-by-case basis in the operating plans. Monitoring required of the mining company will be addressed on a case-by-case basis in the operating plan.

@0940-03 Prohibited Areas

Four letters had comments on mineral extraction in general. Some respondents wanted all mineral extraction and processing prohibited in riparian zones. Others suggested it should be prohibited everywhere on the forest.

Response:
The Forest Service recognizes the importance of mineral resources to the nation's economy and security. The Mining Law of 1872, as amended, grants the right to locate and develop mining claims on public lands. The Ochoco National Forest seeks to facilitate the environmentally sound development of mineral resources.

On the Ochoco National Forest, wilderness areas, the Ochoco Divide Research Natural Area, Delim- ment Lake and Walton Lake Campgrounds, Ochoco and Rager Ranger Stations, and a strip of land along Highway 26 are withdrawn from mineral location. In other areas, measures are included in operating plans to assure that development will be as compatible as possible with other resource values.

Operating plans are developed and approved on a case-by-case basis. The operating plan must describe in detail the technical aspects of the proposed activity, the location and magnitude of any potential surface disturbance, and the rehabilitation measures that will follow the activity. To insure that rehabilitation work is performed, a bond based on the cost of that work will be required before any surface-disturbing activities are approved.

Chapter 3 of the FEIS, Affected Environment, discusses the mining law and operating plans.

The development of common variety materials (for example, gravel and sand) is governed by the Materials Act of 1947, as amended. The Forest Service has the authority to develop these sources, and mining claims may not be located for these materials. As stated in Chapter 4 of the Plans, these sources will not be developed in riparian areas.

@0940-04 Withdrawals

The U.S. Department of the Interior stated that the definition of withdrawals needs to be reviewed. The agency noted that staking of new claims and establishment of new leases may be prohibited depending on the individual withdrawal, but that development of leases and claims established prior to the date of withdrawal is not necessarily prohibited.

DOGAMI stated that, in cooperation with the BLM, that agency has identified a potential gold mineralized area just to the south of Haystack Butte, and that this area should not be withdrawn from mineral location or leasing.

DOGAMI also said that a mineral inventory should be completed before areas are chosen to be Research Natural Areas.

Response:
Withdrawal is defined as the withholding of an area of Federal land from settlement, sale, location, or
entry under some or all of the general land laws for the purpose of limiting activities under those laws in order to maintain other public values in the area. Most of the withdrawn areas on the Ochoco National Forest are withdrawn from the mining laws, but not the mineral leasing laws. Wilderness areas are withdrawn from both the mining and mineral leasing laws. In either case, valid existing rights (leases and claims established prior to the date of withdrawal) are respected.

The Department of the Interior has the authority to make, modify or revoke withdrawals. The Chief of the Forest Service reserves the right to concur or not concur on all withdrawals involving leasable minerals. The Forest Service makes recommendations to the Department of the Interior (Bureau of Land Management) on withdrawals involving locatable minerals. Before an area is withdrawn, both the Forest Service and the Bureau of Land Management assess the mineral potential and analyze alternatives to withdrawal.

Refer to Chapter 3 of the FEIS, “Affected Environment,” for a discussion on withdrawals.

@0940-05 Rockhounding

There were two letters with comments on rockhounding. One respondent stated that more lands should be held open for rockhounding. The other expressed concern that incidental non-commercial rockhounding is considered a mining activity. It was suggested that the Ochoco take action to make sure non-commercial rockhounding and mineral collection remain as such.

Response:

Rockhounding on National Forest lands does not require a permit or mining claim as long as the activity does not conflict with existing rights, and the specimens are collected for personal, noncommercial use. If the specimens are sold commercially, the activity is considered mining, not rockhounding, and the mining laws or mineral sales laws apply.

Individuals have the statutory right to locate and develop thunderegg and gemstone deposits on public lands. This prevents recreational rockhounds from digging in these areas without the claimant’s permission. To prevent this problem, two rockhound clubs have located claims which are open for free public use. This option is open to any club interested in maintaining claims.

Subject Area 1000
Transportation System

@1000-01 Road Closures (Permanent and Seasonal), Road Density

Ninety-five letters were received with comments concerning road closures. The majority of the respondents recommended that the Ochoco undertake an aggressive road closure plan to protect the environment, improve conditions for wildlife, and insure cost-effectiveness of the transportation plan. Most felt that the Forest has built too many roads in the past and that any new roads built for timber harvest should be closed immediately upon completion of harvest activity.

Some suggested a system of temporary or limited road closures, with harvest access allowed but other access denied. Others wanted roads closed only during hunting season. Still others indicated that roads closed and replanted could add to the timber base.

One respondent recommended closing feeder roads on a rotating basis to provide areas for non-motorized recreation and big game habitat.

Many other respondents disagreed with road closure. Some felt that public land should be open to all members of the public at all times. Others stated that the elderly and handicapped would have no access to the National Forest if road closures took effect.
Some stated that they would agree to road closures only in certain areas and in very wet seasons. A few reviewers supported the road construction plans in Alternative B-Plus or E-Departure.

Several respondents, among them the EPA and ODFW, commented on road density.

Varying opinions were voiced concerning road density. Recommendations ranged from less than one mile per square mile to more than the four miles per square mile proposed in the draft Plan. Most felt that current road density is too high and is having adverse effects on wildlife and recreation.

A few respondents stated that road densities are especially high in sensitive areas such as draw bottoms.

ODFW noted that the Plan stated 4.1 miles of road exist for each square mile of developed area, but that since most of the road mileage is in the southern two-thirds of the Forest, the road density there is probably as high as 5-7 miles per section.

The EPA said that, as the phrases “short term” and “long term” are defined in the glossary, increases in road density could create impacts in a period of time shorter than “short term.”

One respondent stated that the amount of mileage in the proposed plan would not allow Forest recreation to keep up, let alone to grow.

Response:
The Forest and Grassland recognizes the need to balance access with the needs of other resources. The Standards and Guidelines in Chapter 4 of the Forest and Grassland Plans will provide direction on how on- and off-road access would be managed. A Travel Map has been developed for the Forest and Grassland which incorporates the direction from the plans. It clearly displays how and where access to the Forest and Grassland could be gained. The discussion of access in the Plans and the FEIS is supplemented by Appendix D which provides further information on how the travel map was developed and how access management for the Forest and Grassland will be implemented.

The access closures and restrictions, provided in the Standards and Guidelines and Travel Map, provide a range of road densities to meet a variety of management area prescriptions and user needs. In some areas, such as big game winter range, most of the roads will be closed (1 mile/section) during the winter months when the area is critical to big game. During hunting seasons a number of roads in several areas within the Forest and Grassland are closed, under the green dot system. Other seasonal and limited closures will occur to reduce resource damage, to provide for public safety, and/or to reduce maintenance costs. The road density objective under the Preferred Alternative for general forest/general forage areas will be three miles per section.

New local roads will be managed to meet identified objectives and will be closed or deactivated if there are no defined objectives for use after the initial purpose is served. Roads closed for future intermittent use (Maintenance Level 1) will be blocked to eliminate unwanted use and will receive the minimum maintenance treatment to prevent erosion. Roads with no foreseeable use will be rehabilitated to meet the prescription for the management area.

The environmental consequences of the road management direction by alternative is discussed in Chapter 4 of the FEIS and the miles of roads by category and closures are displayed in Table 2-8 in Chapter 2.

@1000-02 New Roads and Road Standards

There were 59 comments concerning new roads and road standards.

Most, including the Crook County Soil and Water Conservation District, recommended no new road construction unless absolutely necessary. The County suggested the Ochoco limit permanent road building and put more emphasis on temporary roads.

Many respondents were displeased with what they perceived to be the economic loss occurring through
the road construction program. They felt the timber companies should bear the full cost of road construction.

Some encouraged searching for new harvest methods that would not require road building.

Those that did not recommend a halt to road construction for the most part suggested that the Forest lower its road standards to lessen the impacts on wildlife of high-standard roads. Some, on the other hand, wanted a greater degree of maintenance on existing roads and higher standards for new roads.

One person noted that in the draft Plan and EIS, forest access did not decrease significantly even in those alternatives with lower harvest levels.

Response:
The amount of new construction and reconstruction of existing roads is closely related to timber harvest. The amount of road needed per acre harvested varies in response to many factors, e.g., logging system used, topographic relief, and environmental factors. Several years ago the Forest Service adopted new guidelines for establishing road design standards by service level which assures that the minimum standards to serve the resource will be utilized. All long-term roads are used for more than one year. Some of the road costs can be considered an investment for future uses.

Roads normally deteriorate because of use and weather impacts. This deterioration can be reduced through adequate maintenance or restriction of use. All system roads will be maintained to at least the basic custodial care required to maintain drainage, protect the road investment, and minimize damage to adjacent land and resources. This level is the normal prescription for roads that are closed to traffic. Higher levels of maintenance may be chosen to reflect greater use or resource protection.

New roads and total miles needed for all alternatives are discussed in Chapter 4 of the FEIS.

Subject Area 1100 - Protection

@1100-01 Toxic Chemicals and/or Catastrophic Accidents

Four respondents, including the EPA, noted that none of the draft proposals addressed toxic chemicals and/or catastrophic events such as oil spills. The respondents wanted to know if the Forest had a plan for such events, and whom to contact in an emergency.

Response:
The Forest Plan does not deal directly with this concern. Instead, the Plan is tiered to the Pacific Northwest Region’s Environmental statement for Vegetation Management (1988), and all actions under the plan are required to be in compliance with NFMA regulations 36 CFR 219.27 (b). In addition, all Federal agencies are required to be in compliance with the Renewable Resource and Conservation Act (RCRA), and the RCRA amendments. The Forest also has an emergency spill plan which relates not to activities conducted by the Forest or Grassland, but to transport of materials on highways through the area.

Emergency procedures and RCRA requirements for spill maintenance plans have been incorporated into the final documents. See Appendix H of the Forest Plan and Appendix L of the Grassland Plan.

Subject Area 1110 Fire

@1110-01 Fuel Buildup

Eighteen letters were received with comments on fuel buildup. Most of the respondents were concerned that allowing slash and down material to
accumulate creates a fire hazard. Most encouraged allowing firewood collection to help mitigate the dangers. Many commented that grazing should be allowed over much of the Forest to cut down on fuel buildup.

Even-aged management was also targeted by some as a cause of serious fire hazards. Some felt that selective cutting would reduce the danger, stating that organisms of like age are more susceptible to disease and fire.

Some respondents felt that any areas closed to logging are fire hazards. They recommended that dead and diseased trees be harvested wherever they occur to reduce fire dangers.

One respondent suggested leaving more fuel for risk analysis. This, according to the reviewer, would help the Forest to formulate a better plan to coordinate fuels management.

Another respondent commented that broadcast burning is permissible for disturbed, undisturbed, and surface-buried cultural resource sites, but was left out of the fuel treatment options for buried disturbed sites.

One reviewer was confused by the tables and text covering disposal of Forest residues by burning. This person wished to know what the common denominator is between particulates, described in “thousand tons;” slash burning, described in “acres;” and salvage firewood, described in “cords.”

Response:
The Forest shares the concern over potential fire hazards mentioned in the above comments. New sections have been added to the FEIS and Forest Plan which help address this issue. These will help guide the forest residue management.

Forest residues accumulate through natural processes. These conditions will be monitored and when conditions approach maximum acceptable levels identified in each management area prescription, appropriate treatments will be instituted. This will maintain a mosaic of residues providing an acceptable fire risk and meeting other ecosystem needs.

Activity residues hazard abatement is an integral part of project level planning and is one of many residue management goals considered in the Forest’s Residue Management Plan.

While the Forest will have a younger average stand age under a managed situation, the mosaic of stand ages will help prevent catastrophic insect outbreaks, disease, and the resultant increased fire hazard associated with large areas of older stands. Younger stands certainly are at higher risk in the event of fire, but only if the residues are not managed at an acceptable level of risk.

The cultural resource oversight has been corrected in the discussion on fuel treatment options for buried disturbed sites (see Chapter 4 of the FEIS).

The common denominator requested is forest residues. The first two subjects (particulates and slash burning) are related in that the second produces the first. They are discussed together in the section on Air Quality in the FEIS, Chapters 3 and 4. The change in amount (acres) of burning over time gives an indication of expected change in atmospheric visibility due to the amount (tons) of smoke particulates produced. The third subject, salvage firewood, is a method of residue treatment emphasizing utilization rather than disposal, and the most common unit of measure is cords.

The Forest has developed additional direction in new sections in the FEIS and Plan which deal with Residue Management. A number of new analysis techniques are coming online which will assist in the risk analysis as well as the economic analysis included in such decision making. See FEIS Chapters 3 and 4, and Forest Plan Chapter 4 for further discussion.

@1110-02 Prescribed Burning

Nineteen letters contained comments on prescribed fire. The majority of the respondents were in favor of continuing or even expanding the prescribed burning program, stating that the Forest and Grassland are in dire need of large-scale treatment. Some included Wilderness and Research Natural Areas in
their recommendations. In addition, many felt that the Forest Service should allow naturally occurring fires to burn out on their own.

Others, however, registered opposition to the prescribed fire program. They felt that slash burning destroys many trees unintentionally, and that broadcast burning is simply too destructive to soils and vegetation. Some stated that prescribed fire encourages non-native plants to be introduced to burned areas.

One respondent suggested removal of only 25-40 percent of the volume per acre than is the present practice, and treatment of the resultant slash. This, it is felt, will be far less disturbing than removing 12-20 MBF per acre and burning 35-60 tons per acre of slash all at once.

One respondent noted that the old growth definition does not include an understory description, and that it is necessary to know what structural characteristics and vegetation the Forest is attempting to produce within each plant community before applying a forage and/or fire treatment prescription.

Response:

Fire is a natural process of recycling and renewal in local ecosystems. However, because of the random nature of its occurrence it sometimes conflicts with the timing of management. Realizing late in this century the importance of fire in ecosystem maintenance and its usefulness as an economically efficient means of vegetation and residues control, the Forest now “prescribes” the use of fire in terms of when and where it will occur.

Used initially in reducing activity fuels, it has become widely used locally in treating “natural” fuel accumulations in order to mimic historic fire cycles which allowed for the establishment of “large” diameter old growth pine stands on so much of the Forest.

The discussions on these subjects in the FEIS, Chapter 3 and 4, and in the Forest Plan, Chapter 4, have been expanded in response to the above comments to clarify the points raised. New sections dealing with Forest Residues also relate to some of the comments above and can be found in FEIS Chapter 4, and Forest Plan Chapter 4. The detailed decisions on the proper application of prescribed fire are carried out on a case by case basis in the project planning environmental assessments under the broad guidelines of the Forest Plan. See Chapter 4, Forest Standards and Guidelines, and Management Area Prescriptions.

Prescribed fire will not be used in mixed conifer old growth until adequate research provides the desired vegetation description. This will most likely occur within the next planning period (next ten years) and thus will not be a major departure from experienced fire history in this type of stand. Moderate use of prescribed fire is being allowed in ponderosa pine old growth since this species is seral and will disappear in the absence of fire (see Chapter 4 of the FEIS). It is likely that a variety of treatment prescriptions will evolve due to the different vegetation types involved.

@1110-03 Risk Management

There were four letters with comments on fire suppression. The respondents were unanimous in suggesting that all areas on the Forest should be open to road building for fire access. One reviewer stated that areas for wildlife winter range without roads become fire hazards and will prove difficult to protect from fire.

Response:

Fire suppression access has been considered in the transportation planning for the Forest and is commensurate with the values at risk and the management objectives of each Management Area.

The Forest has developed additional direction in new sections in the FEIS and Plan which deal with Residue Management. A number of new analysis techniques are coming on line which will assist in the risk analysis as well as the economic analysis included in such decision making. See FEIS Chapters 3 and 4, and Forest Plan Chapters 2, 3, and 4 for further discussion.
@1110-04 Fire Protection

Three respondents, among them the Oregon State Forester, commented on fire protection.

The State Forester remarked that the Oregon Department of Forestry supports the Forest Service’s policy of applying aggressive suppression action to wildfires that threaten life, private property, public safety, improvements, or investments.

One reviewer stated that the Plan needs to place more emphasis on low-impact Wilderness management, including fire control. The person stated that he was angry to find a cat line in the Bridge Creek Wilderness Area that had been used for fire suppression.

The third respondent stated that the 100 acre per decade maximum for burning seemed arbitrary and recommended that acreages burned be decided on a case-by-case basis.

Response:
Protection of life, property and investments is a common concern of all wildland fire protection agencies and will continue to be the Ochoco’s primary policy direction to minimize losses and cost of suppression.

The fireline mentioned in the Bridge Creek Wilderness was cut several years prior to the designation of the area as wilderness. Since that time rehabilitation requirements have been instituted on all such suppression techniques, even those outside of wilderness areas. This fireline has been brought to the attention of the District, and rehabilitation will be carried out as necessary.

The maximum acceptable burn acreage per decade is a function of the size of the Management Area, the probability of occurrence of a fire at Fire Intensity Level (FIL) III in that Management Area, and, given that occurrence, the likely area burned at that FIL prior to containment of the fire. It also takes into account how much impact such an area of intense burn will have on the management objectives for the Management Area in question. Each fire, as it occurs, will be dealt with on a case-by-case basis in comparison with the objectives (including maximum area at FIL III per decade) for the Management Area(s) involved. See FEIS Chapter 4, and Forest Plan Chapter 4 for further discussion on this topic.

Subject Area 1120
Pesticides

@1120-01 Prohibition

Three letters were received with comments on pesticide and herbicide use. Concerns were voiced about the effects of pesticide use on non-target species and long-term effects on the environment. Some felt that pesticides and herbicides should be prohibited, or that if they do again become legal, a rigorous set of application guidelines and monitoring safeguards should be implemented.

Response:
In December of 1988 the Regional Office published an Environmental Impact Statement entitled “Managing Competing and Unwanted Vegetation.” This document sets forth the direction for all National Forests in the Pacific Northwest Region for Vegetation Management. Pesticide and Herbicide use are dealt with in that EIS, and Vegetation Management activities on the Ochoco will comply with those guidelines. The projected outputs from this plan do not depend on the use of herbicides, although the availability of herbicides would lower reforestation costs in some cases. Insecticides may be used to control insects but this is not the preferred method. See response to Insects and Disease, and also the Forest Health section in Chapter 4 of the Plan.
Subject Area 1130
Insect and Disease Control

@1130-01 Diseased Trees and Insect Control

There were many comments on the management of the Ochoco National Forest as it related to insects and disease.

Thirty-four letters contained comments on insect and disease control. Among them was the letter from the Oregon State Forester.

Most of the comments, including that of the State Forester, were to the effect that the Ochoco should place more emphasis on insect and disease control. Some felt that controlling damage from disease and insects is vital to maintain sustained yield. Others stated that disease will spread if action is not taken quickly.

Some respondents were against clearcutting because they felt that even-aged management contributes to insect and disease problems.

One individual felt that the public should be educated concerning the need to depart from normal harvest practices when dealing with insect and disease problems.

Response:
The effects of each of the alternatives on insects and disease are covered under “Forest Pests” in Chapter 4 of the FEIS. The Forest Plan has been rewritten to include Standards and Guidelines for treating each major forest pest group (see Forest Health, Chapter 4). These guidelines are specific to each Management Area. The actual on-the-ground activity will depend on a project-level analysis which will be guided by above direction. These and the Timber guidelines encourage the prompt harvest of dead and dying material when compatible with direction for the management area, and allow varying the harvest level when necessary as a result of catastrophic events.

The basic strategy for insect and disease control is to prevent damage by managing stands through species and stocking manipulation. Diversity in size and species is one of the keys to this (see discussion on Diversity). It will take several decades to get stands in the desired condition, but in the long run this should prove the most effective control. Spraying or other direct control measures may be used if within the direction for the management area and supported by an EA or EIS. This would be a back-up measure, and spraying has been planned or included in costs considered necessary for projected outputs. There are Entomologists and Pathologists available to help in on-site evaluation and/or treatment recommendations.

Effects of insects and disease on timber yields have been incorporated in the yield tables by basing yields, including mortality and defect, on historical data. The effects of individual pests cannot be isolated, nor will this reflect the loss that will occur in a specific year, but should be a fairly accurate estimate of losses over a rotation.

Subject Area 1140 Law Enforcement

@1140-01 Enforcement

Two comments were received concerning Law Enforcement.

One respondent felt the best way to improve conditions for big game would be to enforce existing laws, especially those dealing with road hunting and using CB radios to track animals, and to increase fines for poaching.

The other respondent wanted the entire Forest opened up to hunting. This person suggested a less complicated program of law enforcement, desiring a
more positive relationship between Forest Service personnel and the public. The individual also stated that the Forest should review some of its rules for appropriateness.

Response:
Poaching, road hunting and the use of radios are violations of existing state game laws. The Forest Service has a Memorandum of Understanding with the Oregon State Police, in which the role of each agency in game law enforcement is identified. In effect, it states that the Oregon State Police will have the primary role of enforcing game laws. The Forest Service agrees to monitor and report known or suspected violations.

The primary objective of any law enforcement program is to prevent violations.

One way the Forest Service attempts to do this is through public education. Another is the prosecution of those individuals found to be in violation. Most Forest Service field employees receive 40 hours of law enforcement training. The subject emphasized most heavily is making a law enforcement contact in a positive, safe, effective manner. Like all law enforcement agencies, the Forest Service reports violations to a prosecuting body, in this case the U.S. Attorney's Office. Appropriate action is then determined by that office. The Forest Service has no control over actions taken by the U.S. Attorney's Office, but Forest Service personnel are working with that office to improve the situation.

Most Forest Service regulations are imposed by Congress or by the Secretary of Agriculture. They are therefore outside the scope of the Ochoco National Forest Plan. Occasionally, the Forest Supervisor may impose specific, local regulations. These are intended to assist in managing unique, local problems which may arise. These generally relate to special fire prohibitions or road closures for resource protection purposes, and are required to be reviewed annually.

Subject Area 1200
Economic Considerations

@1200-01 Local Economics

One hundred respondents, including the Oregon Labor Market Economist, said they did not favor the Preferred Alternative, or any alternative that would harvest less than 130-137 MMBF, because they believed that it would cause significant problems due to unemployment, low payments to counties, and other economic problems.

Response:
The Ochoco National Forest compared the results of all the alternatives to the “current situation,” that is, an average picture of the communities over recent years. The results do not predict any major changes under the Preferred Alternative I. In fact, the prediction is for a slight positive change.

1200-01.1 Mill Modernization

Seven respondents pointed out that the wood products industry has been, and is, modernizing. The State Economist states that any economic estimates which are based on old data regarding technology are questionable estimates. Some parties say that an attempt to maintain employment levels by increasing harvest levels will not work.

Response:
The Ochoco National Forest has added a section to Chapter 3 of the FEIS which discusses mill modernization. The IMPLAN model has also been updated to reflect 1987 mill performance (see Appendix B, Section 5).
1200-01.2 Timber Sale Projections

The State Economist and the Director of the State Economic Development Department questioned whether the projections from timber sale revenues might be too high. One question was whether all sales would sell. Another question was when the harvest would occur and the receipts come in.

Response:
From past experience, the Ochoco projects that it will have no problem in selling its sales. Receipts may come in at uneven rates, but the average receipts are accurate.

1200-01.3 Errors

The State Forester pointed out that in DEIS Table III-4, there is an error in Deschutes County’s population. The population of 65,300 is reported as 15,300.

Response:
The error has been corrected in the FEIS (FEIS Chapter 3).

1200-01.4 Data/Analysis

The State Forester’s Office commented that DEIS Table III-4 displayed incomes for the affected counties and the State, but not the U.S. This was deemed misleading.

Response:
Information for the United States has been included in the FEIS Chapter 3 text.

1200-01.5 Data/Analysis

The State Forester’s Office referred to the analysis of county economic bases as reflected in DEIS Figure III-3. The Forester wanted to know the source of the data. The Office also disagreed with the statement that combining the government and the manufacturing sectors overstated the importance of timber to the county economies.

Response:
The data is derived from the 1985 Business and Employment Outlook, JTPA Districts 10, 12, and 14. The statement which was challenged was questionable and has been withdrawn.

1200-01.6 Local Log Sales

One participant discussed the topic that Willamette Valley mills purchase central Oregon logs. The basic point was that the Forests of central Oregon are big enough to meet the needs of central Oregon, but not big enough to meet the needs of Valley mills also. Questions were asked such as:

- Why should local Forests increase harvest levels when there is no guarantee that the increase will produce local jobs?
- Could the local Forests restrict log sales as has been done in the Lakeview area?
- How can central Oregon enable its wood processing industry to compete more effectively with Valley sawmills and remanufacturers?

Response:
The question of who successfully bids for local logs is a valid one. Some of the eastside Forests, such as the Deschutes NF, are more affected than the Ochoco NF; but effects on the Ochoco NF are likely to increase. Chapter 3 of the FEIS contains a discussion of the effects of the Ochoco NF statewide, as well as on local economies.

The Forest participates in one program which tends to favor local firms: the small business set-aside program. The U.S. Department of Agriculture is authorized to participate in such programs with the Small Business Administration (Small Business Act, 15 U.S.C. 631). Participation tends to favor local small business because more distant small businesses are less likely to bid on sales.
The policy of the Forest Service which underlies this program is that small businesses should have the opportunity to purchase a fair share of the timber sales off National Forest lands. The small business "fair proportion" of the annual timber sale program is determined by the Regional Forester and provided to the Forest as part of the timber program. The Forest Supervisor maintains a continuing record of sale volumes purchased by large and small businesses. The record provides the basis to determine if there is a need for a set-aside program in the area during any six-month period.

Speaking more generally, the Ochoco National Forest does not intend to be involved in programs which tend to favor local mills. Being a National Forest, it is obligated to all the people of the nation. The needs of central Oreganians have been specially addressed in this document and in other ways, but it is not felt proper that the ONF give special preference to local residents. It is believed that the best way to serve competing bidders from near and far is to sell the timber in an open market fashion.

In a similar way, many local residents can explore ways to benefit local wood processors in competition with Valley wood processors, however, it is not appropriate for the ONF to be involved in these discussions.

1200-01.7 Departure Harvest

One respondent pointed out that 25 percent monies are assumed to rise and fall with timber revenues; whereas the two do not necessarily move in the same directions or at the same rates. The comment was directed toward the fact that the DEIS Preferred Alternative was a Departure; it said that the 25 percent monies, in particular, would decline in the third decade and beyond, depriving the communities of a stable economic base.

Response:
It is true that 25 percent monies may move differently than timber revenues. Elsewhere in this Appendix, there are comments regarding the Departure, and also concerning the Forest's commitment to long term community stability. See Forest responses to Departure Harvest under Timber, and responses to Community Harvest under Social Considerations.

1200-01.8 Small Business Impacts

One reviewer stated that the economic impact of the proposed Plan is understated, especially for small businesses. He stated that more analysis of the effect upon small businesses is required by Public Law 96-354, the Regulatory Flexibility Act.

Response:
Public Law 96-354 applies to governmental agencies who generate regulations which might apply to small businesses, small not-for-profit organizations, or small governmental bodies. Since the Forest Service does not regulate in this manner, the law does not apply to it.

Nevertheless, the Forest Planning process under the National Forest Management Act has much in common with the provisions of Public Law 96-354. Regulatory agencies publish proposed new regulations in the Federal Register; this corresponds to the Draft EIS which was released in 1986 and which was also referred to in the Federal Register. Comments are solicited from the public in both processes. And those comments help to shape the regulatory agency's final regulations, just as the Final EIS is shaped by the comments listed in this Appendix.

@1200-02 Economic Impacts

There were 23 comments addressing the issue of employment multipliers. The concern was that the multipliers used were too low. The Ochoco NF multiplier was said to be only 1.5, when comparable multipliers range between two and three.

Two respondents made their own estimates of the effect of the Preferred Alternative. The DEIS estimated that the Preferred Alternative would pro-
duce an additional 63 jobs and an additional $0.3 million in payroll. Brian Long, an economist hired by the Central Oregon Economic Development Council, projected a loss of 289 jobs and $5.8 million. (Mr. Long's estimate of the combined effects of the draft plans of the Ochoco NF and the Deschutes NF was a loss of 317 jobs and $6.5 million). Jim McClain of the Northwest Forest Resource Council predicted a loss of 118 jobs and $2.0 million. Other reviewers quoted these figures and preferred them to the Ochoco NF estimates.

State officials voiced concerns about the multipliers. Two Labor Economists, the Director of the State Economic Development Department, and the State Economist all said that the multiplier should range between two and three. The Director of the State Economic Development Department predicted a loss, not a gain, in employment.

Response:
Two questions are addressed here. One is, What is the correct employment multiplier? The other is, What will be the effect of the Draft Preferred Alternative on income and employment?

The DEIS never reported a value for employment multipliers. The multipliers as computed by others were deduced from data in the following tables:

Table IV-2--Employment changes by alternative, decade 1;
Table IV-3--Employment changes by alternative, decade 2;
Table B-V-3--Employment changes by alternative by county, decades 1 and 2; and
Table B-V-1--Employment per unit of Forest output.

Table B-V-1, for example, states that 1 MMBF of ponderosa pine will produce eight wood products jobs and four jobs in other industries. The concern expressed is that this implies an employment multiplier of 1.5. This is perhaps a reasonable conclusion from the information given. However, the line labels in the table were misleading. The table, when correctly labeled and correctly understood, does not contain data which could be used to compute a multiplier.

To understand the question of multiplier values, it is first necessary to define what a multiplier is. IMPLAN (or any input/output model) classifies employment into the following three categories.

Direct employment--the employment involved in creating products which will be exported from the local economy or purchased for final consumption within the local economy. Examples would be exported molding, exported 2x4's, or 2x4's purchased locally for new construction. For the local wood products industry, 99% percent of employment is involved in preparing exported products.

Indirect employment--the employment involved indirectly in creating the above products. Millwork operations buy dimension lumber from sawmills, who buy logs from loggers, who buy gasoline from local operators, and so on.

Induced employment--The employees involved in the above activities will purchase goods and services for their households, thereby producing employment in trade and service sectors.

Any change in employment will produce direct effects, indirect effects, and induced effects. The definition of the input/output model multiplier is critical, it is the ratio of the total effects to the direct effects.

The terms "direct effects" and "indirect effects," as defined above, are different from the way in which a person might use them in a non-technical sense. They are also different from the way that they are used in Tables IV-2, IV-3, and B-V-3. For Alternative E-Departure, for example, the timber harvest declines slightly. This results in some lost jobs in the wood processing industry, which in turn causes other jobs to be lost. Tables IV-2, IV-3, and B-V-3 refer to these losses as "direct effects" and "indirect effects," but the use of these terms is technically wrong. The change in the wood processing industry, here called "direct effects," is actually the sum of the direct effects and the wood processing portion of the indirect effects (about two-thirds of the total

I-3-116
indirect effects). This change should be re-labeled as “Employment Changes in the Wood Products Industry Due to Changes in the Timber Harvest Level.” The change called “indirect effects” is the remaining portion of the indirect effects plus the induced effects. The correct label for this change would be “Employment Changes in Non-Wood-Products Industries Due to Changes in the Timber Harvest Level.”

These terminology changes are significant. If the values reported as “direct effects” were truly direct effects, the data would indicate an employment multiplier of around 1.5. But the true direct effects are smaller than those shown, and the multiplier is therefore larger.

The same type of confusion has occurred concerning Table B-V-1. The figures in this table show that 1 MMBF of ponderosa pine produces eight jobs in the wood processing industry and four jobs in other industries. Similarly, 1 MMBF of other species produces four wood processing jobs and two other jobs. This has led some to say that the multiplier is only 1.5. But because the eight jobs include both direct and indirect effects, the multiplier will be larger than 1.5.

Employment multipliers were not shown in the DEIS. Neither was the “direct effect” data which would allow the multipliers to be computed. However, the employment multiplier, when computed, is 2.0. This is at the low end of the range mentioned by all the reviewers. Since the county economies are small, it is considered that this value is reasonable.

The second question which needs to be addressed is whether the DEIS estimates of employment change are realistic. The key question here is what harvest level should be used as a comparison point. Mr. McClain and the Director of the State Economic Development Department compared the harvest under the Preferred Alternative to the Potential Yield of 137 MMBF. Mr. Long used the 1984-1986 average level of 147 MMBF. The Oregon State Forester takes a different approach and recommends basing the “current situation” on the average 1976-1985 employment level.

Response:
This is an important question because changes in employment and income are determined relative to the “current situation.” The “current situation” used in the DEIS was the 1984 harvest level of 127.3 MMBF.

The Ochoco agrees that to use a single year as the “current situation” is not appropriate. The wood processing industry has traditionally gone through cycles. In addition, in recent years, it has been affected by resource use debates, lawsuits, and other actions which affect timber harvest levels. To examine a short period of time is to invite unreasonable results.

The Forest does not believe that use of the Potential Yield level is appropriate because it does not reflect a “current situation.” The 1984-1986 figures, though current at the time, were also known to be abnormal due to the recession recovery and the repurchase of timber under the timber buyback program. The concept of comparing to employment levels is interesting, and the long time frame is appropriate. However, employment levels include many factors beyond the control of the National Forest.

What is needed is a measure that reflects actual conditions over a period of several years -- long
enough to even out cyclical conditions or other short term effects. The ONF has chosen to use the average harvest over the years 1980-1988, which represents a harvest level of 110.7 MMBF.

1200-02.2 Recreation-Related Employment

Four reviewers, among them the Oregon State Office of Economic Analysis, the State Economist, and the State Labor Economist, said that employment gains associated with recreation -- in particular, with fishing -- appear to be too high.

Response:
An error was discovered in the Draft in the estimation of employment due to fishing. As a result, employment levels for all alternatives were too high and have been recomputed.

1200-02.3 Employment/Income Change

One comment concludes that based on DEIS figures on employment change, the figure containing the change in income is wrong. Looking at Table IV-2, the letter states that there would be 69 lost timber jobs at $24,200 per year, and 59 gained recreation jobs at $18,000 per year. The computed loss in income over one decade would be over $11 million, even before multiplier effects were computed.

Response:
Table IV-2 was misunderstood -- partially due to confusing line labels. See the section on multipliers for a fuller explanation. The change in wood products jobs would equal:

-50 (Crook County)
+23  (Harney County)

-27  Total change in wood products jobs

The jobs labeled/mislabeled as “Timber, Indirect Effects” are not jobs in the wood products industry. Rather, they are jobs in other industries which are affected by changes in the wood products industry. The total change in non-wood processing jobs is:

-19 (Crook County, “Timber, Indirect Effects”)
+59  (Crook Cty, “Recreation, Wildlife and Range Effects”)
+15  (Harney County, “Timber, Indirect Effects”)
+22  (Harney, “Recreation, Wildlife and Range Effects”)

+77  Total change in non-wood-products jobs

1200-02.4 Effects on Recreation

One reviewer questioned the effects on “recreation-related industries.” The respondent pointed out that the effects included many economic sectors that were not directly related to recreation.

Response:
The line label perhaps should have been more explicit. When jobs directly caused by recreationists increase or decrease, other economic sectors are affected. The total effects caused by recreation activities were termed “recreation-related.” See the discussion of multipliers for more discussion of problems with line labels in some tables.

1200-02.5 Non-Cash Benefits

One person wrote that non-cash benefits such as recreation, fishing, and hunting were given misleading high cash values and included in the economic analysis. Two respondents believe that the “amenity” values are too low.

Response.
The cash benefits associated with amenity outputs are derived from gains or losses in jobs and the income resulting from those jobs. Therefore, they are true cash benefits.
The derivation of these benefits is an involved matter. The Forest Service started with an economic model with 528 economic sectors. For a given activity -- twelve hours spent hiking in Wilderness, for example -- the anticipated expenditure for each sector was computed. (For example, twenty cents will be spent on dairy products.) For each area analyzed -- for example, Crook County -- expenditures were totaled for all the existing economic sectors.

The value associated with, say, an RVD would depend on the expenditure per sector, and the criteria for including that sector's expenditures. Values can run higher or lower depending on what assumptions are made. The Forest believes that this analysis is accurate and adequate.

1200-02.6 Wheeler County

Three reviewers, including a State Labor Economist, stated that effects on Wheeler County should be computed because the 25 percent moneys are a significant contribution to the county's budget.

Response:
Wheeler County was modeled in the FEIS analysis. (See FEIS Chapter 4, and Appendix B Section 5.)

1200-02.7 IMPLAN

Three comments said that IMPLAN analysis should be redone using the 1982 IMPLAN model. The IMPLAN work was criticized because it was based on data that was as much as nine years old.

Response:
The 1982 IMPLAN model (Version 2.0) was used in the FEIS. This model incorporates various improvements over IMPLAN 1.1. More importantly, it was based on 1982 data rather than 1977 data.

The Ochoco felt that 1982 data was still not current enough for adequate analysis. Information for the wood products industry was obtained privately from the area's mills and updated to 1987. The remainder of the 1982 data were examined and concluded to be accurate enough to meet the needs of the planning process.

1200-02.8 IMPLAN

Two respondents stated that the IMPLAN model should span Crook, Harney, Jefferson, Grant, and Wheeler counties. According to the respondents, this would allow better estimation of the effects of the wood products industries and consumer expenditures.

Response:
An IMPLAN model should determine the "boundaries" of a local economy and be sized accordingly. The Forest treated Crook County, Harney County, and Wheeler County as three distinct economies for two reasons:

Consumer expenditures are well "bounded" by county lines. Neither residents of Fossil, nor residents of Burns, do much shopping in Prineville.

To some extent, county lines serve as good boundaries for the wood products industries. Little or no timber from Crook County is milled in Harney County. Nearly all the timber remilled in Harney County comes from Harney County.

It is true that wood processing stretches far beyond county lines. The IMPLAN models go to some length to capture these effects. For example, for timber harvested in Harney County, the models distinguish between the following:

Timber milled in Harney County,
Timber milled in Crook County,
Timber milled neither in Harney County nor in Crook County;
Timber milled in Harney County and remilled in Harney County, and
Timber milled in Harney County and remilled in Crook County.
The Ochoco National Forest believes that the IMPLAN models constitute a good model of the area, and represent reality much more closely than a multi-county model.

1200-02.9 Employment Changes

One individual requested the calculation of changes in employment and income for the year 2030.

Response:
IMPLAN, like any input/output model, assumes that the economy modeled will stay the same. It allows for no technology change or any other changes in the basic industrial structure. Especially given the rapid rate of modernization in the wood products industry, the ONF does not believe that changes in employment or income that were projected out to the fifth decade would be valid.

1200-02.10 Economic Analysis

Ten respondents requested that additional economic analysis be performed. Some thought that impacts on employment and income should be done in greater detail, or that more analysis should be done. One reviewer suggested comparing employment levels to what would happen if the mills ran at full capacity. Others requested additional analysis of recreational or forage values. Still others desired additional studies on impacts on service industries and small businesses, and on county and school budgets. Some requests for further analysis related to the value of inputs such as recreation or forage.

Response:
The Forest believes that it has used appropriate values. See the section on “IMPLAN values associated with amenities” for further information on how these values were obtained.

Most of these comments request additional detail or additional analysis of the effects of the Preferred Alternative. The Ochoco National Forest attempted to present the effects in enough detail to describe the impacts of all the alternatives, including the Preferred Alternative.

1200-02.11 Economic Analysis

Two comments questioned the DEIS projection that Harney County would gain jobs during the first decade, while Crook County would lose employment. One of these comments came from the State Economist.

Response:
In the new Preferred Alternative, which schedules harvests differently, there is no significant difference between the effects on Crook and Harney counties.

1200-02.12 Capacity

Four letters referred to capacity. One recommended that mill capacity be considered in estimating impacts on employment.

Response:
Mill capacity has no direct effect on employment. It represents no historical level of employment and is therefore not an appropriate number to use for a “current situation” comparison. The subject of mill capacity did not play a part in the selection of the Preferred Alternative.

@1200-03 National Economics

One comment expressed the concern that while PNV calculations seem to be major influences on FORPLAN outputs, they are not responsive to the ICO’s. This respondent requested that the relationship of FORPLAN PNV calculations to the national concern of economic efficiency be addressed in depth.

Response:
Economic efficiency is a major planning criteria addressed in NFMA and its implementation regulations. The major use of PNV is not the control of
FORPLAN outputs, nor is it directly related to ICO's. PNV is used 1) to ensure that scheduled activities and practices are cost effective, 2) to select the most efficient activities and practices to achieve a set of goals and objectives, and 3) as one of the decision criteria in deciding which alternative best maximizes Net Public Benefits.

@1200-04 Timber Economics

One comment was received stating that PNV analysis promotes the liquidation of old growth ponderosa pine by discounting future value.

Response:
Of all benefit/cost analysis techniques, Present Net Value (PNV) is considered the most appropriate for land management problems of this scale. Economic efficiency analysis using PNV does associate a time value with money. Put another way, a dollar today is worth more than a dollar ten years from now. As a result, given the choice of harvesting a high value product today or in the future, PNV analysis will choose to harvest today.

In the DEIS, only Alternative H-Departure was designed and developed with the main objective of maximizing PNV. The objectives of all other alternatives were based on public issues, management concerns and opportunities (ICO's). The maximization of PNV was the criterion then used to assure that each alternative had the most economically efficient combination of outputs and activities needed to meet its objectives.

In the FEIS, three alternatives (I, B-Modified, and C-Modified) incorporate uneven-aged management for ponderosa pine. Alternative I also incorporates extended rotation ages for ponderosa pine. These objectives slow the rate of harvest for large diameter pine and increase the size of pine that will be managed in the future.

Refer to Chapter 2 of the FEIS for a description of the Alternatives and to Appendix A of the FEIS for a description of the quantified indicator of the issues.

@1200-05 Multiple Use Management

One comment expressed the concern that PNV is a valid comparator only if it can accurately account for all priced and unpriced, market and nonmarket, and direct and indirect costs and benefits. The respondent stated that the costs and benefits described as being evaluated in the economic analysis are not all significant factors applicable to decisions based on multiple use resource management of public lands.

Response:
It is true that all criteria important to the decision maker are not part of economic efficiency analysis (PNV). Appropriate methods to quantify certain nonpriced values (for instance, visual quality, old growth, and snag habitat) have not been developed. These values need to be considered in qualitative and subjective terms.

PNV is considered a valid comparator because it puts many of the priced resource values, both market and nonmarket, on similar terms for the purpose of comparison. However, both market and nonmarket priced resources have factors besides economic considerations. As with unpriced values, priced resources should also be evaluated qualitatively. Therefore, PNV should be, and is, only one of the criteria used to evaluate resource outputs.

NFMA regulations charge the Forest Service with identifying the alternative which comes closest to maximizing net public benefits (NPB). NPB represents the overall value to the nation of all outputs and positive effects (benefits) whether they can be quantitatively valued or not. Net public benefits include both priced and nonpriced resource outputs, less all costs associated with managing the area. All priced outputs and all costs associated with managing the Forest are included in the calculation of PNV. The net subjective values of the nonpriced outputs must be added to this in order to arrive at the overall NPB of an alternative. The Forest then chooses the alternative with the greatest NPB as the Preferred Alternative.

Appendix B, Section 8 of the FEIS displays the
major criteria used to compare the alternatives’ responsiveness to the ICO’s. PNV is only one of these criteria.

See Forest Response to Multiple Use Comments, 0350 and 1300-10.

**Subject Area 1215 Social Considerations**

@1215-01 Future Generations

Thirty-nine respondents commented on the ecological and/or social need for old growth, older trees, wildlife, streams, recreation and wilderness. The Columbia River Inter-Tribal Fish Commission stressed the need for fish habitat. Many reviewers feared that poor decisions would harm their resources for future generations.

Response:
The Ochoco National Forest is aware of the need to manage all the Forest’s resources with long-range goals and objectives in mind. The Ochoco National Forest has attempted to meet these goals through the forest planning process, and will continue to plan for the future of all Forest users, keeping in mind the needs and desires of all Forest users.

@1215-02 Community Stability

Ninety-six respondents, among them the Crook County Soil and Water Conservation District, said that a primary concern in Forest Planning should be the economic stability of the affected communities.

Response:
Community stability is a specific requirement for the selection of the Preferred Alternative.

1215-12.1 Community Stability

Eighty-two respondents stated that a decline in harvest levels would undermine community stability, both now and in the future.

Response:
The Forest recognizes the importance of community stability. Community and economic stability concerns were specific considerations in the development of the Preferred Alternative (Chapter 2, FEIS). The results of all the alternatives were compared to the “current situation,” that is, an average picture of the communities over recent years. The results of this comparison predict a slight increase in benefits to local communities under the Preferred Alternative I over the present.

@1215-03 Lifestyles - Elderly, Handicapped

Fifteen respondents said that more consideration should be given to the elderly and handicapped. (Many of these comments were made in connection with access to Lookout Mountain, and some of the comments referred to snowmobiles. Refer to these specific discussions in the Recreation section.)

Response:
The Forest Service has been seeking to increase the opportunities available to elderly and handicapped people. Forest offices have been barrier-free for several years, and now barrier-free facilities are being provided on the Forest and Grassland.

The ONF has provided barrier-free day use facilities at the Walton Lake area. By summer, 1989, a barrier-free fishing platform is scheduled for completion at the lake. The Forest and Grassland Plans will provide other barrier-free trails and campsites in future years.
@1215-04 Lifestyles

Two respondents stated that firewood availability is essential to their way of life.

Response:
Firewood levels will be difficult to maintain over several decades (see Chapter 4 of the FEIS for details on firewood and how it relates to other activities and goals). Nevertheless, the ONF recognizes the historical, current, and future importance of firewood and will attempt to meet that need. See response to Firewood comments, 0750-01.

@1215-05 Lifestyles - Native Americans

One respondent questioned whether the predicted effects of the alternatives on Native Americans and Hispanics would in fact occur. He stated that, in Harney County, only five percent of Native Americans were employed in wood products jobs, and a similar situation existed for Hispanics. In addition, the respondent claimed, less than three percent of minority people would be affected by increased federal budgets under the EEO program.

Response:
The Forest has reviewed its data and it appears that the above comments are accurate for Harney County, and for Crook County as well. Comments relating to the EEO program have been modified, and the rest of the predictions that were on DEIS pp. 102-103 regarding employment effects on American Indians have been deleted in the FEIS.

@1215-06 Taxes

One hundred sixty-one respondents said that they did not want any alternative that would increase taxes or decrease income.

Response:
The ONF compared the results of all of the alternatives to the “current situation,” that is, an average picture of the local communities over recent years. The results predict a slight increase in income under the Preferred Alternative (I), and the Forest can see no reason why this alternative would cause taxes to increase.

Subject Area 1230
Budget

@1230-01 Budgetary Concerns

Two respondents expressed concern about the large increase in proposed budgets over historic levels.

Response:
The Ochoco National Forest understands that the large difference between the planned budget amounts shown in the draft and the average budget levels of the past may seem unreasonable. Those differences are part of the reason that our process included the use of a “draft.” The information was a first attempt to figure the costs of all the variables included within the document for such a long time frame. In this effort each resource area staff was asked to provide the true cost of the total effort required to insure the highest quality products and services. Allowing for factors including federal budget levels, inflation, consumer price indexes, wage rates and emerging technological advances made some inputs hard to substantiate in the early phases. With implementation some of the figures will undoubtedly fluctuate, but the experience will give the Ochoco a sounder basis for comparison.

See Chapter 5 of the Final Forest Plan for Budget Proposals.
@1230-02 What if the Proposed Budget Fails to Materialize?

Sixteen letters contained comments regarding effects of federal budget practices on Forest budgets.

Several references were made to the Gramm-Rudman act and how it may affect funding for the Forest Service. In particular, the viability of non-revenue-generating projects such as water development, range and forage production, fisheries, and trails were questioned. Some suggested that the Ochoco attempt to maximize receipts while providing a sustained yield in order to offset future budget constraints.

Many other respondents were concerned about future availability of funds. Several asked which programs would be cut or reduced if funds were not forthcoming from Congress. One reference was made to Region 4 National Forests in Idaho which have a 25 percent constrained budget alternative in their DEIS.

It was felt that the Ochoco's planning documents failed to consider the possibility of future cutbacks in funding in any of the alternatives.

Particular areas of concern were the budgeting of reforestation projects and forest recreation.

CRITFC recommended that timber and grazing quotas be tied to both budget and environmental goals, so that if either of the latter were not met, the allowable cut and AUM's would drop respectively.

Response:

As with all agencies of the Federal Government, the Ochoco National Forest is subject to varying budget levels based on national economic conditions. These budget levels are submitted to Congress as part of the program for the United States Department of Agriculture. Congress sets the final program dollar and output levels for all Federal Agencies.

To prevent wide swings in any agency's program, the Congress requires a range of opportunities to consider for funding in any individual year. The long term nature of our planning effort is really a plus in displaying this range of opportunities on a long term basis. This process is called the PROGRAM BUDGET.

Nationally the program budget process is an incremental process designed to provide the budget information necessary to implement Forest Plans within various constrained funding levels and/or rates of implementation. Each Forest submits a level known as "Implement Forest Plan" for a specific year and the total need for the decade. Forests are not constrained in funding; however, they must be able to accomplish implementation within current work force, skills, and environmental requirements. Forests also submit a list of programs or projects that can be foregone. This list of programs can be up to a forty percent reduction in individual years and includes an accelerated program of up to ten percent. These lists are used for priority setting to develop program levels to meet Regional constraints. The Regional Office then submits these varying levels to the Washington Office Headquarters. Typically five to seven levels are submitted. Forest plans will be implemented to the extent practical within funding constraints and targets tied to plans submitted to the Washington Office. Each Forest's information goes forward to the Washington Office Headquarters for use in the Explanatory Notes that are sent to Congress. This program is updated to better reflect the national and local economic conditions each fall.

Using a broad spectrum of alternatives, long time frames, and detailed information produces a product that negates wide program swings in any individual year, but allows Congress to adjust national budgets to meet the nation's economic condition. In the case of the Forest Service, Congress can do this with detailed knowledge of economic opportunity and resource effects.

See Chapter 5 of the Forest Plan for details concerning Budget Proposals.
Livestock Concerns

One individual cited an article in *Fishing and Hunting News* magazine which stated that the Ochoco National Forest's Range Management Program loses approximately $360,000 per year. The reviewer questioned the proposed increases in Range expenditures in the DEIS in light of this deficit.

Response:
The figures available when the Ochoco National Forest published its draft planning document did not contain adequate data to do accurate cost-benefit analysis. The Forest Service began to address this problem area in cooperation with the General Accounting Office as directed by Congress in October 1984. The initial effort is detailed in "TIMBER SALE PROGRAM INFORMATION SYSTEM" (TSPIRS), Final Report to Congress. This program systematically addressed Forest Service cost centers to identify elements similar to private industry. This resulted in a financial statement that provides a clearer look at investments, operation costs and revenues in a short- and long-term framework. The process presents a consistent depiction of the cost/benefit relationship. This "new" tool provides an opportunity for the Forest Service manager to invest dollars where the greatest benefit is available. The success of this program has led to "All Resource Accounting." The concepts refined in TSPIRS are now being applied to all resource areas. Reports should be available in 1990 or 1991.

Even though the returns to the Forest Service from grazing fees do not cover administrative costs, the benefits to the local economy are deemed to outweigh those costs. All programs administered by the Forest Service do not necessarily make a profit, nor would it be practical to expect them to.

See Chapter 5 of the Final Plans for details on budget proposals.

Subject Area 1275
Indian Rights

Rights Adequately Addressed

One respondent felt that the issues important to Native Americans had been adequately addressed in all the alternatives in the DEIS. The observation was made that since less than five percent of the Native American workforce is employed in timber-related jobs, the likelihood was low that Native Americans would be affected by any of the alternatives in terms of employment.

Response:
Five percent may be the national average, but in Crook County the percentage is much higher due to the presence of Warm Springs tribe members.

In addition to the relationships between Native American employment and harvest levels of the different alternatives, the ONF tried to address Indian treaty rights, the American Indian Religious Freedom Act (AIRFA), cultural resources and burial sites with the rights and interests of the Native American community in mind. As the Forest and Grassland Plans are implemented, the ONF encourages the public to continue to assist us in meeting treaty obligations, handling AIRFA issues, identifying cultural areas important to Native Americans, and providing input to all cultural resource management activities.
Subject Area 1300
Planning Comments

@1300-01 Planning

1300-01.1 Planning in General

There were 59 comments on planning in general.

Some reviewers felt that the Forest has been managed well in the past and that this planning process is merely changing for the sake of change. They wanted the Ochoco to find an acceptable plan and stick with it.

Many were displeased with the bulk of the DEIS and Draft LRMP. They felt that the documents were wordy and redundant and that the public was not given adequate time or notice to review the DEIS. The planning documents were also said to be far too complex (especially the sections on Economics and FORPLAN modeling) for the average reader to grasp.

Several people stated that the analyses were flawed, or that the quality of work in preparing the plan was poor. Some claimed that data were omitted or conclusions did not follow from the information presented.

Others felt the process was adequate, and that the documents were professional and well done. Several complimented the ONF on the DEIS and Draft Plan.

Some commented on the Forest Service personnel who worked on the plan. A few felt the document was a waste of money and a way to “make work” for Forest Service employees. Others thought the Ochoco could be run better with fewer employees. Still others stated that they were confident the personnel now in place would come to the best conclusion for all concerned.

There were also a few comments urging a plan that would benefit the majority.

Response:

Planning on the National Forest is directed by law under the National Forest Management Act of 1976. Other laws relating to management of resources on the National Forest also contain provisions that are required to be incorporated into National Forest Planning; for example, the National Environmental Policy Act of 1969, Endangered Species Act of 1973, Wild Horses and Burros Protection Act of 1971, Clean Water Amendments to the Federal Water Pollution Control Act of 1972, etc. The process and procedures for National Forest land and resource management are described in part by Federal Regulations CFR part 219 - Planning, the Forest Service NEPA implementation regulations, policies, and procedures; FSM 1900; and specific procedures, policies, and guidelines contained in Forest Service manuals, handbooks and the 1984 Pacific Northwest Regional Guide.

The subject of planning for management of the National Forest resources is by nature a large, complex and technical undertaking involving many disciplines and varied political, public and legal interests, which requires dealing with a wide range of natural resource issues over time. It follows that planning for the National Forests requires, by law and regulations, following certain procedures. Documentation of information, processes, results, and decisions is one of these procedures. Satisfying legal requirements sometimes results in redundancy and the structuring of documents in a manner which may not always contribute to ease of understanding or readability.

Given the above comments on planning document preparation and format, complexity can be expected to vary based on the particular individuals, interest groups, or agencies reviewing them. Summaries, tables of content, indices, figures, tables, and glossaries have been included to assist document reviewers. Materials and documents were edited to assist readability and reduce volume. A reviewer’s guide was also published to assist readers. Intentions are to continue to improve readability and understanding in the FEIS/LMP.
1300-01.2 Planning Analysis

Six public responses, including that of the U.S. Department of the Interior, commented on the analysis issue of the planning process.

Some felt that given the limitations of current scientific knowledge and computer technology, scientific uncertainty is a fact of life in National Forest Planning. In addition, some stated that attempting to combine objective, quantifiable resource data with subjective values and public interests invalidates the modeling process. They believed that subjective values have no place in computer modeling.

Some comments indicated that the DEIS should be more understandable in its descriptions of modeling used to evaluate various solutions, more explicit as to the value of linear programming in making decisions, more accessible in its use of "planning documents" which were not provided to reviewers, and should use more widely accepted meanings of English words and phrases.

The U.S. Department of the Interior stated that the Plan should make it clear that the development of new research questions and methods will, in most cases, not be a consequence of project level identification and avoidance activities. They stated that it will come largely through broad-based planning studies, non-project survey, and data recovery projects.

The Office of Economic Analysis stated that each Forest should circulate its alternatives for comment prior to making computer runs. This, they feel, will allow for a cost-effective method of examining a wider range of alternatives.

Response:

The planning process data base and modeling assumptions are described in detail in Appendix B of the FEIS. Additional information is contained in the Planning Records on file at the Forest Supervisor's Office in Prineville, Oregon.

1300-01.3 Planning Coordination

Some letters, including that of the Grant County Court, stated that they would like to see more coordination and cooperation in planning between adjacent Forests. The Grant County Court recommends that no single Forest Plan be implemented until all area Plans have been finalized.

Reviewers noted that in order for State agencies to agree on an alternative which satisfies their concerns, the alternative must recognize and incorporate State objectives utilizing statewide programs and policies. They feel, therefore, that the alternative must consider the effects, on a regional basis, of implementation.

The Oregon Division of State Lands commented that the Forest had not addressed the effects the Plan will have on similar resources managed by the State or adjacent private lands. They stated that the Federal Government, as the major landowner in a geographical area can, with its management policies, enhance or stifle the economy, or alter the development of that area.

Response:

Forest Service planning is conducted on several hierarchical levels. A Regional Guide (1984), as well as a Vegetation Management EIS (1988) and other plans, were prepared to give broad overall guidance to planning on National Forests in Region 6. In addition, various Forest Service manuals and handbooks exist which provide coordinating directives.

The Pacific Northwest Region conducted an "Aggregate Analysis" of alternative outcomes for various resources based on the draft Forest Plans. This analysis dealt, for instance, with regional timber supply and provided an overview of the effects of alternative courses of action. On a more local basis, National Forests did coordinate on location of management area boundaries and development of certain standards and guidelines.
A great deal of attention was given to consistency in dealing with certain issues between adjacent Forests. Other agencies, such as the BLM and Bureau of Reclamation, were involved throughout the process.

Finally, the Forest has worked closely with the State of Oregon and other agencies in the development and selection of a final alternative. This involved a great deal of coordination and interaction with State Agencies and the Governor's office. The Governor's office provided a State-wide view for the process.

1300-01.4 Planning Coordination

The Columbia River Inter-Tribal Fish Commission noted that the Forest Service coordination with Pacific Northwest fisheries enhancement activities is required by law, and that the Ochoco National Forest DEIS and proposed Plan do not reflect the consideration of these processes required by the NFMA.

The Commission further suggests that, to adequately assess the environmental impacts of its actions as required by NEPA, the Forest Service must study and disclose the cumulative impacts of all 17 Forest Plans in the Region on the Columbia River anadromous fish runs and the four Columbia River treaty tribes.

Response:

The Forest Service has coordinated its planning with the Columbia River Inter-Tribal Fish Commission (CRITFC). The Ochoco National Forest and Crooked River National Grassland are involved with the Forest Service's "Rise to the Future" incentives, and the riparian and wildlife habitat improvement projects scheduled in the Plan reflect this. The ROD specifically mentions the Forest's agreement with CRITFC to involve them early on in the scoping phase of projects potentially affecting anadromous fisheries.

@1300-02 Monitoring/Implementation/Mitigation

Several respondents, including the U.S. Environmental Protection Agency, indicated that the Forest's monitoring system was not intensive enough. They suggest that it be more frequent than once every three to five years if the habitat for wildlife and anadromous fish is to be protected before significant damage occurs.

Some, including Governor Vic Atiyeh, suggested that the definition of monitoring be improved by adding a clause that will indicate certain deviations as a trigger for revision of management practices. Others, among them the Oregon Water Resource Department, remarked that there is no timeframe for the measurement of riparian improvements and that aspects of the Plan which pertain to meeting Federal or State mandated standards or regulations should be mentioned so the public will be better able to monitor the results of the program.

The reviewers suggested that the monitoring and evaluation program of the Forest Plan should be expanded to provide greater detail by species and monitoring objective. In addition, some felt that threatened, endangered and federally listed species should be added as an action and effect to be monitored.

Many, among them the State Forester, stated that the Ochoco had provided a very good framework for its monitoring and evaluation plan. However, they felt the plan needs to be improved in the following areas, funding of the monitoring process, flexibility of the plan to accommodate growth factors when they are greater than forecasted, and monitoring of logging operations.

Others felt that compliance with standards and guidelines or management prescriptions is generally not monitored, and that the public will not be able to tell if the Forest Service is trying to meet Plan objectives. In addition, they stated the monitoring plan, as presented, will not accomplish its presumed objective because monitoring compliance with many LMP objectives is not addressed.
One person indicated that the monitoring surveys should be conducted by independent technicians under contract in order to insure the highest level of impartiality.

Response:
Monitoring is required under NFMA Sec. 6(8)(1)(c). The monitoring process is described in Chapters 5 of the Plans. The environmental analysis (NEPA) process is tied into the monitoring and implementation program. This process provides for public involvement. Significant amendment or revision to the Plan as a result of monitoring will include public involvement and publication of a decision notice.

@1300-03 Management Strategies (Alternatives)

There were 91 letters with comments concerning alternatives in general. Most respondents expressed displeasure with either the number of alternatives or the range of resource outputs in the alternatives.

Some felt that eleven alternatives were far too many and confused the issue. Others were unhappy with the major discrepancies between the Forest Service alternatives and those proposed by private industry. These respondents wanted an alternative that emphasized timber yields and commodity outputs.

Others asked that the Forest Service not allow harvest levels to determine management strategies. They recommended that the Forest be managed with an emphasis on wildlife and biological diversity. Many of these respondents expressed disappointment with what they considered the narrow focus of the plan on timber and beef production. Some stated that any Forest Service alternative would be better than an alternative proposed by the timber industry.

Most respondents simply stated that the alternatives failed to satisfactorily deal with the issues and that they could not support any proposed alternative. Some, however, were pleased with the way the issues were responded to in the DEIS.

The major concern of the respondents seemed to be that the Forest Service implement a plan with the needs of the majority in mind.

One individual suggested that the Ochoco combine the best policies of forests all over the world into its program.

Response:
Under the requirements of the National Environmental Policy Act (NEPA) and the National Forest Management Act (NFMA), a range of alternatives, which might realistically be implemented, is required to be considered. Eleven such alternatives were analyzed in the draft (DEIS); in addition, another alternative was presented in a Supplement (SEIS) to the draft. Represented were a range in alternative management plans, from intensive timber management to emphasis on noncommodity resources with reduced timber yields. Other alternatives attempted to portray a more "balanced mix" of resources and outputs. Three alternatives incorporated "departures" from even-flow of timber. The departure alternatives maintained high levels of timber supply for the forest product industry during the decade to follow.

The complexities of planning requirements, and the difficulty and frustrations in understanding the alternatives, are reflected in the above range of public comments (also see comments under 1300-1 Planning). Likewise the Forest Service's problem of attempting to meaningfully apply public comment in decision making is demonstrated by the range of responses above. Comments specific to particular alternatives are addressed under other headings.

In the Final, the Forest Service has reduced the number of alternatives considered in detail. Alternatives in the Draft, which received little, if any, public support or interest, have been treated under a section of the FEIS entitled, "Alternatives considered, but eliminated." (See FEIS Chapter 2.) Six alternatives are analyzed in detail in the Final. The decision to present the six particular alternatives in the Final is based on NEPA requirements, legal considerations and public input.
The Final Preferred Alternative, Alternative I, is a new alternative. It represents an amalgamation of new information, parts of the draft alternatives, and incorporation of public comment. The formulation of the Preferred Alternative involved changes which were primarily in response to public comment (see Chapter 2, FEIS). The Final Preferred Alternative is within the decision constraints for alternatives as identified in the DEIS.

@1300-04 Management Strategies (Alternatives B+, B, B-Departure, B-Modified)

There were 106 comments on Alternatives B, B-Departure, and B-Plus (the timber industry alternative).

The vast majority of the respondents indicated a preference for Alternative B-Plus on the grounds that it emphasized timber and commodity production. They felt that only B-Plus would permit the economy of Central Oregon to survive.

A few were opposed to B-Plus because they felt it would deplete the resources in the region, damage the environment, and reduce big game populations.

Some Preferred Alternative B, feeling it offered a balance between commodity and amenity production.

A few recommended B-Departure with amendments to balance near- and intermediate-future timber yields and to ensure strong emphases on community stability.

The Crook County Soil and Water Conservation District suggested the Ochoco implement a combination of Alternatives B-Plus and E-Departure.

Some expressed concern that the form letters sent in by those preferring the timber industry’s alternative (B-Plus) would receive less consideration from the Forest Service than would other forms of response.

Response:

Alternative B in the Draft Plan and DEIS was designed to attempt to meet Regional Guide 1980 RPA timber and range program targets. The alternative's focus was on intensive management for timber and range, but other resources were managed at minimum levels. To meet the RPA target all available forested lands were planned to be managed intensively for timber production in this alternative. In addition, another similar alternative was developed - Alternative B-Departure. It was found that even with departure harvest, neither alternative could meet 1980 RPA timber targets for all 50 years while simultaneously meeting other RPA objectives. With the exception of Alternative H-Departure, Alternatives B and B-Departure offered the greatest timber yields of any considered in the Draft.

The forest products industry used Alternative B as a basis for its own plan, called Alternative B-Plus. This alternative was strongly supported by the timber industry lobby and local communities through form letters and organized efforts (see Public Comment Analysis, Appendix A).

Timber industry officials and personnel of the Ochoco National Forest met and formulated a modified B-Plus alternative, called B-Modified in the Final Plan. B-Modified is an amalgamation of parts selected by industry from Alternative I and Alternative B. It represents an entirely new alternative and is fully addressed in the FEIS and Final Plan. In reality, industry's final version of Alternative B-Modified is more closely related to Alternative I than to Alternative B.

In terms of numbers alone, Alternative B-Plus received the most positive comments. This was a result of intensive organized efforts by the forest products industry. The questionable aspects of this alternative, and its poorly developed nature (except for the section on timber harvest) were recognized by the industry, as evidenced by the formulation of Alternative B-Modified in the FEIS.
None of the B alternatives discussed above (B, B-Departure, B-Plus) were selected for the reason that, while they provided high short-term economic benefits, they did not represent balanced or equitable resource mixes and they had potentially undesirable environmental and socioeconomic effects over time. Options would be reduced with the adoption of any of these alternatives and the risk of irreversible environmental effects was high.

See Chapter 1 of this appendix and 1300-17 Public Involvement Responses in this chapter for Public Participation information.

@1300-05 Management Strategies (Alternative C)

Many respondents favored Alternative C because they felt the reduced harvest levels would help heal the land from the many years of overharvesting. Also, many felt that this alternative best protects the Forest's natural values, such as riparian areas and wildlife, and would decrease the harmful effects of grazing.

Some felt that this Alternative would provide a suitable mix of recreational and commercial uses of public lands. Furthermore, many stated that this Alternative comes closest to meeting NFMA requirements.

Many felt that this alternative would maintain steady Old Growth. Reviewers said that Old Growth is a unique resource, and should be protected until fully understood.

Some opposed Alternative C because it would limit commodity production and would cause undue stress and hardships on local communities that depend on the timber production.

Response:
Alternative C was the conservation community's Preferred Alternative. It emphasized amenity or non-monetary values. A newspaper flier supporting this alternative was widely distributed by conservation organizations and individuals. There are environmental benefits associated with alternative C, but implementation could be only done with very high costs and radical change to established local, social and economic settings. In the Forest's opinion, Alternative C does not provide a balance between environmental considerations and the economic realities of dependent communities, and therefore was not selected. It is presented in the FEIS as one of the final alternatives after being modified to include uneven age management and legislated changes such as classified Wild and Scenic Rivers.

@1300-06 Management Strategies (Alternative D)

A letter was received from one respondent suggesting that Alternative D comes the closest to true multiple use and protection of basic resources.

Response:
Alternative D emphasized fish and wildlife, especially big game. Timber and range outputs were significantly reduced, as was scenic and unroaded recreation. In emphasizing one resource, wildlife habitat, the alternative failed to incorporate other resource management opportunities. Reasons for nonselection were similar to those described under Alternative C.

@1300-07 Management Strategies (Alternatives E, E-Departure)

Some respondents favored Alternative E because they felt it reflects a wise allocation of land, good objectives and sound management practices. They also note that it preserves greater than 97 percent of the employment base and provides a lessened long-term economic impact on local communities while still protecting the natural environment.
Many respondents Preferred Alternative E over E-Departure because they felt it meets the overall environmental needs prudently. Some felt that any departure from even-flow would cause long-term social, economic and environmental impacts.

Some, including Richard Kuczek, Labor Market Economist for Wheeler and Grant Counties, stated that they favored Alternative E-Departure on the grounds that it provides fairly high levels of non-market resources while maintaining current timber harvest levels for the first decade.

Others, including Governor Victor Atiyeh, opposed Alternative E-Departure because they felt it does not reflect a real balance between environmental concerns, recreation and the economy. In addition, they suggested that it is not compatible with State goals and does not maximize net public benefits. Some people stated that this alternative avoids controversial decisions by proposing a massive over-utilization of the Ochoco’s resources which will result in a future crash where Forest utilization must be drastically decreased to allow recovery.

A few individuals opposed Alternative E because they felt it is too extreme and benefits the Forest, but not the people who use it.

Response:
Alternative E-Departure was the draft Preferred Alternative. There was strong public opposition to departure (see response to Timber Comments, 0700-01). Nearly all segments of the public felt that departure harvest was inappropriate. Using the public comment, new information, and additional analyses, the Forest Service created Alternative I - the Preferred Alternative in the Final Plan. The changes and reasons for change are summarized in Chapter 2 of the FEIS and Section 4 of the ROD.

@1300-08 Management Strategies (Alternative G)
A few respondents, particularly the State of Oregon in its original response, felt that Alternative G provides the best basis from which to create the Forest’s and the State’s Preferred Alternative. However, they noted that Alternative G needed some revisions to make it a more useful alternative. These included: retaining current levels of timber harvest for a stable local economy; improving riparian zone management, wildlife habitat and livestock management conditions; compliance with approved State and Federal plans for air and water quality standards, and maintenance of the current level of semi-primitive motorized and non-motorized recreation trails as presented in Alternative E.

Response:
Alternative G was the State of Oregon’s original preference for an alternative among those displayed in the draft subject to the above modifications. Since then the Forest Service has continued to work closely and in cooperation with the State to assure that both agencies are in accord with the Preferred Final Alternative.

The State developed its own alternative and held public meetings in April 1989. There were no significant differences between the State’s alternative and the Forest Service Alternative I in the FEIS.

@1300-09 Management Strategies (Alternative H)
Some public respondents favored Alternative H. They claimed this alternative has the best mix of timber, wildlife, water and recreation. Some also felt this alternative provided the most use for the most people while maintaining natural resources.

Response:
Alternative H emphasized management of timber and range resources in a manner that yielded the greatest economic returns with minimum attention given to other resources. It did not represent a balanced mix and was rejected in the selection of a final for reasons similar to those given under the comments on the B alternative.
@1300-10 Management Strategies (Multiple Use)

There were 363 comments concerning Multiple Use. Many felt the Ochoco has been managed primarily for the timber and cattle interests and that commodity production should be secondary to environmental and recreational concerns. These comments favored minimal development and greater emphasis on Fish and Wildlife and other nonconsumptive uses of the Forest.

Others were of the opposite opinion. They felt that commodity production should be stressed on all available acres. They commented that the Forest should be open for public use, not closed as a private playground. Some cited the Multiple Use Sustained Yield Act and a requirement for the maintenance of a viable timber industry. Others stated that, in order to serve the greatest numbers of people, commodity outputs had to be stressed on the Ochoco.

Still other respondents expressed the desire for a balance between commodity and amenity outputs. Some of these individuals stated that past Forest practices have been adequate and should not be changed. Some stated that some harvest is acceptable, but clearcutting is not.

Response:
The issue of definition and application of multiple use is addressed in response to comments under 350-Multiple Use.

The above comments raised two other commonly expressed viewpoints relating to multiple use management strategies and planning: 1) don't change things, keep them as they are; and 2) management, or the Plan, is biased toward timber and range.

First, the Forest Service is required by law - the National Forest Management Act of 1976 - to prepare plans for the management of the National Forests. The regulations or requirements for those plans require that certain alternatives be considered, furthermore, certain things are required to be done differently than they are in existing plans to meet the intent of the law.

Other recent legislation, such as the Oregon Wilderness Act and the Oregon Wild and Scenic Rivers Act, both affecting the Forest and Grassland, are further examples of changes that have taken place which the Forest Service, in order to act responsibly, must respond to. New information on Forest resources is available, and the Forest Service is required to update its plans for timber management every decade. These are but a few examples of things that have changed or continue to change. National Forest and Grassland management is not static. Planning and management are required to be flexible and dynamic.

Second, the Plan and FEIS alternatives represent different ways the Forest and Grassland may be managed. Different resource mixes, emphases and outputs are reflected by the alternatives. In the selection and preparation of the FEIS, the ONF has attempted to take a multiplicity of factors and concerns into account. In the Forest's judgment, Alternative I represents a "balanced mix" of resources, emphases, and outputs for the Forest and Grassland that is truly a multiple use alternative. It is certain though, that not every interest group or user group will be satisfied. Most will demand more, such is the nature of allocation of resources on public lands. However, making those demands under the auspices of "multiple use" is a corruption of the meaning and intent of multiple use management.

@1300-11 Standards and Guidelines

Some felt that the Standards and Guidelines were well thought out and very implementable.

Several respondents stated that Standards and Guidelines have two separate and distinct meanings. In addition, they felt these meanings are not carried over into the Plan, which gives no indication as to which requirements are mandatory standards and which are non-mandatory guidelines.

Some stated that meadow protection was not adequate and that the subjective guidelines were not sufficient.
According to the U.S. Environmental Protection Agency, the annual budget will influence the level of projected outputs and Plan implementation. However, they feel that certain categories of activities should not be excluded at the expense of others. In particular, they felt the mitigation measures and Standards and Guidelines designed to protect or enhance resources should not be tabled while other goals are met.

Some doubted, based on the current economic situation and past project costs, that very many projects would be cost effective over the long term. Others felt, however, that it is quite possible such projects may be necessary to mitigate some of the other negative effects which will appear as the character of the Forest lands change.

Response:
Standards and Guidelines, and management area prescriptions, are given in Chapters 4 of the Forest and Grassland Plans. There are numerous directional statements in the Plans representing Standards and Guidelines, which deal with all resources.

The distinction between a standard being an absolute or mandatory requirement, as compared to a guideline, has not been made by the Forest Service.

The “MR’s,” or Management Requirements, are standards or guidelines which deal specifically with NFMA requirements. They are the ways that the legal requirements of NFMA have been incorporated into the planning process. The distinction is that standards and guidelines are established to meet management objectives, whereas management requirements carry the additional necessity of meeting NFMA legal requirements. This is described in detail in Appendix F of the FEIS.

@1300-12 Management Areas (MA 1)

Many respondents stated that they oppose the inclusion of any National Forest lands in the Draft Management Area 1 prescription. They suggested that, while timber production is an appropriate use of the Ochoco, the dominance it would be accorded in this allocation violates multiple-use management requirements.

Some stated that Management Area 1 is not suitable for the Ochoco National Forest because it emphasizes the rights of the cattle and timber industries while minimizing the rights of the public at large. Some expressed concern that too much Management Area 1 would mean too much clearcutting and too much grazing.

A few reviewers suggested the Forest needs to recognize the importance of the roaded “General Forest” area for recreation and establish guidelines to manage for this.

Response:
In the Final EIS, the Forest has continued a similar allocation termed MA-22 General Forest. Under requirements of the NFMA, “suitability” is a factor that must be considered in planning and allocation. For the ONF, 533,177 acres have been determined to be suitable, as per NFMA, for timber management purposes. About 93 percent of this area has been allocated to General Forest (MA-22) in Alternative I, subject to requirements to provide protection of other resources. These requirements have an estimated opportunity cost in terms of allowable sale quantity (ASQ), which contradicts the above comments and assertions that the General Forest is being managed to the exclusion of other multiple use values.

Refer to 350 Multiple Use and 1300-10 Management Strategies comments (the converse of those represented here) and the Forest Response to those comments.

@1300-13 Environmental Effects/Impacts

Some comments indicated that with population growth and resulting heavier recreational use of the Forest, conservation becomes increasingly important for both economic and social reasons.
Others stated that they have watched the National Forest being destroyed year after year with an “irreversible, detrimental impact” due to lazy management and poor conservation practices.

Some noted that they felt the goal of a management plan should be no degradation of the resource.

Others noted that the DEIS should reflect a more conservative approach to irreversible commitments of National Forest resources. They felt that unavoidable adverse effects vary by alternative and should be compared as objectively as possible in the DEIS. Also, they felt the irreversible commitments of the DEIS should acknowledge that the adoption of a departure alternative is an irreversible commitment of future options.

Response:
In the preparation and selection of a final alternative, retaining options and minimizing environmental effects (particularly irreversible and irretrievable ones) were taken into consideration. The effects of the proposed action and alternatives on the environment have been taken into account throughout the planning process in alternative formulation, and allocation selection, Standard and Guideline development, and in mitigation and monitoring procedures (see Chapters 4 and 5 of the Final Plans). Adverse effects that cannot be avoided and irreversible and irretrievable commitment of resources were dealt with in the FEIS Chapter 4.

@1300-14 NEPA, NFMA, and RPA Comments, MR’s

1300-14.1 NEPA Requirements

Several respondents indicated that the Draft Management Plan and DEIS was not in compliance with either NFMA or NEPA. One indicated that the DEIS does not present a worst-case analysis as is required by NEPA regulations.

Some remarked that the draft document fails to present a full range of alternatives in regard to several important issues, contrary to NEPA regulations.

Several respondents felt the DEIS should have included objective guidelines describing the analysis criteria which will be used to determine whether a resource management activity will require a categorical exclusion, an environmental analysis, or an environmental impact statement to comply with NEPA.

A few people indicated that, from a procedural standpoint, the DEIS was inadequate in several areas, including unavoidable adverse environmental effects, short term uses of the environment and maintenance of long term production, and irreversible commitment of resources.

Response:
A full range of Alternative plans were analyzed through the NEPA process—12 in the DEIS and 6 in the FEIS. The environmental consequences and comparisons of alternatives were analyzed in detail in Chapters 4 and 2 respectively. A full range of alternatives for each resource activity, such as ORV use or grazing, was not investigated. However, a “benchmark alternative” with minimum levels of grazing and other resource uses was formulated and used in the analysis process. The planning process was issue-driven, and alternatives, allocations, and standards and guidelines were developed to address the issues identified. The Plan is intended to be programmatic in nature, and as such it generally does not deal with project specific decisions.

The process and documentation for preparing the Plans closely followed the NEPA and NFMA requirements.

Worst-case analysis generally relates to proposed projects or actions that are specific or singular in nature. For the multiplicity of issues addressed in the Forest and Grassland Plans this is simply unrealistic. Worst-case analyses are generally not conducted in Forest planning unless specific issues emerge where such analysis is necessary or implied. No such issues were determined to exist for the Forest or Grassland.
1300-14.2 NFMA, Management Requirements

Many reviewers felt that the Forest needed to provide sufficient background to explore various ways to mitigate projected harvest reductions and that the Plan should discuss the individual impacts of each Management Requirement.

Some felt that the "minimum" Management Requirements in the Plan were more like "maximum" requirements and should be revised to be realistic and show a minimum need. In addition, some said they were unable to find where Management Requirements MR's are described in full or summary form.

A few felt that the EIS alternatives did not include variations of MR's. In addition, many felt the Forest must look at a range of alternatives for MR's.

Some commented that the Forest should have examined alternative ways to achieve the objectives of the MR's in the most cost-efficient manner.

Response:
Management requirements that are specified in NFMA were discussed and analyzed in the draft in the DEIS Appendix B, pages 59-61. Additional information and analyses on management requirements were also given in the Supplement to the DEIS, pages 17-34. In these analyses, alternative ways to achieve the requirements or objectives, and the opportunity costs in timber yields, were examined and displayed. Detailed information on management requirements is presented in Appendix F of the FEIS.

1300-14.3 No Change Alternative

One person noted that NFMA requires the development of a "no action" alternative, and that the Region, including the Ochoco National Forest, has chosen to include new scientific information and "management requirements" in the current direction alternative. The respondent felt that this does not allow the public an opportunity to make an unbiased comparison to determine the true resource trade-offs and resulting economic losses or gains.

Response:
The Forest prepared and displayed two "no action" alternatives in the draft--Alternative A and "Current Direction with NFMA." In the Supplement to the DEIS the Forest described still another "no action" alternative which was a continuation of management under existing plans, particularly the 1979 Timber Resource Plan. The latter alternative is not implementable, since it does not incorporate all legal requirements. The No Change Alternative has also been described in Chapter 2 of the FEIS.

1300-15 National Grassland Management

1300-15.1 Grassland Plan

Many felt the Forest and Grassland should not be included in the same long-range plan. Some felt the Grassland should be separate as it is almost completely a forage producing area with very little timber.

Response:
The Forest Service recognizes the validity of the above comments. There are some good reasons to treat the Forest and Grassland separately.

Some of the laws and requirements for management of the National Grassland are different from those for the National Forest, and the resources on the Forest and Grassland are also different. The National Grassland and its management were overshadowed by the National Forest in the Draft. Specifics for the Grassland were difficult to separate from those of the Forest in the documents. Important resources and uses occurring on the Grassland were simply overlooked in the Draft. The Draft Plan recognized only eight management units or areas for the Grassland; the Final Plan now recognizes 15.
Two separate plans have been prepared in the Final, one for the Grassland and one for the Forest. The two plans and processes for their development are treated under a single Environmental Impact Statement and Record of Decision.

1300-15.2 Grassland Management

Many respondents felt that the Crooked River National Grasslands is a unique resource deserving of multiple use management. However, they felt the grassland is managed mostly for cattle grazing and should be managed to provide wildlife and all other resources.

Some felt that the Grassland has a long way to go before it returns to its natural balance. However, others felt that at present the Ochoco National Forest and Crooked River National Grassland is managing the grasslands reasonably well.

In addition, some commented that the livestock industry pays for the usage of the Grasslands, not only through grazing fees, but by water and land developments which help the entire multiple use program.

Response:

National grasslands are established under the provisions of the Bankhead-Jones Farm Act which requires management to maintain and improve soil and vegetation cover, and to demonstrate sound and practical principles of land conservation and multiple use (36 CFR 213.1). This law applies to the Grassland only, not the National Forest. Other laws affecting the management of public lands and resources also apply to the Grassland.

The National Grassland has a complex ownership pattern. Resources are frequently managed in cooperation with State and other Federal agencies. The Final Grassland Plan has 15 management areas, which reflect a diversity of uses, resources, and management prescriptions, in order to attain or maintain desired future conditions. The Plan deals with all resources, and truly reflects the multiple resource values and management occurring on the Grassland.

@1300-16 Analysis (FORPLAN)

1300-16.1 FORPLAN

One comment questioned the analysis used in the planning process. This respondent stated that the information needed by the public to evaluate the validity of the FORPLAN calculations was not provided in the DEIS and suggested that the FEIS provide a more understandable explanation of how linear programming was used to influence planning decisions.

The respondent asked that the EIS identify the objective constraint values used and the validation for their use. He pointed out that only a few modeling constraints were quantified or objectively defined in the DEIS.

He also suggested that the EIS contain a "benchmark" which drives the linear programming model to minimize "unavoidable adverse impacts.”

This respondent also addressed the size and efficiency of analysis units. The question of whether a 3-acre analysis unit could be efficiently managed, or managed at full intensity, was raised.

Finally, the respondent suggested that the way in which the weaknesses of the computer models were overcome should be explained in the EIS.

Response:

There is no legal requirement to develop detailed documentation of FORPLAN models so that the public could review and interpret all outputs, calculations and options used. Documentation of this nature presently exists in the FORPLAN Users Guide and Mathematical Programmer’s Guide, which are available for review in the Ochoco National Forest Supervisor’s Office. Probably the best means of communicating information of this sort to inter-
Estimated publics would be through small group meetings rather than through additional technical documentation.

The usefulness and appropriateness of FORPLAN and other linear programs is well documented. Excellent reviews of FORPLAN can be found in "Proceedings of the Workshop on Lessons from Using FORPLAN," and "The Genesis of FORPLAN." Dennis Teeguarden, in his paper, "FORPLAN: An Evaluation of a Forest Planning Tool," stated:

A simulation or optimizing model such as FORPLAN, creatively used by knowledgeable persons, provides a powerful tool for Forest planning. However, the nature of the planning problem makes it unlikely that any single model will ever satisfy all the requirements. It is probably best to think of the planner/decision-maker as operating in an environment of several different models or processes. Some, such as FORPLAN or input-output models such as IMPLAN, will be quantitative and objective in nature, while others are qualitative and subjective.

Thus, it is useful, if not essential, to have a computer system that can provide a framework within which to address the analytical requirements of both NFMA and NEPA. There are limitations and weaknesses associated with all models, and no model is a perfect representation of reality. As a result, they must be used and interpreted with care. The bottom line is that any model is just a tool. The decision makers must use various tools and professional judgement in managing the Forest.

There is no requirement to display the value of the constraints used in the FORPLAN model. Only the purpose and effect of a constraint must be discussed. Constraint values are included in the FEIS when this helps in understanding the purpose or effect of the constraint.

Some constraints (for example, Legal Policy and Management Requirements #1 and #2) are internal to the FORPLAN model. These constraints were comprised of complex mathematical formulas and would be of value to only a few individuals. These types of constraints are documented in "FORPLAN Version 1: Mathematic Programmer's Guide," which is available for review in the Ochoco National Forest Supervisor's Office.

Benchmarks were used in the planning process to establish the maximum and minimum resource output levels. This range of output levels defined a "decision space" in which a range of alternatives addressing the ICOs was developed. Thus, it would be difficult to develop a benchmark which measured adverse impacts. Because the term "adverse impact" is somewhat subjective, the decision as to which alternative best meets this criterion would be based on individual preferences.

The basic units used in FORPLAN are referred to as analysis areas. They represent aggregations of many individual non-contiguous mapping units with identical delineators. The mapping units which make up an analysis area are considered homogeneous in terms of costs and yields (See Figure B-3-1 in the Appendix B of the FEIS). Without reference to these individual units, analysis areas, and therefore FORPLAN analyses, lose site specificity.

Appendix B describes the major Ochoco National Forest planning problems in relation to the inherent weaknesses of linear programming. A summary of the analyses undertaken to help remedy these shortcomings is included.

1300-16.2 Present Net Value

One comment expressed the concern that while Present Net Value (PNV) calculations seem to be major influences on FORPLAN outputs, they are not responsive to the ICO's. This respondent requested that the relationship of FORPLAN PNV calculations to the national concern of economic efficiency be addressed in depth. The concern was also expressed that PNV does not address the national interest of ensuring that the Forest and Grassland is managed in a financially prudent manner while the quality of the physical environment is protected and enhanced.
Response:
Economic efficiency is a major planning criteria addressed in NFMA and its implementation regulations. The major use of PNV is not the control of FORPLAN outputs, nor is it directly related to ICO’s. PNV is used 1) to ensure that scheduled activities and practices are cost effective, 2) to select the most efficient activities and practices to achieve a set of goals and objectives, and 3) as one of the decision criteria in deciding which alternative best maximizes Net Public Benefits.

Thus, PNV does not directly relate to the quality of the physical environment. Instead, Standards and Guidelines are used to protect and enhance the environment. Only if a practice was built into or left out of an alternative due to high costs or the cumulative effects of selecting cost-effective practices would PNV indirectly interfere with maintaining or enhancing the environment.

1300-16.3 Tradeoff Analysis
One comment addressed the use of tradeoffs in FORPLAN analysis. The respondent interpreted tradeoff as meaning a positive or negative change in PNV and ASQ, and objected that increases in PNV or ASQ are actually benefits, not tradeoffs. He also pointed out that a number of tradeoffs, including big game numbers, RVDS, fish numbers, riparian habitat, water quality, and soil retention, were not evaluated.

Response:
Appendix B does consider tradeoffs involving criteria besides PNV and timber outputs. Increases in PNV and ASQ are benefits, not tradeoffs. This has been clarified in the FEIS.

Appendix B analyzes the effects of major resource objectives on PNV and ASQ. It is correct that the effect of raising or lowering PNV or timber volume on other resources is not displayed in a similar fashion. These effects are disclosed in Chapters 2 and 4 and in Section 8 of Appendix B of the FEIS.

1300-16.4 FORPLAN Analysis
One comment addressed the marginal effects on “willingness to pay.” The respondent stated that the value of an output should be greater in alternatives that produce less of that output. For example, the respondent felt the value of semiprimitive, nonmotorized recreation visitor days (SPNM RVD's) should be higher in Alternative E than in Alternative C, because Alternative E produces fewer SPNM RVD's. Similarly, it was felt that the value of timber should be greater in Alternative E than in Alternative B.

Response:
The Ochoco National Forest and Crooked River National Grassland used a horizontal rather than a downward sloping demand curve in its analysis. In other words, regardless of whether the Forest offers one board foot or one million board feet of timber, or one SPNM RVD or one thousand SPNM RVD's, the value per unit of output will be the same. Economic principles do suggest that supply and demand for a given product will interact in the marketplace and influence price. However, the Ochoco National Forest is only one supplier. Therefore, the derived demand for any one product also depends on the supply of that product from other sources.

The assumption made for timber is that the demand for timber is great enough to consume any quantity that the Ochoco National Forest could offer. In addition, the Ochoco National Forest will have a minimal influence on current prices because of the mobility of logs and timber purchasers and the response of other owners to opportunities created.

The value of an output will not vary between alternatives when supply exceeds demand. This is the case with SPNM RVDs in Alternatives C and E for the first and second decades.

1300-16.5 Opportunity Costs
One comment addressed opportunity costs. The respondent pointed out that the DEIS did not explain how the opportunity costs were generated, nor did it address opportunity costs in terms of other
resource values lost for each incremental increase in PNV.

Response:
The explanation of how opportunity costs were generated has been included in Appendix B, Section 7 of the FEIS.

Appendix B displays all tradeoff comparisons and sensitivity analyses required by Regional and National direction. Opportunity cost analysis for resource values based on incremental changes was not performed.

It has been the intent of planning analysis to define resource output decision space and to identify the significant opportunity costs associated with various legal, policy and discretionary constraints imposed in the process of formulating benchmarks and alternatives. Because of the uncertainty of basic data such as production coefficients and future prices, a good deal of sensitivity analysis and trade-off analysis has been incorporated in the FEIS. The purpose of such analyses has been to provide information that can be used to explain the PNV differences between alternatives and to identify the implications of using uncertain information in decision making. Because of the time pressures involved in Plan completion schedules and the overwhelming volume of potential analysis that could be conducted, efforts have been focused on providing the public with relative opportunity cost information where major resource trade-offs occur.

PNV is dependent upon the interactions of all priced and non-priced resource outputs, not the other way around. In order for PNV to vary, one or more of the resource outputs must vary.

The Forest has examined and displayed the type of information which might address this concern in a more quantitative and objective manner. For example, Section 8 of Appendix B displays some of the key non-priced outputs along with PNV of the alternatives. It also displays the PNV and certain priced and non-priced outputs both as an absolute value and as a percent of the maximum.

@1300-17 Public Involvement

1300-17.1 Administrative Appeals System

One respondent stated that the environmentalists will be forced to use legal and other coercive methods to handle what should have been addressed in the planning process.

Response:
Within the newly revised Administrative Appeal procedures, (CFR 36-217 and CFR 36-251 February, 1989), opportunities for negotiating/mediating public concerns of line officer decisions is encouraged. In addition, the appeal procedures continue to provide a formal review of these line officer decisions. Individuals still not satisfied can seek relief through the judicial system.

1300-17.2 Administrative Appeals System

The Grant County Court expressed the feeling that anyone who has the opportunity to participate in this planning process, and does not, should not have the option of appealing and holding up the implementation of the Plan. To allow this, according to the Court, is essentially to say that the planning process is not sufficient, and negates the purpose of having a Plan in the first place.

Response:
The USDA Forest Service's Administrative Appeal procedure is a process open to all American citizens to ensure that they have an opportunity to formally contest line officer decisions. Under the revised appeal regulation (February 1989), the appeal of individuals who have not participated in the planning process or the discussion of pertinent issues will not be given the same merit in an administrative appeal as those who have participated in such processes.
1300-17.3 Public Information

Some respondents recommended that the ONF start an educational program in the schools, similar to the Smokey Bear program, to teach children that the public domain is for everyone to enjoy and that all groups must work together to keep it beautiful, productive, clean and available for all.

One reviewer felt that the Forest needs to get more people involved in the management of the forest through stewardship programs, meetings, videos and environmental education news items.

Response:
The Ochoco National Forest has sponsored several environmental education activities involving school age children. The 1988 Crook County Fair included an educational program involving twelve different organizations and agencies, entitled “Safety Town,” which was visited by over 400 children and their parents. The Forest also has coloring contests and Learning Tree instruction activities with school age children. The Forest’s Smokey Bear fire prevention program and Woodsy Owl anti-vandalism campaign are highly visible and are effective means of teaching youth to respect and appreciate our public lands.

In addition, the ONF is very interested in seeking and establishing partnerships and public involvement in management activities. In February, 1989, the Forest met with representatives from more than 20 different special interest groups and concerned citizens to seek and establish better ways to incorporate public involvement in annual project planning. The Crooked River National Grassland has been cooperatively involved with several private and governmental organizations in riparian enhancement and received national recognition in 1988 from the American Fisheries Society.

The Forest also has Adopt-A-Campground programs and on the Prineville District, a local equestrian group is contributing to the development of a horse camp. Through a cooperative effort with the Oregon Army National Guard, there are nine recreation-related projects that were be completed on the Big Summit Ranger District in mid-June 1989.

The push for cooperative funding and/or staffing of programs previously sponsored solely by governmental agencies alone is well understood by the National Forest and the Ochoco has been working very hard to promote cooperative partnerships.

1300-17.4 Public Involvement Methods

One person felt that an issue of this magnitude requires the Forest Service to actively pursue public comment by making contact not only with interest groups, but by making the entire process more visible to the people it will affect the most.

Some respondents felt that the Forest should listen to a broad spectrum of citizens, not just from those who are supporting special interest groups.

Response:
The Ochoco National Forest and Crooked River National Grassland have held over thirty meetings with the public, involving individual citizens as well as various interest groups. The Forest has a planning newsletter which was sent to about 2,600 people on the planning mailing list. (The mailing list is made up of those people who responded to the Draft Environmental Impact Statement or Draft Plan and also include those agencies and elected officials required under NEPA.) The ONF also disseminated a great deal of information with the help of the media. See the Introduction to this Appendix.

Additionally, the Forest encourages all interested individuals to participate in annual project planning activities and to get on the Forest Plan Report mailing list. The ONF does not promote any one group over another and everyone’s opinion is given thorough consideration by Forest officials.

1300-17.5 Public Involvement

One individual believed that the process the ONF is undertaking will prove in the end to be one of the best processes that have been undertaken in regard
to the stewardship of the National Forest. The respondent believed this process will for the first time actively involve the local community to a large extent.

Response:
The ONF hopes that the land management planning process will prove to be a beneficial practice as it relates to resource management and involvement of all publics.

1300-17.6 Public Comment Period

The Office of Economic Analysis felt that each Forest should circulate its alternatives for comment prior to making computer runs. The agency feels that this will allow for a cost-effective method of examining a wider range of alternatives.

Response:
Prior to development of alternatives, the Forest identified issues, concerns, and opportunities (ICO's) as defined by the public through the public involvement process. The ICO's were an integral part of the creation of the wide range of alternatives offered in the Draft Environmental Impact Statement (DEIS).

The framework for each alternative was conceptualized by the Forest Management Team (FMT) and the Interdisciplinary Team (ID Team). The computer model was built to reflect the objectives that the FMT and ID Team have established for each alternative. Throughout the entire analysis process, there was ongoing refinement of the computer model, and hence of the various alternatives. Alternatives could have been circulated for public comment prior to computer analyses, but until the analyses had been completed, the forest did not know the outputs and environmental consequences in enough detail to fully define the alternative. As a result, the Forest chose to do a more detailed analysis prior to circulation of the alternatives for public comment. After formal public review of the draft forest plan in 1986, public comments have been used to a great extent in designing the final Preferred Alternative. See summary and chronology of the Public Involvement process in the Introduction to this Appendix.

1300-17.7 Public Involvement - Local vs. Other

Some respondents felt that the community closest to the Forest being considered in the plan should be taken into consideration before those who do not live in the community.

A few felt that most of the input should come from local groups that derive a living from Forest lands, and not from the special interest groups from large metro areas.

One person felt that the Ochoco National Forest people are listening to the wrong people and don’t seem to care about what happens to the local economy.

Response:
The Forest Service realizes the importance of the National Forest and Grassland to the local economy and does not take that relationship lightly. However, the National Forest and Grassland is a National forest or Grassland and managed according to legal mandates. The Forest must consider all public comment and give thorough consideration to each person and/or group regardless of proximity to the forest or whether the person(s) or organization responding are from an urban or rural area.
Appendix I

Response to Public Comment

Section 4

Comments from Elected Officials, Agencies and Indian Tribal Governments
The Forest's major goal is to identify cultural resources in advance of timber sales and other projects and to avoid or mitigate impacts to those determined to be significant. This approach is considered necessary for compliance with the National Environmental Policy Act (NEPA) and the National Historic Preservation Act (NHPA). The content of the Plan implies that this will be the Forest's primary cultural resource activity for the next decade.

The DEIS, however, indicates that the Forest is currently exploring cultural resource planning beyond the project level. This type of planning has become increasingly useful, and we recommend that it be incorporated in the Plan as an equally important goal. This is because of the growing management problems associated with project-by-project identification and avoidance of cultural resources. The placement of the Forest's resources in broader planning contexts will eventually allow more critical appraisals of resource significance and investigation/protection needs.

NEPA, NHPA, and attendant regulations state that Federal agencies have an affirmative responsibility to protect and enhance cultural resources within their jurisdiction. This responsibility can best be served through comprehensive planning at both Forest and State levels. We encourage the use of overview, predictive models, and sampling to identify cultural resource topics relevant to Ochoco National Forest and logical environmental areas that require survey beyond the project level. The use of these methods coordinated with the State Historic Preservation Officer's (SHPO) statewide goals and priorities will result in the contexts necessary for evaluating the Forest's cultural resources and planning their long-range treatment.

For each Management and Wilderness Area, the Plan should discuss affirmatively what will or will not be done to identify, evaluate, protect, and interpret cultural resources. For most of these areas, cultural resources are not mentioned. It should also explain the basis of the following statements made in reference to several of the areas: "Do not enhance or interpret cultural resources," "Avoid enhancing and interpreting cultural resources."

Wild and Scenic Rivers

No units of the National Park System will be adversely affected by the proposed action. However, the National Park Service has certain responsibilities for Wild and Scenic Rivers and is the Custodian of the Nationwide Rivers Inventory, which was conducted under the authority of the Wild and Scenic Rivers Act.

The proposed plan states that segments of the Deschutes, North Fork Crooked, and mainstem Crooked Rivers which have been "inventoried suitable for classification as scenic or recreational rivers will be protected until Congress resolves their status." We suggest that you recommend, in the final EIS and Plan, designation of the rivers found suitable for inclusion in the Wild and Scenic River system. Until such time as Congress acts on the recommendation, we concur with your proposal to establish special management provisions for these rivers to preserve their eligibility and suitability for designation.

Mineral Resources

A mineral potential map is needed. It should be at the same scale as the alternative maps for direct comparison with the alternatives. The Okanogan National Forest
PLRMP/DEIS contains a good example. Illustrations and a more detailed discussion of mineral potential for each of the roadless areas in the appendices are needed.

A discussion is needed in the DEIS of how minerals are affected by each of the alternatives. The DEIS from the Wenatchee National Forest, Washington, provides a good example of point-counterpoint discussion of how minerals affect other resources and how decisions affecting other resources will, in turn, affect minerals.

A narrative section on minerals, containing history of development and mineral production, value of past production, projected mineral demand and current operations in locatable, leaseable, and salable minerals is needed. The Beaverhead National Forest PLRMP/DEIS has one of the best examples.

A list of current mineral withdrawals, areas involved, and mineral potential for locatable and leaseable would be useful. The best example is in the PLRMP/DEIS for the Los Padres National Forest, California.

The meaning of existing access for locatable minerals should be clarified. It should be noted that although an area may have many access restrictions because of a lack of roads, rough terrain, etc., a claimant does have the statutory right to develop reasonable and good access to claims if necessary. Recent court cases have demonstrated that excessive restrictions on access to mining claims may constitute unlawful taking of private property, the mining claim, without just compensation.

The documents acknowledge that the continuing emphasis on protection of other resource and amenity values can place increased restrictions on mineral exploration and development. However, it would be helpful to also point out the responsibilities of the Forest Service to accommodate mineral development on lands open to mineral development in order to comply with Federal mining laws.

Water Resources

The statement should address the range of yields from the water wells and estimate the usage of ground water on the Forest. The current quality of ground water should be addressed. The Plan indicates that at tee campgrounds drinking water quality is to be monitored. The statement and plan should also indicate monitoring plans for other ground-water sources of drinking water made available to visitors and staff on the Forest and Grasslands. Effects of changes under the Plan, such as increased visitation, should be discussed in terms of potential impacts resulting from disposal of solid waste generated within the Forest.

Hazards

This area has been repeatedly subjected to the effects of volcanism, both tephra falls and flows. Landslides, both volcanically induced and otherwise, do occur in this region. These potential hazards should be evaluated.

Coordination with other Federal Agencies

While the plan and EIS reflect coordination in some programs, provision for additional coordination with the Bureau of Land Management (BLM) regarding utility corridors and timber/firewood sales should be made.

It does not appear that the proposed land use plan addresses utility corridors as required by Sec. 503 of the Federal Land Policy and Management Act of 1976. Planned and existing corridors identified by the Western Regional Corridor Study (May 1980) are not addressed in the Plan, nor are maps provided. The Ochoco National Forest should coordinate utility corridors with the BLM since utility lines, etc., pass through both jurisdictions. An update to the Corridor Study is expected to be issued by the Western Utility Group in early 1987.

Discussion in the Plan of firewood and timber sales coordinated between USFS and BLM would assist the public's understanding of land use interrelationships. More effective combined sales could be accomplished and cumulative effects better analyzed for the public.

SPECIFIC COMMENTS

DEIS
Page 73, Vegetation: The discussion of "sensitive" plants fails to use the categories for Federal listing. The Oregon Natural Heritage Data Base categories are not necessarily comparable. This section should reflect the Federal status in addition to that listed in the March 1985 Data Base.

Species 3-5  Allium mediun, A. pleianthus, A. tolmei platyphyllum are "limited in abundance," thus are category 3 in the 1985 report.
Species 10: Calochortus longipalatus peckii is Federal Candidate 2 (Federal Register September 27, 1985).
Species 11: Calochortus macrocarpus is Federal Candidate 2 (Federal Register September 27, 1985).

The BLM's Prineville District Office lists several other threatened and endangered T&EE/sensitive plant species on public lands. We urge coordination with Burns and Prineville District Office botanists regarding inventory of species which may also be present on the adjacent Ochoco National Forest.

Reference is made to the possible need for monitoring category 4 plants. Monitoring T&EE/sensitive plant species did not appear to be directly referenced in the plan.

Page 79, Cultural Resources: The DEIS should explain the past, current, and planned treatment of "lithic scatter" sites, a class of resource that has been determined eligible for the National Register of Historic Places.

Page 83, Minerals and Energy Resources: The Bureau of Mines has suggested a modification of Table 11-17, using percentages rather than acreages. This may make it easier to envision the comparison and comprehend the effects each alternative may have on mineral resources. Sample tables have been provided to the Forest under separate cover.

Page 107-111, Riparian (Fishes): Described mitigation measures tend to emphasize expensive, structural techniques. Consideration or inclusion of more preventive, careful, and minimal road construction, location criteria for roads, etc., is suggested.
Plans for management actions near streams should consider the effects on fisheries, water quality, etc., rather than stream class designations alone. In Eastern Oregon, Class III streams are often used by fish during part of the year for spawning. This is especially true for anadromous fish (steelhead in particular) in the John Day watershed. Class IV streams can have an indirect affect on fisheries of streams to which they are tributaries.

Page 161, Cultural Resources Assumptions and Interactions The PLRMP and the DEIS differ in regard to the Forest's proposed use of its identified sites. The DEIS states that "the expansion of recreation facilities would serve "a concomitant increase in cultural resource inventories" and "an inceased or opportunities to enhance and interpret significant cultural resource sites for public education and enjoyment." In all but one instance, however, the Plan specifically excludes Management Areas from opportunities to enhance and interpret sites for the public benefit. This apparent conflict is not resolved.

Page 165, Cultural Resources, Transportation This section should address the indirect negative impacts of improving access in areas, especially those previously for from roads. These effects on cultural resources, in the form of artifact collecting, vandalism (looting) and inadvertent damage, are not limited strictly to recreational use of the forest. The Forest's plan to survey linear historic or ethnologic features in their entirety should prove increasingly useful for planning purposes as projects intersect them in the future.

Page 152, Assumptions and Interactions The definition of withdrawals needs to be reviewed. Staking of new claims and establishment of new leases may be prohibited depending upon the individual withdrawal. Development of leases and claims established prior to the date of withdrawal is not necessarily prohibited, depending on the type and specifics of the individual withdrawal.

Page 178, Irreversible or Irretrievable Commitment of Resources We agree with the statement that "continued avoidance of cultural resources poses a threat to undermine efforts to acquire data which would expedite future site evaluations." However, we do not agree that data recovery should be the exclusive, or even primary method, to generate data for the management of the Forest's cultural resources. Whenever data recovery is conducted on sites, the opportunities for doing such work in the future, with improved technology, are precluded. The evaluation phase prior to data recovery can be most efficiently and economically served by intensifying field efforts to properly identify the character of each site discovered during survey and by establishing Forest-wide, regional, and/or State-wide historic (or prehistoric) contexts for comparative purposes.

Proposed Land and Resource Management Plan (PLRMP)

Page 13, Vegetation Cross-referencing to the DEIS, page 73, discussion of sensitive plants would assist the reviewer.

Page 21, Desired Future Conditions of the Forest and Grassland. The Plan should make it clear that the development of new research questions and methods will, in most cases, not be a consequence of project level identification and avoidance activities. This will come largely through broad-based planning studies, non-project survey, and data recovery projects.

Page 43, Research Natural Areas It would be helpful to include a description of the features of these RNAs proposed for designation. We also suggest that a discussion on management objectives, constraints, and other management-related information be included for each RNA. A reference to both Appendix E (Appendix Volume) and Appendix E-1 (PLRMP volume) would also assist the reviewer.

Silver Creek Research Natural Area is a name already used by BLM. We suggest communication with the Burns BLM District Office to see if RNA cell needs have already been met by BLM.

Page 45, Cultural Resources. The basic character of the Inventory Plan needs to be explained. This should be more a schedule of surveys done in connection with timber sales, etc. The Inventory Plan represents an opportunity for the Forest to consult with the SHPO and implement field investigations and studies that are based on and/or will result in broader planning contexts. This approach is recommended so that the Forest can better understand the significance of its numerous cultural resources and be more selective about funding their protection and management.

Page 46, Ecosystem Management. It is unclear whether threatened and endangered plant species are included in monitoring activities under item 12. Table V-2 apparently combines both plant and animal species, making it difficult for the reviewer to differentiate possible plans to monitor T&Esensitive plants.

Page 44 and App. D-1&2 Item 7. This statement implies that the applicable Native American group will only be contacted if it reiterates in-place is not possible. The issue would be more in line with Oregon State Law and the American Indian Religious Freedom Act if a statement was followed "... The Native Americans should be contacted in any case dealing with a prehistoric burial or cremation. Notification of the Oregon State Historic Preservation Officer and the Oregon Commission on Indian Services is appropriate action.

Page 49, Mining Claims. The sentence concerning approval of mining activities states "Approval will be given when the Forest's concerns are mitigated in a responsible and responsive manner." To clarify this section, the text could reflect that Federal law gives claimants the statutory right to develop their mining claims.

Explaining what the words "responsible" and "responsive" mean would also be helpful. These words, and phrases such as "as much as possible," found throughout the mineral discussions, lack clarity.

Page 56, Threatened, Endangered and Sensitive (Plant) Species

Items 1-2. It would seem that field examinations would be important especially where no sensitive species are shown by existing data, the absence of data may be due to an area never having been inventoried. Also, periodic reinventory may be necessary since new sensitive species are continuously being added to lists.

Item 7. Rare Plant Survey forms are available from the Oregon Natural Heritage Data Base. The Data Base is the "central file" for all threatened and endangered plant and animal species information in Oregon and would be a depository for this information. Also, information exchange with other Federal agencies in the Forests' ecological province would be valuable. E.g., BLM has an active T&E plant program in the Prineville and Burns District Offices.

Page 84, Minerals Locatable. While all reasonable and practicable measures will be
token to prevent undue and unnecessary degradation of the wilderness values, the rights accorded holders of valid unpatented mining claims should be recognized in this discussion.

Appendix C-1, Page C-3. Under the paragraph heading "Cutting of Excess Numbers within the Original Territories" the document indicates "... mature horses will probably never develop into gentle saddle horses." We suggest this statement be revised as follows: "Any person interested in acquiring a mature wild horse should realize that some of these animals may never develop into a gentle saddle horse."

Appendix C-1, Page C-5. Public Law 92-195, as amended, (commonly called the Wild Free-Roaming Horse and Burro Act of 1971) permits the humane use of motor vehicles and aircraft by authorized officers, except that no motorized vehicle other than a helicopter can be used for pursuing and gathering.

Appendix J, Page J-1. This appendix contains a brief list of 13 sites representing "the more significant cultural resources on the Forest and Grassland". This document would be more useful if it summarized the various classes of prehistoric and historic resources recorded within the Forest; discussed which are considered important in relation to recent research; explained the evaluation process used when such resources are identified; listed how many of the 1,700 sites, structures or classes have been determined eligible for the National Register in consultation with the SHPO, and specified how significant sites are being and will be protected.

APPENDICES

Since several appendices duplicate sections of the PLRMP, comments made on the PLRMP are also relevant in the corresponding appendix.

MAPS

Management Area No. 11 is not detectable on the Alternative maps. While existing Forest recreation sites are shown (as part of the base map legend), proposed sites are not, thus the impact of management on future recreation sites cannot be visualized. Both existing and planned sites could be shown by use of symbols on the 1/2 inch = 1 mile maps. Figure IV-4 (page 66 in the PLRMP) does not show Management Area No. 11 either, probably due to the scale.

Thank you for the opportunity to comment on your Proposed Plan and Draft EIS

Sincerely,

Charles S. Polityko
Regional Environmental Officer

United States Department of the Interior
OFFICE OF THE SECRETARY

Dave Rittersbacher, Forest Supervisor
U.S. Department of Agriculture
Forest Service
Ochoco National Forest, P.O. Box 480
Prineville, Oregon 97754

Dear Mr. Rittersbacher:

This is in regard to your transmittal of September 11, 1986, requesting the Department of the Interior's review and comments on the draft environmental statement and proposed land and resource management plan concerning the Ochoco National Forest and Crooked River National Grassland, Oregon.

This is to inform you that the Department will have comments but will be unable to reply within the allotted time as we have just received your transmittal. Please consider this letter as a request for an extension of time in which to comment on the statement.

Our comments should be available about January 19, 1987.

Sincerely yours,

Bruce Blandine, Director
Environmental Project Review
Mr. David Rittersbacher  
Forest Supervisor  
Ochoco National Forest  
P.O. Box 490  
Prinevile, Oregon 97754  

Dear Mr. Rittersbacher,

SUBJECT: DRAFT ENVIRONMENTAL IMPACT STATEMENT (DEIS) AND PROPOSED LAND AND RESOURCE MANAGEMENT PLAN FOR THE OCHOCO NATIONAL FOREST AND CROOKED RIVER NATIONAL GRASSLAND, OREGON (1980 LNP)

The DEIS and Proposed Land and Resource Management Plan have been reviewed by this office and are found to have the following deficiencies:

1. The report needs a mineral potential map. It should be at the same scale as the alternative maps for direct comparison with the alternatives. The Okanogan National Forest in Washington is a good example.

2. It needs illustrations and a more detailed discussion of mineral potential for each of the roadless areas in the appendices.

3. It needs a discussion to go along with table IV-20 of how minerals are affected by each of the alternatives, and a section in the summary that compares how minerals fare by all of the alternatives.

4. It needs a point-counterpoint discussion of how minerals affect other resources and how decisions affecting other resources will, in turn, affect minerals. The best example to date is the DEIS from the Wenatchee National Forest, Washington.

5. It needs a narrative section on minerals, containing history of development and mineral production, value of past production, projected mineral demand, and current operations in locatable, leasable, and salable minerals. The Beaverhead National Forest is one of the best examples.

6. It also needs a list of current mineral withdrawals, acres involved, and mineral potential for locatable and leasable. The best example is the Los Padres National Forest, California.

We have reviewed most of the forest plans of the far western United States and have noted certain methods of presentation that are improvements over other forest plans. The following are offered as suggestions for improvement.

1. We suggest a modification of table III-17, as shown on enclosure 1, using percentages rather than acreages. We feel it is easier to envision the comparison and comprehend the effects each alternative may have on mineral resources.

The potential classification consists of five parts, with a range from high potential to very low potential based on current knowledge. The availability classification consists of four categories, including withdrawn, specific legal protection measures, special management conditions, and standard operating conditions.

2. Expand your Evaluation Criteria for Nonenergy Minerals such as that from the Wallowa Whiteman National Forest, Oregon (enclosure 2).

3. Provide a definition of access restriction categories such as that from the Beaverhead National Forest, Montana (enclosure 3).

Overall, the documents are quite good, with most minerals issues being treated well with respect to their abundance on the forest. We sincerely hope you incorporate our suggestions in your final EIS and modify the documents accordingly.

Sincerely,

Re: Mr. Dave Rittersbacher
Forest Supervisor
Ochoco National Forest
P.O. Box 450
Prineville, OR 97754

BPA has reviewed the Proposed Land and Resource Management Plan and Draft Environmental Impact Statement (EIS) for the Ochoco National Forest and Crooked River National Grassland. We offer the following comments for your consideration:

1. Of particular importance to BPA is the designation of both existing and planned transportation and utility corridors. Although no corridors on the EIS and Plan maps listed as "designated," nor there any mention of corridors designations in the text. Designation of corridors should help avoid a proliferation of rights-of-way and should facilitate the timely and orderly development of future utility projects. Therefore, we request that you add this information to both documents.

2. To assist you in identifying corridors, we have enclosed a marked-up Proposed Alternative (Alternative E) Map illustrating existing BPA transmission grid lines as well as Central Electric Coop and Pacific Power & Light Co. (PPL) lines. These lines should be shown on the other alternative maps also. Most of these transmission lines were not shown on the Land Adjustment Map in Appendix B. BPA has no new projects in its current 10-Year Plan that would affect your Management Plan. You might want to contact utilities in your area for information on their plans or concerns.

3. It is difficult to identify in the Plan and EIS which management areas are considered "avoidance" or "exclusion" areas for energy transmission corridors. It would be desirable to have this information summarized in one section of the documents.

4. We recommend that the Plan and EIS address renewable energy resources such as wind, hydropower, geothermal, small hydroelectric, or biomass. You could identify the type and amount of potential resources and the conflicts that may be associated with resource development. BPA has information available on Northwest energy resources, which we could provide to you.

Enclosure 3

1-4-7
5. The proposed alternative does not appear to have any adverse impacts on existing or planned transmission projects, therefore, we find it satisfactory from the corridor planning standpoint.

If you should have any questions on these comments or need more detailed information on planned and existing transmission corridors, please contact John Booson, of the Division of Land Resources, Office of Engineering and Construction, at 230-3299 (FTS 429-3299).

Thank you for the opportunity to participate in the scoping process.

Sincerely,

[Signature]

Anthony J. Morrell
Environmental Manager

Enclosure

Proposed Alternatives Map
The intent of our comments is to be constructive. We are confident that by addressing our concerns and comments the ONF can present a Final EIS and Plan which clearly shows that important resources will be adequately protected while providing ONF personnel with the necessary flexibility to manage day to day activities on the ground.

Thank you for the opportunity to review this DEIS and Plan. If you have any questions about our review, please contact Ann Uhrich of our EIS and Energy Review Section at (FTS) 399-8512.

Sincerely,

Robert S. Burd
Director, Water Division

6 Repairing damage caused by adverse effects that exceeded predictions
7 Upgrading BMPs or prescriptions to correct inaccurate predictions

The DEIS and Plan did a good job of describing the available data base and best management practices (BMPs). In general, the monitoring and evaluation program plan appears to be adequate for the various actions and effects to be monitored, though it would be improved by expanded discussion in the text (versus the condensed format of Table V-2) Selection of BMPs, on-site inspection, repairing damage, and upgrading BMPs have weaker commitments and are not clearly described.

The most important component that is missing is a good description of how these elements are related and dependent on each other. It would also be well to stress the iterative nature of the forest management planning process, in that information from the on-site inspections and monitoring can flow up to the management level to be used not only to modify management practice, but also to assist in the development of the forest's multi-year budget proposals. In an attempt to help circumvent implementation problems due solely to inadequate funding as opposed to technical difficulties.

Water Quality and Monitoring

The DEIS notes that Increased grazing (p 131) and exceeded threshold levels on individual watersheds (p 133) could each have negative impacts to water quality under the preferred alternative, but that these impacts "should be offset by the fairly high level of mitigation proposed." The DEIS then very aptly makes the statement that "this points to the need to develop and administer an effective monitoring plan to assure that minimum management requirements are met and that an effective level of mitigation is undertaken" (p 133). With this in mind, we believe the discussion of water quality monitoring and evaluation in the Plan (p 106) should be expanded. For example, when and how would projects be selected to receive monitoring and mitigation? Also, monitoring helps assure standards and guidelines are met, not just minimum management requirements.

The adequacy of the monitoring plan to assess environmental impacts, and methods to ensure that the assessments are used in management decisions, are key factors in EPA's ability to evaluate the adequacy of Forest Plans and EISs. The monitoring plan together with the standards and guidelines should serve to highlight how the Plan will be implemented. The Final Plan should clearly outline how monitoring will be carried out such that mid-course corrections can be made in forest management. This serves as a system of accountability, reduces anxiety for any uncertainties in predicting Plan impacts, and makes it clear to the public how the plan will be implemented. As the uncertainty in being able to protect against water quality and fish habitat effects increases, a higher level of monitoring becomes necessary.

Domestic and Irrigation Water Supplies

According to discussions with the ONF planning staff, only one instance of domestic use of surface water (actually, spring water) occurs on the National Forest. To ensure that any current and future drinking water supplies are protected, information on the existing source should be included in the Final EIS, including location, size, source, and municipality or number of people served. Statements as to the lack of any other public supply watersheds should also be made. Also, any instances of waterborne disease occurrences should be summarized, as should any pertinent water quality monitoring information (e.g., for turbidity and fecal coliform levels).

Other questions relative to the domestic source are as follows. Is the existing source in a highly sensitive watershed? What management areas activities are planned for that watershed? Sensitive areas may be defined by such factors as the physical features of the watershed, the number of water users in the watershed, the type of water treatment employed, the location of water intakes, and past history of water quality problems. The DEIS nicely identifies watershed sensitivity (p 75), but does not relate this to the existing public source. This should be done even if the agreement with the users is of a verbal nature. There may also be effects on ground-water supplies across the ONF and DRW. The potential impact of the proposed Plan on drinking water aquifers should be addressed.

Fisheries/Fish Habitat

Chapter III of the DEIS provides a very good overview of existing knowledge of the status of fish habitat and fish populations on the ONF by drainage. However, since riparian areas and fishery impacts are discussed together in Chapter IV, it would be helpful if one more column was added to Table III-13, to be called "present riparian condition." Appendix A-4 in the Plan identifies one of these drainages as being in "poor" condition (Bear Creek), but the condition of the other drainages in Table III-13 is not identified. The condition of all the drainage should be included in the Final EIS.

Chapter IV of the DEIS presents a good description of the impacts to riparian areas and to fish habitat resulting from the various alternatives (pp 107-111), but the heading for the section is simply "Riparian." It should either be "Riparian and Fish Habitat," or perhaps "Fish Habitat" should be the title separately in its own section. The latter would probably be most appropriate since fish habitat is not solely a function of riparian condition, but is also closely tied to water quality (and water quality is a function of timber management, grazing management, ORV use, sanitary facility management at recreational facilities, and mining management as well as riparian area condition).

We agree with emphasis being placed on undertaking fish habitat/riparian improvement projects. It should also be emphasized that fish habitat improvement work, while important and potentially very successful, does not take the place of avoiding impacts to the greatest extent practicable from the beginning.
It is unclear how land was allotted to management areas 13 and 14 (riparian areas). Since they are not mapped, they should be described in the text, at least in terms of the distance from each stream type, etc.

We are pleased that the DEIS considered not only presently utilized fish habitat on the ONF, but also included potential fish habitat of the 200 miles of streams that have potential for additional cold water fisheries, how many miles are part of the John Day or Deschutes River drainages (and therefore potential habitat for anadromous fish). Also, if Bear Creek presently supports anadromous fish, would it not follow that the Crooked River drainage (which includes Bear Creek) is also of importance to anadromous fish (though admittedly perhaps not as great as the other two major drainages)?

Four of the streams listed in Table III-13 of the DEIS (Badger, Cottonwood, Black Canyon, and Wind Creek) are not listed in Appendix A-4 of the Plan, which lists streams with riparian areas to be maintained or enhanced for fish production. Are they sub-drainages of streams listed in Appendix A-4 or were they inadvertently omitted?

We note that alternative C has the greatest potential for increasing habitat capability for rainbow trout and steelhead (p 108). The preferred alternative, E-Departure, would also increase capability, but not nearly as much as alternative C. While it is realized that alternative C primarily attains its level of habitat capability goals by reduction in harvest level and livestock grazing (DEIS, p 135), other differences between the two alternatives appear to mainly relate to the number of improvement projects, which can be summarized as follows:

<table>
<thead>
<tr>
<th>Alternative</th>
<th>E-Departure</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fencing</td>
<td>300 ac</td>
<td>500 ac</td>
</tr>
<tr>
<td>Beaver Transplants</td>
<td>50</td>
<td>100</td>
</tr>
<tr>
<td>Rock Structures</td>
<td>50</td>
<td>100</td>
</tr>
<tr>
<td>Woody Material</td>
<td>300</td>
<td>500</td>
</tr>
<tr>
<td>Log Hels</td>
<td>300</td>
<td>500</td>
</tr>
<tr>
<td></td>
<td>1,000 ac</td>
<td>1,700 ac</td>
</tr>
</tbody>
</table>

Since K-V funds increase as timber harvesting increases, we would anticipate that more funds would be available under the preferred alternative for habitat improvement than under alternative C. It is therefore surprising that the amount of improvement work proposed under E-Departure is substantially less than for alternative C.

Grazing

The ONF and CRNG provide a significant amount of livestock grazing in the Pacific Northwest Region. It is not surprising, then, that certain range management problems exist. Several specific allotments are identified where obligated AUM's exceed the estimated carrying capacity (Plan, Appendix F) and impacts due to overgrazing, particularly in riparian areas, are discussed in the DEIS (e.g., p 107, 123, 130). Though damage to soil, vegetation, and water quality is mentioned as occurring, specific problem areas are not identified. Of the drainages listed in Appendix A-4 of the Plan, it can be inferred that most of those are degraded because of grazing related rather than timber related impacts. Adverse impacts related to grazing would therefore seem to be rather widespread.

The Final EIS should identify the areas where grazing related water quality or other riparian area problems exist. A table which combines the data presented in Appendix A-4 with those of Table III-13 (DEIS, p 73) would then nicely suffice as a summary of how the anadromous fish habitat would be maintained or improved.

In general, domestic water supply watersheds and anadromous fish habitat should be managed for particularly high levels of protection. Where it is determined that impacts to these beneficial uses have occurred or would be unavoidable, serious consideration should be given to major as an incompatible use and livestock should be excluded. The ONF is to be commended for recognizing and incorporating this fact via plans for fencing, as described in Riparian Enhancement (DEIS, p 150). The U.S. Bureau of Land Management (BLM) conducted a fencing study along Camp Creek (tributary to the Crooked River) which was highly successful (1). No doubt such a strategy could be successful on the ONF and CRNG as well.

Riparian Area Management

The importance of riparian zones to water quality and fish and wildlife habitat quality greatly exceeds the actual area occupied by riparian vegetation. Any evaluation of the cost effectiveness of timber harvesting or grazing in these areas should reflect this fact. It is essential to carefully explain how activities such as timber harvesting and livestock grazing can be made compatible with other riparian area resource values (e.g., protecting and enhancing water quality and fish habitat potential), keeping in mind that it may not be possible to replace these other resource values elsewhere on the Forest.

It was gratifying to see Riparian Area management standards separately presented in the Plan. It is also commendable that those drainages listed as sensitive are those ones to be maintained or improved to "excellent" riparian conditions. However, the implication that fair to excellent riparian conditions will automatically result in good small habitat and/or streams meeting state water quality criteria (DEIS, p. 93, App A, p. 30) are assumptions that will need to be confirmed via the planned monitoring program. Hence, we believe the discussion of riparian monitoring and evaluation in the Plan (pp. 105-106) should be expanded. For example when and how would drainages be selected to receive monitoring?

It is apparent that several drainages need to be improved such that they could even meet MNRs. Will this effort be undertaken first and then implementation of prescriptions 13 and 14? If so, this should be stated in the Plan. Also, as proposed, timber harvest and grazing would be allowed in essentially all riparian areas as long as Standards and Guidelines (and prescriptions 13 and 14) were met. We would submit that this, again, points to the need for monitoring and mitigation programs that are built into the budget process for the forest. For example, the Plan states that additional water developments would be constructed "where analysis shows these developments to be cost efficient" (p. 67). Since additional water developments may very well be critical to the success of riparian prescriptions (p. 94), we propose that serious consideration should be given to funding such developments from this standpoint.

Minerals

It is well to state in the standards and guidelines that management or operating plans will be developed for each area where a mineral source is to be developed, and list the items to be covered in such plans (Plan, p. 49). However, for locatable minerals we believe the Plan should include water quality monitoring requirements for sites with the potential to affect water quality and beneficial uses. Water quality monitoring data may be needed to ensure compliance with the minerals management plan.

The ground-disturbing potential of energy development or mining activities is discussed under cultural resources (DEIS, p. 145), but not under mineral exploration (DEIS, pp. 152-154). This potential and subsequent potential environmental impacts on water quality, as well as cultural resources, should be discussed under mineral exploration, not simply how other activities could impede such exploration.

Air Quality

Approximately 13,100 cords of firewood are projected to be taken for personal use from the ONF each year over the first decade. There has been a 233% increase in firewood permits issued by the Forest and Grassland from 1971 to 1981. The DEIS correctly identifies indirect effects on water quality in local urban communities via the firewood provided by the ONF and CRMG. However, it is not stated that there are potential health effects.

Forest land managers that provide firewood have a unique opportunity to educate the public regarding firewood use and air pollution through the permit process. Pamphlets discussing the association between wood stoves, air pollution, and health concerns, or providing tips on efficient wood stove operation, for example, could be distributed with firewood permits. If appropriate literature is not readily available, we would be happy to provide examples that are being used elsewhere.

The Plan should provide more guidance on minimizing air quality impacts from slash burning (p. 43). How does the ONF propose to meet the Oregon SIP (e.g., regulating timing and amount of slash burning, etc.)? The Plan should describe the measures to be used to assure that peak air quality impact episodes will be kept to a minimum, as well as those to be used to assure that average annual emissions do not exceed standards.

Cumulative Impacts

We have discussed the use of "area analyses" with other national forests and generally support their use. It appears that much of the detailed analysis we believe to be necessary, but which the Forest Plan does not provide and can be missed by individual project evaluations, could be performed at this level of study. Area analyses would be the most appropriate vehicles for evaluating the cumulative effects of many similar activities, and the combined effects of different types of activities, occurring in a fairly large area and over a period of time.

Because detailed and specific analyses of cumulative impacts is extremely important, the Final Plan should discuss in some detail the process for assessing these effects. For example, for how large an area (2nd order drainages?) would such analyses be performed? What period of time between projects would be considered? Would all activities producing sediment in the area be included (e.g., timber harvest, plus roads, mines, grazing, etc)? How will multiple ownership drainages fit into these analyses? Will documents be prepared and available for public review and comment?

We believe that an area analysis would be appropriate for all watersheds in which development is planned near important aquatic resources. We further believe that such analyses should generally receive public review as Draft EAs or EISs, depending upon the source conflict potential of the projects.

SPECIFIC COMMENTS ON DEIS

XVII Table S-4 Management Area numbers were omitted from column one.

XI A short description of how these directives were incorporated would be helpful (e.g., are they part of MNRs or Standards and Guidelines?).

XIII Are there any ongoing activities on the ONF or CRMG which involve toxic and hazardous materials? If so or if not, this should be mentioned.
As "short-term" and "long-term" are defined in the glossary, increases in road densities could create impacts in a period of time much shorter than "short-term."

Since the Plan covers essentially the next 15 years, we would suggest that this be the time period for "long-term effects" and that a shorter period, say 5 years, be the time period for "short-term effects." In the glossary (p 203 & 210). There are many environmental effects, water quality among them, for which 15 years would be considered long-term.

Which streams have fallen below state water quality standards? For which stream segments, and for what parameters?

The riparian acreage in alternative D totals 19,400 acres. Is this correct? We understood 19,000 acres to be the maximum total.

The riparian area in alternative E totals 20,500 acres. Is this correct?

Can we assume that stream condition categories "fair" through "excellent" meet state water quality standards, but that "poor" does not?

It is our understanding that there are 24 major watersheds on the NF and CRNG, 22 on the forest and 2 on the grassland. Is this correct?

Two watersheds are apparently missing from Table III-11. Also, since there are about 800 miles of streamside areas (p 68), essentially all of the streams would appear to be potentially suitable for trout. Is this correct?

Cottonwood, Black Canyon, and Wind Creek drainages are not mapped on p 74. Are they part of larger drainages? If so, which ones?

Of the 800 mining claims currently located on the forest, how many are placer mines? Drift claims?

The text mentions six roadless areas, but the figure (p 88) shows eight. Which is correct?

In Table III-25, line IV appears to be in error. Should it not be as follows: 575,375 - (231,072 + 23,551-12,425) = 533,177.

Acreages for wilderness areas listed here do not agree with those on p 4 of the DEIS, nor with numbers presented in the Plan.

Column 2, paragraph 3, last sentence. This sentence seems to have lost part of its meaning.

It is our understanding that, as of this writing, the state of Oregon has not completed revising its existing SIP for managing air quality. The text implies there is currently no such plan.
In prioritizing the development of forest level plans, we would encourage making the Allotment Management Plan one of the first (if not the first) to be prepared. This is because it will have a direct bearing on riparian areas, water quality, and the protection of beneficial uses. Also, it would seem that guidance for mineral extraction would be helpful to forest managers, perhaps in the form of a Mineral Extraction Management Plan.

The acreages cited here for wilderness areas do not coincide with those cited in the DEIS on page 24. Which is correct?

Under Current Situation/Resources there is no discussion of soils. This should be added.

How will research needs be prioritized? How will they be funded? For example, given that state water quality standards are not now met by certain streams on the ONF and CRNG, we believe the riparian area research needs cited here to be of utmost importance. What assurances are there that they will be carried out in a timely manner?

It is stated that livestock will have less impact on riparian areas and will be better distributed, due in large part to water developments. However, in management prescription #1 (pg 67) it is stated that water developments would be constructed “where project level analysis shows these developments to be cost efficient.” If not found to be cost efficient, do we assume that impact to riparian areas could continue? This is confusing.

Is there a commitment to improving a certain number of acres per year in riparian areas? To realize the goal of 7,500 acres of improvement by the year 2000 will require timely implementation of enhancement projects and management strategies under prescriptions #13 and #14.

The items listed under a minerals management plan are good, but the Forest Service role in monitoring and enforcement of the operating plan requirements should be described, particularly with regard to water quality. Also, a general description of the process under which operating plans would be approved or disapproved in sensitive areas would help to strengthen this portion of the Plan.

The riparian discussion should refer the reader to appendices A-1 and A-4.

MANAGEMENT AREA PRESCRIPTIONS

The total acreage of management areas #13 and #14, as given here, is 15,805 acres. This does not coincide with the 19,000 acre figure given throughout the rest of the Plan and the DEIS for total riparian area. Why? Also, it is stated that these prescriptions will apply to designated watersheds. This implies that some watersheds would not be designated and would therefore lack specific protection under these prescriptions. Would the remaining acres simply be covered by the other standards and guidelines? If not mapped, these areas should at least be described as to which drainages they occur in.

How would ORV use be “discouraged”?

“Water Management” practices should refer to the monitoring plan so as to describe how goals would be attained.

MONITORING PLAN

This is a nice summary of such a plan, however, further detail should be provided, particularly on aspects of the plan which pertain to meeting federally or state mandated standards or regulations, such that reviewers can ascertain that correct parameters will be monitored at the correct times.

The reporting period for habitat condition monitoring of wildlife and anadromous fish would need to be more frequent than every 5 years if individual projects are to be revised before significant damage has occurred.

A similar argument as the one above can be made for riparian areas.

A portion of the title of Table V-3 seems to be missing.

This table does not address future maintenance or improvement of the following anadromous fish drainages: Badger, Cottonwood, Black Canyon, and Wind Creek. Why not?

Is it the case that there are 22 major watersheds on the Forest and that 20 of these are forested? Are the other two watersheds in range?

UHRICH "Merc*$254E"
January 16, 1987

Dear Mr. Rittersbacher,

This is in reply to your agency’s letter of October 2, 1986 which was received on October 8, 1986, requesting formal consultation with the Fish and Wildlife Service (the Service) as described and required by Section 7(a) of the Endangered Species Act of 1973, 16 U.S.C. 1531 et seq. (the Act). This consultation addresses the possible effects of selecting Alternative E-Departure of the Draft Environmental Impact Statement (DEIS), Proposed Land and Resource Management Plan (Forest Plan), and Appendices. The subsequent impacts of this proposal to the bald eagle (Haliaeetus leucocephalus), federally classified as threatened in Oregon and peregrine falcon (Falco peregrinus anatum), federally classified as endangered within the State of Oregon, are discussed herein.

Candidate species are not subject to the provisions of Section 7 of the Endangered Species Act. Therefore, the determination of jeopardy or non-jeopardy to candidate species will not be addressed in this Biological Opinion. However, candidate species will be discussed since they occur or may occur on Ochoco National Forest and Crooked River National Grasslands and may be affected by Forest actions.

On January 16, 1987, we completed our endangered species review of the proposed project. During the course of our review other individuals were contacted who had special knowledge or expertise concerning the proposed project, project area, or threatened and endangered species in the area. These include:

Bernie Carter, Ochoco National Forest, Prineville, Oregon
Dr. Robert Anthony, Oregon State University Cooperative Wildlife Research Unit
Frank Isaacson, Oregon State University, Cooperative Wildlife Research Unit
Harlan Scott, Oregon Department of Fish and Wildlife, Prineville, Oregon
Mary Walters, Oregon Department of Fish and Wildlife, Corvallis, Oregon
Rich Howard, U.S. Fish and Wildlife Service, Boise, Idaho
Robert Parenti, U.S. Fish and Wildlife Service, Boise, Idaho

An extension was requested by the Service on December 17, 1986 and acknowledged by Ochoco National Forest on December 29, 1986. A biological assessment on bald eagle and peregrine falcon was received on October 21, 1986.

**BIOLOGICAL OPINION**

It is our Biological Opinion that implementation of the proposed Alternative E-Departure of the Ochoco National Forest and Crooked River National Grasslands Forest Plan is not likely to jeopardize the continued existence of the bald eagle and peregrine falcon. Further informal consultation will be needed and further formal consultation may be needed on project-specific actions as the Forest implements the Plan.

**DESCRIPTION OF ACTIVITY**

The proposed Forest Plan sets forth Forest-wide goals and objectives, land use allocations, management area prescriptions, standards, and guidelines, and monitoring and evaluation requirements to establish direction for management of the Ochoco National Forest over the next 50 years. The Forest Plan will be revised on a 10-year cycle. The Forest Plan is based on the preferred Alternative E-Departure.

Alternative E-Departure emphasizes a combination of timber production, roadless recreation, and wildlife habitat. Timber is scheduled as a departure from non-declining yield. Timber harvests are scheduled so that first decade volumes remain close to current levels, and then decline over the next 10 to 50 years. The departure is designed to maintain local jobs in the short term. All resources are managed or maintained at some moderate level.

**Bald eagle**

Management guidelines for the protection of bald eagle nest and roost trees occupied during the breeding season outlined in the Forest Plan (page 62) and Appendix D (page D-26) have been adopted from the Bald and Golden Eagle Protection Act.
The Forest Plan (page 61) and the Biological Assessment indicate that the preservation of actual and potential bald eagle winter roost sites is a goal. In addition, it is the expressed intent of Ochoco National Forest to utilize the findings and recommendations of the 1986-1987 bald eagle winter roost survey conducted by the Oregon Cooperative Wildlife Research Unit. Preliminary recommendations include the development of site-specific management plans for each roost site with input from the Service through Section 7 consultation (Isaacs et al., 1986). No written management plans have been prepared for any roost as of yet. However, management plans are on schedule for development in 1988-1989 (Carter, pers. comm.) where roosts have been located. Modifications to the timber harvest schedule have been made in consultation with the Service.

Regarding recovery and Recovery Plans, a general statement has been included in the Forest Plan (page 62) and Appendix D (page D-25) that recovery plans take precedence over other management direction. No other details regarding recovery plan implementation are provided in the Forest Plan.

Peregrine falcon

No management provisions have been included in the Forest Plan specifically for the peregrine falcon. Some general guidelines have been prescribed for the protection of raptor hawk and prairie falcon nesting habitat (Forest Plan, page 62-63, Appendix D, page D-29 and D-27).

Candidate species

Regarding federal candidate wildlife species, the Forest Plan (page 63) and Appendix D (page D-25) indicate that consultation with the Service will be initiated when conflicts between project activities occur, when habitat needs cannot be resolved, when uncertainty exists, when species management guides are developed or when other technical assistance is needed. In addition, inventories of essential habitats are to be maintained.

Regarding federal candidate plant species, the Forest Plan (page 56, item 1) and Appendix D (page D-18, item 1) indicate that project activities will be screened for known and suspected locations of sensitive (which include federal candidate) species. When suitable habitats or reported locations are suspected to occur, a field reconnaissance is to be performed (item 3). Item 4 indicates that safeguards will be identified, and project personnel notified and held responsible for implementation of safeguards. Item 6 indicates that if other high values or uses would be foregone if the proposed activity were modified or deferred, additional study and assessments may be needed before an appropriate course of action is determined with input from appropriate state and Federal agencies.

Bald Eagle

There are currently no known active bald eagle nesting territories within the Ochoco National Forest and Crooked River National Grassland. Historical records indicate that a bald eagle breeding territory was once associated with Big Summit Prairie.

The draft Pacific States Bald Eagle Recovery Plan indicates that Big Summit Prairie and Lake Billy Chinook may have the potential for supporting one and two bald eagle breeding territories respectively. It is likely that potential bald eagle breeding territories in these areas would involve Ochoco National Forest and Crooked River National Grassland.

A population of wintering bald eagles occurs along the upper Crooked River drainage in central Oregon. As many as 115 bald eagles have been observed during peak periods. In addition to roosts on private lands, bald eagles roost in forest lands adjacent to valley foraging areas along the Crooked River. Roost trees tend to be the largest, dominant or co-dominant conifer trees in roost stands. Coniferous roost trees are larger than the United States Department of Agriculture. Forest Service minimum old-growth specifications for ponderosa pine forest type (Isaacs et al., 1986).

The primary food source available to bald eagles in this area consists of dead cattle, road kill deer, dead calves and afterbirths, and ground squirrels (Carter, pers. comm., Isaacs et al., 1986).

Inventories and surveys were conducted in 1983, 1984 and winter of 1985-1986 to locate winter roost areas. The 1983 and 1984 inventory resulted in locating two roosts (Pine Springs Canyon, Miller Canyon) on the Snow Mountain Ranger district and one roost on Bureau of Land Management lands accessible through Forest Service roads.

A 2-year survey which began in the winter of 1985-1986 was conducted out by Ochoco National Forest to the Oregon Cooperative Wildlife Research Unit to investigate and locate suspected winter roosts in the Pine Creek drainage, Shoshone Creek drainage, Wolf Creek drainage, Sugar Creek drainage around Big Summit Prairie and McKay Creek. Winter roosts are expected in these areas because they contain coniferous trees with suitable characteristics for roosting by bald eagles and/or sightings of eagles flying in the direction of these areas have been noted.

Peregrine Falcon

No active nests have been observed on the Ochoco National Forest or Crooked River National Grassland. No records of nesting or nest sites on Ochoco National Forest are known to exist. Peregrine falcon sightings noted by or reported to the Forest Service and the Oregon Department of Fish and Wildlife occur at a frequency of one or two every winter.
Potential habitats for breeding and overwintering by peregrine falcons have not been evaluated to any detail. Cliffs, talus, and cave habitats are available on the Ochoco National Forest. While such habitats may provide suitable habitat for peregrine falcons, these habitats are currently occupied by prairie falcons.

The Recovery Plan for Peregrine Falcon (Pacific Population) indicates that no further evaluation is needed for two breeding pairs in the management unit which includes portions of Ochoco National Forest.

Candidate Species

Federal candidate wildlife species which may occur on Ochoco National Forest and Crooked River National Grasslands include Swainson's hawk, Ferruginous hawk, western sage grouse, western snowy plover, tricolor blackbird, spotted bat, Townsend's big-eared bat, California wolverine, and California bighorn sheep. Based upon available information, the following federal candidate plants may occur on Ochoco National Forest and Crooked River National Grasslands:

<table>

D - Documented
S - Suspected

2 - Category 2 consists of taxa for which existing information indicates that listing may be warranted, but for which substantial biological information to support a proposed rule is lacking.

3B - Category 3B consists of taxa which are not being considered for listing on the basis of current taxonomic understanding. These taxa could be reevaluated in the future on the basis of subsequent research.

3C - Category 3C consists of taxa which are not being considered for listing on the basis of being more abundant or widespread than previously believed or lacking any identifiable threats. These taxa could be reevaluated in the future should further research or changes in land use indicate a significant decline.

It should be noted that candidate species have no protection under the Endangered Species Act. Additional protection for these species may be provided by internal policy.

Effects of the Action

Bald eagle

The plan (page 62) and Appendix D (page 25) itemizes prescriptions to protect bald and golden eagle nesting, roosting, and perch trees utilized during the breeding season. While these prescriptions may be in conformance to the Bald and Golden Eagle Protection Act, they do not incorporate the best scientific data available on the protection and management of bald eagles. Bald eagles are held to the same level of protection as the peregrine falcon during the breeding season at Ochoco National Forest. No breeding bald eagles are anticipated at this time from the proposed action.

The biological assessment indicates that timber harvest activities and road construction could affect bald eagle winter roosting without implementation of management constraints. However, there appears to have been considerable effort to identify winter roost sites. While not all roosts have been identified to date, surveys are currently being conducted to identify existing and potential winter roost areas in suspected areas on and adjacent to Ochoco National Forest and Crooked River National Grassland. The biological assessment indicates that it is the intent of Ochoco National Forest to utilize the findings of the surveys and follow the management recommendations for preserving the integrity of actual and potential bald eagle winter roost sites. The biological assessment further indicates that these management guides will be developed with input from Oregon Cooperative Wildlife Research Unit, U.S. Fish and Wildlife Service, Oregon Department of Fish and Wildlife, and Oregon Natural Heritage Data Base.

While the Forest Plan (page 62) and Appendix D (page 25) indicate that recovery plans will take precedence over other management directions, no specific actions have been identified in these documents that address the protection of potential or suitable bald eagle nesting habitat.

Peregrine falcon

Based upon recorded sightings, the peregrine falcon appears to be a rare migratory species through Ochoco National Forest. The likelihood that a peregrine falcon would be affected by a forest action at present time appears extremely remote.

Wildlife management guidelines directed to protect breeding prairie falcons and their nesting habitat should provide some measure of protection for peregrine falcons in the event peregrines establish an eyrie within Ochoco National Forest.

As recovery efforts for the peregrine falcon gain momentum in the Pacific Northwest, the importance and magnitude of monitoring should increase over the next 10 years. The level and rate of increase is impossible to predict with available information.
Candidate Species

Management guidelines have been outlined for various raptors which should provide some management for nesting habitat for candidate hawk species. However, similar guidelines are lacking for other candidate species and non-breeding habitat requirements of raptors. In addition, inventory and monitoring procedures are not clearly defined for any candidate wildlife species. No implementation plan has been provided for various candidate wildlife species. References to inventories are generally made with no clearly defined time or monetary budgets to indicate what minimum level of effort is expected to occur during implementation of the Forest Plan.

It is unclear whether or not items 4 and 6 (see DESCRIPTION OF ACTIVITY). Candidate species apply to candidate or only listed plant species. Should items 4 and 6 apply only to federally listed threatened and endangered plant species and not candidates, then the action the forest will take on candidate plants or in determining the action to be taken on candidate plants has not been defined in the Forest Plan. If these items extend to consideration of candidate species, then the procedures would appear to be in place to avoid impacts wherever possible. However, if a decision is made to proceed with an activity which may or will adversely affect a candidate species, the outlined procedures do not indicate that monitoring of the impact and/or a post-project evaluation of effect to the population will be documented. Such information would provide a valuable basis for consideration of similar activities in the future.

The sensitive plant species list provided in the DEIS (page 73) does not reflect accurate information regarding federal candidate plant species. If this list is used as a basis for management decisions and as long as a procedure for the periodic updating of a candidate species list is not defined, some avoidable forest actions may have an adverse effect on candidate plant species.

Cumulative Effects

Cumulative effects are those impacts of future State and private actions which are reasonably certain to occur. A non-federal action is "reasonably certain" to occur if the action requires the approval of a State or local resource or land-use control agency, and such agencies have essentially approved the action. In regard to the bald eagle and peregrine falcon, we know of no cumulative State or private actions that will occur in areas adjacent and within Ochoco National Forest at this time.

Incidental Take

We anticipate the incidental take attributable to implementation of the Forest Plan preferred Alternative 2-Departure to be zero (0).

Conservation Recommendations

In the furtherance of the purpose of Section 5(c) and 7(a)(1) of the Act.

which mandate federal agencies to carry out programs for the conservation of listed species, we recommend that the following conservation measures be implemented to further conserve and avoid adverse impacts to bald eagles, peregrine falcons and candidate species.

General

1) Management Areas with known or suspected essential, critical, or potential habitat for listed species should be noted in Section V of the Forest Plan (pages 93-98). An alternative would be to designate a separate Management Area which provides for the management and protection of known and suspected essential, critical, and potential habitats of threatened and endangered species (and selected sensitive species). This alternative was used by the Deschutes National Forest.

2) The Monitoring and Evaluation Program Plan of the Forest Plan (Table V-2, pages 102-109) should be expanded to provide greater detail by species and monitoring objectives, i.e., bald eagle productivity survey, bald eagle winter roost inventory, peregrine falcon inventory, bald eagle potential nesting habitat survey, peregrine falcon inventory, candidate species and habitat status determination, habitat enhancement actions.

3) Threatened, endangered, and candidate species should be added as an action and effect to be monitored under the following resource/activity categories: Recreational, Timber, Range (Forest Plan, page 102-109).

4) Coordinate with the Oregon Natural Heritage Program, the Oregon Department of Fish and Wildlife, and the Service to exchange information on the status and distribution of threatened, endangered, and candidate (or sensitive) species. This should be added as an item to the section on Threatened, Endangered, and Sensitive Wildlife Species in the Forest Plan (page 62) and Appendix D (page D-25).

Bald eagle

1) Develop site specific habitat management plans for each individual bald eagle winter roost site and breeding territory in informal consultation with the Service. An implementation plan for the development of these habitat management plans should also be documented in the Forest Plan or referenced in the Forest Plan if one already exists.

2) Conduct an inventory of potential breeding habitat. Tree stands with characteristics suitable for nesting bald eagles should be identified and protected. If necessary, develop management prescriptions designed to preserve or enhance desirable nest tree characteristics in informal consultation with the Service. An implementation plan for conducting this inventory should be developed.

3) Prescriptions to protect bald eagle nest trees should be developed in consultation with the Service. Regarding the section on Bald and Golden Eagles in the Forest Plan (page 62) and Appendix D (page D-26) the following changes should be made:

Either

OCHOCO DR ZE DD DIX 01/15/87

7
a Delete all references to bald eagle in this section, and

b Indicate that Section 7 consultation with Service will be initiated in the event bald eagles establish a breeding territory in or adjacent to Ochoco National Forest and/or Crooked River National Grassland lands

Or

a Change "March 1" to "January 1", and

b Indicate that additional management considerations may be necessary to protect bald eagle breeding and non-breeding habitats and that these will be determined in consultation with the Service

4 Maintain winter inventories of bald eagles which can be used to establish long-term winter population trends

Peregrine falcon

1 Maintain records of sightings to establish long-term trends

2 Conduct periodic inventories to determine status of the species on forest lands

3 Identify and preserve the integrity of potential nesting and non-breeding habitat

Candidate Species

1 Adverse impacts to candidate species should be avoided wherever possible and technical assistance sought from appropriate state and federal agencies and academic organizations or institutions when adverse impacts appear to be unavoidable. When adverse impacts to candidate species are unavoidable, the effects should be monitored and documented

2 On page 56 of the Forest Plan, the Section name is mistitled and should read "Plant" rather than "Wildlife"

3 In the Forest Plan, references to "jeopardize" on item 4, page 56 should be changed to "may adversely affect" to avoid confusion with the legal definition of the term "jeopardize"

4 Coordination with the Oregon Natural Heritage Program should be added to the Forest Plan, page 56, item 7

5 An accurate candidate plant list should be provided in the DEIS, page 73. A statement which clearly defines the procedure and time frame to be used for the periodic updating of plant status information should also be included in the DEIS (page 73), the Forest Plan (page 56), and/or Appendix D (page D-10)

This concludes formal consultation on this project. If the proposal is significantly modified in a manner which would change the impacts on bald eagles and/or peregrine falcons as discussed in this Opinion, if new information is learned about these species that could change the conclusions of this Opinion, or if a new species occurring in the area is listed or if there is incidental take of bald eagle and/or peregrine falcon which exceeds that specified in this Opinion, formal consultation should be reinitiated. Your decision regarding the recommendations presented in this Opinion should be sent to this office.

We appreciate the cooperation expressed by your staff members during this consultation.

Sincerely,

Russell D. Peterson
Field Supervisor

OCHOCO DH ZE ODISK2 01/15/87

1-4-19
The Oregon Department of Fish and Wildlife staff has reviewed the Ochoco National Forest Plan documents and has attached comments to this letter.

The Ochoco National Forest is to be congratulated on their completion of the Draft EIS and Draft Forest Plan. We recognize that this is a culmination of many years of work by a very dedicated staff. Review of this plan, years in preparation by many people, in the very short time frame provided, by a small staff is at best an arduous task. Hopefully we have not misunderstood the issues or information provided. Our comments and recommendations are meant to be constructive and hopefully will lead to positive results.

We find no alternative that we can support in total. The land allocations for commodities (MA1) and big game (MA2 and 3) are at extremes in each alternative. We feel that there is a need for an alternative with a better balance of integrated resource management. There are issues responses scattered through the alternatives that would meet demand, as we see it, for fish and wildlife resources during the life of the plan. Our comments are used on what we feel are wildlife resource needs and we hope our recommendations will be reflected in the selected alternative.

It should be pointed out that the forest plan in use now offers any departure alternative objectionable because wildlife resources would be diminished by overall education of habitat for a short term economic gain. Accelerated harvest will affect recreational opportunities associated with fish and wildlife.

His response to the Forest Plan is based on our understanding of NFMA and key provisions of the policy of the State of Oregon which, by statute, in part state:

"wildlife shall be managed to provide the optimum recreational and aesthetic benefits for present and future generations of the citizens of this state. In furtherance of this policy, the goals of wildlife management are..."
1) To maintain all species of fish and wildlife at optimum levels and prevent the serious depletion of any indigenous species.

2) To develop and manage the lands and waters of this state in a manner that will enhance the production and public enjoyment of wildlife.

It is to these ends we reiterate messages we have continued to send forest managers about habitat components that are at risk with or benefit from commodity extractions. The State of Oregon needs:

1) Its basic soil resources and productivity
2) Dependable supplies of clean water
3) A diverse and dynamic range and forest ecosystems, changing over time and in arrangement with multiple resource management, but never losing its inherent capacity to deliver all kinds of public benefits
4) Forage management for grazing animals that is intolerant of resource degradation
5) Management of riparian vegetation in a condition meeting 1979 interagency optimal guidelines
6) Forestwide management of motorized vehicle use

We feel we are exposing a realistic and reasonable position on the amounts and condition of needed habitats. The forest has been supplied the Department's forest planning review criteria as an aid. A wealth of research has been compiled that describes what is necessary to enhance wildlife and wildlife habitats. Our response also addresses maintenance of non-diminishing hunting opportunities and enhancement of all wildlife related resources.

In reviewing the plan we find that there are five issues that have not been satisfactorily addressed:

1) Riparian conditions on the Forest are below standard. The Plan did not follow definitions or inventory methods described in "Managing Riparian Ecosystems for Fish and Wildlife in Eastern Oregon And Eastern Washington, 1979." The plan does not place acceptable emphasis or direction for riparian zone restoration.

2) Information on livestock grazing is not sufficient for an EIS. There is not enough data on management systems, condition and trend, actual use, or improvement programs to evaluate effects of the grazing program.

3) Roadways poses a problem for wildlife managers. The Plan is deficient in resolving the impacts of roadways on habitat effectiveness and hunting quality.

4) Much big game winter range on the Forest was not acknowledged as such. Important transition ranges were also omitted.

5) Snag management proposals will not meet future requirements for snag dependent species.

These five issues will be discussed in detail as we address our planning criteria, but it is important that these issues be pointed out at the onset.

Sincerely,

Jim Fisher
Director

Attachments

1-4-21
This portion of the comments deal with how the Proposed Plan addresses the 12 issues identified by the Ochoco National Forest with respect to fish, wildlife and habitats.

Additional comments are added to express the Oregon Department of Fish and Wildlife (ODFW) concerns and recommendations for Forestwide Standards and Guidelines, Management Area Standards and Guidelines, and the proposed Monitoring Plan. Additional comments and questions on sections of the plan are listed under General Comments.

Issue One Timber Production

The proposed plan states that the Forest has 495,006 acres of land suitable for timber production. We recognize that most of this suitable timber land is allocated to intensive timber management (MA1) while lesser amounts are spread across MA2, 3, 5, 6, 7, and 10.

The proposed plan allocates 547,072 acres to MA1 general forest which is approximately 52,000 acres more than the suitable timber base. With this in mind and the fact that various amounts of the suitable timber base acreage are in other land allocation areas, there appears to be room to better integrate the general forest allocation with other resource allocations.

Seven of 11 alternatives allocated zero acres to either general forest or big game (an all or nothing situation). In alternatives E, E-Departure, and G the allocation of general forest is 7 to 8 times that of big game winter range. Alternative "A" allocation to general forest is approximately 20 times that of big game winter range.

Salvage Program To ensure that this program is not working an opposition to and at the expense of snag objectives, baseline snag levels need to be determined for the defined management area.

As mentioned in the cover letter, we do not support a departure alternative due to long-term impacts on wildlife, wildlife habitat and wildlife-based recreation for short-term economic gains.

In reference to demand, the Proposed Plan (p 14) states "The Forest does not have the capability to meet local demand for timber." While on Page 13 the Plan states "The average annual sale volume between 1975 and 1984 was 134 mbf. The average annual cut, 1975 to 1984 was 106 mbf." The average annual cut is a reflection of demand and as displayed in the figures above, the Forest was more than capable of meeting local demand. We support the harvest level identified in "The Forest Program for Oregon, 1980."

Issue Two Social and Economic

No Comment

Issue Three Livestock Grazing

We do not support an increase in the Forest grazing program. We find it difficult to justify continuation of the current grazing program considering the Standards and Guidelines in the proposed plan. The Plan states that 28 percent of the range resource is in poor condition and 42 percent is in fair condition. It also states "Utilization of riparian forage by livestock ranges up to an estimated 80 percent in places."

The Forest has mentioned three items that would decrease grazing in some areas:

1. Forestwide Standards and Guidelines for Ecosystem Management state "Encourage recovery or prevent deterioration where activities may be leading to poor condition, downward trend, and loss of diversity"
2. MA2 (Big Game Winter Range) allocates all fall green-up to big game.
3. The two riparian MA's place tighter controls on grazing use.

In order to counter this decrease the Forest proposes to increase utilization in other areas. We feel that before an increase in livestock MA's is implemented the Forest needs to demonstrate that the above items can be met with the current grazing program. The key to accomplishing the above does not rest solely with range improvements, the driving factor should be stronger administration of Forest Grazing Permits. The Forest has the direction and authority to accomplish all three items but has not elected to do so.

We have a concern for the utilization level (actual use) of other specific vegetation types of the Forest, (e.g. dry meadow, wet meadow, shrubland). We can not address this concern without allotment use data. The concern lies with maintaining cover for nongame wildlife species and suitable habitat for state and federally listed plants.

The first priority for range improvement funds (either RBF or RM) should be restoration of degraded sites. We urge the Forest to use the key area concept to determine stocking rates and season of use.

Issue Four Riparian

The Affected Environment section on Riparian and Fisheries Habitat identifies the importance of riparian zones to wildlife and recreation use. The write-up states "The three most important riparian area factors...are stream temperatures, streambank stability and large woody debris." While these are important factors for fish resource, habitat diversity and wildlife values need to be emphasized also.
Region 6 MWR Direction for wildlife states a need for Forests to select a management indicator species for riparian habitats, if a species is not selected for riparian habitat then the reasons must be stated. We recommend the Forest designate the ruffed grouse as a management indicator species for riparian areas. This species is a good indicator of habitat conditions and its population on the Forest has decreased due to degradation of riparian habitat.

The Forest has selected steelhead, rainbow trout, and brook trout as management indicator species. We recommend resident trout be used as an indicator species. The Department policy for wild fish is "The protection and enhancement of wild stocks will be given first and highest consideration." The Forest recognition of wild fish as an indicator species would provide support to Department policy.

The proposed plan addresses the management of 19,000 acres of riparian zones on Class I and II streams. Table IV-2 on Page 30 lists streamside management units for Class I and II streams, as having 36,046 acres. What is the basis for the discrepancy between these figures? The Forest goal for riparian areas is to maintain or restore the inherent values of riparian ecosystems. This goal needs to apply to all areas meeting the definition of riparian areas, including all or part of an estimated 3,943 miles of Class III streams.

In 1978 the Regional Forester signed "Managing Riparian Ecosystems (Zones)" for Fish and Wildlife in Eastern Oregon and Eastern Washington. This document established standards for optimum habitat conditions and established an inventory procedure for evaluating riparian habitats. We strongly urge the Forest to follow the above document in managing the riparian areas. The Forest has not displayed the riparian areas or their conditions.

Page 23 of the proposed plan states that "The following acres are enclosed with the construction of the following structural improvements, 3,000 acres of fencing, 300 acres improved by woody debris additions, 300 acres of log weir construction, 50 acres of rock structures, and 50 acres of habitat from shrub plantings." The Riparian Improvement Schedule on Page 4 states "Rehabilitation activities will include 1,175 improvement acre equivalents of fencing, seeding." Which set of improvement figures would be used if the proposed plan were implemented? The Forest needs to program and budget improvement projects for resident trout habitat that is separate from anadromous fish.

We feel that Silver Creek should be allocated to a MA-14 prescription. Silver Creek is a major water source with important fish values that needs additional protection.

Issue Five Road Management

The plan states that 4 1 miles of road exist for each square mile of developed area. Since most of the road mileage is in the southern two-thirds of the Forest, the road density there could be 3-7 miles/square mile. High road densities in the MA-1 areas would reduce NEH to a fraction of optimum. We have a concern for the adverse effects of open roads have on big game in the Ponderosa Pine type allocated to General Forest. The proposed plan calls for maintaining 10 percent cover for big game in all winter ranges allocated MA-1. Thermal cover is one element of the habitat effectiveness equation. The proposed plan further states "Evaluate road densities to determine their influence on habitat effectiveness for elk. Initiate road closures where appropriate." What does the term "where appropriate" mean? Roads are tied to habitat effectiveness and should be quantified. ODWF believes road closures are appropriate on all Forest land to keep road densities at or below 2.5 miles per section.

We encourage more physical road closures on the Forest that are in addition to the green dot system. These actions would benefit wildlife, reduce the potential for resource damage, and maintenance costs.

Reading was found to be the single greatest concern of elk hunters in ODWF elk workshops.

Issue Six Habitat for Big Game

The Affected Environment Section on Wildlife does not adequately address the big game winter range requirements on the Forest. It should include how many acres of winter range and transition range, as identified by big game use, are on the Forest, and why they are important. It should also include a land type break-down by percentage for the winter ranges.

What percent of the 72,991 acres allocated to Big Game Winter Range is capable of meeting optimum habitat effectiveness (HEI)?

ODWF provided the Forest with maps of summer, transition and winter ranges. Attached is a map that displays all "E. MA-2 allocations, transition winter range, and areas that we feel need to be allocated to MA-2. These areas are essential for wintering deer and elk. Maintenance of the identified winter ranges at optimum HEI is necessary to assure deer and elk productivity.

Forestwide Standards and Guidelines for deer and elk address maintenance of viable populations. Explain why the habitat standard has been set for viable populations when the proposed plan identifies much higher population level. The standard must be related to the herd size and distribution to be managed for. The fact that big game habitat is a public issue would justify a higher standard than viable population.

Elk were chosen as an indicator for the big game issue because they have a greater sensitivity to man's activities than do deer. The failure to use deer as an indicator has results in deficiencies in the analysis relating to seasonal deer habitat requirements. The DEIS needs to address the cumulative effects of the alternatives on the deer herd. To correct this deficiency, we recommend mule deer be used as a management indicator species with elk. We recommend a better distribution of MA-2 allocations across the Forest that meets the needs of both deer and elk.

We do not know how the Forest converted HEI figures to population numbers. The Forest needs to explain the process used to select the
winter range allocations in the preferred alternative More discussion relating to the above may answer our concerns

The 10 percent cover standard for the MA-1 areas will not provide enough thermal cover to maintain population levels. The hiding cover element during hunting season would also be deficient.

Issue Seven Roadless Recreation

We support the MA-9 roadless area allocations in Alternative F for Lookout Mountain, Silver Creek, Green Mountain, Rock Creek, and Cottonwood. We recommend that the standard for timber harvest be changed to read "No Harvest" and that this intent be maintained by a nonmotorized roadless environment. The intent would be lost if timber harvest or salvage were allowed.

We support the allocations for Deschutes Canyon-Steelhead Falls in Alternatives E and G.

Issue Eight Scenic Values

Under the proposed plan approximately 82 percent of the Forest would be subject to vegetative manipulation. The Forest will need a strong monitoring program to ensure that soil resources and plant community diversity standards and goals are met.

We support the Scenic Travel Corridor allocations in Alternative C. The rationale for this support is tied to the old growth and the 3-toed woodpecker. The Forest should manage the preferred corridor to move from one area to the next. The Forest Scenic Travel Corridors and Riparian Management Areas will help meet that need.

We support the allocations for Deschutes Canyon-Steelhead Falls in Alternatives E and G.

Issue Nine Old Growth

Region 6 MM2 Direction for wildlife lists old growth species for the Ochoco as pileated woodpecker, marten, and northern 3-toed woodpecker. The Forest has addressed the pileated woodpecker but not the marten or the northern 3-toed woodpecker. The Department has data that show that the northern 3-toed woodpecker occurs on the Malheur National Forest not far from the Ochoco. There is no reason to believe that this species does not occur on the Ochoco. We do not have data that show marten use on the Forest. We recommend that the Forest include the 3-toed woodpecker as an old growth indicator species for mature lodgepole pine stands. We further recommend that the Forest select a MIS for the 3-toed woodpecker. The size and dispersal distance of marten units was also intended to meet the needs of other old growth related species. These species still need to be represented, whether or not marten actually exist on the Forest.

The Forest has selected the common flicker as an indicator for old growth juniper. Will the 40 acre old growth juniper stand be mapped? What measures will be taken to maintain the old growth juniper stands?

New data from westside pileated woodpecker study indicate that this species needs more than 300 acres for a core area. The area that was studied on the Starkey Experimental Forest had a higher snag density than that on the Ochoco. With these two points in mind we recommend that the Ochoco allocate 460 acres to the pileated woodpecker core area for this planning period.

How does the distribution of the old growth prescription (MA-4) fit with the Malheur National Forest?

The proposed plan does not contain sufficient information to evaluate the old growth situation. In order to do so the maps should indicate which areas are suitable or capable, and the plant communities they represent.

How will the Forest delineate and manage the 300 acre foraging area for the pileated woodpecker? We recommend that the minimum snag size in the foraging area be 15 inches. Research has found this snag size to be necessary for a prey base of carpenter ants.

It is important that a number of replacement stands be designated in the plan. The numbers should be equal to the expected loss for the next 150 years.

As 40 percent of the MA-4 areas are capable an equivalent amount of suitable habitat should be retained, on a drainage by drainage basis, until the capable areas reach a suitable condition. Replacement stands should be managed for 100 percent potential population levels of primary cavity excavators.

Issue Ten Firewood

Our comments on firewood will be addressed under Forestwide and MA Standards and Guidelines for dead and down woody material.

Issue Eleven Snags

Region 6 MM2 Direction for wildlife states: Each Forest will determine their management indicator species for this MM2. (Primary Cavity Excavators). The Forest has not selected a MIS for snags. ODW recommends that the Forest use the hairy woodpecker as a MIS for the ponderosa pine, mixed conifer, white fir, lodgepole pine, and subalpine fir communities. We also recommend the downy woodpecker as a MIS for the riparian communities.

With a designated MIS for snags the Forest can establish specific criteria for meeting snag distribution on the Forest. In-unit snags should be left as well as clumps to provide for primary as well as secondary cavity users.
Region 6 established MMR's for wildlife to meet an NFMA requirement. The Forest was directed to use MMR's as a constraint for benchmark runs and alternatives that are commodity oriented. The level at which the Forest operates above these constraints is established by standards and guidelines. We want to emphasize that managing for 100 percent of potential population of primary cavity excavators does not mean managing for 100 percent snag retention. With this understanding we will make recommendations for snags in the Standards and Guidelines Review.

Issue Twelve Winter Recreation

We recommend that the Forest control use of winter recreation in areas of wintering big game and bald eagle wintering areas.

Response to Standards and Guidelines

For the purpose of the DEIS and the Proposed Plan the Forest has defined guideline and standard as:

1. Guideline - An indication or outline of policy or conduct that is not a mandatory requirement (as opposed to standard, which is mandatory)

2. Standard - Performance criteria indicating acceptable norms or specifications that actions must meet. A principle requiring a specific level of attainment, a rule to measure against.

1 Range: Under Forestwide S & G's no standards have been set except for use on crested wheatgrass. Most of the statements appear to be goals. We recommend that specific utilization standards be applied to decrease species. A generic approach to utilization does not protect decrescer species, and does not protect sites with moist soils. Under Forest Wide Utilization #2 the word "integrity" is subjective. The Forest needs a standard to measure against to determine protection needs for a riparian zone. In #3 state a distance for salt location from water -- establish a standard.

Under Range Improvements we recommend establishing standards for protection of water sources and overflow areas. We recommend the following as additional standards and guidelines:

4 "Protect newly developed water sources with a fenced enclosure. The enclosure will have no gates. If a stock tank has an overflow pipe, the overflow should be piped away from the tank. Protect the overflow site as stated above for developed water sources" (Sanitary water sources are a defense against disease and parasite transmission between wild and domestic animals and man.)

5 "Each Ranger District will establish a priority list for protecting existing water sources to the same standard established for new water developments. The priority list will allow for the protection of all existing water developments by September 30, 1989."

6 The use of prescribed fire as a method to improve forage quality should be designed to protect important browse stands such as mountain mahogany thickets. Prescribe burns should be coordinated with wildlife biologists.

We support the MA-2 standard to reserve all fall green-up for big game. The fall green-up is important on transition ranges and winter ranges not allocated to MA-2. Fall green-up should be maintained on all areas that were delineated as transition or winter range by ODFW.

2 Residue Management: In #1 establish a Forest standard for what must be left. ODFW recommends two logs (>12' by 20') per acre and/or two brush piles (>3' dia.) per acre except in riparian areas. In riparian areas allow for natural accumulation of dead and down woody material. Logs must be uncharred.
3 Riparian: Riparian and Shh and Fish Habitat #2 include "wildlife habitat protection"

   Please explain what IS meant by "is significant degradation of water quality"? There is a need to establish the standard for water quality that addresses sediment in riparian areas. The standard for ground cover should be 80% percent.

4 Soils: MA-13 and 14 have a standard to "maintain 90 percent of the area in an acceptable productive condition". How will the Forest determine "acceptable productive condition"?

   We have a concern for soil compaction and displacement on the Forest. What is the background level of soil loss on the Forest? P. 117 of DEIS the Forest indicates 105,000 acres have compacted soils and that figure will increase to 127,000 acres in the first decade. What will be the long term effect be on productivity from these compacted acres?

5 Fragile Areas: When considering standards for fragile areas, scablands, bogs, springs, we meadows, dry meadows, etc. two elements must be addressed. First, standards to protect the site from adverse effects of management activities, second, standards that protect the values of the edge habitat around the fragile area. A standard is not for over-story removal of a portion of the edge while maintaining a screen of understory vegetation would meet the intent of number 2. Protection of fragile areas from adverse grazing impacts may require fencing.

   Dead and down woody material on the edges of fragile areas and natural openings should be maintained for 100 percent potential population levels.

   The Forest should address state and federally listed plants under this category and the special management consideration for each species or group of species.

6 Timber Management: OFDW supports the Forestwide S & G described under Silviculture. We recommend the following be added to §9 (1st para.) "A screen of understory vegetation will be left along the edge of natural openings and along roads to reduce the sight distance.

   Under MA-2 and MA-3 the standards for reforestation should be driven by big game cover objectives not an annual or decade timber target. Base a need to plant trees on a need to increase or replace cover for big game.

   MA-2 and MA-3 precommercial thin-stocking rate should be based on cover needs for big game not Managed Yield Tables.

   The MA-7 Harvest standards would all meet partial retention of middleground except the rotation age. Activities under partial retention must remain subordinate to the characteristic landscape. A rotation age of 30 to 100 years will over time change the character of the landscape by removing large mature and old growth trees. The rotation age should be the same as MA-6.

7 Transportation System: Traffic Management §2 recommend adding the following paragraph:

   "Road closures for big game will be needed to maintain higher habitat effectiveness and assure hunting quality. If habitat effectiveness drops below MEI = 35 roads will be closed." Entry to new roads should be designed for easy and effective closure.

8 Wildlife: As stated in the Issue response we feel the Forest should establish the northern 3-toed woodpecker, downy and hairy woodpecker as MIS and should select a replacement species for the marten.

   We also recommend the ruffed grouse and resident trout as MIS for riparian areas.

   Primary Cavity Excavators: Recommend dropping §? This is confusing and the specific levels are identified in the prescriptions.

   Recommend a minimum snag size of 15" for pileated woodpecker forage areas.

9 The size of the clumps should reflect the needs of indicator species.

   A. The area of evaluation should be on a subwatershed basis

   B. Hard and soft snags must be left in harvest units

   C. Clumping alone will not meet cavity user needs.

10 Threatened, Endangered and Sensitive Species: We recommend that a bald eagle roost area be established at the grasslands within 1/4 mile of Lake Billy Chinook. We recommend that the Forest use criteria in "Management of Wintering Bald Eagles" (1978, USFWS) to protect roost sites.
Species Associated with Dead and Downed Trees See Residue Management

Species Associated with Various Plant Communities. The statement 'diversity is to be provided through time' is a goal and a legal requirement. How does the Forest propose to accomplish this task?

Snag Management: As stated in the Issue response the snag levels by MA could be higher. We recommend the following

a Varies by plant community
b Forest management would not affect level of snags

Snags must be uncharred. The recommended height and numbers by DBH are identified in Thomas (1979)

Raptors: The plan should reference and support the guidelines for cliff and rimrock habitats in ‘Wildlife Management in Managed Forests’

Monitoring Plan

Wildlife

Old Growth -
Under ‘Methods’ 5% per year is not a method, it’s a frequency. At 5% per year it would take 20 years to verify that the MA-4 areas are in place. This time period is too long for a resource that is being managed at a low level. We recommend 20% per year is verified and utilize remote sensing as a method to inventory and monitor.

Snags -
Recommend moving snag information on Page 103 under Fish and Wildlife, Range to Page 102 under Snags.

Anadromous fish -
Recommend monitoring for resident fish be included.

Elk Habitat -
Recommend establishing an HSI Management Objective for Variability Threshold.

Soils -
Place stronger emphasis on project level monitoring for compaction and displacement.

Recommend that 5 year monitoring reports be sent to coordinating agencies.

Recommend that the monitoring plan address Dead and Down Wood Material.
General Comments

1 ODES Affected Environment

Vegetation
The Forest lists 12 plant species from "Rare, Threatened, and Endangered Plants of Oregon", March 1985. How will these species and their habitats be protected?

2 ODFW supports the RNA allocations in Alternative E.

3 ODFW encourages stricter enforcement of ORV regulations.

4 Recommend that the Delmont Lake improvement project be added to the fish and wildlife capital investment plan.

5 Appendix A5
Timber Sales - Are the timber sales scheduled in MA-2, MA-3, MA-13, and MA-14 designed to meet specific wildlife and riparian objectives?

6 Chapter IV of Proposed Plan

P 25 Riparian "Maintain or restore inherent values". Only MA-14 would meet this goal. Does the Forest propose to increase the MA-14 allocation in the next planning process to work toward this goal? Due to the poor condition of the riparian area, recovery will be a slow process.

P 28 Desired future condition: "Vegetation composition will change over time giving way to weedy, adventive, and annual species." We recommend that the Forest delete the above paragraph. This condition is not desirable and is not consistent with forestwide standards and guidelines for Ecosystems Management. Encourage recovery or prevent deterioration.

P 96 of the Proposed Plan
What is the rationale for the difference of 10^2 and 10^4 in the temperature standards for the Deschutes and John Day Rivers?

In an effort to have better data and species inventories for the next planning period, we recommend that the Forest identify the needs in the statewide Comprehensive Fish and Wildlife Plan. The Department will cooperate when possible to help gather this information.

The following comments list how well the proposed plan accommodates the Fish and Wildlife Habitat Protection Criteria for Forest Lands (March 1985, Reformatted and Revised September 1986) - copy attached.

Old Growth

1 Forest will maintain only three percent in old growth. ODFW criteria is 5-15%.

2 Does not include northern 3-toed woodpecker as indicated in R-6 ORVs.

3 The Forest is dedicating old growth stands, plan does comply.

4 No fuelwood cutting, may be roaded in some areas.

Snags

1 Inventory by TRI compartment or watershed needs to be completed.

2 Will be met, ODFW recommends core area of 460 acres.

3 Not met, Forest MA snag levels vary from 40% to 100%.

4 In S & G's.

5 Plan does comply.

Dead and Down

1 In plan, recommend as standard under residue.

2 Same as #1.

3 Plan does not comply.

Hardwoods and Minor Conifer Species

1 Would be met under diversity requirement.

2 N/A.

3 Only portion of winter range considered, most of transition areas and winter ranges not considered.

Riparian

1 No map to show location and condition.

2 All addressed but no sediment standard.

3 Will be met on 10,000 acres of Class I and II streams.

4 Is planned for part of degraded area.

5 Yes for a portion of area.

6 Yes.

Meadows, Freshwater Wetlands, Natural Openings

1 Not sure.

2 No, only 66% ensured - made recommendation for remainder.

3 No, 2/3 of area will have trees but may not be in natural condition.

4 The direction is there.

5 Does not comply.
Cliffs, Rim rock, Caves, and Talus
1 Recommend that Forest use standards in (Thomas 1979)

Aquatic Habitats
1 Yes on a limited basis
2 No
3 Yes
4 For anadromous fish only, recommend monitoring of resident trout

In-stream Habitat
1 Yes, but not for all acres

Water Quality
1 Temperature ok (but not for all acres), sediment—no standard
2 Yes

Water Quantity
1 Yes, but not for all acres
2 Yes

Elk and Deer Habitat
1 Yes, on 24% of Forest, ODFW management objectives will not be met on
2 N/A allocations
3 No
4 No discussion of current condition
5 Only on portion of Forest and not by geographic area
6 Not in total
7 a Not complete
   b Not complete
   c Yes
8 Yes
9 No

Species of Concerns
1 Bald eagle
   a Yes
   b Yes
   c Yes
2 Peregrine falcon -- N/A
3 Spotted Owl -- N/A
Dear Jim:

We have reviewed the draft of the Ochoco National Forest Plan with an emphasis on its impact on the Division's programs - parks, scenic waterways, trails, and recreation in general. We have relied on the 1983 Statewide Comprehensive Outdoor Recreation Plan (SCORP) endorsed by Governor Atiyeh and the 1983-89 Oregon State Parks System Plan adopted by the Oregon Transportation Commission.

Our review paid special attention to the plan's provision for recreational diversity (as shown by the Recreation Opportunity Spectrum).

The Ochoco plays an important role in providing outdoor recreation opportunities in Oregon. It provides high quality hunting and river dependent opportunities as well as winter nordic activities. It also will become an important trail connector between the Pacific Crest and Desert Trail systems. Our specific areas of concern are:

1. Predictions for future recreation use are based on state population growth. Much recreation grows faster than population. Predictions of future use would be better grounded based on historic trends in the Ochoco.

2. We endorse expansion of the trail system, especially the development of the East-West intertie which will join the Pacific Crest Trail with the Desert Trail.

3. We agree with management of the Deschutes Canyon-Steelhead Falls area to retain wilderness values until designated or released by Congress.

4. We also agree with maintenance of scenic and recreational values on those described portions of the Crooked, North Fork Crooked and the Deschutes River until Congressional decision is made. Oregon State Parks has recently completed a state scenic waterway study of the Deschutes from Lake Billy Chinook upstream.

Jim Brown
State Forester
Oregon Department of Forestry
2600 State Street
Salem, OR 97310
Major reductions are being made in those lands providing semi-primitive motorized and non-motorized recreational opportunities, to the extent that demand has or soon will outstrip supply. The reduction of these opportunities pose a loss of recreational diversity as delineated by the recreational Opportunity Spectrum. We suggest that this issue be reevaluated in the Ochoco.

Methods employed to estimate the economic values of recreation are flawed and result in a serious undervaluation of recreation. This undervaluation becomes particularly of concern in those areas of the forest where irreplaceable recreational opportunities may be traded for low value timber resources.

We are pleased to offer these comments. If you have any questions, please contact Don Eixenberger at 378-6597.

Sincerely,

Alan J. Cook, Manager
Planning and Grants

STATE OF OREGON
Interoffice Memo
Parks and Recreation Division

FROM: Don Eixenberger
Research Analyst

SUBJECT: Review of Ochoco National Forest Plan, 1986

The U.S. Forest Service (USFS) plays a major role in the provision of recreation in the State of Oregon. It is an indispensable element in maintaining a diverse quality of recreational opportunity which will gain even greater importance as the state's population grows and as out-of-state tourism plays an even more crucial role in the state's economy. For example, federally administered lands provide over 30% of the state's campsites and picnic tables, 50% of its hiking and bridle trails and 60% of its ORV areas. Thus, while the plan states that the USFS provides 7.5% of outdoor recreation nationally, in Oregon, it is likely 3 to 4 times that amount or more.

The USFS is also the sole provider of certain types of recreation in the state. Much river recreation, snow activities and primitive and semi-primitive recreational opportunity are greatly dependent on public lands managed by the USFS. Forests such as the Ochoco form a mosaic of recreational richness and diversity that are irreplaceable.

Recreation

Overall, the plan adequately describes the general recreational issues in the Ochoco National Forest. We have concerns, however, in using state population projections in estimating future recreational demand. Forests have varying degrees of recreational attractiveness; activities within a forest can have differing rates of demand. Some of these may follow population growth; others may greatly exceed it. Basing demand on population risks inappropriate planning for future use. Projections based on historical growth rates for specific activities would likely be more accurate.

Dispersed Recreation

The Ochoco has no primitive recreation opportunities, excluding wilderness, its semi-primitive motorized and non-motorized opportunities are limited. Currently, there are some 59,000 acres of land providing such experiences. The preferred alternative (E departure) would reduce this to about 52,000 acres or 8.8% of some 843,000 acres of forested land. Yet demand for semi-primitive opportunities according to USFS data is increasing in the forest.
Ample supplies of developed and roaded natural opportunities exist through all years of the planning horizon. Yet demand for semi-primitive motorized presently exceeds supply by over 100% demand for semi-primitive non-motorized will exceed supply by the year 2005. The problem would not be so crucial if this were an isolated case. But the diminishment of both primitive and semi-primitive opportunities is also projected in other Forests. The reduction of these opportunities pose a loss of recreational diversity as delineated by the Recreational Opportunity Spectrum.

The U.S.F.S. is nearly the sole provider of these opportunities. We suggest that this issue be reevaluated in the Ochoco. Perhaps a regional analysis should be made to examine the status of the supply and demand for primitive and semi-primitive opportunities and the cumulative effects the current round of planning will have on them.

Trails

We endorse the expansion of the trail system, especially the development of the East-West intertie which will join the Pacific Crest Trail with the Desert Trail.

Wilderness

We agree with management of the Deschutes Canyon-Steelhead Falls area to retain wilderness values until designated or released by Congress.

Scenic Rivers

We agree with maintenance of scenic and recreational values on those described portions of the Crooked, North Fork Crooked and the Deschutes River until Congressional decision is made. Oregon State Parks has recently completed a state scenic waterway study of the Deschutes from Lake Billy Chinook upstream. A copy of this study is available upon request.

Developed Recreation

The plan proposes four new developed sites in the Ochoco. According to the State Comprehensive Recreation Plan, the counties influenced by the Ochoco have large surplus of campsites through the foreseeable future. However, as described, several campsites in the forest are at peak use and development of new sites is needed and justified.

Economic Concerns

Methodology

Each of the 11 management alternatives has a calculated Public Net Value (PNV) expressed in millions of dollars. This is the difference between the discounted value (benefits) of all outputs to which the monetary values or established market prices are assigned and the total discounted costs of managing the planning area. As such, PNV is an estimate of the total monetary benefits gained through the various mixes of resource tradeoffs across the alternatives.

In formulating these values, a 1 percent per year real price trend for stumpage was used for harvest scheduling analyses. These were applied for the first fifty years and a 0 percent price trend was used for the remaining 100 years of the planning horizon. A 0 percent real price trend for all other resources was used during the development of the benchmarks and the alternatives. In other words, their future nominal values will change at rates equal to inflation. According to the plan, recreational resources will not increase in real values; their contribution to PNV in real dollars remain static throughout the 50 year planning period.

In addition, the contribution of recreational values to PNV were reduced 37.5% for use in comparing resource allocation choices. This was based in part on dissatisfaction with travel cost methods of determining recreational activity values. To arrive at this 37.5% reduction, the following method was used:

First it was estimated that nationally, a 5 percent increase in price would result in a 1 percent decrease in quantity of outdoor recreation demanded for a price elasticity of -0.2.

P.E. = quantity demanded / price demanded

It was also estimated that in 1982, the Forest Service provided 7.5% of all outdoor recreation and that as a consequence, there will be a 5 percent decrease in price for each percent of the 7.5 percent Forest Service creates a 37.5% decrease in the price of outdoor recreation. For example, the initial value of $24 for a day of resident trout fishing was reduced to $15.
Discussion

The methodology used to estimate the current and future value of recreational resources merits careful consideration if responsible planning of our shrinking resource base is to occur.

1. Assigning a 0 percent real price trend for all non-timber resources, including recreation flies in the face of economic reality. The demand for much, if not most, outdoor recreation is growing at an accelerated pace.

Skiing and river-dependent recreation are two prime examples of this growth. The supply available for many of these activities is sluggish or even static. It is a well established fact that as demand grows faster than supply, real price increases.

The assumption of a 0 percent real price trend gravely undervalues the contribution of outdoor recreation to the PNV of all the alternatives.

2. Adjusting recreational activity values 37.5 percent downward is clearly erroneous.

The values for many of these activities were generated using Forest Service sites and when Forest Service contributions to the overall supply were present. It is erroneous to assume that the Forest Service land is an addition to quantity which lowers these values when that land was already a part of the total quantity when the values were estimated.

3. A nationwide demand elasticity is likely misrepresentative of the demand elasticity for specific recreation activities and may not be relevant to Oregon and the Ochoco National Forest.

4. It is faulty to assume that because nationally the Forest Service provides 7.5% of all outdoor recreation, the same holds true for the Ochoco Forest. Also many of the opportunities offered by the forest have no reasonable substitutes. Mountain climbing, wilderness travel, skiing are examples of this.

5. There is no reason to believe that Travel Cost methodology consistently overestimates trip length, and therefore no reason to adjust those values downward as a result of this contention.

Their net effect is to seriously confound and underestimate the value of recreational resources and their contribution to present net value. Consideration of resource allocations in the Ochoco Forest will be distorted unless appropriate recreation value estimates are refigured throughout the alternatives.

*Corroboration of these points are provided in the accompanying comments by Rebecca L. Johnson, Assistant Professor, Resource Economist, Department of Resource Recreation Management, Oregon State University, Corvallis. While these comments were made pertinent to the Deschutes NF; the same methodology was used in the Ochoco and is relevant to it.

DE:10
1661D
In summarizing the rationale for adjusting the initial values of the Resource Evaluation Group, the plan states that TCM values need to be adjusted to be comparable with marginal values of other forest outputs. The nationwide demand elasticity of 0.2 is used to show that if the Forest Service quantity of outdoor recreation in the nation by 7% (their current share of quantity), price should decrease by 37.5%. There are several problems with this logic:

-- The prices which are being adjusted downward were estimated when the Forest Service land was a part of the total quantity. In fact, many of the studies which were used to generate the recreation values were done for Forest Service sites. Studies that were done on non-Forest Service sites would frequently have had Forest Service sites as substitutes, and regional models would have included these Forest Service substitutes directly in the estimation. It is erroneous to assume that the Forest Service land is an addition to quantity which will lower these values which were estimated at a time when Forest Service land was already a part of the total quantity.

-- A nationwide demand elasticity for outdoor recreation may be a poor representation of the elasticity for specific recreation activities. Similarly, the percentage of the total quantity of outdoor recreation in the U.S. that the Forest Service land represents may be a poor representation of the percentage that is relevant in the Deschutes National Forest. If adjustments are to be done, an attempt should be made to use regional or Forest-related factors for adjustment whenever possible.

Other reasons stated for adjusting the values downward were related to problems with the TCM, including an assertion that TCM studies typically are done for higher quality sites, substitutes are not accounted for, and trip length is not accurately measured. While any of these may be true for a particular study, several points should be made:

-- Values for some activities were based on CVM studies instead of TCM studies. Adjusting these values downward for problems with the TCM is clearly erroneous.

-- Not all of the studies used single-site TCM models, and therefore an adjustment for substitutes may or may not be necessary. There is clearly no single factor to adjust all of the values by to account for exclusion of substitutes — it would vary by site.

-- Aside from the argument of whether or not TCM studies accurately measure trip length, there is no reason to believe that trip length is consistently over-estimated, and therefore no reason to adjust these values downward as a result of this contention.

If the planners for the Deschutes National Forest are not satisfied with the activity values estimated by the Resource Evaluation Group, they should make an attempt to find recreation valuation studies which have been done in the Pacific Northwest region for specific activities which are provided on their forest. It appears that planners want recreation values to be comparable to other forest resource values, and therefore the same effort should be made to find values which reflect as accurately as possible the conditions that exist on the Deschutes National Forest.

Salem, OR 97310

ATTN: Dave Store - Ochoco National Forest Comments

Dear Mr. Brown,

We have reviewed the Ochoco National Forest and Crooked River National Grassland Proposed Land and Resource Plan. The Water Resources Department has no preference for any plan finally selected. However, we recommend that the goal of protecting water resources originating on forest lands be included in any management plan implemented.

As identified in Table IV-6, The Plan, water yields could diminish by a few percent per decade for the next three decades. Data is not available to determine if this is the result of projected precipitation patterns or management programs. The Department would encourage implementation of a monitoring program to measure the effects of various forest management techniques on runoff. A comprehensive monitoring program may provide the necessary data for additional evaluation on the effects of various management techniques on runoff.

Specific comments - DEIS

The DEIS should acknowledge state water resource policies and the relationship to the various alternatives presented in pages 74 and 175.

Proposed plan

Page 13 The last sentence in the water section should be clarified as to specific meaning. Does the sentence mean needs will outpace water resources or water will still be sufficient to meet demands?

Page 27 This section should put more emphasis on improvement of the watersheds in the poor to fair condition

A-1 Water rights will be required for the water development projects identified in the report.

I-11 Potential developers should be aware of state policies affecting hydroelectric projects.

Enclosed is the basin program for the area. Thank you for the opportunity to review the report.

Sincerely,

WILLIAM H. YOUNG
Director

01093
Before the Water Resources Commission of the State of Oregon

In the matter of formulating an integrated, coordinated program for the use and control of the water resources of the John Day River Basin

John Day River Basin

December 2, 1985

WHERAS the State Water Resources Board under the authority of ORS 536.300 has undertaken a study of the John Day River Basin as delineated on State Water Resources Board Map, File 670146;

WHERAS results of this study have been published in the State Water Resources Board Report, John Day River Basin and the Water Resources Department has conducted further studies pertaining to the development of water resources of the basin;

WHERAS in these studies consideration was given to means and methods of augmenting, conserving and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control; and

WHERAS the Water Resources Commission under the authority of ORS 536.300 through ORS 536.340 may classify or establish minimum perennial streamflows on the water resources of the John Day Basin;

WHERAS as a result of said studies the following findings and conclusions have been reached by this Commission:

1. The total basin yield is adequate on an average-year basis to supply all existing and presently contemplated needs and uses of water.

2. There are areas where the yield is not adequate to supply existing needs during a critical year.

3. Flows are not sufficient during low-flow months to meet existing or future instream or out-of-stream demands.

4. Simultaneous use of a major portion of the existing consumptive water rights results in flows at or near the zero level in many streams during the summer and early fall months.

5. Flows at or near the zero level also occur under existing conditions on many streams having little water under appropriation.

6. Augmentation of the water supply in periods of need can come through more efficient use of presently appropriated water.

7. There are many physically feasible storage sites.

8. Available data indicate that the ground water resource is limited.

9. Ground water represents an important source of water, primarily in meeting existing domestic, livestock, and municipal needs.

10. There are substantial quantities of unappropriated water.

11. Over 1,400,000 acre-feet of the waters of the John Day River and its tributaries were withdrawn in 1915 by the State Engineer for out-of-basin diversion for irrigation, power and domestic purposes. This withdrawal amounts to more than the average annual discharge of the John Day River at McDonald Ferry.

12. No water has been applied to beneficial use under the aforementioned withdrawal.

13. Utilization of this withdrawal and its priority will preclude maximum beneficial use of the waters of John Day River within the basin.

14. More than 25 percent of the land holding water rights is no longer irrigated. More than 75 percent of the water appropriated for mining and power uses is no longer utilized for these purposes.

15. There is need to investigate modification or recession of the aforementioned withdrawals and unused rights.

16. There is need to insure water for domestic, livestock, municipal, and wildlife uses which, while small, are of great importance.

17. There is need to develop stock water facilities for better range utilization.

18. Irrigation is and will continue to be the major consumptive use of water.

19. Irrigation development is restricted by the limited acreage of bottom land and the unfavorable location of other arable land.

20. Most irrigated lands do not receive an adequate supply of water throughout the irrigation season in an average water year and experience severe shortages in a critically low water year.

Storage would be necessary to provide an adequate water supply for irrigated and irrigable lands.

22. The hydroelectric power potential of the basin is limited.
23. Existing stream regimen and water use reduce the desirability of hydroelectric power development in the basin.
24. Present industrial use of water is small and is not expected to increase materially.
25. There is potential for increased mining activity.
26. Present mining use of water is small and is not expected to increase materially.
27. Water-based recreation is limited by low seasonal streamflows and the small number of lakes and reservoirs.
28. The natural lakes have significant recreational value.
29. The main stem of the John Day River from Service Creek Bridge (river mile 157) to Tuwater Falls (river mile 10) is designated as a State Scenic Waterway.
30. Aquatic life, including fish life, is and will continue to be the major nonconsumptive use of water.
31. A major conflict exists between irrigation and fish life use of water.
32. There is potential for enhancement of fish life and recreation.
33. Storage or other watershed management measures would be required to attain flows for enhancement of fish life and recreation.
34. Flows recommended by fisheries agencies are substantially higher at many locations than the flow levels that exist during an average water year.
35. Maintenance of minimum perennial streamflows would benefit fish life, wildlife and recreation.
36. Thirteen minimum perennial streamflows included in the Senate Bill 225 (1983) application are located in the John Day River Basin.
37. The proposed minimum streamflows would protect flows during parts of the year for important populations of wild anadromous and resident fish in the mainstem John Day River and its North, Middle, and South Forks; Beech, Canyon, Cottonwood, Rock and Bridge Creeks tributary to the mainstem John Day River, Clear Creek tributary to Middle Fork John Day River, and Granite Creek tributary to the North Fork John Day River.
38. Municipal use for Mitchell, Dayville, and Mt. Vernon is of greater importance than support of fish life and should be exempted from minimum perennial streamflows.
39. Existing industrial use is more important than fish life use in the river reach from gage 1400550 to the North Fork.
40. Exemption of industrial applications filed before December 2, 1986 would allow development of alternative sources for existing and future industrial demands.
41. Criteria for the determination of desirable base flows commensurate with all beneficial uses of water have not been developed.
42. Agriculture is a more important use than increasing the existing minimum flows on the North Fork John Day.
43. Pollution of surface and ground water is local, intermittent in occurrence, and is not a serious basinwide problem.
44. Utilization of flows to minimize pollution should only be permitted if it does not limit or conflict with the multiple-purpose objectives for water use in the basin.
45. Flooding and streambank erosion are serious local problems in some areas.
46. Erosion of cropland and rangeland is a major problem and often results in siltation of streams.
47. Major drainage problems occur on irrigated lands.
48. Because of physical and economic factors, classification of certain waters for limited-purpose use would be in the public interest.

NOW THEREFORE BE IT RESOLVED that this Commission hereby adopts the following program in accordance with the provisions of ORS 536(3)(a) pertaining to the water resources of the John Day River Basin.

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the John Day River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, pollution abatement, wildlife and fish life uses. The waters of the John Day River Basin are hereby so classified with the following exceptions:
1. The maximum economic development of this state, the attainment of the highest and best use of the waters of the natural lakes of the John Day River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, irrigation of lawn or
noncommercial garden not to exceed one-half acre in area, power
development not to exceed 7-1/2 theoretical horsepower,
recreation, wildlife and fish life uses, and the waters of the
natural lakes of the John Day River Basin are hereby so
classified.

2. The maximum economic development of this state, the attainment
of the highest and best use of the waters of the John Day River
from Service Creek Bridge (river mile 157) to Tunwater Falls
(river mile 10), and the attainment of an integrated and
coordinated program for the benefit of the state as a whole
will be furthered through utilization of the aforementioned waters
only for domestic, livestock, municipal, irrigation, industrial,
mining, recreation, wildlife and fish life uses;

8. For the purpose of maintaining a minimum perennial streamflow
sufficient to support aquatic life, no appropriations of water except
for domestic or livestock uses shall be made or granted by any state
agency or public corporation of the state for the waters listed below
and as shown in Table 1:

1. The Middle Fork John Day River above its mouth or of its
tributaries for flows of the Middle Fork John Day River at USGS
Gage 14-0440 at Ritter (SW 1/4 NW 1/4 Section 8, Township 8
North, Range 30 East) below 10 cubic feet per second measured
at said gage except that this limitation shall not apply to waters
legally stored or legally released from storage.

2. The North Fork John Day River above townships or of its
tributaries for flows of the North Fork John Day River at USGS
Gage 14-0480 at Humaid (SE 1/4 SW 1/4 Section 22, Township 9
North, Range 27 East) below 35 cubic feet per second measured
at said gage except that this limitation shall not apply to waters
legally stored or legally released from storage.

3. The North Fork John Day River above its mouth or of its
tributaries for flows of the North Fork John Day River at USGS
Gage 14-0460 at Bonneville (SE 1/4 SW 1/4 Section 2, Township 9
South, Range 27 East) below 35 cubic feet per second measured at
said gage except that this limitation shall not apply to waters
legally stored or legally released from storage.

4. The John Day River above USGS 14-0465 at Service Creek (N 1/2
Section 18, Township 9 South, Range 23 East) or of its
tributaries above said gage for flows of the John Day River
below 30 cubic feet per second measured at said gage except that
this limitation shall not apply to waters legally stored or
legally released from storage.

5. The John Day River above its mouth or of its tributaries for
flows of the John Day River at USGS Gage 14-0480 at McDonald
Ferry (NW 1/4 Section 9, Township 1 North, Range 19 East)
below 20 cubic feet per second measured at said gage except that
this limitation shall not apply to waters legally stored or
legally released from storage.

C. To support aquatic life and minimize pollution, in accordance with
Section 3, Chapter 796, Oregon Laws, 1963, no appropriation of water
shall be made or granted by any state agency or public corporation of
the state for waters of the streams and tributaries in Table 1 when
the flows are below the levels specified. This limitation shall not
apply to:

a. Water legally stored or released from storage.
b. Domestic and livestock uses.
c. Municipal uses on Bridge Creek, South Fork John Day River, and
the John Day River from USGS gage 14038530 to the North Fork.
d. Industrial use rights and industrial use under permits with
priority dates before December 2, 1966 on the John Day River
from USGS gage 14038530 to the North Fork.

Attainment of the specified flow levels during some portion of the
year will require use of stored water or other measures to augment
flows.

D. Applications for the use of the waters of the John Day River Basin
shall not be accepted by any state agency for any other use and the
granting of applications for such other uses is declared to be
prejudicial to the public interest and the granting of applications
for such other uses would be contrary to the Integrated and
coordinated program for the use and control of the water resources
of the state.

E. Rights to use of water for industrial or mining purposes granted by
any state agency shall be issued only on condition that any effluents
or return flows from such uses shall not interfere with other
beneficial uses of water.

F. Structures or works for the utilization of the waters in accordance
with the aforementioned classifications are also declared to be
prejudicial to the public interest unless planned, constructed and
operated in conformity with the applicable provisions of OAR 534.330
and such structures or works are further declared to be
prejudicial to the public interest which do not give cognizance to
the multiple-purpose concept.

Signed December 2, 1985

WATER RESOURCES COMMISSION

William A. Young
WATER RESOURCES DEPARTMENT

10A
BEFORE THE WATER RESOURCES COMMISSION
OF THE
STATE OF OREGON

In the matter of formulating an integrated, coordinated program for the use and control of the water resources of the John Day River Basin
December 2, 1985

WHEREAS the State Water Resources Board under the authority of ORS 536.300 has undertaken a study of the John Day River Basin as delineated on State Water Resources Board Map, File 6.70146;

WHEREAS results of this study have been published in the State Water Resources Board Report, John Day River Basin and the Water Resources Department has conducted further studies pertaining to the development of water resources of the basin;

WHEREAS in these studies consideration was given to means and methods of augmenting, conserving and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control; and

WHEREAS the Water Resources Commission under the authority of ORS 536.300 through ORS 536.340 may classify or establish minimum perennial flow streams on the water resources of the John Day Basin;

WHEREAS as a result of said studies the following findings and conclusions have been reached by this Commission:

1. The total basin yield is adequate on an average-year basis to supply all existing and presently contemplated needs and uses of water.

2. There are areas where the yield is not adequate to supply existing needs during a critical year.

3. Flows are not sufficient during low-flow months to meet existing or future instream or out-of-stream demands.

4. Simultaneous use of a major portion of the existing consumptive water rights results in flows at or near the zero level in many streams during the summer and early fall months.

5. Flows at or near the zero level also occur under existing conditions on many streams having little water under appropriation.

6. Augmentation of the water supply in periods of need can come through more efficient use of presently appropriated water.

7. There are many physically feasible storage sites.

8. Available data indicate that the ground water resource is limited.

9. Ground water represents an important source of water, primarily in meeting existing domestic, livestock, and municipal needs.

10. There are substantial quantities of unappropriated water.

11. Over 1,400,000 acre-feet of the waters of the John Day River and its tributaries were withdrawn in 1915 by the State Engineer for out-of-basin diversion for irrigation, power and domestic purposes. This withdrawal amounts to more than the average annual discharge of the John Day River at McDonald Ferry.

12. No water has been applied to beneficial use under the aforementioned withdrawal.

13. Utilization of this withdrawal and its priority will preclude maximum beneficial use of the waters of John Day River within the basin.

14. More than 25 percent of the land holding water rights is no longer irrigated. More than 75 percent of the water appropriated for mining and power uses is no longer utilized for these purposes.

15. There is need to investigate modification or rescission of the aforementioned withdrawals and unused rights.

16. There is need to insure water for domestic, livestock, municipal, and wildlife uses which, while small, are of great importance.

17. There is need to develop stock water facilities for better range utilization.

18. Irrigation is and will continue to be the major consumptive use of water.

19. Irrigation development is restricted by the limited acreage of bottom land and the unfavorable location of other arable land.

20. Most irrigated lands do not receive an adequate supply of water throughout the irrigation season in an average water year and experience severe shortages in a critically low water year.

21. Storage would be necessary to provide an adequate water supply for irrigated and irrigable lands.

22. The hydroelectric power potential of the basin is limited.

23. Existing stream regimen and water use reduce the desirability of hydroelectric power development in the basin.

24. Present industrial use of water is small and is not expected to increase materially.

25. There is potential for increased mining activity.

26. Present mining use of water is small and is not expected to increase materially.

27. Water-based recreation is limited by low seasonal streamflows and the small number of lakes and reservoirs.

28. The natural lakes have significant recreational value.

29. The main stem of the John Day River from Service Creek Bridge (river mile 157) to Twin Falls (river mile 10) is designated as a State Scenic Waterway.

30. Aquatic life, including fish life, is and will continue to be the major nonconsumptive use of water.

31. A major conflict exists between irrigation and fish life use of water.

32. There is potential for enhancement of fish life and recreation.

33. Storage or other watershed management measures would be required to attain flows for enhancement of fish life and recreation.

34. Flows recommended by fisheries agencies are substantially higher at many locations than the flow levels that exist during an average water year.

35. Maintenance of minimum perennial streamflows would benefit fish life, wildlife and recreation.

36. Thirteen minimum perennial streamflows included in the Senate Bill 225 (1983) application are located in the John Day River Basin.

37. The proposed minimum streamflows would protect flows during parts of the year for important populations of wild anadromous and resident fish in the mainstem John Day River and its North, Middle, and South Forks; Beech, Canyon, Cottonwood, Rock and Bridge Creeks tributary to the mainstem John Day River; Clear Creek tributary to Middle Fork John Day River, and Granite Creek tributary to the North Fork John Day River.

38. Municipal use for Mitchell, Dayville, and Mt. Vernon is of greater importance than support of fish life and should be exempted from minimum perennial streamflows.
39. Existing industrial use is more important than fish life use in the river reach from gage 14038530 to the North Fork.

40. Exemption of industrial applications filed before December 2, 1986 would allow development of alternative sources for existing and future industrial demands.

41. Criteria for the determination of desirable base flows commensurate with all beneficial uses of water have not been developed.

42. Agriculture is a more important use than increasing the existing maximum flows on the North Fork John Day

43. Pollution of surface and ground water is local, intermittent in occurrence, and is not a serious basinwide problem.

44. Utilization of flows to minimize pollution should only be permitted if it does not limit or conflict with the multiple-purpose objectives for water use in the basin.

45. Flooding and streambank erosion are serious local problems in some areas.

46. Erosion of cropland and rangeland is a major problem and often results in siltation of streams.

47. Major drainage problems occur on irrigated lands

48. Because of physical and economic factors, classification of certain waters for limited-purpose use would be in the public interest

NOW THEREFORE BE IT RESOLVED that this Commission hereby adopts the following program in accordance with the provisions of ORS 556.300(2) pertaining to the water resources of the John Day River Basin

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the John Day River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses. The waters of the John Day River Basin are hereby so classified with the following exceptions

1. The maximum economic development of this state, the attainment of the highest and best use of the waters of the natural lakes of the John Day River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, irrigation of lawn or noncommercial garden not to exceed one-half acre in area, power development not to exceed 7-1/2 theoretical horsepower, recreation, wildlife and fish life uses, and the waters of the natural lakes of the John Day River Basin are hereby so classified.

2. The maximum economic development of this state, the attainment of the highest and best use of the waters of the John Day River from Service Creek Bridge (river mile 157) to Tumwater Falls (river mile 10), and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, industrial, mining, recreation, wildlife and fish life uses.

B. For the purpose of maintaining a minimum perennial streamflow sufficient to support aquatic life, no appropriations of water except for domestic or livestock uses shall be made or granted by any state agency or public corporation of the state for the waters listed below and as shown in Table 1:

1. The Middle Fork John Day River above its mouth or of its tributaries for flows of the Middle Fork John Day River at USGS Gage 14-0465 at Ferry (SH 1/4 NM 1/4 Section 2, Township 9 South, Range 19 East) below 30 cubic feet per second measured at said gage except that this limitation shall not apply to waters legally stored or legally released from storage.

2. The North Fork John Day River above former USGS Gage 14-0415 near Dale (SE 1/4 SE 1/4 Section 35, Township 6 South, Range 23 East) or of its tributaries above said gage for flows of the North Fork John Day River below 35 cubic feet per second measured at said gage except that this limitation shall not apply to waters legally stored or legally released from storage.

3. The North Fork John Day River above its mouth or of its tributaries for flows of the North Fork John Day River at USGS Gage 14-0460 at Monument (SE 1/4 Section 2, Township 9 South, Range 22 East) below 55 cubic feet per second measured at said gage except that this limitation shall not apply to waters legally stored or legally released from storage.

4. The John Day River above USGS 14-0465 at Service Creek (N 1/2 Section 18, Township 9 South, Range 23 East) or of its tributaries above said gage for flows of the John Day River below 30 cubic feet per second measured at said gage except that this limitation shall not apply to waters legally stored or legally released from storage.

5. The John Day River above its mouth or of its tributaries for flows of the John Day River at USGS Gage 14-0480 at McDonald Ferry (SH 1/4 Section 11, Township 1 North, Range 19 East) below 20 cubic feet per second measured at said gage except that this limitation shall not apply to waters legally stored or legally released from storage.
C. To support aquatic life and minimize pollution, in accordance with Section 3, Chapter 796, Oregon Laws, 1983, no appropriation of water shall be made or granted by any state agency or public corporation of the state for waters of the streams and tributaries in Table 1 when the flows are below the levels specified. This limitation shall not apply to:

a. Water legally stored or released from storage.

b. Domestic and livestock uses.

c. Municipal uses on Bridge Creek, South Fork John Day River, and the John Day River from USGS gage 1403850 to the North Fork.

d. Industrial use rights and industrial use under permits with priority dates before December 2, 1986 on the John Day River from USGS gage 1403850 to the North Fork.

Attainment of the specified flow levels during some portion of the year will require use of stored water or other measures to augment flows.

D. Applications for the use of the waters of the John Day River Basin shall not be accepted by any state agency for any other use and the granting of applications for such other uses is declared to be prejudicial to the public interest and the granting of applications for such other uses would be contrary to the integrated and coordinated program for the use and control of the water resources of the state.

E. Rights to use of water for industrial or mining purposes granted by any state agency shall be issued only on condition that any effluents or return flows from such uses shall not interfere with other beneficial uses of water.

F. Structures or works for the utilization of the waters in accordance with the aforementioned classifications are also declared to be prejudicial to the public interest unless planned, constructed, and operated in conformity with the applicable provisions of ORS 556.310 and any such structures or works are further declared to be prejudicial to the public interest which do not give cognizance to the multiple-purpose concept.

Dated December 2, 1985

WATER RESOURCES COMMISSION

William M. Young
Director
WATER RESOURCES DEPARTMENT

4918A
Before the Water Policy Review Board

Of the

State of Oregon

WHEREAS the State Water Resources Board under the authority of ORS 536.300 completed a study of the Deschutes River Basin; and

WHEREAS results of that study were published in State Water Resources Board Report, Deschutes River Basin, dated January 1961; and

WHEREAS the Water Policy Review Board under the authority of ORS 536.340 may reclassify the water resources of the Deschutes River Basin; and

WHEREAS the Water Policy Review Board under the authority of ORS 536.300 and 536.340 has undertaken a restudy of the water resources of the Deschutes River Basin; and

WHEREAS in this study consideration was given to means and methods of augmenting, conserving, and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control; and

WHEREAS as a result of said study the following findings have been reached by this Board:

1. The total quantity of water is sufficient on an average year basis to satisfy all existing and contemplated needs and uses of water with the exception of utilization of water to minimize pollution.

2. Flows are not sufficient on many streams during the summer months of average water years to supply existing and future demands.

3. Simultaneous use of a major portion of existing consumptive rights results in flows at or near the zero level on some streams during the summer months.

4. Augmentation of the water resources can be achieved through storage of surplus winter and spring runoff; reduction of storage, channel, and transmission losses; and more efficient use of presently appropriated water.

5. There are physically feasible storage sites in the basin.

6. Unappropriated waters of the Deschutes River and its tributaries above Bend, Tumalo Creek above Columbia-Southern Canal, Crooked River, Ochoco Creek and White River and its tributaries have been withdrawn for special uses.

7. The established limited purposes of existing storage developments restrict multiple beneficial use of the water resources.

8. The existence of ground water has been established in certain sections of the basin, but quantities have not been determined.

9. Domestic, livestock, and municipal uses of water, while important, represent minor quantities in existing and contemplated future water use.

10. Irrigation is and will continue to be the major consumptive water use in the basin.

11. Adequately irrigated agricultural lands represent only a small portion of the total irrigated area.

12. The existing irrigated acreage could be more than doubled providing an adequate supply of water were available.

13. The basin has substantial potential for power development.

14. The basin has potential for industrial development.

15. Sufficient water will not be available in many locations for major water-using industries without provision for seasonal storage, acquisition of existing rights, or development of ground water resources.

16. The use of water for mining purposes is slight and is not expected to increase materially in the foreseeable future.

17. Recreation is a major use of water and an important factor in the economy of the basin.

18. There is an abundance of reservoirs, lakes and streams available for water-based recreation in the western portion of the basin.

19. There is potential for more extensive use of existing waters for recreation purposes.

20. In the area of intermittent streams, reservoirs provide water-based recreation.

21. Water consumption by wildlife does not represent a significant quantity.

22. A major conflict exists between irrigation and fish life use of water.

23. A major conflict exists between power and fish life use of water.

24. Reduction of present reservoir and stream level fluctuations, maintenance of minimum reservoir levels and improved streamflows would enhance fish life and recreation.

25. River related recreation is important to the economy of the upper Deschutes Basin.

26. The support of resident and stocked fish is essential to river-related recreation.

27. Recommended base flows suggested by fisheries agencies are substantially higher in many locations than flow levels that can be obtained during average water years under current stream regimen and existing water rights and priorities.

28. Storage and scheduled releases of excess winter and spring runoff, reduction of channel and transmission losses, or acquisition of some existing rights would be necessary to obtain the flows recommended by fisheries agencies. The economic feasibility of such measures has not been determined.

29. Pollution of surface and ground water is not a significant problem at present.

30. Floods, drainage and streambank erosion are not major problems.

31. Major foreseeable quantitative uses of water in the Deschutes River Basin will be for irrigation, power, recreation, and fish life uses.

32. Utilization of flows to minimize pollution should not be permitted if such use limits or conflicts with the multiple-purpose concept.

33. Establishment of restrictions on further appropriations would prevent an increase in depletion potential on some streams which would aid in maintaining minimum flows.

34. Where streams are seasonally overappropriated, the establishment of restrictive actions would have no immediate physical effect until additional flows become available.

35. Criteria for determination of desirable base flows commensurate with all beneficial uses have not been developed. Flow levels for recreational use may be substantially greater than flows recommended for the support of aquatic life.

36. It is imperative that single-purpose development of available sites does not preclude optimum utilization of the resource.

37. Certain major rivers, or river sections, and numerous lakes, minor streams, and creeks are by nature of their physiography, location, land ownership, or economic potential available only for limited resource uses.

38. Physical features, degree of economic development, and water use requirements vary from subbasin to subbasin.

NOW THEREFORE BE IT RESOLVED that for reason of variance in physical features, degree of economic development, and water use requirements from subbasin to subbasin, the Board adopts the following findings and issues program statements for each of the subbasins of the Deschutes River Basin.

UPPER DESCHUTES RIVER

WHEREAS the State Water Resources Board under the authority of ORS 536.300 has undertaken a study of the Upper Deschutes River Basin as delineated on State Water Resources Board Map, File 5.7014;

WHEREAS in this study consideration was given to means and methods of augmenting, conserving and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control, and

WHEREAS as a result of said study the following findings have been reached by this Board:

1. The total quantity of water is sufficient on an average-year basis to satisfy all existing and contemplated needs and uses of water with the exception of utilization of water to minimize pollution.

2. There is not enough water legally available on a critical-year basis to meet existing and contemplated consumptive needs within this basin.

3. Maldistribution exists with regard to physical location and with respect to availability during time of need.

4. Many streams do not provide enough flow for present nonconsumptive public uses in periods of relatively low as well as critical flow.
5. Augmentation of the water resources in periods of need would require storage of surplus runoff.

6. There are physically feasible storage sites in the basin.

7. The existence of ground water has been established in certain sections of the basin, but quantities have not been determined.

8. All unappropriated waters of the Deschutes River and its tributaries above Bend have been withdrawn by the State Engineer for domestic, irrigation and power purposes.

9. A major portion of the withdrawn waters has been appropriated.

10. There is need to insure water for domestic, livestock, and municipal uses which, while small, are of benefit to the state.

11. Irrigation use of water is small in this basin and is not expected to increase materially in the foreseeable future.

12. Substantial quantities of water have been appropriated for irrigation use in downstream basins.

13. Power development appears to be economically and physically feasible.

14. There is limited potential for industrial use of water.

15. There are no existing water rights for mining operations in the basin. Potential for such use of water appears to be minor.

16. The basin has potential for expanded recreation use of water. The natural lakes and reservoirs constitute valuable recreation assets.

17. Water consumption by wildlife does not represent a significant quantity.

18. There are no anadromous fish in the basin, but resident fish constitute an important asset of the state.

19. There is potential for development of anadromous fish, but this cannot be achieved without the improvement of fish passage and low-flow conditions.

20. Conflicts exist between fish life and irrigation uses of water.

21. Pollution of surface and ground water is not a significant problem.

22. Drainage and reclamation of drained lands are not significant factors in present and contemplated water use.

23. Flood problems are minor.

24. Utilization of flows to minimize pollution should not be permitted if such use interferes with the multiple-purpose concept.

25. Certain lakes are, by nature of their physiography, location, land ownership, or economic potential available only for limited resource use.

26. The maximum beneficial use of the waters of the Upper Deschutes River Basin will be for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses.

NOW THEREFORE BE IT RESOLVED that this Board hereby adopts the following program in accordance with the provisions of ORS 536.300(2) pertaining to the water resources of the Upper Deschutes River Basin.

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the Upper Deschutes River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses and the waters of the Upper Deschutes River Basin are hereby so classified with the following exception:

The maximum economic development of this state, the attainment of the highest and best use of the waters of the natural lakes of the Upper Deschutes River Basin, except for Crescent Lake, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, irrigation of lawn or noncommercial garden not to exceed one-half acre in area, power development not to exceed 7 1/2 theoretical horsepower, recreation, wildlife and fish life uses and the waters of the natural lakes, Upper Deschutes River Basin, except for Crescent Lake, are hereby so classified.

B. To support aquatic life and minimize pollution, in accordance with Section 3, Chapter 796, Oregon Laws, 1983, no appropriation of water shall be made or granted by any state agency or public corporation of the state for waters of the Upper Deschutes River and tributaries when flows are below the levels specified in Table 1. This limitation shall not apply to:

1. Human and livestock consumption.
2. Water legally released from storage.

Attainment of the specified flow levels during some portions of the year will require development of water storage or implementation of other measures to augment flows.

1-4-45
C. Applications for the use of the waters of the Upper Deschutes River Basin shall not be accepted by any state agency for any other use and the granting of applications for such other uses is declared to be prejudicial to the public interest and the granting of applications for such other uses would be contrary to the integrated and coordinated program for the use and control of the water resources of the state.

D. Rights to use of water for industrial or mining purposes granted by any state agency shall be issued only on the condition that any effluents or return flows from such uses shall not interfere with other beneficial uses of water.

E. Structures or works for the utilization of the waters in accordance with the aforementioned classifications are also declared to be prejudicial to the public interest unless planned, constructed and operated in conformity with applicable provisions of ORS 536.310 and any such structures or works are further declared to be prejudicial to the public interest which do not give proper cognizance to the multiple-purpose concept.

WHEREAS the State Water Resources Board under the authority of ORS 536.300 has undertaken a study of the Middle Deschutes River Basin as delineated on State Water Resources Board Map, File 5.7014.

WHEREAS in this study consideration was given to means and methods of augmenting, conserving, and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control; and

WHEREAS as a result of said study the following findings have been reached by this Board

1. The total quantity of water is sufficient on an average-year basis to satisfy all existing and contemplated needs and uses of water in this basin with the exception of utilization of water to minimize pollution.

2. Maldistribution exists with regard to physical location and with respect to availability during time of need.

3. Simultaneous use of a major portion of existing consumptive rights results in flows at or near the zero level on many streams during the summer months.

-8-
4. The existence of ground water has been established in certain sections of the basin, but quantities have not been determined.
5. There are legislative restrictions on the use of waters of Tumalo Creek.
6. There is need to insure water for domestic, livestock and municipal uses which, while small, are of benefit to the state.
7. Irrigation is and will continue to be the major consumptive use of water.
8. Natural flow and present degree of regulation are insufficient to satisfy existing irrigation requirements.
9. Water supply will be a limiting factor in developing potential irrigable land.
10. Augmentation of the water resources in periods of need can be achieved through storage of surplus winter and spring runoff, reduction of storage, channel, and transmission losses; and more efficient use of presently appropriated water.
11. There are physically feasible storage sites.
12. There is substantial potential for power development.
13. The development of the power potential could seriously conflict with recreation and fish life values.
14. There is considerable potential for industrial use of water.
15. Storage and scheduled releases of surplus winter and spring runoff; reduction of channel and transmission losses; or acquisition of some existing rights would be necessary to obtain the waters needed by major water-using industries.
16. Use of water for mining purposes is slight and is not expected to increase materially in the foreseeable future.
17. Recreation is a major use of water.
18. The Metolius River is superior as a natural recreation value.
19. Water consumption by wildlife does not represent a significant quantity.
20. There is inadequate streamflow for fishery requirements.
21. Base flows recommended by fisheries agencies are substantially higher in many locations than flow levels that can be obtained during average water years under current stream regimen and existing water rights and priorities.
22. Pollution of surface and ground water is not a significant problem.
23. Major foreseeable quantitative uses of water will be for irrigation, power, recreation and fish life.
24. Utilization of flows to minimize pollution should not be permitted if such use limits or conflicts with the multiple-purpose concept.
25. Maintenance of minimum perennial streamflows would generally benefit recreation, wildlife and fish life.
26. Criteria for determination of desirable base flows commensurate with all beneficial uses of water have not been developed.
27. Certain river sections, minor streams, creeks and lakes are by nature of their physiography, location, land ownership, or economic potential available only for limited resource use.
28. The maximum beneficial use of the waters of the Middle Deschutes River Basin will be for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses.

NOW THEREFORE BE IT RESOLVED that this Board hereby adopts the following program in accordance with the provisions of ORS 536.300(2) pertaining to the water resources of the Middle Deschutes River Basin.

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the Middle Deschutes River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses and the waters of the Middle Deschutes River Basin are hereby so classified with the following exceptions:

1. The State Water Resources Board program, Lower Main Stem Deschutes River, adopted April 3, 1964, as modified by the Water Policy Review Board.
2. The maximum economic development of this state, the attainment of the highest and best use of the waters of the main stem, Metolius River, above river mile 13.0, and the attainment of an integrated and coordinated program for the benefit of the state...
as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, irrigation of lawn or non-commercial garden not to exceed one-half acre in area, power development, recreation, wildlife and fish life uses and the waters of the main stem, Metolius River, above river mile 13.0, are hereby so classified.

3. Further, no out-of-basin diversions of the waters of the mainstem Metolius River, above river mile 13.0, shall be permitted for any use.

4. No further appropriations except for domestic or livestock uses shall be permitted for waters of the mainstem Deschutes River, from the head of Lake Billy Chinook near river mile 120 to the North Canal Dam near river mile 165.

5. The maximum economic development of this state, the attainment of the highest and best use of the waters of the natural lakes of the Middle Deschutes River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, irrigation of lawn or non-commercial garden not to exceed one-half acre in area, power development not to exceed 7-1/2 theoretical horsepower, recreation, wildlife and fish life uses.

B. For the purpose of maintaining a minimum perennial streamflow sufficient to support aquatic life, no appropriations of water except for domestic or livestock uses shall be made or granted by any state agency or public corporation of the state for the waters of Lake Creek or its tributaries above the confluence of Lake Creek with the Metolius River for flows of Lake Creek below 20 cubic feet per second measured at the mouth of Lake Creek except that this limitation shall not apply to waters legally stored or legally released from storage (priority date - May 24, 1962).

C. Applications for the use of the waters of the Middle Deschutes River Basin shall not be accepted by any state agency for any other use and the granting of applications for such other uses is declared to be prejudicial to the public interest and the granting of applications for such other uses would be contrary to the integrated and coordinated program for the use and control of the water resources of the state.

D. Rights to use of water for industrial or mining purposes granted by any state agency shall be issued only on condition that any effluents or return flows from such uses shall not interfere with other beneficial uses of water.

E. Structures or works for the utilization of the waters in accordance with the aforementioned classifications are also declared to be prejudicial to the public interest unless planned, constructed, and operated in conformity with the applicable provisions of ORS 536.310 and any such structures or works are further declared to be prejudicial to the public interest which do not give proper cognizance to the multiple-purpose concept.

LOWDER DESCHUTES RIVER

WHEREAS the State Water Resources Board under the authority of ORS 536.300 studied the Lower Deschutes River Basin as delineated on State Water Resources Board Map, File 5.7014;

WHEREAS the Water Policy Review Board under the authority of ORS 536.300 and 536.340 has undertaken a restudy of the Lower Deschutes Basin;

WHEREAS in this study consideration was given to means and methods of augmenting, conserving and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation and flood control; and

WHEREAS as a result of said study the following findings have been reached by this Board for the tributaries of the Deschutes River within the Lower Deschutes River Basin:

1. The total quantity of water is sufficient on an average-year basis to satisfy existing needs and uses of water with the exception of utilization of water to minimize pollution.

2. Maldistribution exists with regard to physical location and with respect to availability during time of need.

3. Many streams do not provide enough flow for nonconsumptive public uses at present in periods of relatively low as well as critical flow.

4. Simultaneous use of a major portion of existing consumptive rights results in flows at or near the zero level on many streams during the summer months.

5. Flows, unless augmented by storage, would not be sufficient on most streams during the summer months to supply future consumptive and nonconsumptive demands.

6. The existence of ground water has been established in certain sections of the basin, but quantities have not been determined.

7. All unappropriated waters of White River and tributaries have been withdrawn by the State Engineer for special uses.

-11-
8. There is need to insure quantities of water for domestic, livestock, and municipal uses which, while small, are of benefit to the state.

9. Irrigation is and will continue to be the major consumptive use of water.

10. Potential exists for the development of the agricultural economy through expanded irrigation.

11. The unavailability of dependable supplies of adequate water in the future would be a restriction on the development of the agricultural potential of the basin.

12. Power development appears to be economically and physically feasible.

13. There is limited potential for industrial use of water.

14. Use of water for mining purposes is slight and is not expected to increase materially in the foreseeable future.

15. Recreation is an important use of water in the basin.

16. Water consumption by wildlife does not represent a significant quantity.

17. Full development of the anadromous fishery potential cannot be achieved without the improvement of fish passage and low-flow conditions.

18. Material improvement of minimum flows for fish life cannot be achieved without the development of surface water storage.

19. Pollution of surface and ground water is not a significant problem.

20. Major foreseeable quantitative uses of water of the Lower Deschutes Basin will be for irrigation, recreation, and fish life.

21. Drainage and reclamation of drained lands are not significant factors in present and contemplated water use.

22. Limited flood problems exist, mainly on the eastern tributaries of the Deschutes River.

23. There are physically-feasible storage sites within the basin.

24. Small reservoirs on minor tributaries could reduce flash floods and streambank erosion and provide late-season irrigation water.

25. Utilization of flows to minimize pollution should not be permitted if such use limits or conflicts with the multiple-purpose concept.

26. Maintenance of minimum perennial streamflows would be in the public interest.

27. Certain lakes are by nature of their physiography, location, land ownership, or economic potential available only for limited resource use.

28. Criteria for determination of desirable base flows commensurate with all beneficial uses of water have not been developed, although information is available on flow requirements for aquatic life.

29. The maximum beneficial use of the waters of the tributaries of the Deschutes River within the Lower Deschutes Basin will be for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses.

NOW THEREFORE BE IT RESOLVED that this Board hereby adopts the following program in accordance with the provisions of ORS 536.300(2) pertaining to the water resources of the Lower Deschutes River Basin:

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the Lower Deschutes River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses and the waters of the Lower Deschutes River Basin are hereby so classified with the following exceptions:

1. The State Water Resources Board program, Lower Main Stem Deschutes River, adopted April 3, 1964, as modified by the Water Policy Review Board.

2. The waters of Boulder Lake in Hood River and Wasco Counties are classified only for domestic and livestock uses; power development not to exceed 7-1/2 theoretical horsepower; recreation, wildlife and fish life uses; and irrigation not to exceed 100 acre-feet annually from water stored in the lake.

3. The maximum economic development of this state, the attainment of the highest and best use of the waters of the other natural lakes of the Lower Deschutes River Basin, and the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, irrigation of lawn or noncommercial garden not to exceed one-half acre in area, power development not to exceed 7-1/2 theoretical horsepower, recreation, wildlife, and fish life uses and the waters of the natural lakes of the Lower Deschutes River Basin are hereby so classified.
B. For the purpose of maintaining a minimum perennial streamflow sufficient to support aquatic life, no appropriations of water except for domestic or livestock uses shall be made or granted by any state agency or public corporation of the state for the waters of the White River or its tributaries above the confluence of White River with the Deschutes River for flows of the White River below the specified flows in Table 2, except that this limitation shall not apply to waters legally stored or legally released from storage.

C. Applications for the use of the waters of the Lower Deschutes River Basin shall not be accepted by any state agency for any other use and the granting of applications for such other uses is declared to be prejudicial to the public interest and the granting of applications for such uses would be contrary to the integrated and coordinated program for the use and control of the water resources of the state.

D. Rights to use of water for industrial or mining purposes granted by any state agency shall be issued only on condition that any effluents or return flows from such uses shall not interfere with other beneficial uses of water.

E. Structures or works for the utilization of the waters in accordance with the aforementioned classifications are also declared to be prejudicial to the public interest unless planned, constructed, and operated in conformity with the applicable provisions of ORS 536.310 and any such structures or works are further declared to be prejudicial to the public interest which do not give cognizance to the multiple-purpose concept.

WHEREAS the State Water Resources Board under the authority of ORS 536.300 has undertaken a study of the Deschutes - Upper Crooked River Basin as delineated on State Water Resources Board Map, File 5, 1984.

WHEREAS in this study consideration was given to means and methods of augmenting, conserving and classifying such water resources, existing and contemplated needs and uses of water for domestic, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses, and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control, and

WHEREAS as a result of said study the following findings have been reached by this Board.

1. The total quantity of water is sufficient on an average-year basis to satisfy all existing rights to water in this basin.

2. There is not enough water on a critical-year basis to meet existing consumptive needs.
3. Maldistribution exists with regard to physical location and with respect to availability during time of need.

4. Simultaneous use of a major portion of existing consumptive rights results in flows at or near the zero level on many streams during the summer months.

5. Most streams do not provide enough flow for nonconsumptive public uses at present in periods of relatively low as well as critical flow.

6. The existence of ground water has been established in certain sections of the basin, but quantities have not been determined.

7. There is need to insure quantities of water for domestic, livestock, municipal and mining uses which, while small, are of benefit to the state.

8. There are no municipal water systems in the basin.

9. Irrigation is and will continue to be the major consumptive use of water.

10. Most irrigated lands in the basin do not receive an adequate supply of water.

11. Substantially more than the average annual yield of the Upper Crooked River Basin has been withdrawn by the State Engineer for irrigation purposes.

12. Power development appears to be economically and physically feasible.

13. There is limited potential for industrial use of water.

14. Water-based recreation will become a more significant use of water in this basin.

15. Water consumption by wildlife does not represent a significant quantity.

16. Game fish populations are limited because of extreme low flows, high water temperatures, and extensive populations of rough fish.

17. Pollution of surface and ground water is not a significant problem.

18. Drainage and reclamation of drained lands are not significant factors in present and contemplated water use.

19. Flood problems exist mainly on the mainstem of Crooked River.

20. There are physically feasible storage sites within the basin.

21. Small reservoirs on minor tributaries could reduce flash floods and streambank erosion and provide late-season irrigation water.

22. Utilization of flows to minimize pollution should not be permitted if such use limits or conflicts with the multiple-purpose concept.

23. Criteria for determination of desirable base flows commensurate with all beneficial uses of water have not been developed.

24. The maximum beneficial use of the waters of the Upper Crooked River Basin will be for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses.

NOW THEREFORE BE IT RESOLVED that this Board hereby adopts the following program in accordance with the provisions of ORS 536.300(2) pertaining to the water resources of the Deschutes - Upper Crooked River Basin:

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the Deschutes - Upper Crooked River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses and the waters of the Deschutes - Upper Crooked River Basin are hereby so classified.

B. Applications for the use of the waters of the Deschutes - Upper Crooked River Basin shall not be accepted by any state agency for any other use and the granting of applications for such other uses is declared to be prejudicial to the public interest and the granting of applications for such other uses would be contrary to the integrated and coordinated program for the use and control of the water resources of the state.

C. Rights to use of water for industrial or mining purposes granted by any state agency shall be issued only on condition that any effluents or return flows from such uses shall not interfere with other beneficial uses of water.

D. Structures or works for the utilization of the waters in accordance with the aforementioned classifications are also declared to be prejudicial to the public interest unless planned, constructed, and operated in conformity with the applicable provisions of ORS 536.310 and any such structures or works are further declared to be prejudicial to the public interest which do not give proper cognizance to the multiple-purpose concept.
WHEREAS the State Water Resources Board under the authority of ORS 536.300 has undertaken a study of the Deschutes - Lower Crooked River Basin as delineated on State Water Resources Board Map, File 5.7014;

WHEREAS in this study consideration was given to means and methods of augmenting, conserving, and classifying such water resources, existing and contemplated needs and uses of water for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses and for pollution abatement as well as other related subjects including drainage, reclamation, and flood control, and

WHEREAS as a result of said study the following findings have been reached by this Board:

1. The total quantity of water is sufficient on an average year basis to satisfy all existing and contemplated consumptive needs and uses of water.
2. There are streams within the basin whose average annual yield is not sufficient to satisfy existing rights.
3. Maldistribution exists with regard to physical location and with respect to availability during times of need.
4. Simultaneous use of a major portion of existing consumptive rights results in flows at or near the zero level on many streams during the summer months.
5. Most streams in the basin do not provide enough flow for nonconsumptive public uses at present in periods of relatively low as well as critical flow
6. The existence of ground water has been established in certain sections of the basin, but quantities have not been determined.
7. There is need to insure water for domestic, livestock, municipal and mining uses which, while small, are of benefit to the state.
8. Irrigation is and will continue to be the major consumptive use of water.
9. There is additional potential for irrigation use of water.
10. Power development appears to be economically and physically feasible.
11. There is potential for industrial use of water.
12. Sufficient water will not be available in many locations for major water-using industries without the provision of seasonal storage.
13. Reservoirs will provide a major portion of water-based recreation.
14. The waters of the Crooked River, including Opal Springs, from river mile 6.5 to river mile 18.0, are a valuable source of municipal, irrigation, and industrial water.
15. Little potential for enhancement of fish life exists and is dependent upon securing adequate streamflow.
16. Increases of population and the need to serve presently unsewered areas will require municipal sewage works to be expanded
17. Limited flood problems exist.
18. A coordinated plan of operation of Ochoco and Prineville Reservoirs will materially alleviate flood damages in the Prineville Valley.
19. There are physically feasible storage sites within the basin.
20. Small reservoirs on major tributaries could reduce flash floods and streambank erosion and provide late-season irrigation water.
21. Utilization of flows to minimize pollution should not be permitted if such use limits or conflicts with the multiple-purpose concept.
22. Certain river sections, major streams and creeks are by nature of their physiography, location, land ownership, or economic potential available only for limited resource use.
23. Criteria for determination of desirable base flows commensurate with all beneficial uses of water have not been developed.
24. The maximum beneficial use of the waters of the Deschutes - Lower Crooked River Basin will be for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses.

NOW THEREFORE BE IT RESOLVED that this Board hereby adopts the following program in accordance with the provisions of ORS 536.300(2) pertaining to the water resources of the Deschutes - Lower Crooked River Basin:

A. The maximum economic development of this state, the attainment of the highest and best use of the waters of the Deschutes - Lower Crooked River Basin, and the attainment of an integrated and coordinated program for the benefit of the state as a whole will be furthered through utilization of the aforementioned waters only for domestic, livestock, municipal, irrigation, power development, industrial, mining, recreation, wildlife and fish life uses and the waters of the Deschutes - Lower Crooked River Basin are hereby so classified with the following exceptions:
1. The State Water Resources Board program, Lower Main Stem Deschutes River, adopted April 3, 1964, as modified by the Water Policy Review Board.

2. No further appropriations of water except for domestic or livestock uses shall be made or granted by any state agency for the waters of Ochoco Creek and its tributaries.

B. Applications for the use of the waters of the Deschutes - Lower Crooked River Basin shall not be accepted by any state agency for any other use and the granting of applications for such uses is declared to be prejudicial to the public interest and the granting of applications for such other uses would be contrary to the integrated and coordinated program for the use and control of the water resources of the state.

C. Rights to use water for industrial or mining purposes granted by any state agency shall be issued only on condition that any effluents or return flows from such uses shall not interfere with other beneficial uses of water.

D. Structures or works for the utilization of the water in accordance with the aforementioned classifications are also declared to be prejudicial to the public interest unless planned, constructed and operated in conformity with the applicable provisions of ORS 536.310 and any such structures or works are further declared to be prejudicial to the public interest which do not give proper cognizance to the multiple-purpose concept.

Re: Ochoco National Forest Agency Response

Dear Bob:

Our concern is that the Forest Service has not addressed the effect their management plan will have on similar resources managed by the state or adjacent private lands.

The federal government, as the major landowner in a geographical area, can, with its management policies, enhance or stifle the economy or alter the development of that area. We feel this is a very important aspect which needs attention in the management plan.

Thank you for your consideration in this matter. I will look forward to seeing you at the meeting on November 24.

Sincerely,

SALEM OR 97310

Dear Jim:

The proposed Land and Resource Management Plan of the Ochoco National Forest and Crooked River area is within the Jefferson, Wheeler, Grant, Crook, Deschutes, and Harney County Soil and Water Conservation Districts. Each of these districts are governed by a Board of local elected Directors. Under the Oregon Soil and Water Conservation District Law (ORS 568), each of these districts have the responsibility to work with the Oregon Forestry Department as described in the Memorandum of Understanding between the Department of Agriculture and the Forestry Department.

ORS 568.205 empowers the districts to provide for the conservation of renewable natural resources of the state, to conserve and develop natural resources, and to prevent soil erosion, control floods, conserve and develop water resources and water quality, preserve wildlife, conserve natural beauty, and promote recreational development.

Each chapter of the Ochoco National Forest and Crooked River proposed Land and Resource Management Plan identifies areas where the soil and water conservation districts would have concerns. Such as, how the implementation would affect the soil and water runoff, and to what extent erosion and sedimentation would be kept to a level within acceptable standards.

The study, as written, defines areas that show what is being proposed to minimize soil and water problems. If these suggestions are followed throughout the program, and if assistance from Soil Conservation Service and Soil and Water Conservation Districts is utilized, there would be greater chance of improved soil and water conservation practices being followed throughout the study area.

Sincerely,

George C. Stubbart, Administrator
Soil & Water Conservation Division

SUBJECT Ochoco National Forest and Crooked River National Grassland
Proposed Land and Resource Management Plan

Dear Mr. Brown

The Oregon Department of Energy has reviewed the Forest and Grassland Proposed Land and Resource Management Plan, DEIS and Appendices. The Department has no problems with the Proposed Forest and Grassland Plan.

Areas of interest to the Department are siting of major energy facilities and policies concerning development of energy resources. Major energy facilities include fossil-fueled, geothermal, hydroelectric and biomass plants over 25 MW in size, biomass-fueled co-generation plants in excess of 50 MW capacity, high voltage transmission lines and large pipelines. Our comments are below.

Fossil Fuels: The DEIS suggests that 90 percent of Ochoco lands are potentially suitable for oil or gas resources. ODOE feels the lack of conclusive data, other than speculative leases, may not support that conclusion. However, ODOE agrees that any post leasing activities will be evaluated through NEPA and prescriptions developed in this plan. In addition, there appears to be little potential of siting a fossil-fueled power plant in the Forest and Grassland. Thus, none of the alternatives presented by the DEIS, including the Preferred Alternative, appear to have any effect on siting these facilities.

Geothermal: The low potential of finding exploitable geothermal resources in the Forest and Grassland is indicated in the DEIS. ODOE agrees with this conclusion and the resulting lack of specific policies addressing development of this energy resource. In addition, other federal standards exist, should development ever appear likely.

Hydroelectric: There appears to be little potential to develop additional hydroelectric facilities which are larger than 25 megawatts in the Forest and Grassland. Thus, none of the alternatives presented in the DEIS appear to have any effect on siting these facilities.

The Oregon Department of Energy is an Equal Opportunity Employer.
MT ~ames
E Brown
November 1, 1986
Page 2

Biomass  There appears to be little potential of siting a biomass-fired power plant in the Forest and Grassland in the next ten to fifteen years. Thus, none of the alternatives presented by the DEIS, including the Preferred Alternative, appear to have any effect on siting these facilities.

Transmission lines and pipelines  The DEIS indicates that transmission lines and pipelines cross portions of the Forest and Grassland, and that additional facilities are likely in the future. The DEIS states that all alternatives allow the transmission of power through the area. Thus, the Department has no objection to the Proposed Alternative. However, the DEIS contains no discussion of the effects of the alternatives on siting transmission lines and pipelines. Given the likelihood that future transmission lines and/or pipelines will need to cross the Grassland, the DEIS would benefit from including such a discussion.

Mr. James E. Brown
Department of Forestry
2600 State Street
Salem, Oregon 97310

Dear Jim,

We have prepared this response to the Draft Environmental Impact Statement to the Proposed Land and Resource Management Plan for the Ochoco National Forest & Crooked River National Grassland.

Apparently the planning team has a minimal background in geology and mineral resources. A different set of standards were used for minerals than for other resources. For example, a dollar value was placed on campers using the forest but the thousands of dollars worth of mineral exploration that has occurred in recent years was not counted. Thousands of dollars worth of gemstone production from commercial and recreational sites was not counted. The $999,000 ($3.00 per ton for 333,000 tons) of road metal (aggregate) was not counted; however, a cost figure of $866,080 was used for mineral operations and maintenance program management.

Appendix B - Description of Analysis Process contains no inventories for minerals, no maps showing rock quarries, mining claims, gemstone mines or metal mines. The data base does not reflect the gold and other geochemical anomalies found in the Department's open-file reports 0-83-4 and 0-86-5, which suggest mineral potential. It is surprising that the land was rated as moderate or high mineral potential without an adequate mineral resource data base.

The following detailed comments may be helpful in revising these documents.

Sincerely,

[Signature]

J. Frank
Director

Appendices - Draft Environmental Impact Statement

Page Comments
A-5 The issue of "Provide a mining and mineral inventory" and "Geothermal energy opportunities should be studied and developed" were deferred for resolution outside of Forest Plan. However, judgments were made in these documents that could only be made based on inventory data.

B-4 If inventories could be performed on recreation, cultural resources, ecoclass, and soil and water, why not minerals including energy?

B-44 On this page minerals had a cost of $866,080. Under Benefits pages B-45 to B-50 minerals are not listed except as something that would hurt the protecting of historic and cultural resources. Under Priced Benefits should include the value of road metal, gemstone production, and mineral exploration. Oil and gas and geothermal energy lease revenues should also be included under Priced Benefits.

C-5 & C-8 For the Lookout Mountain roadless area on page C-5 only 2 mines are within the roadless boundaries, on page C-8 there are 200 mining claims within the boundaries.

C-40 How was the grading of Moderate Potential for the Greer Mountain roadless area derived? The potential given for those roadless areas with mining, claims, mines, and mining districts are listed as unknown.

D-3 The Department and BLM have identified a potential gold mineralized area just to the south of Haystack Butte. This area should not be withdrawn from mineral location or leasing.

Draft Environmental Impact Statement

Page Comments
12 Under Net Public Benefits, only Federal minerals are listed as having a market value. The market value of the exploration, development, and mining of locatable minerals should be added. It is shown that Alternative II would emphasize market opportunities. This is the alternative that is used until formal mineral inventory is completed.

79 The Forest Service has not performed a mineral resource inventory but under "Cultural Resources" minerals and mining camps have been inventoried.

63 The statement is made that "Mineral and Energy Resources on Forest and Grasslands" have been classified in terms of potential value and existing access restrictions. How can this be so when there has not been a mineral inventory?

146 The statement is made that the forest and grassland have no known geothermal resources. The Department’s geothermal maps show a warm water spring on the Forest.

162 The bias against mineral production is shown in the statement that several old mines may meet the National Register and that potential could be used against re-establishing any of these mines. The jasperoid being mined may be an indicator of a hot spring gold systems and rockhound sites should not be withdrawn from being located under the mining law.

165 A mineral inventory should be completed before areas are picked for Research Natural Area. No geologist or mineral people were listed as preparers.

217-226 No mineral or geology reports were listed in the references.

Sincerely,

John D. Beauleue
Deputy State Geologist

Subject: Draft Environmental Impact Statement and Plan for the Ochoco National Forest and Crooked River National Grassland

Dear Mr. Brown,

The Department has reviewed the Draft Environmental Impact Statement (DEIS) and Plan for the Ochoco National Forest and Crooked River National Grassland and provides the following comments for the Forest Service to use in preparing the State's coordinated response. These comments are related to air quality and water quality impacts of the proposed Plan. The Department does not recommend a "preferred alternative" at this time. The deficiencies outlined below reflect a need for background information that is necessary for the Department of Environmental Quality to evaluate and select an alternative. After this information is included in the EIS, the Department would be more capable of recommending a preferred alternative.

Regarding air quality, the Department's main area of concern is that of air quality impacts related to forest prescribed burning. The EIS indicates that significant increases in emissions from prescribed burning are likely under most alternatives over the next 20-30 years. If emissions are expected to increase above 1977-78 baseline levels, an analysis needs to be included in the plan regarding the impact of the proposal with respect to the Clean Air Act and Oregon Clean Air Implementation Plan requirements; the impact of planned burns on nearby Class I and II areas; the impact of proposed prescribed burning activities on the Visibility Protection Plan; and consistency of the proposed Plan with Federal and State environmental policies.

Regarding water quality, the Department's concerns are that the Plan be consistent with Oregon's adopted Statewide Water Quality Management Plan for forest practices as required by the Clean Water Act. It is important to ensure that the proposed activities of timber harvest, road construction, chemical handling and usage, sewage disposal, livestock grazing and other forest land activities comply with Oregon's water quality standards and guidelines. Adequate information exists in the draft EIS for

Comments on the Draft Environmental Impact Statement and Plan for the Ochoco National Forest and Crooked River National Grassland

1. AIR QUALITY

The checklist summarizes Department of Environmental Quality, Air Quality Division concerns that should be included in the Environmental Impact Statement (EIS) for the Ochoco National Forest and Crooked River National Grassland that was submitted for Department review. This list is not intended to be all inclusive, but should rather be viewed as a framework outlining the major areas which should be addressed in the EIS. Statements which fail to address the concerns listed will be considered inadequate to meet Department approval.

The checklist is organized into 4 major sections, each of which should address the adequacy and consistency of the proposed plan with respect to the following elements:

1. Attainment and Maintenance of Air Quality Standards
2. Prevention of Significant Deterioration Requirements
3. Visibility Protection of Class I areas
4. Consistency with respect to Federal and State of Oregon environmental policies

Current information describing air quality monitoring activities and summarizing air quality conditions across the state may be found in the Air Quality Division's Annual Report. Copies of this report and other information can be obtained by writing to the Division or calling (503) 239-5380. Technical assistance and guidance in the preparation of EISs is available from the Department on request.

In reviewing forest plan EISs, the principal issue of concern to the Department related to air quality is that of air quality impacts related to forest prescribed burning. A basic requirement related to air quality of an EIS is presentation of an analysis of planned burning in relation to past burning activities. Generally, if it can be shown that projected annual and daily air pollutant emissions do not exceed, or are expected to be less than that which occurred during the baseline period, then issues discussed in Sections 3 and 4 are satisfied and no additional technical analysis of these issues is required. Since the baseline used in the analyses reflects current emissions, an evaluation of current versus 1977-

Comments on the Draft Environmental Impact Statement and Plan for the Ochoco National Forest and Crooked River National Grassland

78 emission levels is required to include projected emissions and impacts to the PSD baseline period.

In the DEIS section on air quality effects of each alternative (pages 103-104), it is projected that all of the alternatives (with the exception of None) will result in a reduction in emissions 20 to 30 years in the future. In the interim, increases in emissions of as much as 39% above current levels are expected to occur. The projected increase in emissions (as much as 4,000 tons per year) is significantly above the emission baseline and will require completion of a detailed analysis of emission impacts on PSD increments, Class II area visibility, attainment/maintenance of air quality standards and consistency with environmental policies.

1. Attainment and Maintenance of Air Quality Standards

A basic requirement of the EIS is to evaluate the impact of the proposal with respect to the Clean Air Act and the Oregon Clean Air Implementation Plan requirements. The first issue that must be addressed is that of impacts on air quality standards attainment and maintenance. Specifically, the EIS must show that the proposed action does not cause or significantly contribute to air quality standard violations. Air quality impacts within an attainment area, such as where the Ochoco National Forest is located, must not exceed Prevention of Significant Deterioration (PSD) increments (see attached Table 2) or may the impacts cause violations of air quality standards.

2. Prevention of Significant Deterioration

Part C of the Clean Air Act, requires the Department to insure that pollutant increments in Class I areas do not exceed specific limits adopted by Congress irrespective of the originating source (see attached Table 2). To ensure that these increments are not exceeded due to planned increases in prescribed burning emissions, a technical analysis of the impact of planned burns on nearby Class I areas (see DEQ Annual Air Quality Report) and Class II lands is required. If the analysis indicates significant impacts, specific quantifiable measures designed to mitigate the impacts must be described in the EIS.

3. Visibility Protection For Class I Areas

The Oregon Visibility Protection Plan, adopted by the Environmental Quality Commission on October 24, 1986, requires the protection of visibility within Class I areas during the period of the July 4th weekend to Labor Day, inclusive. The EIS should describe the Forest's

Department policy (OAR 340-20-001) requires that Highest and Best Practicable Treatment and Control be applied to pollution sources within Oregon OAR 340-13-005, Environmental Standards for Wilderness Areas, sets forth policy on environmental impacts within wilderness lands while USDA Forest Service Region VI policy (Service Manual No 2400, Supplement 347, March 1985) requires that, in recognition of the value of forest residues utilization, prescribed burning only be accomplished for those units where all other alternative treatments are unacceptable. The EIS should include a statement addressing the consistency of the proposed plan with respect to these policies, stating the degree to which alternatives to prescribed fire have been considered.

For further information regarding air quality, contact John Core (220-5389).
IX WATER QUALITY

The Management Plan and DEIS were reviewed within the concept that land management activities have the potential to beneficially or adversely impact the quality of the waters in the forest land downstream of the forest. The Management Plan has the opportunity to improve existing degraded resources and to maintain or protect existing desired resource conditions. The level of emphasis placed on water quality conditions and the processes used to protect that quality play an important role in providing guidance to the managers in the future on a project-by-project basis.

The Water Quality Division comments are detailed in the following five sections:

1. Consistency with Provisions of the Clean Water Act

The Plan provides a goal statement to maintain or improve water quality. It also has a goal of maintaining or restoring inherent biological, physical, and aesthetic values of riparian ecosystems. We believe these are comparable goals, both of which will maintain or improve water quality in the forest. Two comments need to be made regarding these goals: (1) We request that specific references to Oregon's Water Quality Standards (OAR chapter 629, Division 4) and Oregon's Forest Practice Rules (OAR chapter 629, Division 24) be added to the water quality goal statement (page 25, Proposed Plan) (2) There are no existing state water quality standards for riparian areas as stated in DEIS Table 8-3, "Riparian Conditions." We agree that the condition of the riparian zone can have an impact on the water quality. That is the concept used in the current forest practice rules and in the proposed riparian rules currently before the Board of Forestry. We believe the statements made in Table 8-3 are necessary but would suggest the following clarifying word change "Any degraded riparian areas found to be adversely affecting water quality will be improved to assure that the water quality meets State Water Quality Standards." We agree with the streams listed for riparian improvement in the Plan's Appendix M.

The proposed Plan appears to be consistent with the state's Water Quality Management Plan for the John Day and Deschutes River Basins. The "Secured Condition" statement for river temperatures is accurate.

It is obvious that the Forest Service staff are aware of the problem areas and those solutions necessary to correct the water quality problem. This is apparent by the discussion in the DEIS beginning on page 107. What is not clear in the discussion is whether the proposed improvements and mitigation efforts for forest management are solely directed at mitigating forest harvest impacts or are in concert with the proposed grazing activities. The Proposed Plan shows an increase in animal unit months (AUMs) by range allotment with many allotments showing an increase in grazing pressure. How does the Forest Service propose to handle the increased grazing pressure and yet improve riparian zone conditions? What specific forest grazing procedures will be used? We believe the response to these questions should be displayed in the Plan and be included in an expanded discussion on page 111 of the DEIS.

The Plan discusses standards and guidelines for water quality. The discussion translates these standards into levels of activity for forest management. This is appropriate in the Plan if the process of translating watershed sensitivity into forest management requirements is described in the DEIS or the Plan. We commend this effort and strongly support the concept of using an equivalent clear-cut area (ECA) standard. These comments indicate, however, that there are issues that need to be addressed in the discussion of ECAs and their utility (1) What criteria were used to derive the ECA values from the stream sensitivity values? (2) How will the ECA value be determined and implemented for a specific watershed?

The Plan also discusses standards for sewage disposal. We request you include the following language: "Septic treatment and disposal facilities shall be approved by the Department of Environmental Quality or its contract agents and shall be in compliance with rules of the Environmental Quality Commission."

We would like to recognize the Forest Service staff's effort to make predictions of sediment yield for each alternative and to predict changes over time. The various tables where these predictions are shown generate some questions:

(1) Is the unit of measure correct for sediment in DEIS Table II-4A part 2 and Table 8-2 part 2? Should it be tons/acre/year? If the unit of measurement is correct as stated, then we would disagree with the predicted 18 ton/year value for the preferred alternative and would like to see the analysis supporting the prediction.

(2) Are the values for sediment yield displayed in the same tables an average for the forest? If so, are there watersheds with larger amounts of sediment production and are these the same watersheds listed in Plan Appendix A?

(3) Do these values incorporate erosion from grazing?
Discussion of existing water quality and trends is inadequate considering the public value placed on the forest for visual quality, recreation, and water quality. We suggest the Plan and NEPA provide the existing water quality in a section of the Appendices to the NEP. Is the material in the Plan Appendix II also those streams with the poorest water quality? With the magnitude of the potential impacts that this Plan can have on water quality, it is vitally important to display the baseline water quality conditions in some detail prior to implementation of the Plan.

2 Review of Water Quality Monitoring Plans

Statements of goals and the accompanying Plan to achieve the goals and objectives in our estimation, are only a portion of what is necessary in a plan. The Plan must also include a process to assess its effectiveness in protecting the water quality during the life of the Plan. The monitoring Plan that was reviewed is contained in Tables V-2 and V-3 in the Plan. We find the proposed monitoring in the soil resource section adequate for water quality. We did not find the same activity proposed for ranges, wildlife, or wilderness areas. We believe that water is a resource that needs management and monitoring for quantity and quality. A suggested modification to Table V-2 to cover our concerns would be to add "water" to the "Resource/Activity" column and add "quality" in the "Action and Effect Monitored" column. In the "Units of Measure" column, add "pesticides, herbicides as appropriate."

3 Review of Management Strategies and Alternatives

We suggest the preferred alternative can maintain or improve water quality (as suggested on page 27 of the Plan), then the NEPA could support the preferred alternative. However, we are not convinced from what we have been presented for review that this goal can be fully achieved. This assessment is based on a lack of information on grading techniques and the effectiveness of SOA as proposed. Included in this concern is our understanding that the Forest Service is proposing to encourage harvest of tree species that are located closer to streams. Such harvesting practices will potentially place greater pressure on the water resources.

4 Review of Management of Special Use Watersheds

We concur with the management prescriptions designed for wilderness and "semi-primitive nonmotorized" areas. The management prescriptions for "semi-primitive nonmotorized" areas lack a prescription for protecting water quality. It is our opinion that a major source of sediment production can come from these areas if they are not controlled for erosion. Increased sediment production to the streams will occur without mitigation and should be so stated. A prescription for erosion control should be included.

The Plan does not discuss management considerations for small private water systems that might include the national forest as part of their watersheds. Protection should be provided to all such watersheds in the Ochoco National Forest. The Plan should also describe how the protection program will be monitored.

5 Review of Plan for Ground Water Quality Protection

The Plan virtually ignores the ground water component of the hydrologic cycle. Although ground water probably will be minimally affected by forest management activities, the plan should recognize the importance of ground water quality protection and discuss the following points.

a) Activities that affect ground water quality will eventually affect surface water quality. Conversely, change in surface water quality might be reflected in ground water quality.

b) Lakes with unique pristine water quality may need special ground water protection requirements to prevent nutrient enrichment, particularly with regard to sewage disposal practices associated with intensive recreational use.
Comments on the Draft Environmental Impact Statement and Plan for the Ochoco National Forest and Crooked River National Grassland

c) All sewage disposal practices need to be in compliance with state requirements. Please state those requirements by reference in the Plan.

d) Ground water protection planning should be included in all chemical handling practices in the forest. This would include, but not be limited to, herbicides, pesticides, fertilizers, and degreasers solvents at maintenance shops.

e) Activities and procedures that minimize erosion, and surface water runoff also will increase infiltration, allowing for more stable year round stream flows.

For further information regarding water quality, contact John Jackson at 229-6035.

Department of Land Conservation and Development

November 10, 1986

James E. Brown, State Forester
Department of Forestry
2600 State Street
Salem, OR 97310

Dear Jim:

The purpose of this letter is to provide DLCD comments for the state response to the proposed resources plan and draft environmental impact statement for the Ochoco National Forest.

As you know, the statewide goals and acknowledged comprehensive plans outside Oregon's coastal zone do not have any binding effect over federal resource planning activities, like the Forest Service's management plans. Nevertheless, DLCD is quite concerned that the Forest Service demonstrates that such plans (and their various alternatives) are developed to be as compatible as possible with the affected communities' acknowledged comprehensive plans.

Our preliminary review reveals that the Ochocoa's planning staff has endeavored to produce the proposed resources plan and DEIS with extensive interest group and local involvement. We are pleased that the DEIS on page 172 discusses the general compatibility of the various management alternatives with the acknowledged county comprehensive plans in the area. Such information in the DEIS not only serves to strengthen federal-local coordination but hopefully can aid in easier identification of a preferred alternative from the state's perspective.

In order to assure that information in the selected alternative and final EIS is as up to date and complete as possible, we suggest that the Ochoco staff request that the affected counties check to make sure that the cited land use...
references are correct and accurate. This would seem to be in order particularly for Grant County whose plan was recently acknowledged by LCDC. Second, the counties should be consulted by the Ochoco about which city land use plans in their areas, if any, should be reviewed, especially from an economic standpoint.

I hope these comments are helpful in preparing Oregon’s response to the Forest Service’s plan for the Ochoco National Forest. Please feel free to contact Jim Knight of our office if you have any further questions about our letter.

Sincerely,

James E. Brown
November 10, 1986

Page 2

Department of Forestry Resources Planning Section and field staff have reviewed the Ochoco National Forest Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (LRMP). Our review concludes that the Department cannot support implementation of the Forest’s Preferred Alternative, “Endeavor.” Instead, adoption of Alternative “H” is recommended for the following reasons:

1. The Forestry Program for Oregon timber harvest targets for the Ochoco are met for 40 years without a departure from nondeclining evenflow.
2. Riparian conditions are significantly improved while maintaining grazing potential.
3. Economic efficiency is maximized.
4. Job numbers, personal income, and payments to counties are maintained at satisfactory levels throughout the planning horizon.
5. Intensive forest management levels exceed the Forestry Program objective.
6. Department of Fish and Wildlife management objectives for elk are exceeded for at least the next 20 years.
7. Most of the remaining unroaded areas are allocated to prescriptions which allow timber management.
8. The Deschutes Canyon-Steelhead Falls area and portions of Lookout Mountain are managed to provide needed semi-primitive, nonmotorized recreation opportunities.
Therefore, the Ochoco National Forest should modify its Final EIS and LRMP by selecting Alternative "H" as the preferred alternative in order to maximize net public benefits.

The Department of Forestry's review also compares the Ochoco DEIS and LRMP to the objectives and policies expressed in the Forestry Program for Oregon and identified factual errors and omissions in the documents. A detailed analysis of the Ochoco National Forest Plan is attached.

By considering these comments and recommendations, the Forest could further improve the performance of Alternative "H". Particular attention should be given to the Ochoco's economic assumptions and analysis, timber yield tables and salvage program, and big game management strategies.

STATE OF OREGON

INTEROFFICE MEMO

TO
James Brown, State Forester
State Forestry Department

FROM
Ann Nolan Hanus, State Economist
Office of Economic Analysis

SUBJECT
Summary of Findings and Recommendations for the Ochoco National Forest Plan

Overview

I have reviewed the Draft Environmental Impact Statement (DEIS) for the Ochoco National Forest. The Department of Economic Development and the Employment Division have provided their analyses (attached) which have been critical for my response. I have discussed the plan with Forest Service planners, industry representatives, members of the Council of Economic Advisors, and local officials.

The counties most directly affected by the Ochoco National Forest Plan are Crook, Harney, Jefferson, Wheeler, and Grant. These counties, especially Crook, rely heavily on the Forest for their mainstay. For example, over 1,600 Crook County workers are directly employed in lumber and wood products, mainly in Prineville. The forest products industry in Prineville consists essentially of four lumber mills (Pine Products, Consolidated Pine, Ochoco, and Prineville Sawmill Company) which employ about 500 people. Two millwork plants (Clear Pine Mouldings and American Forest Products) employ another 920 workers. Including several other small operations and logging firms brings the total to 1,620 workers. Overall, Crook County is more dependent on timber than the state average.

The 1,640 lumber and wood products employees comprise 36 percent of the total 4,450 employment covered by unemployment insurance. If Forest Service employees were included, the percentage would be raised from 36 to 42 percent. Considering the indirect effects from lumber and wood employment, industry and Forest Service payroll in 1985 amounted to 54 percent of total covered payroll.

Local governments also depend upon the Forest for revenues. Twenty-five percent of timber receipts are given to counties for schools and roads. Crook and Wheeler counties derive thirty to forty percent of their revenues from the Ochoco National Forest timber sale revenues.
Lifestyles are tied closely to the Ochoco not only do most people earn their living from it, but they also derive much enjoyment from various forms of recreation. Furthermore, water quality and availability are closely linked to the forest.

The Forest Service's preferred Alternative E-departure emphasizes a combination of timber production, roadless recreation, and big game habitat. Timber harvests are scheduled so that first decade volumes remain close to current levels, and then decline over the next 10 to 50 years. According to the Forest Service, the departure harvest schedule was designed to maintain local jobs in the short term.

Comments

1 The Forest Service selected Alternative E-departure on the grounds that it would boost the economy in the first decade of the plan. Thereafter, the harvest would fall substantially, and the economy would be harmed significantly. The long-term cost of the departure cannot be justified by a short-term gain, particularly when it would be so damaging to the region's long-term economic stability.

The departure schedule provides for 123 MMFB per year for the first decade, 118 MMFB per year in the second, and 89 MMFB in the subsequent decades. The current harvest level is 160 MMFB while the 1975 to 1984 average is 134 MMFB. The current harvest level is unusually high because loggers are taking advantage of renegotiated prior year contracts. The departure schedule would result in a significant number of job and local government revenue losses in decades following the first. This would undermine the region's long term economic stability. Furthermore, the reduction may come at a time when the demand for Northwest timber is rising if projections are correct that show declines in Canadian and Southern states' timber harvests.

The proposed schedule could have an adverse effect on the industry's incentive to make large capital investments necessary to process smaller dimension logs. In the future, smaller dimension logs will comprise a much larger share of the timber harvest. Industries will need to retool and perhaps modify products. The preferred alternative may not provide sufficient economic incentive for industry to make these capital investments since the future timber harvest would decline drastically.

2 The Forest Service should correct its estimates of employment effects and clarify the methodology and terminology behind its multipliers. The figures for direct and indirect employment imply very low multipliers — less than two for direct timber jobs. This multiplier should be around two to three. In addition, the figures used for employment gains due to recreation, wildlife and resource effects appear to be too high. For example, in the first decade the plan estimates a loss of 27 "timber, direct" jobs, a loss of only four "timber, indirect" jobs and a gain of 96 "recreation, wildlife and range resource" jobs.

The direct employment impacts in the timber industry may be incorrect if they are based upon historical relationships between mill employment and timber harvest. Gains in labor productivity in recent years have been significant, especially in areas like Harney County where new, more efficient mills began operating in 1982.

The Forest Service should re-examine its assumptions about employment shifts between Harney and Crook Counties. The assumption that the shift in timber harvest emphasis to the Snow Mountain District will boost Harney County at the expense of Crook County is questionable. The Prineville mills already compete successfully for sales on Snow Mountain and will probably continue to do so.

3 The Forest Service excluded the impact on Wheeler County entirely. This cannot be justified when the Ochoco comprises 10 percent of Wheeler County's total land area. Also, Wheeler is the gateway for tourists, campers and hunters entering the Ochoco. Although Wheeler's population is relatively small, it is heavily dependent on the Ochoco for its economic welfare. Logging still accounts for 10 percent of its private sector wage and salary employment.

4 The changing species mix and availability of old growth Ponderosa Pine will have a major impact on the industries. Ponderosa Pine provides, by far, more jobs per million board feet than any other species in the forest. The Forest Service should explore harvesting and silvicultural techniques that would increase the harvest of Ponderosa Pine.

5. The Forest Service proposes the reduction of timber full yield acreage. Currently, 423,000 acres are managed for full yield. Under E-departure, 284,500 acres would be managed at full yield and 232,000 at partial yield (50 to 90 percent). The Forest Service should explain its reasons for this shift and the implications for timber harvesting. The land base for timber harvesting has been eroding over the last ten years with consequential negative impacts on timber harvests.

6. The projections for local government revenues from timber sales may be high. Currently, the Forest Service assumes that all timber offered for sale will be sold for a projected price. This yields a projection of the maximum revenue a county might receive. Actual receipts could be lower if all the timber offered for sale is not harvested in the same year. A range of probable county receipts should be shown.

7. The Forest Service should address the implications of its shift from uneven aged management to even aged management. If uneven aged management was successfully used in the past, why is it no longer
The economic impact of the alternatives for the management of the Ochoco National Forest cannot be fully determined without considering how changes in other forest plans -- particularly the Malheur -- will affect the region. For example, Harney County receives much timber from the Malheur National Forest than from the Ochoco. If harvests are reduced on the Malheur, competition for timber on other forests would increase. Also, recreational opportunities should be considered in the context of total opportunities available from not only the Forest being studied but also from adjacent National Forests and wilderness and other reserved areas.

Recommendation

Alternative E-departure should be rejected because it would significantly damage the region's economy in the long term. Alternative H should be selected because it maintains a sustained yield timber harvest close to the 1975-1994 harvest level. A sustained, predictable harvest level is more likely to benefit the area's economy without the severe disruption that would be caused by Alternative E-departure.

Alternative H's present net value is higher than any of the other alternatives except Alternative H-departure. Alternative H provides for jobs slightly higher and returns to counties considerably higher than the current level. Livestock grazing would be significantly higher (+10 percent) than the present. Elk habitat would support 90 percent more than the current population in the first decade, and riparian zone management would be excellent in all areas with high recreational use or potentially high use. The tradeoff would be less old growth and roadless recreation. Wilderness acreage, however, under Alternative H would not change from the current amount of 36,000 acres.

It should be noted that Economic Development Department has recommended Alternative B because of its higher timber sales ($37 million per year). They believe that Alternative B would have "the least amount of negative impact on local communities."
Forest's Draft Environmental Impact Statement (OEIS) and Proposed Land and Resource Management Plan

The Oregon State Department of Forestry's Resource Planning Section, in cooperation with other Department staff, has reviewed the Ochoco National Forest's Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (LRMP). Our comments focus on four areas of concern: (1) Compatibility of the Ochoco DEIS and LRMP with the basic objectives of the Forestry Program for Oregon (FPFO), (2) Factual errors and omissions in the document, (3) Comparison of the DEIS and LRMP view of the future with the Forestry Program for Oregon, and (4) Preferred alternative recommendations.

SUMMARY

The Ochoco DEIS and LRMP documents are well written, comprehensive and informative. The Forest has set a standard that the Department hopes other Oregon National Forests will attempt to match. However, our review has indicated that several important technical problems remain. In addition, the Department does not support the selection of Alternative "E-departure" as the preferred alternative. Instead, adoption of Alternative "F" is recommended. The following comments are the Department of Forestry's recommendations for improving the Ochoco plan when it is issued in final form. Each of these comments should be considered as substantive and all should be addressed in the final EIS.

COMPATIBILITY OF THE OCHOCO DEIS AND LRMP WITH THE BASIC OBJECTIVES OF THE FORESTRY PROGRAM FOR OREGON

Treatment of the Forestry Program for Oregon - (DEIS, page 172) The Department of Forestry appreciates the text devoted to addressing the goals and objectives of state, local and other Federal agencies. In particular, the Ochoco has provided a good overview of the FPFO. Unfortunately, the Forest has failed to meet the requirements of the May 13, 1986, Regional direction to the Ochoco on comparing the DEIS alternatives with the basic objectives of the FPFO. The DEIS has incorrectly compared the alternatives to the Forestry Program's timber harvest targets alone and has failed to consider the actual objectives which include:

1. To maintain the maximum potential commercial forest land base consistent with other resource use while assuring environmental quality.

2. To identify and implement economically feasible levels of intensive forest management required to achieve cost effective growth and harvest.

3. To maintain community stability, by remaining flexible for increases in future harvest levels that would offset projected shortages.

The May 13, 1986 Regional direction provided specific compatibility standards by which the DEIS alternatives can be compared with these objectives. An example which makes this comparison for the Ochoco alternatives is attached. This information must appear in the final EIS.

FACTUAL ERROR AND OMISSIONS IN THE DOCUMENTS

Wilderness Acres - (DEIS, page 42) Figure II-3 incorrectly portrays the number of acres that would be managed for wilderness under Alternatives "B" and "B-dep". The acreages shown are only one-tenth of the actual amount allocated under these two alternatives.

Old Growth Acres - (DEIS, page 42, 139) The DEIS in Figure II-3 and Table II-3A misrepresents the amount of old growth timber that will be preserved by the different alternatives. For example, Alternative "F" is shown to preserve 17,743 acres old growth. Figure IV-6 illustrates that this alternative will actually provide around 57,000 acres of old growth when lands allocated to other management areas that will provide old growth conditions are considered. This same discrepancy occurs in the other alternatives as well.

This example illustrates a larger problem in National Forest planning. The public has not been fully informed about the wildlife, recreation and scenic values that are currently being produced through land allocations such as Wilderness, RWA's and other management areas which limit or prohibit timber management. Timber values that have been lost to these and other management designations are not clearly presented in the plan analysis. Therefore, the public cannot easily determine the actual level of values provided by the National Forest. They also cannot examine tradeoffs that have been made by previous land allocation processes nor trace the continued erosion of the commercial forest land base.

To leave out a discussion of the valuable contributions to recreation, wildlife habitat, watershed protection and other non-market values that accrue to the public from legislative and administrative designation and from management strategies that are not decided through the current planning process is doing the public a great disservice and, in addition, may violate NEPA and NFMA requirements.

Change in Jobs and Personal Income - (DEIS, page 46) According to planners for the Ochoco, employment and personal income levels for 1984 were used as the basis for comparing the changes proposed in the alternatives for these parameters. Instead of using a single year for this analysis, the Department recommends using the 1976 to 1985 average levels. This ten year average results in 2,013 lumber and wood products jobs compared to the 1984 level of 1,950 jobs. Using an average recognizes that the lumber and wood products industry in cyclical and that new technology also changes employment patterns.
The State Economist's most recent population estimates show the state's population to be increasing at an annual rate of roughly 2 percent. Which population growth estimate was used in calculating the recreation demands shown in Table 11-13 of the LRMP? If the Ochoco has used a 2 percent growth trend, the analysis of recreation demand may provide unrealistically high results. The State Economist's most recent population growth projections for this portion of the state or another accepted methodology should be used in this analysis to estimate recreation demand. Regardless of the method used, both the Ochoco's estimate of the growth in recreation demand and the Forest's selected alternative should be consistent with the recreation and population projections of existing local land use plans.

Potential Timber Yield - (DEIS, page 59) The text incorrectly defines potential yields as "... the total harvest level that could be sustained assuming intensive forest practices on all available acres". A more accurate definition is that potential yield is "... the optimum perpetual sustained-yield harvesting level attainable with intensive forestry on regulated areas considering the productivity of the land, conventional logging technology, standard cultural treatments, and interrelationship with other resource uses and the environment" (from Ochoco 1979 Timber Management Plan). This latter definition makes "potential yield" equal to "allowable sale quantity" (ASQ). However, the text states that potential yield is equivalent to a maximum timber FORPLAN run and is not comparable to the DEIS alternative ASQ levels. The Department disagrees with this conclusion and urges the Ochoco National Forest to provide additional discussion on the relationship between existing potential yield and the alternative allowable sale quantities in the final EIS.

Comparison of Past, Present, and Predicted Timber Outputs - (DEIS, page 60) Table II-8 would be more useful if the planned volume by alternative was given for each of the five decades rather than just the high and low decades. Cubic foot comparisons should also be given.

Social and Economic Setting - (DEIS, page 64-66) Several points in this discussion must be revised.

1. Deschutes County population in 1985 should be 65,300 not 15,300

2. Table III-4 is misleading in that it does not provide total U.S. economic data for comparison. Oregon's per capita income is only 90 percent of the U.S. average. Therefore, even if the county data shown is near the Oregon average it is still below the national average.

3. What units were used to develop the graphs in Figure III-3? The Department disagrees with the statement that combining government and manufacturing sectors overestimates the importance of timber to the economy. The importance may actually be understated since the greater direct, indirect, and induced personal income created by timber and manufacturing is not shown. Both in DEIS Table VI-2, and in Appendix Table D-V3, comparisons of personal income derived from timber versus other resources should be displayed. IMPLAN just totals job numbers and fails to differentiate if they are part-time or full-time. Concentrating on employment numbers rather than personal income levels downplays timber's contribution to the economy, particularly with respect to family-supporting incomes. A more accurate portrayal would show both job numbers and total personal incomes.

Prescribed Fire and Air Quality - (DEIS, page 67) The text makes several references to the contribution of prescribed fire to airshed degradation. The DEIS fails to note that prescribed burning reduces the risk of catastrophic natural and man-caused wildfires which could generate severe and unplanned reductions in visibility. Forest smoke will originate on the Ochoco whether or not prescribed burning occurs. Through the use of smoke management techniques and by employing today's controlled burning methods, the effect of prescribed fires on visibility can be minimized. The Department supports full use of this and other management tools in order to prevent the significantly greater air and quality problems and costs which would result from wildfires in areas of untreated fuel accumulations.

Elk Management Objectives - (DEIS, page 77) The text provides the current and proposed Department of Fish and Wildlife management objectives (MO) for elk and states that these objectives "... have been used as indicators of demand during the planning process". The DEIS then states on page 175 that "If the alternative selected is a habitat management level that varies significantly from ODFW's MO, it is anticipated that ODFW will assess the consequences and readjust the MO if necessary". The latter statement appears to depict the management objective as a measure of supply rather than demand. Given this discrepancy, the Department of Fish and Wildlife's management objective seems to be of little value in comparing the merits of the different alternatives. The final EIS should clarify the relationship between the Forest plan and the ODF elk management objective.

Assumptions Concerning Leisure Lifestyles - (DEIS, page 99) This discussion centers on the point that greater recreation opportunities will bring more money into the local economy. However, the DEIS has noted elsewhere that most of the recreation use on the Forest comes from local residents. If higher paying timber industry jobs are lost to provide more leisure time opportunities, recreation use could actually decrease as families move to other areas seeking employment. The remaining population would not make up this lost income and local businesses would suffer rather than benefit. Wallowa County provides an example of this scenario. The Ochoco should reevaluate its assumptions on the economic effects of changing recreation supply...
Effects of Timber Harvesting on Soils - (DEIS, page 115) While it is true that the intensity of site disturbance is greater with the clearcut harvest system than with the selection harvests, the text should also emphasize that the frequency of entry into stands is higher when the selection system is used. Overall, soil damage may be more significant in partial cuts. Soil characteristics at the time of entry, the number of entries, and the type and degree of disturbance all determine potential for soil damage. The Department supports the mitigation measures outlined on pages 121 and 122 to minimize forest soil damage.

Semi-Primitive Recreation - (DEIS, page 157) A significant amount of the recreation use on the Ochoco National Forest occurs in the form of hunting. Regulated road closures provide opportunities for semi-primitive non-motorized recreation during the hunting season while providing roaded recreation opportunities throughout the rest of the year. Has this source of semi-primitive, non-motorized recreation been considered in the estimates of supply provided by the different alternatives?

Development of Timber Yield - (App., page B-26) It appears that the substantial drop in potential yield from that previously established by the 1979 Ochoco Timber Management Plan is mostly caused by changing managed yield tables. This is similar to the drop in potential levels we and others have experienced in our projections. The magnitude of the drop on the Ochoco, however, is greater than expected.

While we agree that the approach taken in building these tables is technically correct, we suggest that you review them to determine where intensive management could further increase timber outputs. For example, setting the PROGNOSIS keyword BAMY for the Ochoco would seem to take away from the existing potential timber yield of 137 MMBF, but does for recreation, wildlife and range resources. The text also indicates that no income from any of the resources is spent in Deschutes County, the primary shopping hub of Central Oregon. These conclusions appear to be incorrect and should be revised to more accurately portray the economic importance of the Ochoco National Forest.

Is the "current situation" harvest level of 127 MMBF the correct basis for determining the employment effects of changing the amount of timber sold? Has the contribution of salvage volume been fully considered? If the purpose is to describe potential job losses, would the use of the existing potential timber yield of 137 MMBF be more appropriate? Does the species composition of the "current situation" reflect historic averages?

Harvest Dispersion Constraints - (App., page B-60, LRIP page H-1) Page B-60 states that the watershed harvest dispersion constraints will be between 17 percent and 23 percent. On page H-1 the range of dispersion constraints is given as 25 percent to 35 percent. Which set of figures is correct? What national support for these very restrictive Ochoco harvest dispersion constraints when the Deschutes National Forest satisfied this minimum management requirement (MMR) with a 58 percent constraint?

Wildlife MMR Constraints - (App., page B-61) The final EIS should include a table similar to the August 8, 1984 Wildlife MMR Matrix produced by the Region. This table provides needed information on the number on habitats being protected in the forest from unsustainable levels of harvest. The number of suitable land involved, the effect of these allocations on timber production and other useful details. Such data is critical in determining if the Ochoco MMR constraints are consistent with Regional guidelines and that the constraints are indeed truly minimum requirements.

Elk Numbers - (App., page B-145) Table B-VII-10 presents only the projected elk habitat capability in Decade 5. The document fails to point out that most of the alternatives will support elk numbers above the proposed CPW management objective for at least 30 years, well beyond the life of this plan. As an example, Alternative "H" has an elk habitat capability in Decade 2 which is 2.5 times greater than the current management objective and 1.2 times greater than the proposed objective. The Forest plan should emphasize the irrevocable commitment of resources such as elk habitat rather than citing long-term projections that future planning decisions may alter.

Employment Effects - (App., page B-59) It appears that errors may exist in the documentation of employment effects that could distort the socio-economic analysis of the alternatives. Such distortion could also affect the theoretical performance of the DEIS alternatives. The final EIS must address the following problems and document any revisions that will modify the alternatives.

1. The text states that the ninth line of Table B-V-1 informs the reader that 1009 hunting recreation visitor days spent in Harney County will create one hunting job. Line 6 in the same table already tabulates the employment effects of hunting. Does line 9 double count hunting employment effects by assuming that all semi-primitive non-motorized recreation is hunting?

2. Our research shows that the job multiplier coefficient should be closer to 2 than 0.5 when describing the recreation in the Ochoco and use such a small multiplier to estimate indirect and induced employment?

3. If a multiplier of 0.5 has been used, why are the indirect employment effects for Alternative "B" in Decade 1 in Crook County almost equal to the direct effects?

4. Table B-V-5 shows no indirect effects in Jefferson County from timber harvesting, but does for recreation, wildlife and range resources. The text also indicates that no income from any of the resources is spent in Deschutes County, the primary shopping hub of Central Oregon. These conclusions appear to be incorrect and should be revised to more accurately portray the economic importance of the Ochoco National Forest.

5. Overall, soil damage may be reduced through intensive forest management. For example, setting the selection system is used. The Department supports the mitigation measures outlined on pages 121 and 122 to minimize forest soil damage.

While we agree that the approach taken in building these tables is technically correct, we suggest that you review them to determine where intensive management could further increase timber outputs. For example, setting the PROGNOSIS keyword BAMY for the Ochoco would seem to take away from the existing potential timber yield of 137 MMBF, but does for recreation, wildlife and range resources. The text also indicates that no income from any of the resources is spent in Deschutes County, the primary shopping hub of Central Oregon. These conclusions appear to be incorrect and should be revised to more accurately portray the economic importance of the Ochoco National Forest.
Big Game Thermal Cover - (LRMP, page 1) The plan proposes maintaining at least 40 to 50 percent of the land base in big game ranges in thermal cover. In contrast, research recommends 40 percent of the range in thermal and hiding cover as being optimum. Of that 40 percent, 20-30 percent should be hiding cover, and 10-20 percent in thermal cover in order to achieve optimum conditions. Why is the Ochoco recommending less than optimal levels of hiding cover and forage areas on big game ranges? Without adequate forage areas, the target population cannot be maintained.

Insects and Disease - (DEIS, page 66, 141) The text states that the current thermal and disease conditions should maintain areas of 67 percent of the total volume. This claim is contradicted by information received from the Ochoco planning team. The latter shows the proportion of ponderosa pine varying from a high of 80 percent in decade one of Alternative "A" to a low of 55 percent in decade three of Alternative "E". Maintaining a reasonably constant supply of ponderosa pine to milling and manufacturing plants is critical to the central Oregon economy. Harvest plans of the alternatives should not propose large changes in species mixes, especially reductions in the percentages of ponderosa pine offered.

Demand for Ochoco Timber - (DEIS, page 5, App, 8-41) The text on page 5 of the DEIS states that a lack of a "suitable timber supply from the Ochoco has been portrayed as causing higher stumpage prices..." and that "higher volumes of timber sold from the Ochoco could be processed locally, possibly leading to lower stumpage prices". These statements combined with the fact that much of the ponderosa pine processed in Crook County is transported from outside the area, conflict with discussion in the Appendix which assumes a horizontal demand curve for Ochoco timber.

Big Game Management - (DEIS, page 140) Questions on big game management unanswered by DEIS include:

1. Since some winter range areas receive heavier use than others, would the use management of these preferred ranges and less on the remaining be more desirable and promote both big game and timber with lower overall management costs and higher overall benefits?

2. More challenging hunting opportunities can also be achieved through road closures, limiting the numbers of Hunters, and restricting the harvest to certain types of game (example - Bulls with three or more antler points). To what degree would increased use of these other methods of regulation reduce or eliminate the need to limit timber production?

3. Elk numbers in central Oregon could increase to the point where the availability of winter range would be the limiting factor. Conflicts with other uses on the privately owned, natural winter range would increase. By continuing to optimize the available summer and winter elk range on the Forest, the Ochoco may be managing its land for elk numbers that cannot be supported by the total habitat. In light of the other resource uses on the Forest, at what point will the marginal benefits of additional elk be exceeded by the marginal cost of providing the habitat?

4. What costs and property damage may be incurred by adjacent landowners through elk migration and hunting recreation? How will the Forest's actions affect this problem? How are these costs factored into the Plan's analysis?
Road Management - (DEIS, page 166) The Department supports the efforts of the Ochoco to produce the costs of road construction and to close unneeded roads either seasonally or permanently to increase effective wildlife habitat. Cooperative road closure programs during elk season have proven to be very successful. Benefits of regulated road closures include:

1. Reduced animal harassment through improved hiding cover.
3. Reduced conflicts between timber and wildlife management.
4. Reduced road maintenance costs by eliminating hunter traffic during wet fall months.

The final EIS should emphasize that it is the use of roads the roads themselves which affects wildlife habitat. The Ochoco is moving in the right direction by regulating the use of roads while still allowing access for periodic, cost-effective, timber management activities.

Unroaded Areas - (App C) It is inappropriate that the Forest's preferred alternative retains 26,441 acres or 48 percent of the remaining unroaded areas in an undeveloped state. The Oregon Wilderness Act of 1984 states that unroaded areas not designated as wilderness should be managed for multiple-use and that management for future wilderness consideration is not necessary in keeping with the intent of this law, the Department of Forestry recommends that unroaded lands which support productive forests be returned to the suitable land base and that the timber volume be included in the regulated timber harvest schedule.

Fire Protection - (App., Page D-9) The Department of Forestry supports the Forest's policy of applying aggressive suppression action to wildfires that threaten life, private property, public safety, improvements, or investments. However, the DEIS and LRMP should more clearly explain that writers will determine when a "threat" exists and the "appropriate" suppression response that will follow. Unplanned ignitions should be used as prescribed fires only if compliance with the Oregon Smoke Management Plan can be assured. Coordination of protection planning and suppression efforts with other protection agencies, including this Department, should be included as a part of these guidelines.

Minimum Stocking Levels (App., page D-20) The Ochoco National Forest is proposing minimum stocking levels of between 50 to 75 trees per acre, depending on site. This level of stocking is below the minimum stocking level permitted under the Oregon Forest Practices Act. Since the Forest Service has agreed to meet or exceed the Forest Practices Act requirements, the proposed minimum stocking levels are unacceptable. These standards must be revised to satisfy the requirements of the Act which include establishing at least 100 seedlings or saplings per acre, well distributed over the operation area, within six-years. Refer to OAR 629-24-401 and 402 for details on this requirement. The final EIS should document what effect this higher minimum level would have on future timber yields, big game cover, and other resource outputs.

Regeneration Harvests - (App. D-30) The timber resource practice standards and guidelines for the General Forest Management area and other prescriptions include the statement that regeneration harvests will occur at culmination of mean annual increment (MAI). Is it necessary to extend regeneration harvests past 95 percent of MAI? Whenever shorter rotation lengths will not conflict with the goals of the management area prescription or lower the present net value, 95 percent of MAI should be used. At a minimum, it should be included in the criteria for the General Forest Management area.

Harvest Cutting Methods (App., F) - The Department of Forestry supports the flexible, site-specific approach to the selection of harvest cutting methods as required by the Regional Guide. The Ochoco is encouraged to maintain this flexibility in the Forest plan. When determining the harvest cutting method, economic benefits to the Forest and the timber purchaser should be considered as well as logging feasibility, stand characteristics, silvicultural response, and the effect on other resources and their uses. In addition, uneven-aged management should be considered to maintain timber yield in those areas where clearcutting is limited or prohibited to accomodate other resource uses. The Forest should work to improve knowledge of uneven-aged management applications in eastern Oregon forests through silvicultural research, refined yield tables, and economic analysis.

Research - (LRMP, page 27) The Forest Program for Oregon encourages research to improve forest productivity, the economics of intensive management practices, and to identify the habitat needs of old-growth preferring wildlife. Therefore, the Department supports the research program outlined by the Forest. In addition to the research needs identified by the Ochoco, we believe more research is needed to:

1. Develop new technology to return some of the 2,560 acres removed from the suitable land base for regeneration difficulty to timber management status.
2. Improve knowledge of elk/cattle competition.
3. Gain better silvicultural knowledge on understory management and uneven-aged management.

Timber Salvage Program - (LRMP, page 59) The Ochoco National Forest has an opportunity to improve its timber salvage program by more aggressively harvesting scattered, overmature ponderosa pine. These large, valuable trees are often lost to insects and disease before they can be included within a planned harvest unit. Forest industry estimates that 20 MBF of high-quality, high value timber could be recovered per year. Eighty percent of this salvage work could be conducted on areas suited to tractor logging. As a result of increased salvage, forest industry would obtain the larger ponderosa pine desired to supply its mills and remanufacturing plants, communities would enjoy increased employment and personal income, and the Forest Service would receive higher stumpage revenues. The Forest would also enjoy a higher net timber growth rate through reduced future mortality. Meanwhile, acceptable levels of old-growth and snags would be retained through management area allocations and MAI's. The final EIS should address this recommendation.
The Ochoco has provided a very good framework for its monitoring and evaluation program. The following changes would improve this very important part of the management plan:

1. Change the reporting period for land suitability from 10 to 5 years. The objective for this category should be revised to include the potential for returning lands incorrectly classified as unsuitable to the suitable land base.

2. As new information becomes available, minimum management requirements should be revised to insure that neither under-protection or over-protection occurs.

3. The variability threshold for payments to counties should be more specific than "an unexpected trend up or down". A variability threshold of ± 10 percent is recommended.

4. Personal income should be added as an activity to be monitored. Monitoring frequency should be annual with a ± 10 percent variability threshold.

PREFERRED ALTERNATIVE RECOMMENDATION

The Department of Forestry requests that the Ochoco National Forest select Alternative "H" rather than Alternative "E-departure" when the Forest plan is issued in final form. Alternative "H" provides a more nearly optimum mix of resource outputs which addresses the issues identified by the public, achieves a higher level of long-term net public benefits, and more closely meets the objectives of the Forestry Program for Oregon.

Specifically, the Department supports Alternative "H" for the following reasons:

1. The Forestry Program for Oregon timber harvest targets for the Ochoco are met for 40 years without a departure from non-declining even flow.

2. Riparian conditions are significantly improved while maintaining grazing potential.

3. Economic efficiency is maximized.

4. Job numbers, personal income, and payments to counties are maintained at satisfactory levels throughout the planning horizon.

5. Intensive forest management levels exceed the Forestry Program objectives.

6. Department of Fish and Wildlife management objectives for elk are exceeded for at least the next 20 years.

7. Most of the remaining unroaded areas are allocated to prescriptions which allow timber management.

8. The Deschutes Canyon - Steelhead Falls area and portions of Lookout Mountain are managed to provide needed semi-primitive, non-motorized recreation opportunities.
This memo is composed of the following sections:

I. Background

II. Mills identified as primary and secondary users of timber from Ochoco National Forest

III. Components of the U.S. Forest Service Plan

IV. Economic Development Department's Analysis of U.S. Forest Service Plan

V. Economic Development Department Recommendations

VI. Appendix - General Questions Regarding Forest Service Methodology

Background

The land administered by the Ochoco National Forest and Crooked River Grassland occupies 955,100 acres within Crook, Harney, Grant, Jefferson, and Wheeler Counties of Oregon. The area's economy is highly dependent on forest-related industry, agriculture, and tourism.

In Crook and Harney Counties, over 80 percent of the forest land is in public ownership, most of it is administered by the U.S. Forest Service.

Maximum mill capacity in Crook and Harney Counties is approximately 365 million board feet annually. 1983-84 estimates indicate that approximately 150 million board feet (42 percent of maximum capacity) is being milled annually in these two counties.

Undoubtedly, timber availability from the Ochoco National Forest affects stumpage prices as well as local economic well-being.

All five counties in the affected area of the Ochoco National Forest and Crooked River Grassland are heavily dependent on payments from the Forest Service for their operating budgets. Thirty to forty percent of Crook and Wheeler County revenues are derived from this source. Grant, Harney, and Jefferson Counties receive payments representing 13 percent of their revenue. The timber industry and related government agencies account for approximately half of the area's economic base.
Mills Dependent on Ochoco Timber

Primary Purchasers of Timber from the Ochoco National Forest

- Consolidated Pine, Inc. Prineville
- Ochoco Lumber Co. Prineville
- Pineville Sanmill Prineville
- Pine Products Corp Prineville
- Snow Mountain Pine Co. Hines
- DAW Forest Products Co. Bend

Secondary Users of Raw Material from Ochoco National Forest

- Clear Cedar Pine Corporation Prineville
- American Forest Products Co. Prineville
- D & E Wood Products, Inc Prineville
- Pioneer Cut Stock Co. Prineville
- Woodmark Corporation Hines
- Frenchglen Millwork Co. Hines

Components of Alternative E-Departure are:

1. Reduces the allowable cut for the first ten years of the plan by 9 million board feet (MBF). The 1975-84 sales volume was 134 MBF per year. Alternative E-Departure would provide for 123 MBF per year for the first ten years of the plan.

2. After the first decade the allowable cut would be reduced to 118 MBF per year for the second decade. For the third decade the allowable cut would be 89 MBF per year.

3. After the first decade the species mix will change. Ponderosa pine harvest will decline as a percentage of total harvest and the diameter of the ponderosa pine harvested will be significantly smaller. The species mix will increasingly consist of more Douglas fir, western larch and white fir.

4. Alternative E-Departure forecasts increased employment in the Ochoco region as a direct result of the departure timber schedule:

<table>
<thead>
<tr>
<th>Employment</th>
<th>Crook County</th>
<th>Harney County</th>
</tr>
</thead>
<tbody>
<tr>

<td>115</td>
</tr>
<tr>
<td>Total Employment</td>
<td>-10</td>
<td>-69</td>
</tr>
</tbody>
</table>

Analysis of the U.S. Forest Service Plan

1. The Economic Development Department does not expect the employment increases projected by the Forest Service to actually happen. A reduction in the allowable cut of 9 MBF per year will likely further reduce employment.

   The implicit multiplier used in the above table is extremely low. In timber-dependent communities, a direct timber job usually results in two to three secondary jobs. The above job implies that only a fraction of a job results for each direct timber job. A more reasonable (and conservative) multiplier would assume at least two indirect jobs for each direct job. This means that for the 50 jobs to be lost in direct timber production in Crook County, there is a potential loss of at least 100 indirect jobs.

   Also, there is no reasonable explanation in the plan for how 59 recreation jobs will be created in Crook County or how 22 jobs will be created in Harney County.

2. The potential reductions in the harvest are a real concern. The U.S. Forest Service is predicting a reduction in demand for timber after the first decade of the plan. This reduction in demand will result from a decline in new housing demand in the U.S. after 1995. By 1995, the baby boom generation will have grown up, and completed the purchase of new houses.

   The Economic Development Department disagrees with this analysis, for the following reasons:

   While U.S. demand will decline, so will the supply of timber from the South and from British Columbia as well as areas of the Northwest.

   Additionally, the demand for lumber from Pacific Rim nations is just now beginning. As incomes in these nations increase, the demand for lumber for building is expected to increase.

   The Economic Development Department, State Forestry Department, and the forest products industry are working to develop these markets. This increased demand, coupled with declining supplies elsewhere, may well take up the potential slack in the U.S. domestic demand. So, it is to Oregon's advantage to make sure that the Forest Service maintains the highest reasonable allowable cut.

3. As the species mix changes and the diameter of the timber decreases, the mills in the area will face increasing costs. They will have to retool to be able to process small trees, find a timber supply from outside the area, or close...
This will require capital investment for retooling and the impact on jobs is undefined, i.e., increased productivity may result in job loss.

4. County Revenue Projections

The projections for county revenues from timber sales are not realistic. Currently, the projections assume that all the timber offered for sale will be sold for a projected price. This yields a projection of the maximum revenue a county might receive. Actual county receipts will be less. Based on past trends in timber sales, a range of possible county receipts should be provided.

V. Economic Development Recommendations

1. The Economic Development Department rejects Alternative E-Departure because it predicts a decline in jobs due to timber harvest reductions from the current 160 MMBF per year of actual sales in 1986, to 123 MMBF per year for the first decade and an even worse decline to 118 MMBF per year and 89 MMBF per year for the decades that follow.

2. Table IV-30 of the EIS indicate that the Plan proposes the reduction of acreage in full yield from the current (1979 Timber Management Plan) figure of 423,000 acres to 262,000 acres. This means that less than a third of the land in the Ochoco forest is proposed for full yield (91-99%) management. Approximately half the forest is currently being managed for full yield.

We do not support reducing the acreage proposed for full yield management.

3. The Economic Development Department recommends the adoption of Alternative B with some modifications.

Alternative B has an Allowable Sale Quantity (ASQ) of 137 MMBF per year, which is the current potential yield for the next two decades. (This compares to a reduction of 123 MMBF per year, 118 MMBF per year and 89 MMBF per year for the three decades in the Preferred Alternative.)

Alternative B is the alternative with the least amount of negative impact on the local communities. It also has more elk population in the first decade than the preferred alternative. The loss of some elk population in the third decade could be avoided if the U.S. Forest Service was to have more road closures (with gates, e.g.) to mitigate elk habitat disruption. Additionally, increased watershed management would improve elk habitat.

Alternative B maintains old growth forest at 32,000 acres compared to 50,000 in E-Departure. This is the price for maintaining a strong local economic job base.

While Alternative B would maintain Lookout Mountain as "General Forest" (GF) category, we would recommend that Lookout Mountain Silver Creek be maintained as semi-primitive non-motorized (SPNM) category, as proposed in Alternative E-Departure.
1. Economic dependency of the local area on the Ochoco NF. Since over 80% of commercial timber lands lie within National Forest boundaries in Crook County, mills located in Prineville are largely dependent on publicly owned timber. The forest products industry in Prineville consists essentially of four lumber mills (Pine Products, Consolidated Pine, Ochoco Lumber, Prineville Sawmill Co.) currently employing about 500 employees, and two millwork plants (Clear Pine Mouldings and American Forest Products) currently employing some 920 employes. Several small operations and logging firms bring total current employment to 1620.

The 1620 lumber and wood products employees comprise 36% of the total 4550 employment covered by unemployment insurance. Adding 280 Forest Service employees brings this figure to 42%, or 1900. Assuming a multiplier of 2.0, the county's covered employment not attributable to the lumber and wood products industry would be only 650. Also, industry and Forest Service payrolls in 1985 comprised 64% of the total covered payroll. Essentially, without the presence of the Ochoco NF Crook County would more closely resemble Gilliam County, economically dependent on agriculture and the Les Schwab Tire Co.

2. Comparison of the Crook County economy to that of the state as a whole. The economy of Crook County is narrowly concentrated in three sectors: the manufacture of lumber and wood products, government, and wholesale trade. Statewide, the percentage of covered employment engaged in manufacturing in 1985 was 19% compared to 39% in Crook. In Crook, 98% of manufacturing employment was in lumber and wood products compared to 31.9% statewide. Employment in wholesale trade was 8% of the total in Crook, 6% statewide solely due to the presence of the Les Schwab Tire Co., whose headquarters and remanufacturing operation are located in Prineville. Government employment was 19% in Crook compared to 18.1% statewide due to the presence of the Ochoco NF headquarters and regional offices of BLM and Oregon State Forestry in Prineville.

3. Assessment of the economic analysis and data used in the Ochoco DEIS. Overall, the Plan appears to be a reasonable compromise responding to the often competing demands placed upon the resources of the Ochoco NF, ranging from recreation and wildlife to timber supplies and grazing. The economic analysis appears reasonable in its basic assumptions and input data. However, the computer generated conclusions regarding impacts of the selected alternative (E Departure) on employment are questionable. First, the assumption that the shift in timber harvest emphasis from the Snow Mountain District during the first decade of implementation will boost industry employment in Harney County at the expense of that in Crook County is highly dubious. The Prineville mills already compete successfully for sales on Snow Mountain and will almost certainly continue to do so. Thus, analysis of Plan impacts on employment should be limited to the overall portion of Table A-4-3 (attached). The assumptions regarding direct effects appear reasonable assuming static conditions are maintained during the decade in the local wood products industry (No new plants, but machinery improvements in existing mills which tend to reduce manpower needs).

However, over the past decade in central Oregon losses in basic lumber production have been offset by gains in remanufacturing. Although the Prineville mills are presently basically large old growth Ponderosa processors, given the inevitable change in future timber harvest characteristics implicit in the Plan, it is highly likely that adaptations to more efficiently process smaller logs and new plant(s) for chip or fiber based products will occur. If so, this could offset employment losses, or even produce an overall gain. However, the Plan proposes to sustain the old growth timber harvest during the first decade of Plan implementation at the expense of harvest levels in subsequent decades in terms of both mbf and mmcf (See attached Table B-11-8). Without the Departure, while mmcf would decline as tree dimensions shrank, mmcf would be unchanged (Table IV-4 attached). This fall-off in mmcf might lessen the prospects for chip or fiber based manufacturing. Sacrificing long term harvest levels for short term gains should be carefully considered in the light of local preferences.

Assuming a multiplier of about 2.0, the indirect employment effects seem very conservative, unless they are the net of combined direct and recreation effects. Gains stemming from recreation enhancement appear somewhat optimistic since this activity is highly summer oriented on the Ochoco. Also, recreation is heavily oriented towards camping, with local expenditures largely tied to the purchase of fuels and supplies. Even if correct, jobs created would be of a highly seasonal nature, averaging perhaps $6-8,000 per year, less than half that of jobs in lumber and wood products. This impact is...
reflected in the low overall net income gain ($270,000) given in the overall effects table, despite a net creation of 65 jobs over the first decade.

In sum, assuming the almost certain adjustment of the Prineville mills to the shift in harvest emphasis to the Snow Mountain District, mill employment in Crook County will remain relatively stable, except for the gradual ongoing decline resulting from technological change, over the first decade of Alternative E Departure implementation. Subsequent employment changes will depend on whether or not plants capable of utilizing changing harvest characteristics are built, with the near term boost in timber harvest at the expense of long term harvest volume possibly hindering this development if the Departure variant of Alternative E is adopted.

4 Economic impact of the preferred alternative on the local area and State

In evaluating both the Deschutes and Ochoco NF DEIS there is a growing awareness that the most basic question regarding the management of Ponderosa pine dominated forests has been inadequately addressed. Past harvesting policy appears to have stressed uneven aged management. The new plans stress even aged management, with limited analysis of the comparative advantages of the two systems. This omission leaves unanswered a number of questions. Among them: If uneven aged management was successfully used in the past, why is it no longer advantageous? While even aged management may result in an increased harvest volume, would not the larger trees produced under uneven aged management be of greater value? What about the capital costs incurred by area mills as they are forced to adapt to the processing of smaller, lower value logs? Would not the complexity of the proposed plans and their implied high management costs be greatly reduced under uneven aged management as almost the entire Forest could be managed for timber production since harvesting of any given tract would only occur on a 30 or 40 year rotational basis and natural regeneration would occur to a much larger extent? Would not adoption of even aged management greatly alter the appearance of much of the Forest in a detrimental manner... The retention of uneven aged management on those areas most subject to the public view would certainly seem to be a tacit admission on the part of planners of this concern. Would not species variation be reduced by even aged management with its emphasis on the generation of a single plant species, Ponderosa pine? Why, under natural conditions, do pine stands usually assume an uneven growth pattern? Have public and timber industry views and concerns regarding such a drastic revision of Forest management policy been solicited? Without due consideration of this most basic forest management concern, the validity of any Plan issued in the Ponderosa pine region must be seriously questioned.

Given the sustained yield of old growth Ponderosa pine provided over the next decade under the Preferred Alternative, it is highly likely that all Prineville mills will be able remain in operation, although continuing to experience the slow erosion of employment resulting from technological improvements. In the subsequent decade it appears inevitable that reduced harvest levels will force the closure of at least one mill, with the loss of roughly 100 mill and logging employees, while remaining mills will have to adapt to allow for the processing of smaller dimension logs. However, part or all of this decline could be offset if the growing volume of material unsuitable for lumber encourages the construction of a plant for chip or fiber based products. The impact of the long term reduction in Ponderosa pine lumber production locally on milwork operations is unclear since at present they obtain well over 50% of their lumber requirements from nonlocal sources.

The changing character of the timber harvest in coming decades, with its growing volume of small logs ill suited to lumber production, could well have an impact beyond those communities dependent on the forest products industry. It seems likely that in many cases, for reasons of insufficient volume or lack of capital in a given locality, new plants capable of utilizing this material will tend to be built in centralized locations. Thus, some communities may well benefit from these changes in employment terms, while others will experience significant declines. This development is already underway, with some areas experiencing declines as a result of the decline in sawmill employment of the past few years, while others have expanded remanufacturing operations to replace these losses. The message is clear at both the state and local level. If present employment totals in the Forest products industry are to be maintained, the capital investment needed for new or expanded remanufacturing plants must be attracted.

Comments On The Proposed Ochoco National Forest Management Plan

Prepared by
Richard E. Kuczek
Labor Market Economist

As I am the LNE for Wheeler and Grant Counties, I am, of course, primarily concerned with the impact that the Plan would have on these counties. Most of my comments will directly relate to this concern. Some comments will be more general in nature, as certain overall characteristics of the Plan will certainly have a significant effect on all the counties which have a dependency on the Ochoco.

First, I would like to briefly address Grant County. While 59,000 acres of the Ochoco are in Grant and Grant is very much a timber dependent county, the Ochoco represents a relatively small portion of Grant's forest base, there being far more acreage of the Malheur National Forest in Grant. I agree with the Forest Service's assessment that the Plan will not have a major impact on Grant, though I do believe that some of the undesirable aspects of the plan will have a small but negative impact on Grant. Most comments made about Wheeler County, and about the Plan in general will also apply to Grant, but with less impact and less affect. The real dangers to Grant would come about if the Malheur Plan (still in production) were to include the same undesirable features as the Ochoco. This 'double hit' could have severely detrimental impacts for Grant.

Wheeler County is summarily dismissed by the Forest Service as a county which does not have a major dependency on the Ochoco. I disagree with this. Indeed, Wheeler may very well prove to be the single most impacted county of all those which contain portions of the Ochoco. While Wheeler only contains 127,495 acres of the Ochoco, compared to 223,237 for Harney, and 435,820 for Crook, Wheeler is a relatively small county and the Ochoco acreage is fully 31% of the total county land area. More importantly, it represents a much larger proportion of the county's total forested area. In addition, Wheeler is a gateway for tourists, campers, and hunters to enter the Ochoco. While this tourist trade through Wheeler may be small compared to that through other counties, and while logging activities in Wheeler are minute compared to those of Crook, Harney, and Deschutes, Wheeler is a tiny county with a tiny population and miniscule wage & salary employment. Wheeler related employment is a vital part of the County's private sector economy and a significant contributor to wage employment.

While the timber industry in Wheeler County crashed a few years ago, and the county currently has no mills and little opportunity for regaining one, logging still accounts for 10% of all private sector wage and salary employment. As these logging jobs are among the highest paying jobs in the county, they represent a significant contribution to the county's earned income and provide critical support to the county's small retail trade sector. Retail trade accounts for about 30% of the county's total private sector wage and salary employment. Retail trade also demonstrates a clear seasonal pattern, where employment will increase 50% to 100% during late summer and fall, when recreational and hunting use of the Ochoco is at its peak. Thus a full 40% of the county's private sector wage and salary employment is directly Ochoco related or potentially so. Perhaps of even greater importance is the county government's dependence on payments from the Ochoco. In 1984, payments from the Ochoco accounted for 44.3% of the county's revenues. Obviously, any significant decrease in these payments would create an immediate and severe financial crisis for the Wheeler County government. In particular, any layoffs of local or county employees would severely impact Wheeler, and would severely affect the small retail sector in the county.

I think that it is safe to conclude that Wheeler stands to experience major impacts from the National Forest Plan for the Ochoco. As these impacts will almost certainly be negative, Wheeler could be severely affected.

Wheeler can hardly afford this. Wheeler is totally dependent on agriculture, timber, and recreation as its economic base. As both agriculture and timber have been troubled industries, with declining employment, Wheeler has suffered greatly. Wheeler's population has decreased by 56% over the last 25 years. Potential for growth in agriculture or timber employment is nil, and recreation related employment is unlikely to significantly increase under even the most recreation/big game emphasized alternative for the Ochoco.

The first flaw with the Ochoco plan is that it attempts to be all things for all people and uses. A national forest is a limited resource. Competing demands (timber harvest vs. big game vs. wilderness vs. riparian, etc.) mean that not all demands can be maximally satisfied. This will inevitably result in making anyone unhappy. The Ochoco planners seemed to avoid doing this by decreasing general forest acreage (timber harvest emphasis) and increasing acreage for virtually every other use. Big game management acreage was a particular gainer (the Plan, in all alternatives offered, has, as a primary driver, a Forest Service preference for double the elk population. This mandates increased big game management at virtually any cost to other uses, and distorts and limits all alternatives.) (This driving of the plan by elk population needs resulted from the acceptance of a state issued goal of doubling the Ochoco's elk population in a game management plan as a minimum requirement for all acceptable alternatives. The Ochoco already meets, and could continue to meet, all other big game management objectives, with reduced big game management areas. Elk require large areas per animal, and the major elk population increase requires significant additional land devoted to big game management to achieve this population expansion goal. No purpose other than increasing elk is accomplished by this, and since the model accepts this elk increase as mandated, it will devise no alternative which does not attempt to achieve at least for a period of time. It is also a principal basis (apparently for downgrading some of the alternatives considered). While this keeps everyone but the timber industries happy, it reduces the timber harvest (the E-Alternative). To make the timber industry accept this reduction in logging potential, the preferred plan (E-Departure Alternative) provides for ten years of significant over-cutting to keep the timber harvest up. To put it bluntly, it appears as if, to avoid making the hard, competing decisions as to usage priorities, which result from political pressures, the planners decided to 'burn' the forest for ten years. This proposed massive over-utilization of the Ochoco's resources will
Inevitably result in a future 'crash' where utilization must be drastically decreased to allow the forest to recover. This crash effect is totally allocated to timber harvest under the preferred alternative. The impact on the surrounding and affected counties will be severe. Timber related employment will decrease sharply, payments to counties will be significantly reduced, and secondary economic sectors will be impacted by the spin off. The Forest Service contends that some of this future adverse impact will be alleviated by increases in recreation/hunting retail and service employment. This is not true. The Forest Service equates recreation related jobs with logging and milling jobs. Recreation related employment is much more seasonal (and a much shorter season) than timber related employment, and such jobs pay much less per hour than logging or milling work. The adverse financial impact in terms of lost wages would be severe even if we were talking of a one for one job trade. It is plan from the Plan, that even the Forest Service's optimistic (and unsupported) claim for job increases from increased recreational/hunting use does not come close to one for one replacement of lost timber jobs.

A second flaw is that the Plan does not fully credit the impact of the shift from uneven-age management to even-age management. This will mean a drastic decrease in the harvest of valuable older Ponderosa Pine (which the local mills are designed to handle) and a shift to younger, small trees (which the local mills can't utilize). As in ten years the timber harvest will begin to be reduced severely, there is virtually no incentive for local companies to make the investments needed to build new mills, or to rework existing mills, to handle the small logs which the even-aged management will produce. I am not completely satisfied, either, that the planners adequately have accounted for the difference in value between older Ponderosa and the small logs to be produced in the future. Even-age management also have a detrimental effect on the visual quality of the forest, and upon its attractiveness for recreational use.

A final comment needs to be made about how the comparisons between alternatives was made. Almost all the data, and almost all the comparisons were based upon the first ten years of the alternatives. The preferred E-Departure Alternative looks very good from this perspective. It truly provides all things for all people. But, the severely adverse impacts in later decades, due to sharply reduced timber harvests are minimized in this analysis. Any alternative based upon severe over-utilization of the forest's resources for a ten year period will look good, for the first ten years. The next forty are where the preferred E-Departure Alternative crashes, and very little analysis and data/projections are detailed for these years.

There is little doubt in my mind that the preferred E-Departure Alternative will be highly detrimental to the counties (including Wheeler) which have a significant dependence on the Ochoco. The timber industry will be hurt, in the long run, and county revenues from forest payments will greatly decrease. Wheeler County will experience a major decline in county government revenues which it will have no chance to recover from other sources. As timber related employment drops, the secondary economic sectors will likewise suffer, and the few new jobs created in recreation/hunting related sectors will in no way make up for the lost timber earnings. I see little positive about the long range impacts of the preferred alternative, the visual qualities of the forest will even suffer under it.

If other uses are to predominate over the timber harvest, local timber industries would be far better off to see a steady-yield plan (such as E-Alternative, without the departure schedule) implemented directly. A reduction in timber harvest now will be less detrimental than a much larger reduction, for several decades, beginning ten years down the road. Also, while even-age management will help keep cubic-feet (harvest) up, this is of no great benefit to the timber industry, which would have to invest millions to use the resulting logs. Retention of an uneven-age growth management scheme would do much more to keep the value of the harvest up, without large facility investments, which is at least as important as board feet or cubic feet harvested. Uneven-age management would also have superior visual, riparian, big game, and recreational values, as well as higher timber values.

The other direction the planners could go would be to make those hard (and possibly unpopular) decisions they seem to be trying to avoid, by establishing clear priorities as to forest usage. If non-timber uses are to be given the higher priorities, this should be done out front and with a steady-yield plan, which keeps harvest value, not just cubic feet, as high as possible. Such an approach would facilitate planning for the necessary adjustments and would be far easier for the timber industry to deal with. The least adverse approach, of course, in terms of local (and state-wide) economic impact, would be to set timber harvest as a high priority (both yield and value) and to reduce the emphasis on other, competing uses (particularly the ill-considered mandate to double the elk population). The E-Alternative offered, but rejected, seems to accomplish this in at least a minimally satisfactory way, and would clearly have the least adverse impact on local economies of all the alternatives presented, while preserving some use of the forest of non-timber demands. The preferred E-Departure Alternative is clearly not acceptable.
This letter is in response to your request for an estimate of the employment multiplier for the lumber and wood products industry both statewide and for the non-metropolitan counties comprising the Oregon Consortium.

First of all, let’s define the concept of an economic multiplier. Since local businesses, households, and government agencies purchase goods and services from one another, any new development in a community generates both direct and indirect economic impacts. The multiplier is a single number that estimates the total economic impact of a given change in the local economy. There are many different types of multipliers, including multipliers for business output (or sales), personal income (or earnings), and employment. Most multipliers are estimated as follows.

\[
\text{Multiplier} = \frac{\text{total change}}{\text{initial change}},
\]

In whatever units are being considered—business sales dollars, number of jobs, etc. For our purpose, we will focus only on the employment multiplier (# of jobs, not FTE's) for a particular industry, lumber and wood products. Also, this will be considered a Type II multiplier which aggregates the following impacts:

1. Direct impact - employment change within the lumber and wood products industry.
2. Indirect impact - employment change in other industrial sectors resulting from purchases by the lumber and wood products industry.
3. Induced impact - employment change resulting from purchases by households that receive income through either the direct or indirect effects.

To help you better understand the concept of economic multipliers and avoid their possible misuse, I’ve enclosed several recent papers on this topic.

To derive an employment multiplier for lumber and wood products for Oregon and for local areas within TOC, we enlisted the help of two economists (Stan Detering of BPA and Hans Radtke) who have had considerable experience in this area. The employment multipliers that follow were generated using the IMPLAN system developed and maintained by the U.S. Forest Service. This is a computer-based system which uses input-output analysis procedures and provides forest planners with the capability to develop non-survey based interindustry models and apply them to the evaluation of alternative management programs. The specific IMPLAN computer runs were prepared by the Bureau of Land Management, U.S. Department of Interior. Detering and Radtke believe that the IMPLAN system estimates of employment multipliers tend to be a little higher than employment impacts generated using valid survey-based models. I have enclosed a brief paper describing the IMPLAN system. If you want more detailed information, let me know.
Employment multipliers for SIC 242 and 243 are shown below for the State and a number of local areas:

</table>

Note that, in general, the employment multipliers get larger as the area covered gets larger. This is because the economies of large areas are more diverse, and a larger proportion of income is spent locally on goods and services. This explains why the lumber and wood products multiplier for the state is 2.9, while the one for Eastern/Central Oregon (an 18 county area) is about 2.5. Since you will be doing planning at the sub-district level within TOC, we suggest you use an employment multiplier of 2.2 for lumber and wood products, which is an average of nine individual areas (not the combined area) within TOC for which separate data was available. This average assumes that SIC 242 and 243 are given equal weight, and that they fairly represent the lumber and wood products industry (SIC 24).

Usually, these multipliers are used in the context of analyzing the impacts of new jobs or new industry to an area. Whether these multiplier impacts would be of equal magnitude in the opposite direction if an area lost the same number of jobs is an interesting question. To the extent that these workers remained in the area and received income from transfer payments etc., the downside multipliers would probably be lower, at least in the short run.

I hope that this information will be helpful to you. If you have any questions, please don't hesitate to call me or Jeff Hannum.

Sincerely,

**INTRODUCTION**

The USDA Forest Service has developed a computer-based system referred to as IMPLAN, to assist its land and resource management planning efforts involving economic impact assessment. The IMPLAN system utilizes input-output analysis procedures and provides forest planners with the capability to develop non-survey based interindustry models and apply them to the evaluation of alternative management programs. This paper provides a general overview of the data model building procedures and analysis capabilities that comprise the IMPLAN system.

Input-output models have frequently been used to describe the role of forestry activities in regional economies (Elrod, et al. 1977, Trueman and Porterfield, 1976). Input-output models have also been used to evaluate forest policies and programs (Schellau, et al., 1969, Cunningham and McElroy, 1979). The usefulness and applicability of input-output analysis to forest service planning has been demonstrated (Palmer and Keaton, 1978; Alward and Stewart, 1978). Indeed several of the planning requirements of the National Forest Management Act of 1976 (P.L. 94-588) and its implementing regulations (36 C.F.R. 219 Subpart A, September, 1979) require economic analyses of proposed plans such as those that can be performed using input-output techniques.

Many applications of input-output models have utilized primary data obtained through direct surveys. Consequently, the cost in terms of money and manpower for those studies has been substantial (Bourne and Hansen, 1967). Various techniques for constructing models using secondary data have been proposed (Camanski and Melina, 1969).

**ABSTRACT**
